- All the Hyper-V versions supported by Cohesity for backup is supported for cloning to Azure. For the list of supported Hyper-V versions, see Supported Software.
- Generation 2 VMs are not supported by all VM sizes in Azure. For information on Generation 2 supported VM series, see Microsoft document.
- Cloning of Hyper-V VMs to Azure Stack Hub is not supported.

Cloning VMware VMs to an AWS Cloud has the following requirements:

- Cloning snapshots to an AWS Cloud is supported for VMware VMs with specific Linux operating systems. For information on supported operating systems, see Supported Software
- Cloning Snapshots to an AWS Cloud is supported for VMware VMs with the Windows operating system.
- The disk size of the VMware VMs must be a multiple of 1 MB.
- VMs that have one to ten disks can be cloned.
- When converting and cloning or copying Snapshots of a Linux VM with multiple disks, the disks must be mounted by UUID prior to being backed up by the Protection Group, as shown by the following example entry in a `/etc/fstab`:

  ```
  UUID=e12e623a-c6ee-4718-9b1a-802456e72258 /userdata ext4
  defaults,nofail 0 0
  ```

  For detailed instructions, see Edit /etc/fstab to use UUID.

  For AWS, be aware of the following requirements:

  - In addition, the fstab entry for **CentOS 7.4**, **RHEL 7.4**, **RHEL 6.7**, **SUSE 11** and **Ubuntu 16** operating systems must specify the `nofail` option as shown in the following example:

    ```
    UUID=e12e623a-c6ee-4718-9b1a-802456e72258 /userdata ext4
    defaults,nofail 0 0
    ```

  - In addition, the fstab entry for the **Ubuntu 14** operating system must specify the `nobootwait` option as shown in the following example:

    ```
    UUID=2b262696-41a6-47c9-b173-d02717ee0e10 /mnt/expvol ext4
    defaults,nobootwait 0 0
    ```

- When backing up Windows VMs with multiple disks, before a Protection Group captures the Snapshot, the Cohesity agent and VMware tools must be installed on the VM and the VM must be running. For more information, see Install and Manage the Agent on Windows Servers. In addition, port 50051 must be open in your Firewall. For more information, see Manage Firewall Ports.

  > **Note:**
  > **For Convert and Deploy**: It is mandatory to install the Cohesity agent on the VMs. Windows does not show the data disks if the Cohesity agent is not installed, irrespective of the SAN/Disk Policy.
  >
  > **For Disaster Recovery**: It is mandatory to install the Cohesity agent on multi-disk Windows VMs. Windows does not show the data disks if the Cohesity agent is not installed, irrespective of the SAN/Disk Policy. In addition, the Protection Group capturing the Snapshot must have **Cloud Migration** enabled. For detailed instructions, see Add or Edit a Protection Group for Virtual Servers.

- For a Windows VM, if you want to access the newly created VM in the Cloud service using Remote Desktop, enable the Windows Remote Desktop on the VM prior to capturing the Snapshots of a Windows VM.

2. Create a Protection Group to capture Snapshots of VMs. For more information, see Add or Edit a Protection Group for Virtual Servers. For example, you could create a Protection Group on a Cohesity cluster running in Azure as shown in the bottom workflow in the figure above.
3. Register the Cloud service that the VMware VMs are cloned **to**. For detailed instructions, see either Register an Azure Cloud Source at Subscription Level or Register an AWS Cloud Source.
4. Log in to the Cohesity Dashboard of the Cohesity cluster that contains the Snapshots to clone from. For example, log in to the Cohesity cluster running in Azure or AWS.
5. Clone the VM in the Cloud service such as Azure. For detailed instructions, see Clone VMs.
6. After the Clone task is completed, log in to the new VM in the Cloud service.

   For Azure:

   a. Log in to Microsoft Azure Portal.
   b. Search for the new Virtual Machine name.
   c. Click on the VM name.
   d. Under the **Subscription name**, copy the IP address of the new VM.

e. Log in to the VM using the IP address. If Remote Desktop was installed in the VM that was cloned, you can log in using the Remote Desktop.

For AWS:

a. Log in to the Amazon AWS console using your AWS account.
b. In the top left of the menu bar, select **Services**.
c. Select **Compute** > **EC2**.
d. Select **INSTANCES** > **Instances**.
e. Browse for the new Virtual Machine name.
f. Copy the new IP address from the **Private IPs** field.
g. Log in to the VM using the IP address. Paste the IP address in the browser.

7. Multiple disks are automatically mounted on the Windows VM, if the following conditions are true before the Protection Group captures the Snapshot of a Windows VM:
   - A Cohesity agent is installed on the VM.
   - VMware tools are installed on the VM.
   - VM is running

   If any of the conditions were not true when the Job captured the Snapshot, the `C:` drive is mounted but you must mount the other drives such as `D:` as described here:

   a. If Remote Desktop is installed on the new cloned VM, log in to the new VM, start Remote Desktop Connection, enter the IP of the new cloned VM.
   b. In the new VM, launch the Windows Disk Management.
   c. Right click on a disk that is not mounted and select **Online**. Repeat for all other offline disks.

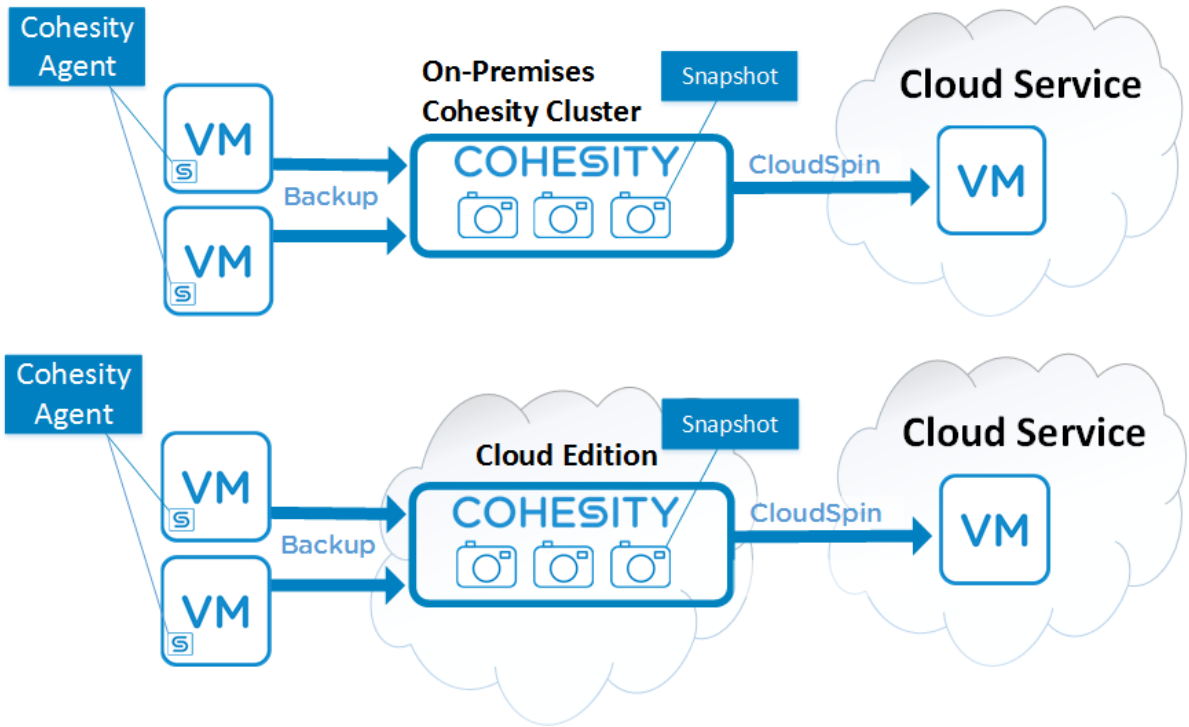
Clone VMs to AWS Cloud Using CloudSpin

On a Cohesity cluster with a Protection Group that captures Snapshots of VMs with a CloudSpin schedule, the cluster clones VMs to an AWS cloud service. You can then launch the VMs to a running state.

What happens during the CloudSpin process is dependent on the cloud service type:

Full	Incremental
When you clone to an AWS Cloud using CloudSpin, the Cohesity cluster copies the Snapshot to an S3 bucket in the specified AWS account and then converts the snapshot from VMDK format to an AMI format using the AWS import service.	On the first CloudSpin run, the Cohesity cluster copies the full VM snapshot data to EBS volumes. The number of EBS volumes corresponds to the number of backed-up VM disks. Once copying is done, Cohesity uses AWS import service to generate an AMI from the EBS volume corresponding to the root volume and generates the EBS snapshots for all other volumes, if any. For subsequent runs, only incremental changes are copied between the snapshots. Incremental CloudSpin to AWS requires a Fleet Instance. The cluster communicates with the Fleet Instance using private IP. Therefore, the on-prem cluster must be on a VPN to AWS VPC.

Cohesity supports CloudSpin on both on-premises Cohesity cluster and Cloud Edition Cohesity clusters:



To use CloudSpin to clone Snapshots to AWS:

1. Verify the following requirements prior to backing up the VMs:
    - For the list of VMs that supports CloudSpin to AWS, see Supported Software.
    - All the VMware vSphere versions supported by Cohesity for backup is supported for cloning to AWS. For the list of supported VMware vSphere versions, see Supported Software.
    - Cloning VMware VMs to an AWS Cloud has the following requirements:
        - Cloning snapshots to an AWS Cloud is supported for VMware VMs with specific Linux operating systems. For information on supported operating systems, see Supported Software
        - Cloning Snapshots to an AWS Cloud is supported for VMware VMs with the Windows operating system.
        - The disk size of the VMware VMs must be a multiple of 1 MB.
        - VMs that have one to ten disks can be cloned.
        - Due to an AWS limitation, performing a CloudSpin to an instance type that has an ENA is not supported. For more information, see Enhanced Networking on Linux.
        - When converting and cloning or copying Snapshots of a Linux VM with multiple disks, the disks must be mounted by UUID prior to being backed up by the Protection Group, as shown by the following example entry in a `/etc/fstab`:

          ```
          UUID=e12e623a-c6ee-4718-9b1a-802456e72258 /userdata ext4 defaults,nofail 0 0
          ```

          For detailed instructions, see Edit /etc/fstab to use UUID.

          For AWS, be aware of the following requirements:

            - In addition, the fstab entry for **CentOS 7.4**, **RHEL 7.4**, **RHEL 6.7**, **SUSE 11** and **Ubuntu 16** operating systems must specify the `nofail` option as shown in the following example:

              ```
              UUID=e12e623a-c6ee-4718-9b1a-802456e72258 /userdata ext4 defaults,nofail 0 0
              ```

            - In addition, the fstab entry for the **Ubuntu 14** operating system must specify the `nobootwait` option as shown in the following example:

              ```
              UUID=2b262696-41a6-47c9-b173-d02717ee0e10 /mnt/expvol ext4 defaults,nobootwait 0 0
              ```

        - When backing up Windows VMs with multiple disks, before a Protection Group captures the Snapshot, the Cohesity agent and VMware tools must

be installed on the VM and the VM must be running. For more information, see Install and Manage the Agent on Windows Servers. In addition, port 50051 must be open in your Firewall. For more information, see Manage Firewall Ports.

- For a Windows VM, if you want to access the newly created VM in the Cloud service using Remote Desktop, enable the Windows Remote Desktop on the VM prior to capturing the Snapshots of a Windows VM.

2. Register a Cloud Source. Select **Data Protection > Sources** and from the **Register Source** drop-down, select **AWS**. A cloud source is a cloud service instance where the snapshots are converted and copied **to**. For details, see the appropriate Source topic:
   - Register an Azure Cloud Source at Subscription Level
   - Register an AWS Cloud Source
3. For a Windows VM, if you want to access the newly created VM in the Cloud service using Remote Desktop, enable the Windows Remote Desktop on the VM prior to capturing the Snapshots of a Windows VM.
4. Create a Policy with a CloudSpin schedule that converts and copies Snapshots to the Cloud Source registered in the previous step. For detailed instructions, see Create or Edit a Standard Policy. Protection Groups that use this policy will automatically convert and copy Snapshots backed up by the Protection Group to a Cloud Source using the specified CloudSpin schedule.

   For AWS:

Full	Incremental
In Full CloudSpin, the AMI and snapshots are created in the specified Region.	Specify the Region, VPC, and Subnet for an incremental CloudSpin. The AMI and snapshots are created in the specified Region. VPC and Subnet are required for the following reason: Incremental CloudSpin requires connectivity between the Cohesity cluster and AWS through VPC and Subnet - During incremental CloudSpin, Cohesity launches a temporary EC2 instance in the provided VPC and Subnet. The temporary instance is used to copy data from Cohesity cluster to AWS. An instance launched in this subnet must be reachable from the Cohesity cluster.

5. Create a Protection Group that uses the Policy created in the previous step.

   After the Protection Group run and the CloudSpin Copy Task are successfully completed, the VM can be launched.
6. Launch the VM created in the Cloud Service:

   Launch VM from the Cohesity Dashboard:

a. Select **Data Protection > Protection**.
b. Click the Job that backed up the VM to launch in the Cloud.
c. Browse for a protection run that contains a Snapshot to convert to a VM. The protection run must have the Status of **Success** and the associated CloudSpin Copy task must be successful .
d. Click the date link of the protection run in the Start Time column to view the protection run details.
e. Click the **ClouldSpin Task** tab.
f. To launch, complete one of the following actions:

- Click the actions menu (⋮) and select **Launch Instance**. The following fields are displayed:
  - **Source**—Displays the registered source.
  - **Resource Group**—Displays the resource pool that stores the cloned VMs.
  - **Storage Account**—Displays the VM size used when creating the cloned VMs.
  - **Storage Container**—Displays the storage container used to store the cloned VMs.
  - **Compute**—Select the Microsoft Azure VM size type to use when creating the cloned VMs.
  - **Availability Set**—Optionally, select the availability set to which the VM has to be cloned. For more information, see Azure Availability Sets.
  - **Virtual Network**—Select the Microsoft Azure Virtual Network for the cloned VMs.
  - **Subnet**—Select the Microsoft Azure Virtual subnet for the cloned VMs.
  - **Use Azure Managed Disks**—To use Azure managed disks, enable the toggle and select the OS Disk Type and Data Disk Type.

    Click **Submit** to save the changes.
- Click **Launch All Instances**.

To tear down a launched VM, see Tear Down a Launched VM from Cohesity Dashboard.

Launch VM from AWS Console:

a. Log in to the Amazon AWS console and select **EC2**. The **EC2 Dashboard** displays.

b. In the left frame, select **IMAGES > AMIs**.
c. In the search field, enter part of the VM name. The generated VM name consists of the Job name, the original name and the Snapshot time.
d. Select a VM and click **Launch**.
e. Enter the required settings and click **Review and Launch**.

To prevent a tear down of a cloned CloudSpin VM, see the How to prevent a tear down of a cloned CloudSpin VM KB article.

Tear Down a Launched VM from Cohesity Dashboard

- In the Cohesity Dashboard, select **Test & Dev**.
- For the clone task to tear down, click the actions menu (⋮) and select **Tear Down**.

Consideration

- AWS Security Token Service (AWS STS) must be enabled in the region where a VM is being Cloud-spun.
- Cohesity does not support CloudSpin of VMware VMs from VMware Cloud (VMC) to AWS.
- Cohesity supports both on-demand and policy-based CloudSpin for snapshots stored on the Cohesity cluster (primary copy).
- Cohesity does not support on-demand and policy-based CloudSpin for archived or CloudRetrieved snapshots.
- Cohesity supports on-demand CloudSpin for snapshots that are replicated to another Cohesity cluster.

Edit /etc/fstab to use UUID

You must edit the `/etc/fstab` file and change the (non-LVM) entries to use UUIDs to identify the disk partitions. These changes must be made to the `/etc/fstab` file before the Protection Group (which captures the Snapshots to be cloned) is run.

For example, the following entry in the `/etc/fstab` table must be changed to use the UUID to identify the partition instead of the device file name of `/dev/sbd1`.

```
/dev/sdb1 /mnt/disk1    ext4    defaults        0 0
```

> **Note:**
> - Use labels or UUIDs instead of device names, as device names may change when other disks are added or removed.
> - Kernel name descriptors must not be used in configuration files as they are not persistent and may change during each boot. UUIDs or PARTUUIDs are preferred over labels.
> - Using only the device name in the absence of UUID or label might cause issues as these names are not unique. This can cause overwrites and eventual loss of an entire volume indexing itself.
> - Each volume must be uniquely identified by an identifier like UUID or label. **A missing unique identifier (UUID/label) can result in dummy volume names being used instead of actual volumes.**

You can determine the UUID by running the `blkid` command, for example:

```
# blkid /dev/sdb1
/dev/sdb1 UUID="12345cac-77bc-46b1-9f79-cb180e438c12" TYPE="ext4"
```

Edit the `/etc/fstab` as root and for this entry replace the device file name with the returned UUID, for example:

```
12345cac-77bc-46b1-9f79-cb180e438c12 /mnt/disk1 ext4    defaults        0 0
```

> **Note:** LVM volume entries should not be updated. LVM volumes start with the `/dev/mapper` prefix, for example: `/dev/mapper/centos-root` and `/dev/mapper/centos-swap`.

Repeat these steps for all entries in the `/etc/fstab` that are not LVM volume entries.

Execute CloudFormation Template to Register AWS Using IAM Role

If you are using an IAM role to authenticate while registering an AWS source with the Cohesity cluster, you must run the CloudFormation template in the AWS account where the S3 buckets to be protected reside.

This CloudFormation template is available for download during the AWS source registration process in the Cohesity cluster.

Executing the CloudFormation template creates the necessary IAM role and policies required for registering the AWS source.

> **Note:**
> You should run the CloudFormation template only once when registering the AWS source for the first time.
>
> If you need to modify the use cases for an already registered AWS source (for example, to add support for Amazon RDS or Amazon S3 backups), do not download and run the CloudFormation template again. Running the template again will fail due to duplicate resource creation. Instead, update the existing CloudFormation stack in your AWS account to modify the permissions as needed.

Run the CFT

To run the Cohesity CloudFormation Template:

1. Log in to your AWS Management Console.
2. Navigate to **All services** and select **CloudFormation**.
3. Click **Create stack** > **With new resources (standard)** to create a stack using the downloaded CloudFormation Template.
4. In the **Prerequisite - Prepare template** page, select **Upload a template file**.
5. Click **Choose File** to browse and upload the downloaded JSON CloudFormation Template.

   You can download the CFT when you register your AWS account as a source with the Cohesity cluster.
6. Click **Next**.
7. Provide a Stack name. The stack name can include letters (A-Z and a-z), numbers (0-9), and dashes (-).
8. In the **Parameters** section, enter the **AccountID** of your AWS account and select source_registration as the **workflow**.
9. Click **Next**.
10. Retain all the default stack configuration options and click **Next**.
11. On the Review page, select the checkboxes that need to be acknowledged and click **Create stack**.
12. Once the stack creation is successful, view the **Resources** tab to check the created IAM roles.
13. The following IAM roles and profiles are created:

- *CohesityInstanceRole*
- *CohesityInstanceProfile*
- *CohesitySourceRegistrationRole*

Once the CFT has executed, you are ready to register your AWS sources with Cohesity.

Update the Existing CloudFormation Template

If you need to change the use cases in a registered AWS source (such as adding Amzon EC2 or Amazon S3 backups), download the updated CloudFormation template while editing the source in the Cohesity UI, and replace the existing stack in your AWS account to update the required permissions. Do not run a new CloudFormation template from scratch, as this may result in errors due to duplicate resource creation.

To update and run the new CFT template:

1. In the Cohesity cluster, update the CFT by editing the AWS source, changing your settings as necessary, clicking **Next**, and downloading updated CFT.
2. Go to your AWS account, and from the Stack page (**CloudFormation** > **Stacks**), select the primary stack created.
3. Select the **Update** tab.
4. On the Update stack page, select **Replace existing template** and **Upload a template file**.
5. Click **Choose File** to browse and upload the downloaded JSON CloudFormation Template.
6. Click **Next**.
7. Click **Next** and select the checkboxes that need to be acknowledged, and then click **Next**.
8. Review the stack details and then click **Submit**.

Your updated IAM role permissions are now associated with your AWS Source registered with Cohesity.

View the Created IAM Role

To view the IAM role created by the CFT:

1. From the Stack page (**CloudFormation** > **Stacks**), select the primary stack created.
2. Click the **Outputs** tab.

   The value column will display the ARN in the following format, from which you can get the name of the role created:

   ```
   arn:partition:iam::<account-id>:role/role-name
   ```

Attaching the IAM Role to Cloud Edition Nodes

To complete registration, attach the **CohesityInstanceProfile** role to all nodes in the Cloud Edition cluster:

1. Navigate to **Services** > **EC2** > **Instances**.
2. Select the cluster created. For a multi node, the IAM role must be attached on all nodes.
3. Select **Actions** > **Instance Settings** > **Attach/Replace IAM Role**.
4. In the **IAM Role** field, enter the name/search for the Instance Profile that was created.

   Example: *CohesityInstanceProfile*
5. Click **Apply**.

   The IAM role is successfully attached to that VM.
6. Click **Close**.

> **Note:** If any new node is added to the cluster, then this role has to be attached to every newly added node in the CE as well.

Completing AWS Source Registration

Once the IAM role is attached, complete the AWS source registration on the cluster, To register an AWS C2S source using IAM Role.

Amazon Simple Storage Service Buckets

Cohesity's software-defined platform provides a simple, fast, and cost-effective data protection solution for the Amazon Simple Storage Service (S3) buckets.

To protect the Amazon S3 bucket, Cohesity leverages the Amazon S3 inventory report. The inventory report contains the list of all the objects available on the Amazon S3 bucket you selected for protection. Cohesity uses this report to perform the first full backup. This report is also used to periodically reconcile the list of objects. The subsequent incremental backups are performed by using the AWS EventBridge capability.

With this protection approach, Cohesity can back up multi-billion objects at a faster rate.

> **Note:**
> - This is an Early Access feature on Physical and Virtual Edition clusters. Contact your Cohesity account team to enable the feature.
> - This feature is not supported on DataProtect for cloud (legacy) in AWS (formerly known as AWS Cloud Edition cluster)
> - This feature is Generally Available (GA) on DataProtect for cloud in AWS (formerly known as AWS NGCE cluster).

Plan and Prepare for Amazon S3 Bucket Protection

Before protecting your Amazon S3 bucket, ensure you have met the prerequisites and reviewed the considerations.

Supported Amazon S3 Storage Class

Cohesity supports the data protection of the following Amazon Simple Storage Service Bucket (S3) storage class:

- Amazon S3 Standard
- Amazon S3 Intelligent-Tiering
- Amazon S3 Standard-IA
- Amazon S3 One Zone-IA

Authentication

To register an AWS account with the Cohesity cluster for protecting Amazon S3 buckets, you can authenticate the cluster using one of the following methods:

- IAM user
- IAM role

Authenticate Using IAM User

In the IAM User authentication method, you must first create an AWS policy with required permissions, and then create an IAM user with this policy attached. The permissions required are provided in the following procedure.

Create an AWS Policy

To create a new policy with permissions:

1. Log in to the Amazon AWS console using your AWS account with admin privileges.
2. In the top left of the menu bar, select **Services**.
3. Under **Security, Identity & Compliance**, select **IAM**.

4. In the left frame, click **Policies**.
5. Click **Create policy**.
6. In the **Create policy** page, select the **JSON** tab.
7. Delete the default JSON code.
8. Copy the following JSON code.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "kms:GenerateDataKey",
                "s3:GetBucketLocation",
                "s3:GetBucketNotification",
                "s3:GetBucketOwnershipControls",
                "s3:GetBucketTagging",
                "s3:GetBucketVersioning",
                "s3:GetInventoryConfiguration",
                "s3:GetObject",
                "s3:GetObjectAcl",
                "s3:GetObjectVersion",
                "s3:ListAllMyBuckets",
                "s3:ListBucket",
                "s3:PutObject",
                "s3:PutBucketNotification",
                "s3:PutInventoryConfiguration",
                "s3:GetObjectTagging",
                "s3:PutObjectTagging",
                "s3:GetObjectVersionTagging",
                "s3:PutObjectVersionTagging",
                "s3:PutObjectAcl",
                "s3:GetObjectVersionAcl",
                "s3:PutObjectVersionAcl"
            ],
            "Resource": "*",
            "Effect": "Allow"
        },
        {
            "Action": [
                "sqs:CreateQueue",
                "sqs:TagQueue",
                "sqs:ListQueues"
            ],
            "Resource": "*",
            "Effect": "Allow"
        },
        {
            "Condition": {
                "StringLike": {
                    "aws:ResourceTag/UniqueTag": "cohesity_*"
                }
            },
            "Action": [
                "sqs:DeleteQueue",

                }
            },
            "Action": [
                "events:DeleteRule",
                "events:PutTargets",
                "events:RemoveTargets"
            ],
            "Resource": "*",
            "Effect": "Allow"
        },
        {
            "Action": [
                "glue:CreateJob",
                "glue:TagResource"
            ],
            "Resource": "*",
            "Effect": "Allow"
        },
        {
            "Condition": {
                "StringLike": {
                    "aws:ResourceTag/UniqueTag": "cohesity_*"
                }
            },
            "Action": [
                "glue:DeleteJob",
                "glue:StartJobRun",
                "glue:UpdateJob",
                "glue:GetJobRun"
            ],
            "Resource": "*",
            "Effect": "Allow"
        }
    ]
}
```

9. Paste the provided JSON code above.
10. Click **Review policy**.
11. In the **Name** field, enter a name of this policy, such as *S3BucketProtection*, and an optional description for the policy, and then click **Create Policy**.

Create an IAM User

Once you create a policy with the required permissions, you can create a new IAM user and attach the policy to it.

To create an IAM user:

1. Log in to the Amazon AWS console using your AWS account with admin privileges.
2. In the top left of the menu bar, select **Services**.
3. Under **Security, Identity & Compliance**, select **IAM**.
4. In the left frame, click **Users**.

5. Click **Add users.**
6. In the **User name** field, enter a user name.
7. For **Access type**, select **Programmatic access** and click **Next: Permissions**.
8. Click **Attach existing policies directly**, then search for the name of the policy you created previously and select that policy.
9. Click **Next:Tags**.
10. Optionally, enter tags for the policy and then click **Next: Review**.
11. Review your choices and then click **Create User**.
12. In the **Secret access key** column, click **Show**.
13. Copy and paste the **Access key ID** and the **Secret access key** in to a text file or click **Download .csv** to save the information onto your desktop or a corporate share.
14. These keys are required when registering the AWS account with the Cohesity cluster.
15. Click **Close**.

Authenticate Using IAM Role

In the IAM role authentication method, you must first create an IAM role using the CloudFormation Template (CFT) available for downloading while registering the AWS source. For information on executing the CloudFormation Template.

IAM User Permissions to Execute CFT

To register an AWS account with the cluster using an IAM role, you need to run the CloudFormation Template on the AWS console. Ensure the IAM user you use has the following permissions to run the CloudFormation Template and to create and view the stack:

> **Note:** Ensure to add these permissions manually.

```
cloudformation:CreateChangeSet
cloudformation:CreateStack
cloudformation:CreateUploadBucket
cloudformation:DeleteStack
cloudformation:DescribeStackEvents
cloudformation:DescribeStackResources
cloudformation:DescribeStacks
cloudformation:GetTemplate
cloudformation:GetTemplateSummary
cloudformation:ListStackResources
cloudformation:ListStacks
cloudformation:UpdateStack
iam:AddRoleToInstanceProfile
iam:AttachRolePolicy
iam:CreateInstanceProfile
iam:CreateRole
iam:DeleteInstanceProfile
iam:DeleteRole
iam:DeleteRolePolicy
iam:DetachRolePolicy
```

```
iam:GetInstanceProfile
iam:GetRole
iam:GetRolePolicy
iam:PassRole
iam:PutRolePolicy
iam:RemoveRoleFromInstanceProfile
iam:TagRole
lambda:AddPermission
lambda:CreateFunction
lambda:DeleteFunction
lambda:InvokeFunction
lambda:RemovePermission
s3:CreateBucket
s3:GetObject
s3:ListBucket
s3:PutObject
s3: PutBucketPublicAccessBlock
```

Permissions for Amazon S3 Data Protection

The following permissions are added to the IAM role when you run the CloudFormation template.

> **Note:** You do not need to add these permissions manually, as they are automatically added when you run the CFT.

Resource	Permissions	Reason
S3	s3:GetBucketLocation s3:GetBucketNotification s3:GetBucketOwnershipControls s3:GetBucketTagging s3:GetBucketVersioning s3:GetInventoryConfiguration s3:GetObject s3:GetObjectAcl s3:GetObjectTagging s3:GetObjectVersion s3:GetObjectVersionAcl s3:GetObjectVersionTagging s3:ListAllMyBuckets s3:ListBucket s3:PutBucketNotification s3:PutInventoryConfiguration s3:PutObject s3:PutObjectAcl s3:PutObjectTagging s3:PutObjectVersionAcl	These permissions are required for the backup and recovery of S3 objects.
iam	iam:SimulatePrincipalPolicy	SimulatePricipalPolicy is needed to ensure that the required actions are allowed on the IAM role we created as part of the Cloud Formation template.
kms*	kms:CreateGrant kms:DescribeKey kms:ListAliases kms:GenerateDataKey	KMS permissions are needed to read data of an encrypted database at the time of backup, as well as write encrypted data to the recovered database. Describe permissions are needed so we can list & identify keys associated with database instances.

Resource	Permissions	Reason
Events	events:DeleteRule events:PutTargets events:RemoveTargets	These permissions are required for capturing the incremental changes on the S3 buckets.
Glue	glue:DeleteJob glue:GetJobRun glue:StartJobRun glue:UpdateJob	These permissions are required for sorting the inventory report. The sorted inventory report is then used to back up the S3 objects to the Cohesity Platform.
SQS	sqs:CreateQueue sqs:TagQueue sqs:DeleteMessage sqs:DeleteQueue sqs:GetQueueUrl sqs:PurgeQueue sqs:ReceiveMessage sqs:SetQueueAttributes	These permissions are required for capturing the incremental changes on the S3 buckets.

Permission for AWS S3 Inventory Report

To allow Amazon S3 to write objects to the Amazon S3 bucket where you want to create the inventory report, you must add the `S3:PutObject` permission to the bucket's policy.

The following is an example of an Amazon S3 bucket policy that allows **s3.amazonaws.com** to write (Put) objects in the Amazon S3 bucket:

```
{
    "Version": "2012-10-17",
    "Id": "S3-Console-Auto-Gen-Policy-1698064515475",
    "Statement": [
        {
            "Sid": "InventoryAndAnalyticsExamplePolicy",
            "Effect": "Allow",
            "Principal": {
                "Service": "s3.amazonaws.com"
            },
            "Action": [
                "s3:PutObject"
            ],
            "Resource": "arn:aws:s3:::<s3bucketname_you_chose_for_inventory>/*",
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": "<account_Id>",
                    "s3:x-amz-acl": "bucket-owner-full-control"
                }
            }
        }
    ]
}
```

Additionally, if you're using Server-Side Encryption with AWS Key Management Service (SSE-KMS) for the bucket where you want to store the inventory report, ensure that the

bucket policy also includes the `kms: GenerateDataKey` permission to allow Amazon S3 to generate data keys for encrypting objects in the inventory report bucket.

The following is an example of an Amazon S3 bucket policy that allows **s3.amazonaws.com** to generate data keys for encrypting objects in the inventory report bucket.

```
{
            "Sid": "Allow Amazon S3 use of the KMS key",
            "Effect": "Allow",
            "Principal": {
                "Service": "s3.amazonaws.com"
            },
            "Action": "kms:GenerateDataKey",
            "Resource": "*",
        }
```

Create a Lifecycle Rule on Amazon S3

To delete the older inventory reports from the Amazon S3 bucket, you must create a lifecycle rule on the Amazon S3 bucket. You can delete all the inventory reports older than 30 days. For information on creating a lifecycle rule, see Amazon documentation.

Permission for Amazon Key Management Service (KMS)

If the Amazon S3 bucket you want to protect is encrypted with Server-side encryption with AWS Key Management Service keys (SSE-KMS) or Dual-layer server-side encryption with AWS Key Management Service keys (DSSE-KMS), then for Cohesity to access the Amazon S3 bucket, you must perform one of the following actions:

- Add the IAM role created by the Cloud Formation template to the AWS KMS user.
- Add the following permission to the Key policy attached to the AWS KMS:
  - kms:Encrypt
  - kms:Decrypt
  - kms:ReEncrypt*
  - kms:GenerateDataKey*
  - kms:DescribeKey

  For example:

```
{
    "Version": "2012-10-17",
    "Id": "AccessKeyId",
    "Statement": [
        {
            "Sid": "Allow use of the key to cohesity role",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::<AWS-ACCOUNT>:role/<ROLE-NAME>"
            },
            "Action": [
```

```
                "kms:Encrypt",
                "kms:Decrypt",
                "kms:ReEncrypt*",
                "kms:GenerateDataKey*",
                "kms:DescribeKey"
            ],
            "Resource": "*"
        }
    ]
}
```

Considerations

- Cohesity does not support:
  - Browse and recover an object in an Amazon S3 bucket. However, you can recover multiple objects by specifying the object prefix in the recovery task under the S3 Prefixes to Recover option.
  - The backup of older versions of the Amazon S3 versioned bucket. Only the latest version of the versioned Amazon S3 bucket is backed up.
  - Cross-region backup and recovery, i.e., the backup and recovery of Amazon S3 buckets located in a different cloud region than where your data is backed up.
- The Amazon S3 buckets where you want to create the inventory report and the Amazon S3 bucket you want to protect must be in the same region.
- If the SQS is deleted between backups, all the changes between these backups will be skipped in the next incremental backups.
- Cohesity will skip the backup of Amazon S3 objects that are present in the following access tiers of the Amazon S3 Intelligent Tiering during the protection:
  - Archive Access Tier
  - Deep Archive Access Tier
- Cohesity does not support restoring only metadata. The metadata of Amazon S3 objects will be restored only if the object itself is also restored.
- Cohesity does not remove older inventory reports from the Amazon S3 bucket. Therefore, you must create a lifecycle rule to remove these objects from the Amazon S3 bucket to avoid storage issues.

Register AWS Source for Amazon S3 Protection

To start protecting an Amazon S3 bucket, once you meet the requirements, you need to register the AWS account as a source with the Cohesity cluster.

To register the AWS Account as the source:

1. Select **Data Protection** > **Sources**.
2. Select **Register** > **Virtual Machines**.

3. From the **Select Hypervisor Source Type** drop-down, select **AWS : IAM User/Role**.
4. Select the AWS category **Standard** or **Gov**. For information on registering AWS account with C2S as the AWS catergory, see To register an AWS C2S source using IAM Role.
5. Select the authentication method:
   - **IAM User**
   - **IAM Role**

   > **Note:** This option to choose authentication method is available only for Cloud Edition and Next-Gen Cloud Edition Cohesity clusters. For Physical and Virtual Edition clusters, only IAM user-based authentication is available.
6. Perform the steps described in the table depending on the authentication method you choose:

Authentication Method	Steps
IAM User	1. Specify the **Access Key ID** for the new IAM user that was created to back up a AWS Cloud source or convert and clone Amazon EC2 to an AWS Cloud Source. For general information about AWS keys, see Access Keys (Access Key ID and Secret Access Key). 2. Specify the **Secret Access Key** for the new IAM user that was created to back up a AWS Cloud Source or convert and clone Amazon EC2 to an AWS Cloud Source. For general information about AWS keys, see Access Keys (Access Key ID and Secret Access Key). 3. Specify the Amazon Resource Name **(ARN)** of the IAM user in the following format: `arn:aws:iam::<account-id>:user/<username>` For more information, see Amazon Resource Names (ARNs). For more information on authenticating Cohesity cluster for Amazon S3 protection, see Authenticate Using IAM User. **Note:** AWS Security Token Service (STS) must be enabled in all AWS regions that are activated in your AWS account.

Authentication Method	Steps
IAM Role	1. Click the **CloudFormation Template** link to download the CFT file. 2. Run the CloudFormation Template in your AWS account to create the IAM roles and policies that Cohesity requires for authentication. For more information, see Run CloudFormation Template. 3. Specify your **AWS Account ID**. 4. Specify the IAM Role in the following format: `arn:aws:iam::<account-id>:role/<role-name>` Where, `<account-id>` is the account ID of the AWS account that has the AWS resources to protect. `<role-name>` is the role created after running the CFT template. For more information on authenticating Cohesity cluster for Amazon S3 protection, see Authenticate Using IAM User. **Note:** • This option is available only for Cloud Editions and not for Physical or VE. • IAM role is not supported for workflows in AWS Gov.

7. (*Applies only for Amazon EC2 instance protection*) **Specify Fleet Settings**: Enable this option to:
   - Specify the VPC and subnet in which the EC2 fleet instance should be launched.
   - Add tags to the EC2 fleet instance.

   By default, this option is disabled and the EC2 fleet instance is launched in the same VPC and subnet of the Amazon EC2 instances that are to be protected.

   Specify the VPC and Subnet

   From the **Fleet Instance location** drop-down list select one of the following options to specify the VPC and subnet in which the fleet instance should be launched.
   - **Same Subnet as protected Amazon EC2**: The fleet instance will be launched in the same VPC and subnet of the Amazon EC2 instances that are to be protected.
   - **Select New**: The fleet instance will be launched in the specified VPC and subnet of the specified region. If the AWS source is not registered with the

Cohesity cluster, the cluster cannot detect the AWS region, and the associated VPC and subnets. To configure a new VPC and subnet for the fleet instance, you must first register the source and then update the registered source to specify the VPC and subnet. For more information, see Configure a New VPC and Subnet for Fleet Instance.

If you have not selected the **Fleet Instance location** after enabling the **Specify Fleet Settings** option, then the EC2 fleet instance is launched in the same VPC and subnet of the Amazon EC2 instances that are to be protected.

Add a Tag

Tags enable you to categorize and identify your fleet instances. A tag consists of a key and an optional value, both of which you define.

To add a tag to the fleet instances, click **Add Tags** and enter a tag key and value. You can add up to 47 tags to a fleet instance.

Delete a Tag

To delete an existing tag, click the **cross** icon next to the tag.

8. (*Applies only for Amazon S3 buckets protection*) Cohesity utilizes the Amazon S3 inventory report to protect the Amazon S3 bucket. Enable **Inventory Report Location**, provide the following information to create the inventory report:
   - **S3 buckets ARN**: Enter the ARN of the Amazon S3 bucket where you want to create the inventory report. The ARN you provide must be of only those Amazon S3 buckets that are in the same AWS account and cloud region as the Amazon S3 you want to protect.
   - **Prefix**: Add a prefix value to the name of the inventory report that will be created.
     - The prefix can contain any character, including white spaces.

       For example, *Report-Source Bucket*.
     - The prefix should not begin or end with a forward slash (/) .
     - The prefix should not contain consecutive forward slashes.
     - You must not upload any files in the prefix of the inventory report.

     The inventory report will be created at *<Prefix>/<Path_to_inventoy_report>* when you initiate the protection. Cohesity creates the path to the inventory report on AWS based on the cluster, Amazon S3 bucket, and protection.
9. Click **Register**.

To register an AWS C2S source using IAM Role

Cohesity supports Commercial Cloud Services (C2S) region in AWS backup and recovery workflows. C2S is AWS's secret region offered by AWS to the US Intelligence community. You can register an AWS C2S source only using an IAM role. Contact Cohesity Support to enable the feature.

1. Select **Data Protection > Sources**.
2. Select **Register** > **Virtual Machines**.
3. From the **Select Hypervisor Source Type** drop-down, select **AWS : IAM User/Role**.
4. Choose **Category** as **C2S**.
5. Configure the following parameters:

Field Name	Description
Base URL	URL of the Commercial Cloud Services (C2S) server that contains the Amazon storage provided by the C2S agency.
Agency	The name of the agency that is providing the Commercial Cloud Services (C2S) server.
Mission	The account name for accessing the Commercial Cloud Services (C2S) server which is provided by the C2S agency.
Role	The IAM role to use when accessing the Amazon storage which is provided by the C2S agency.
Password	The password to read the Client Private Key when accessing the Commercial Cloud Services (C2S) server which is provided by the C2S agency.
Server CA Trusted Certificate	Upload the Certificate Authority Trusted Certificate file to access the Commercial Cloud Services (C2S) server which is provided by the C2S agency.
Client Certificate	Upload the Client Certificate file to access the Commercial Cloud Services (C2S) server which is provided by the C2S agency.
Client Private Key	Upload the Client Private Key file to use when accessing the Commercial Cloud Services (C2S) server which is provided by the C2S agency.

Field Name	Description
Specify Fleet Settings (Optional)	Enable this option to: • Specify the VPC and subnet in which the EC2 fleet instance should be launched. • Add tags to the EC2 fleet instance. By default, this option is disabled and the EC2 fleet instance is launched in the same VPC and subnet of the Amazon EC2 instances that are to be protected. > **Note:** This option is applicable only for the fleet instance created for backing up Amazon EC2. **Specify the VPC and Subnet** From the **Fleet Instance location** drop-down list select one of the following options to specify the VPC and subnet in which the fleet instance should be launched. • **Same Subnet as protected VMs**: The fleet instance will be launched in the same VPC and subnet of the Amazon EC2 instances that are to be protected. • **Select New**: The fleet instance will be launched in the specified VPC and subnet of the specified region. If the AWS source is not registered with the Cohesity cluster, the cluster cannot detect the AWS region, and the associated VPC and subnets. To configure a new VPC and subnet for the fleet instance, you must first register the source and then update the registered source to specify the VPC and subnet. For more information, see Configure a New VPC and Subnet for Fleet Instance. If you have not selected the **Fleet Instance location** after enabling the **Specify Fleet Settings** option, then the EC2 fleet instance is launched in the same VPC and subnet of the Amazon EC2 instances that are to be protected. **Add a Tag** Tags enable you to categorize and identify your fleet instances. A tag consists of a key and an optional value, both of which you define. To add a tag to the fleet instances, click **Add Tags** and enter a tag key and value. You can add up to 47 tags to a fleet instance. **Delete a Tag** To delete an existing tag, click the **cross** icon next to the tag.

Configure a New VPC and Subnet for Fleet Instance

To launch EC2 fleet instance will be launched in the specified subnet when you back up the Amazon EC2 instance to the Cohesity cluster. To configure a new VPC and subnet for the fleet instance:

1. In the Cohesity Dashboard select **Data Protection** > **Sources**.
2. Navigate the hierarchy to the registered AWS source for which you want to configure a new VPC and subnet for the fleet instance.
3. Click **Edit** next to the **Specify Subnet for Fleet Instance** text , or click the actions menu next to the AWS source and select **Edit**.

   The Edit Source page appears.
4. Enable the **Specify Fleet Settings** option if you have not enabled when registering the AWS source.
5. From the **Fleet Instance Location** drop-down list, select **Select New**.
6. Select a region, and its VPC and subnet in which the fleet instance should be launched.

   > **Note:** As the Amazon EC2 sources are mostly located in one region, you can select the VPC and subnet of only one region.
7. Click **Save**

Run CloudFormation Template

If you are using an IAM role to authenticate while registering an AWS source with the Cohesity cluster, you must run the CloudFormation template in the AWS account where the S3 buckets to be protected reside.

This CloudFormation template is available for download during the AWS source registration process in the Cohesity cluster.

Executing the CloudFormation template creates the necessary IAM role and policies required for registering the AWS source.

> **Note:**
> You should run the CloudFormation template only once when registering the AWS source for the first time.
>
> If you need to modify the use cases for an already registered AWS source (for example, to add support for Amazon RDS or Amazon S3 backups), do not download and run the CloudFormation template again. Running the template again will fail due to duplicate resource creation. Instead, update the existing CloudFormation stack in your AWS account to modify the permissions as needed.

Run the CFT

To run the Cohesity CloudFormation Template:

1. Log in to your AWS Management Console.
2. Navigate to **All services** and select **CloudFormation**.
3. Click **Create stack** > **With new resources (standard)** to create a stack using the downloaded CloudFormation Template.
4. In the **Prerequisite - Prepare template** page, select **Upload a template file**.
5. Click **Choose File** to browse and upload the downloaded JSON CloudFormation Template.

   You can download the CFT when you register your AWS account as a source with the Cohesity cluster.
6. Click **Next**.
7. Provide a Stack name. The stack name can include letters (A-Z and a-z), numbers (0-9), and dashes (-).
8. In the **Parameters** section, enter the **AccountID** of your AWS account and select source_registration as the **workflow**.
9. Click **Next**.
10. Retain all the default stack configuration options and click **Next**.
11. On the Review page, select the checkboxes that need to be acknowledged and click **Create stack**.
12. Once the stack creation is successful, view the **Resources** tab to check the created IAM roles.
13. The following IAM roles and profiles are created:
    - *CohesityInstanceRole*
    - *CohesityInstanceProfile*
    - *CohesitySourceRegistrationRole*

Once the CFT has executed, you are ready to register your AWS sources with Cohesity.

Update the Existing CloudFormation Template

If you need to change the use cases in a registered AWS source (such as adding Amzon EC2 or Amazon S3 backups), download the updated CloudFormation template while editing the source in the Cohesity UI, and replace the existing stack in your AWS account to update the required permissions. Do not run a new CloudFormation template from scratch, as this may result in errors due to duplicate resource creation.

To update and run the new CFT template:

1. In the Cohesity cluster, update the CFT by editing the AWS source, changing your settings as necessary, clicking **Next**, and downloading updated CFT.

2. Go to your AWS account, and from the Stack page (**CloudFormation** > **Stacks**), select the primary stack created.
3. Select the **Update** tab.
4. On the Update stack page, select **Replace existing template** and **Upload a template file**.
5. Click **Choose File** to browse and upload the downloaded JSON CloudFormation Template.
6. Click **Next**.
7. Click **Next** and select the checkboxes that need to be acknowledged, and then click **Next**.
8. Review the stack details and then click **Submit**.

Your updated IAM role permissions are now associated with your AWS Source registered with Cohesity.

View the Created IAM Role

To view the IAM role created by the CFT:

1. From the Stack page (**CloudFormation** > **Stacks**), select the primary stack created.
2. Click the **Outputs** tab.

   The value column will display the ARN in the following format, from which you can get the name of the role created:

   ```
   arn:partition:iam::<account-id>:role/role-name
   ```

Protect Amazon S3 buckets

Cohesity utilizes the Amazon S3 inventory report to protect the Amazon S3 bucket. When you register the AWS account, you can specify the Amazon S3 bucket where you want to create the inventory report. The Amazon S3 bucket you specify must be within the same AWS account and cloud region as the Amazon S3 bucket selected for protection.

When you initiate the Amazon S3 bucket protection, AWS will create an inventory report. It may take up to 48 to 72 hours for AWS to create an inventory report. This inventory report will contain the list of all the objects available on the Amazon S3 bucket you selected for protection. Cohesity uses this inventory report to perform the first full backup of the Amazon S3 bucket. Once Cohesity performs the first full backup, Cohesity utilizes Amazon EventBridge and SQS queues to perform incremental backups of the Amazon S3 bucket.

With this protection approach, Cohesity can back up multi-billion Amazon S3 objects at a faster rate.

> **Note:** If you have already registered your AWS account to protect Amazon RDS or Amazon EC2 workloads, then you must Update the Existing CloudFormation Template to update the Cohesity permissions in your AWS account.

Before you Begin

Before protecting your Amazon S3 Buckets, ensure you have met the prerequisites and understood the considerations.

Add Protection to Your Registered Amazon S3 Buckets

To protect your Amazon S3 buckets:

1. Select **Data Protection** > **Protection**.
2. Click **Protect** on the top-right of the page and then click **Protect** > **Amazon S3**.

   The New Protection page appears.
3. Click **Add Objects**, and from the **Registered Source** drop-down list, select the AWS source you want to protect. You can also register a new source with the Cohesity cluster by clicking the **Register Source** option.
4. From the objects list, select the S3 buckets you want to protect.

   Optionally, you can configure auto-protection at the region level and also based on Tags. When enabled at the region level, all S3 buckets added to that region in the future are automatically protected starting from the next protection run.

   When enabled based on tags, any S3 bucket with the specified tags added in the future will also be automatically protected from the next protection run.

   - To auto-protect the Amazon S3 buckets at region level, click the **Hierarchy** icon at the right corner of the page. Select the checkbox of the region, and then select **Auto Protect This Region**.
   - To auto-protect the S3 buckets based on tag, click the **Tag** icon at the right corner of the page. Select the checkbox of a tag and then select **Auto Protect This** to auto-protect the Amazon S3 bucket with this tag.

   You can also exclude the Amazon S3 buckets from auto-protection within a region or by clicking the auto-protect icon ( ) next to the Amazon S3 bucket. The Amazon S3 buckets excluded from auto-protection are displayed with the exclude ( ) icon.
5. Click **Continue**.
6. Provide a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.
7. Choose a policy to specify backup frequency and retention. If you don't have a policy, you can create one. Ensure that the backup frequency set in the policy for Amazon S3

bucket is at most weekly. Backups may fail if the frequency is set for more than a week.

8. If you wish to change or configure any of the additional settings, select **More Options** and perform the below steps, or else, click **Protect**.
9. Under **Settings**, edit the following options if necessary:
    - **Storage Domain**: To store the backed up data, select an existing storage domain or create a new one by selecting Add Storage Domain.
    - **Start time**: Indicates what time the protection run should start. Enter the **Start Time** and select **AM** or **PM**. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone here.
    - **SLA**: Defines how long the administrator expects a protection run to take. Enter:
        - **Full**. The number of minutes you expect a full protection run, which captures all the blocks in an object, to take.
        - **Incremental**. The number of minutes you expect an incremental protection run, which captures only the changed blocks in an object, to take.
10. Under **Additional Settings**, configure the following option:
    - **Skip File on Errors**: Enable this option to continue the protection run even if any error is encountered when backing an Amazon S3 object. By default, this option is enabled. By disabling this option, the protection run will fail if one of the objects in Amazon S3 encounters an error.
    - **Enable ACL Backups**: Enable this option to backup ACL. You can backup ACLs only if ACLs are configured in the Amazon S3 bucket you chose to protect. By default, this option is disabled.
11. Click **Protect**.

Cohesity starts backing up the Amazon S3 buckets you selected.

Manage the Amazon S3 Bucket Backup Configuration

In Cohesity, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

You cannot update the registered AWS source and the assigned Storage Domain in the Protection Group settings.

Add Amazon S3 Buckets to the Protection Group

You can add new Amazon S3 buckets to an existing Protection Group for backup. The newly added buckets are backed up from the next protection run, and it will be a full backup.

To add Amazon S3 buckets to the Protection Group:

1. Select **Data Protection** > **Protection**.
2. On the Protection page, select the Protection Group that you created for protecting the Amazon S3 bucket.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** field, click the **Edit** icon.
5. Select the Amazon S3 bucket you want to add to the Protection Group.
6. Click **Save Selection** > **Save**.

The newly added Amazon S3 buckets will be backed in the next scheduled protection run.

Remove Amazon S3 Buckets from the Protection Group

From the Edit Protection page, you can remove Amazon S3 buckets from the Protection Group that you do not want to back up in the next protection run.

To remove the Amazon S3 buckets from the Protection Group:

1. Select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for protecting the Amazon S3 buckets.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** field, click the **Edit** icon.
5. Unselect the Amazon S3 buckets that you want to remove from the Protection Group.
6. Click **Save**.

The removed Amazon S3 buckets will not be backed in the next scheduled protection run.

Edit Existing Protection Policy

You can edit the existing Protection Policy that is attached to the Protection Group based on your requirement. In the Protection Policy, you can edit the settings listed in the Create or Use an Existing Protection Policy.

To the policy settings:

1. Select **Data Protection** > **Protection**.
2. On the Protection page, select the Protection Group that you had created for Amazon S3 buckets.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Policy** field, click **Edit**.

   The Edit Policy page appears.
5. Edit the settings listed in the Create or Use an Existing Protection Policy and then click **Save**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

You can attach a new Protection Policy to your Protection Group. The new policy is applied to the Protection Group in the next scheduled protection run.

1. Select **Data Protection** > **Protection**.
2. On the Protection page, select the Protection Group that you created for protecting the Amazon S3 buckets.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, from the drop-down list in the policy field, select a new Protection Policy for the Protection Group.
5. Click **Save**.

Start an On-Demand Protection Run

You can instantly start a protection run of the Protection Group that you have created to backup Amazon S3 buckets. It provides you options to back up all the objects or only selected objects in the Protection Group. If the policy associated with the Protection Group:

- Supports multiple backup types, you can select an incremental or full backup.
- If configured with replication targets, you can select those targets.
- If configured with archival targets, you can select those targets.

To start a protection run:

1. Select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for protecting the Amazon S3 buckets.
3. Click the action icon next to the Protection Group and select **Run Now**.
4. In the pop-up window, perform the following:
    a. In the **Backup** drop-down list, select any one of the following:
        - Backup all Objects in the Protection Group
        - Backup only selected Objects in the Protection Group
        - All objects that failed last run
    b. In the **Backup Type** drop-down list, select the backup type.
    c. In the **Replicate** section, select the replication target, the retention duration, and enable the **Replicate only fully successful runs** checkbox if you want to replicate the data only after a successful protection run.
    d. In the Archive section, select the archive target, the retention duration, and enable the **Archive only fully successful runs** checkbox if you want to archive the data only after a successful protection run.
5. Click **Run**.

Pause Future Protection Runs

You can stop the protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for protecting the Amazon S3 buckets.
3. Click the action icon next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run **Pause Future Runs**.

To resume a paused protection run:

1. Select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the action icon next to the Protection Group and select **Resume**.

Delete the Protection Group

Cohesity provides the following ways to delete the Protection Group associated with the Amazon S3 buckets:

- **Delete Protection Group Only**: Delete only the Protection Group. Any local snapshots and or archived snapshots stored on the external targets that were captured by this Protection Group are not deleted
- **Delete Protection Group and Snapshots**: Delete the Protection Group and all Snapshots, any local Snapshots captured by this Protection Group and stored on this Cluster are deleted. In addition, any archived Snapshots stored on external targets that were captured by this Protection Group are also deleted.

To delete the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for protecting the Amazon S3 buckets.
3. Click the action icon next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group**? dialog box, select any one of the following options:
    - **Delete Protection Group Only**
    - **Delete Protection Group and Snapshots**

If the current Protection Group is replicating snapshots to a remote cluster or archiving snapshots to an external target, you should cancel these replication or archive tasks before deleting the Protection Group. For instructions, see Cancel Replication and Archive Copy Tasks of a Protection Group Run.

If the Protection Group is replicating to a remote cluster, the inactive job created on the remote cluster is not deleted. In addition, the snapshots that were replicated (copied) to the remote cluster by this job are not deleted. You can log in to the remote cluster to delete the snapshots and the inactive job.

Recover Amazon S3 Buckets

After you protect your Amazon S3 buckets, you can recover them to their original location or a new location using Cohesity.

Recover Amazon S3 to the Original Location

To recover your protected Amazon S3 buckets to their original location:

1. Navigate to **Data Protection** > **Recoveries**. Click **Recover** on the top-right of the page and then select Amazon S3 as the recovery source.
2. Search for a S3 bucket or Protection Group that contains the snapshots to recover from by entering characters of the S3 bucket name, Protection Group name, or by specifying the wildcard character *.

   You can optionally filter the search results by source, Protection Group, or date.
3. From the list of search results, select an S3 bucket you want to recover.

   By default, the latest snapshot is selected for recovery.

   To recover from a different snapshot, perform the following steps:

   a. From the selected lists, click the edit icon.

      The Edit recovery point for <S3bucket_name> page appears. By default, the page displays the latest snapshot available.

   b. Optionally, you can also select a snapshot from a different date by performing one of the following:

      - Selecting the date from the **Choose a date** drop-down list. Once you select the date, the Edit recovery point page displays the available snapshots on the specified date.
      - Clicking the **List** tab. The List tab displays all the available snapshots of the selected S3 bucket.

   c. Select the snapshots to be recovered.

      By default, the snapshot is recovered from the local cluster.

   d. Optionally, you can also select snapshots archived to the cloud by clicking the

cloud icon if available in the **Location** option.

e. Click **Select Recovery Point** and then go to step 5.

4. Click **Next: Recover Options**.
5. Under **Recover To**, select **Original Location**.
6. Enable **Overwrite Existing Bucket** if you want to recover the S3 bucket by overwriting the original S3 bucket. By default, this option is disabled.

   If the data in the source S3 object and target S3 are the same, then the target S3 will not be updated even if the **Overwrite Existing Bucket** option is enabled. If the target bucket is versioned and the S3 object name of the target and the source match, then a new version of the S3 object will be created.
7. In the **Object Prefix** field, add prefix value to the names of the S3 objects that are recovered by this task. For information about the S3 object naming convention, see the AWS documentation.
8. Select your **Recovery Options**:
   a. **S3 Prefixes to Recover**: To perform granular recovery the Amazon S3 bucket, enable the **Turn ON** to recover specific prefixes option and provide the prefix of the objects to be recovered.

      For example, `Finance/statement/document`.

      You can click the **add** icon to provide multiple prefixes.

      The maximum number of prefixes that you can provide per recovery task is 100.

   b. **Continue on Error**: Enable this option if you want to continue the recovery even if one of the S3 objects encounters an error. By default, this option is disabled and the recovery operation will fail if one of the objects encounters an error.

   c. **Task Name**: Change the default name of the recovery task.
9. Click **Recover**.

Cohesity begins to restore the selected Amazon S3 bucket.

Recover Amazon S3 to New Location

To recover your protected Amazon S3 buckets to a new location:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click Recover on the top-right of the page and then select Amazon S3 as the recovery source.
3. Search for a S3 bucket or Protection Group that contains the snapshots to recover from by entering characters of the S3 bucket name, Protection Group name, or by

specifying the wildcard character *.

You can optionally filter the search results by source, Protection Group, or date.

4. From the list of search results, select an S3 bucket you want to recover.

   By default, the latest snapshot is selected for recovery.

   To recover from a different snapshot, perform the following steps:

   a. From the selected lists, click the **edit** icon.

      The Edit recovery point for <S3bucket_name> page appears. By default, the page displays the latest snapshot available.

   b. Optionally, you can also select a snapshot from a different date by performing one of the following:

      - Selecting the date from the **Choose a date** drop-down list. Once you select the date, the Edit recovery point page displays the available snapshots on the specified date.
      - Clicking the **List** tab. The List tab displays all the available snapshots of the selected S3 bucket.

   c. Select the snapshots to be recovered.

      By default, the snapshot is recovered from the local cluster.

      Optionally, you can also select snapshots archived to the cloud by clicking the cloud icon if available in the **Location** option.

   d. Click Select Recovery Point and then go to step 5.

5. Click **Next: Recover Options**.
6. Under **Recover To**, select **New Location** and provide the following information:

   a. **AWS Account**: Select a registered AWS account as the new recovery destination.

   b. **Region**: Select a destination AWS region.

   c. **S3 Bucket**: Select the S3 bucket on to which you want to recover.

7. Enable **Overwrite Existing Bucket** if you want to recover the S3 bucket by overwriting the original S3 bucket. By default, this option is disabled.

   If the data in the source S3 object and target S3 are the same, then the target S3 will not be updated even if the **Overwrite Existing Bucket** option is enabled. If the target bucket is versioned and the S3 object name of the target and the source match, then a new version of the S3 object will be created.

8. In the **Object Prefix** field, add prefix value to the names of the S3 objects that are recovered by this task. For information about the S3 object naming convention, see AWS documentation.
9. Select your **Recovery Options**:

a. **S3 Prefixes to Recover**: To perform granular recovery the Amazon S3 bucket, enable the **Turn ON** to recover specific prefixes option and provide the prefix of the objects to be recovered.

   For example, `Finance/statement/document`.

   You can click the **add** icon to provide multiple prefixes.

   The maximum number of prefixes that you can provide per recovery task is 100.

b. **Continue on Error**: Enable this option if you want to continue the recovery even if one of the S3 objects encounters an error. By default, this option is disabled and the recovery operation will fail if one of the objects encounters an error.

c. **Task Name**: Change the default name of the recovery task.

10. Click **Recover**.

Cohesity begins to restore the selected Amazon S3 bucket.

Amazon Relational Database Service for MySQL

Amazon Relational Database Service (RDS) for MySQL is a fully managed, cloud-based relational database service offered by Amazon Web Services (AWS). Cohesity natively integrates with AWS to provide a simple, fast, and cost-effective solution for backup, recovery, and data management of Amazon Relational Database Service for MySQL instances.

Backup Methods

You can protect your Amazon RDS for MySQL using one of the following backup methods:

- **AWS Snapshot methods**: Cohesity uses this option to protect Amazon RDS for MySQL instances. For protecting the Amazon RDS for MySQL instances, Cohesity leverages the AWS native snapshot and stores them in the same AWS account and region as the source Amazon RDS for MySQL instance.
- **Ingest method**: Cohesity uses this option to protect the Amazon RDS for MySQL instance at the database level by ingesting the backup data to the Cohesity cluster.

> **Important:**
> - Cohesity supports the protection of Amazon RDS for MySQL on DataProtect for cloud in AWS (formerly known as AWS NGCE cluster) at both the instance level (via AWS snapshot-based protection) and the database level (via ingest-based protection).
> - On DataProtect for cloud (legacy) in AWS (formerly known as AWS Cloud Edition cluster), Cohesity supports the backup and recovery of Amazon RDS only at the instance level.

This topic provides information on how you can protect Amazon RDS for MySQL on DataProtect for cloud in AWS.

Plan and Prepare for Amazon RDS for MySQL Protection

To protect Amazon RDS for MySQL with Cohesity, you must register your AWS account as a source in the Cohesity cluster and perform backup and recovery operations. Ensure you meet the pre-requisites and understand the considerations before registering the AWS account.

Required Permissions for AWS RDS for MySQL Data Protection

IAM User Permissions to Execute CFT

To register an AWS account with the Cohesity cluster, specific IAM roles must be created in AWS to grant required permissions. These roles are created by deploying an AWS CloudFormation (CFT) stack provided by Cohesity. The CloudFormation template must be executed from the AWS Management Console. The IAM user or role used to deploy the stack must have sufficient permissions to create, manage, and view CloudFormation stacks, as well as to create the required IAM roles and policies. The table below lists the minimum permissions required for the IAM user or role to successfully run the CloudFormation template.

> **Note:** Ensure to add these permissions manually.

Permission	Purpose
`cloudformation:CreateStack`	Create a new stack.
`cloudformation:UpdateStack`	Modify the stack during updates or re-registration

Permission	Purpose
`cloudformation:DeleteStack`	Delete a stack.
`cloudformation:ValidateTemplate`	Validate the CFT before deployment.
`cloudformation:DescribeStacks`	View the status of stacks.
`cloudformation:ListStacks`	View the status of stacks.
`cloudformation:GetTemplate`	Fetch template for an existing stack.
`cloudformation:GetTemplateSummary`	View a summary of template resources and parameters.
`cloudformation:DescribeStackEvents`	View stack creation progress/errors.
`cloudformation:DescribeStackResources`	View resources created in the stack.
`cloudformation:CreateUploadBucket`	Create a temporary bucket used for uploading artifacts needed by the stack.
`iam:CreateRole`	Create required IAM roles.
`iam:DeleteRole`	Delete IAM roles when cleaning up registrations.
`iam:GetRole`	Retrieve details of existing roles.
`iam:UpdateRole`	Modify existing IAM role configuration.
`iam:TagRole`	Add tags to IAM roles created by the template.
`iam:UntagRole`	Remove tags from IAM roles.
`iam:PutRolePolicy`	Attach inline policies to IAM roles.
`iam:DeleteRolePolicy`	Delete inline policies from IAM roles.
`iam:GetRolePolicy`	iam:GetRolePolicy
`iam:CreateInstanceProfile`	Create instance profiles needed for EC2-based operations.
`iam:GetInstanceProfile`	Retrieve instance profile details.

Permission	Purpose
`iam:AddRoleToInstanceProfile`	Attach IAM roles to the instance profile.
`iam:RemoveRoleFromInstanceProfile`	Detach IAM roles from the instance profile.
`iam:DeleteInstanceProfile`	Delete instance profiles during cleanup.
`iam:AttachRolePolicy`	Attach managed policies to IAM roles.
`iam:DetachRolePolicy`	Remove managed policies from roles.
`iam:ListPolicies`	List available policies for attachment/validation.
`iam:ListRoles`	Retrieve all roles to validate role existence.
`iam:PassRole`	Allow CloudFormation to pass the IAM role to AWS services.
`s3:CreateBucket`	Create an S3 bucket for storing backup or exported data.
`s3:PutObject`	Upload objects to an S3 bucket.
`s3:GetObject`	Retrieve objects from an S3 bucket.
`s3:ListBucket`	View bucket contents to validate template uploads.

Permissions for Amazon RDS for MySQL Protection

Permissions for AWS Snapshot-based Protection

The following table lists the minimum required permissions included in the CloudFormation template for protecting Amazon RDS for MySQL at the instance level (AWS snapshot-based protection).

> **Note:** You do not need to add these permissions manually, as they are automatically added when you run the CFT.

Resource	Permissions	Purpose

rds	`rds:AddTagsToResource`
	`rds:CopyDBClusterSnapshot`
	`rds:CopyDBSnapshot`
	`rds:CreateDBClusterSnapshot`
	`rds:CreateDBInstance`
	`rds:CreateDBSnapshot`
	`rds:DeleteDBClusterSnapshot`
	`rds:DeleteDBSnapshot`
	`rds:DescribeDBClusterSnapshots`
	`rds:DescribeDBClusters`
	`rds:DescribeDBInstances`
	`rds:DescribeDBParameterGroups`
	`rds:DescribeDBSnapshots`
	`rds:DescribeDBSubnetGroups`
	`rds:DescribeOptionGroups`
	`rds:DescribeSourceRegions`
	`rds:ModifyDBClusterSnapshotAttribute`
	`rds:ModifyDBSnapshotAttribute`
	`rds:RestoreDBClusterFromSnapshot`
	`rds:RestoreDBInstanceFromDBSnapshot`
	`rds:RestoreDBInstanceToPointInTime`
		These permissions are required to register the AWS account on Cohesity with the IAM role which got created by the Cloud Formation template.
		Once the source is registered with Cohesity, described permissions are needed so Cohesity can identify resources present in the account, which will be used for backups as well as at the time of recovery we use this information to provide a list of options to choose from.
		Cohesity creates snapshots of the Amazon RDS instances while backing up and storing the different database instance attributes and tags.
		While recovering the database instance, Cohesity creates DB instance/cluster, it also attaches the original tags.
		Cohesity requires the delete snapshots permissions to delete the expired/old snapshots it creates during the backup.
		The modify snapshot attributes permissions are required for shaing the snapshot across accounts if cross-account recovery is attempted.
		`RestoreDBInstanceToPointInTime` and `RestoreDBClusterToPointInTime` is needed to do the point in time recoveries.

Permissions for Ingest-based Protection

The following table lists the minimum required permissions included in the CloudFormation template for protecting Amazon RDS for MySQL at the database level (Ingest-based protection).

> **Note:** You do not need to add these permissions manually, as they are automatically added when you run the CFT.

Resource	Permission	Purpose
rds	`rds:DescribeDBInstances`	List RDS instances.

Authenticate for Ingest-based Protection

If you are planning to protect the Amazon RDS for MySQL using Ingest-based protection method, you must authenticate the Cohesity cluster to discover the databases of the Amazon RDS for MySQL instance using one of the following methods:

- **Username** and **password** of the Amazon RDS for MySQL instances.
- **IAM-authenticated MySQL user**.

  If you choose the IAM-authenticated MySQL user method, ensure the following:

  - The IAM-authenticated user must be created within the MySQL database and must have the following permissions:
    - `SELECT`
    - `INSERT`
    - `UPDATE`
    - `DELETE`
    - `CREATE`
    - `DROP`
    - `RELOAD`
    - `PROCESS`
    - `REFERENCES`
    - `INDEX`
    - `ALTER`
    - `SHOW DATABASES`
    - `LOCK TABLES`
    - `CREATE VIEW`
    - `SHOW VIEW`
    - `CREATE ROUTINE`
    - `ALTER ROUTINE`
    - `SHOW ROUTINE`
    - `EVENT`
    - `TRIGGER`
    - `SET_USER_ID`
    - `REPLICATION CLIENT`

Example:

```
CREATE USER 'iamuser'@'%' IDENTIFIED BY 'StrongPassword!';
GRANT  SELECT, INSERT, UPDATE, DELETE, CREATE, DROP, RELOAD,
PROCESS,         REFERENCES, INDEX, ALTER, SHOW DATABASES, LOCK TABLES,
CREATE  VIEW,    SHOW VIEW, CREATE ROUTINE, ALTER ROUTINE, SHOW
ROUTINE,         EVENT, TRIGGER, SET_USER_ID, REPLICATION CLIENT

ON *.* TO 'iamuser'@'%'

 WITH GRANT OPTION;
 FLUSH PRIVILEGES;
```

- The IAM role attached to the Cohesity cluster nodes (when registering the AWS account) must include the following trust policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "iam.amazonaws.com",
          "rds.amazonaws.com",
          "ec2.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

Network Access Requirement

- The EC2 instance's (The host applications that connect to the RDS MySQL.) security group must allow outbound traffic to the RDS endpoint on port 3306, or any custom port configured for the RDS MySQL.
- The RDS instance's security group must allow inbound connections from the EC2 instance (or its associated security group).

Considerations for AWS RDS for MySQL Data Protection

Review and understand the following limitations and knows issues before you protect Amazon RDS for MySQL:

- Cohesity performs only full backup of Amazon RDS for MySQL.
- Cohesity protects only the user databases within the Amazon RDS for MySQL. Protection of system databases are not supported.
- The backup and recovery of Amazon RDS for MySQL instance at database level is supported only on AWS DataProtect for cloud.
- You can perform database-level restores of Amazon RDS for MySQL to another region within the same AWS account. However, you cannot restore the database to a different AWS account in another region.
- Restoring a backup taken from a higher RDS MySQL database version to a lower version is not supported.
- You cannot perform ingest-based and snapshot-based protections within the same protection Group.
- If you have selected databases for protection, then you cannot choose snapshot-based policy.
- For protection, if you have selected instances with no databases discovered, then you cannot choose ingest-based policy.

Register and Manage AWS Account

To protect your Amazon RDS for MySQL, you need to register AWS account as a source on the Cohesity cluster. After registering your AWS account as a source, you can:

- Update the AWS source configuration.
- Refresh the source details.
- Unregister the AWS source from the Cohesity cluster.

Register AWS Account

Before registering AWS account as a source, make sure you have completed all prerequisite tasks and reviewed the considerations.

To register AWS account as a source:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Register** at the top-right of the page and then select **Cloud Platforms** > **AWS**.

   The **Register AWS Source** dialog box appears.
3. Enter the **AWS Account ID**.
4. From the list of **AWS services**, select **RDS**.

5. Click **Next** to generate a CloudFormation Template (CFT), which you will use to complete the AWS source registration.
6. Click **Download** to download the CloudFormation Template.
7. On running the CFT, IAM roles and policies are created.
8. Once the roles and policies are created successfully, click **Register**.

Run CloudFormation Template

To complete the registration of the AWS account with the Cohesity cluster, you must run the CloudFormation Template on the AWS account you are registering. You can download CFT from the product UI as you register the AWS source.

When you execute the CFT, it creates an AWS IAM role and the policies.

Executing the CFT Template

1. In the **AWS Management Console**, navigate to **Services** and search for **CloudFormation**.
2. Click **Create stack** > **With new resources** to create a stack under AWS cloudFormation using the downloaded CloudFormation Template.
    1. In the **Prerequisite - Prepare template** page, select **Choose an existing template** > **Upload a template file**.
    2. Click **Choose File** to browse and upload the JSON Cloudformation template. Click **Next**.
    3. Enter a **Stack name** and specify the AWS Account ID where the Cloud Edition cluster is running.
    4. Select **source_registration** for creating IAM role for registration AWS source.
    5. Click **Next**.
    6. Acknowledge the creation of IAM resources by selecting the checkbox, then click **Create Stack**.
    7. Once the stack creation is successful, view the **Resources** tab to check the created IAM roles.
    8. The following IAM roles and profiles are created:
        - CohesityInstanceRole
        - CohesityInstanceProfile
        - CohesitySourceRegistrationRole

Attaching the IAM Role to Cluster Nodes

To complete registration, attach the **CohesityInstanceProfile** role to all nodes in the cluster:

1. Navigate to **Services** > **EC2** > **Instances**.
2. Select the cluster created. For a multi node, the IAM role must be attached on all nodes.
3. Select **Actions** > **Security** > **Modify IAM Role**.
4. In the **IAM Role** field, enter the name/search for the Instance Profile (*CohesityInstanceProfile*) that was created.
5. Click **Update IAM role**.

   The IAM role is successfully attached to that EC2 instance.

   > **Note:** If any new node is added to the cluster, then this role has to be attached to every newly added node in the cluster as well.

Complete AWS Source Registration

Once the IAM role is attached, complete the AWS source registration on the cluster.

Update AWS Account Source Configuration

You can edit the registered AWS account to add or remove the Amazon services protected by the Cohesity from your AWS account.

To edit the AWS account source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select Edit.
3. In the **Edit AWS Source** page, select or unselect the Amazon services.
4. Click **Update**.

Refresh AWS Account Source

You can refresh the AWS account source configuration and fetch the latest changes on your AWS account.

To refresh the AWS source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select **Refresh**.

Unregister AWS Account Source

If you plan to stop taking the backup of your AWS source, you can unregister the AWS source from the Cohesity cluster.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the AWS source.

To unregister the AWS source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select **Unregister**.

Backup Amazon RDS for MySQL

After registering your AWS account as a source in the Cohesity cluster, it uses the IAM user used for running the CloudFormation Template (CFT) to authenticate with AWS Account.

Once authenticated, depending on the services you selected while registering the source, the Cohesity cluster automatically discovers all supported workloads including Amazon RDS for MySQL associated with the specified AWS account ID. The discovered workloads appear under **Data Protection** > **Sources**. When you open the registered AWS account source, each workload type is displayed on its own tab. Select the **RDS MySQL** tab to view all discovered instances.

The **RDS MySQL** tab displays the entity hierarchy for the Amazon RDS for MySQL environment, allowing you to navigate from the account level down to individual databases.

RDS MySQL Entity Hierarchy

The **RDS MySQL** tab displays the entity hierarchy for the RDS instance, allowing you to navigate from the account level down to individual databases.

The **RDS MySQL** entity hierarchy in the Cohesity cluster follows this structure:

Structure	Description
AWS Account	The AWS account registered with Cohesity for RDS protection.
AWS Region	The AWS region where the RDS resources reside.
Availability Zone	The availability zone within the region where the RDS instance is deployed.
RDS Instance	The specific RDS MySQL instance within the selected availability zone.
Database	The individual databases hosted within the RDS MySQL instance.

Backup Scope by RDS MySQL Hierarchy

The Cohesity cluster allows you to back up Amazon RDS for MySQL at different levels of the entity hierarchy. You can choose to back up:

- **AWS Account** – Protect all RDS MySQL instances and databases within the registered AWS account.
- **AWS Region** – Protect all RDS MySQL instances and databases within a specific region of the registered account.
- **Availability Zone** – Protect RDS MySQL instances and databases within a specific availability zone.
- **RDS Instance** – Protect a specific RDS MySQL instance and all databases hosted on it.
- **Database** – Protect individual databases within an RDS MySQL instance by providing the database credentials.

RDS for MYSQL Backup Methods

Cohesity provides the following Protection Types for the protecting Amazon RDS MySQL:

- **AWS Snapshot method**: Cohesity uses this option to protect Amazon RDS for MySQL instances. For protecting the Amazon RDS for MySQL instances, Cohesity leverages the AWS native snapshot and stores them in the same AWS account and region as the source Amazon RDS for MySQL instance.
- **Ingest method**: Cohesity uses this option to protect the Amazon RDS for MySQL instance at the database level by ingesting the backup data to the Cohesity cluster.

Supported Backup Types

Cohesity performs only full backup of Amazon RDS for MySQL.

Protect Amazon RDS for MySQL Using Ingest Method

With the Ingest protection method, Cohesity cluster protects the Amazon RDS MySQL of your AWS account at the database level.

To protect the Amazon RDS MySQL of your AWS account at the database level using the Ingest method, you must provide the credentials of the Amazon RDS MySQL instance while creating the protection. By providing the credentials, Cohesity discovers the databases as objects for protection.

To protect your Amazon RDS for MySQL using Ingest method:

1. In **Data Protection**, navigate to **Sources**.
2. Find the registered AWS account and click into it.
3. Click the **RDS MySQL** tab.
4. Select the Amazon RDS for MySQL for protection using one of the following views listed in the table:

View	Usage	Action
List View	Use this option to select the instances from a flat, searchable list.	1. Click the **List View** icon in the top-right corner of the page. 2. Use the checkboxes to select the Amazon RDS for MySQL instances.
Hierarchy View	Use this option to select instances at various hierarchy levels.	1. Click the **Hierarchy View** icon in the top-right corner of the page. 2. Select the checkbox for a hierarchy level, and then select **Select All Child Objects** to include all instances with that level.
Tags View	Use this option to select the instances based on tags.	1. Click the **Tags View** icon in the top-right corner of the page. 2. Select the checkbox of a tag, and then select **Select All Child Objects** to include all instances with that tag.

5. Click the **lock** icon labeled **Database Credentials** displayed on the right side of the corresponding instance or hierarchy level.

   The Database Credentials for RDS MySQL dialogue box appears.

6. Select one of the following authentication methods for Cohesity to discover the databases of the Amazon RDS for MySQL instances:

   - **Credentials**: Enter the **Username**, and **Password** for the Amazon RDS for MySQL instances.
   - **IAM Authentication**: Enter the **Username** for IAM authentication.

     For information on the authentication requirements, see Authenticate for Ingest-based Protection.

7. Click **Save**.

   The databases of the of the Amazon RDS for MySQL instances are discovered.

8. Optionally, you can configure auto-protection at the following hierarchy levels to automatically protect the new databases that are added to the Amazon RDS for MySQL instances.

- **AWS Account level**: Select the AWS account checkbox, then select **Auto Protect This AWS**.
- **AWS Region level**: Select the region checkbox, then select **Auto Protect This Region**.
- **Availability Zone level**: Select the availability zone checkbox, then select **Auto Protect This Availability Zone**.
- **Instance level**: Select the instance checkbox and then select **Auto Protect This RDS MySQL**.

To auto-protect the databases of the Amazon RDS for MySQL instances based on tags, click the **Tag** icon at the right corner of the page. Select the checkbox of a tag and then select **Auto Protect** This to auto-protect the Amazon RDS for MySQL instances with this tag.

You can also exclude the databases of Amazon RDS for MySQL instances from auto-protection within an account, region, availability zone, instance by clicking the auto-protect icon ( ) next to the database. The databases excluded from auto-protection are displayed with the exclude ( ) icon.

9. Click the **Protect** button above the checkboxes.

   The New Protection dialog box appears.

10. Provide a name for the **Protection Group**. The name can contain alphanumeric characters, underscores, dashes, and periods.
11. The Ingest-based policy is enabled by default. Create or select an existing policy from the **Policy (Cohesity Ingest)** drop-down.
12. Select **More Options** to change or configure any of the advanced settings.
13. Click **Protect**.

Advanced Settings

Section	Setting	Description
Settings	**Start Time**	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
	SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: This option is not applicable. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

Section	Setting	Description
Additional Settings	**Pause Future Runs**	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
	End Date	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
	QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. • **Backup Auto**: This policy achieves similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. The data is written to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
	Alerts	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.

Section	Setting	Description
	Priority	Select a priority for the Protection Group execution. Cohesity Platform supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: • High-priority protection runs • Medium-priority protection runs • Low-priority protection runs
	Description	**Optional**. Enter a brief description about the Protection Group.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.

Protect Amazon RDS for MySQL Using AWS Snapshot Method

With the AWS Snapshot protection method, Cohesity cluster protects the Amazon RDS MySQL of your AWS account at the instance level.

To protect your Amazon RDS for MySQL instance using AWS snapshot method:

1. In **Data Protection**, navigate to **Sources**.
2. Find the registered AWS account and click into it.
3. Click the **RDS MySQL** tab.
4. Select the Amazon RDS for MySQL instances for protection using one of the following views listed in the table:

View	Usage	Action
List View	Use this option to select the instances for protection from a flat, searchable list.	1. Click the **List View** icon in the top-right corner of the page. 2. Use the checkboxes to select the Amazon RDS for MySQL instances you want to protect.
Hierarchy View	Use this option to select instances for protection at various hierarchy levels.	1. Click the **Hierarchy View** icon in the top-right corner of the page. 2. Select the checkbox for a hierarchy level, and then select **Select All Child Objects** to protect all the Amazon RDS for MySQL instances under that hierarchy level. **Auto-Protect Options**: Optionally, you can configure auto-protection at the following levels to automatically protect newly added RDS instances: • **AWS Account level**: Select the AWS account checkbox, then select **Auto Protect This AWS Account**. • **AWS Region level**: Select the region checkbox, then select **Auto Protect This Region**. • **Availability Zone level**: Select the availability zone checkbox, then select **Auto Protect This Availability Zone**. You can also exclude the Amazon RDS for MySQL instances from auto-protection within an account, region, or availability zone by clicking the auto-protect icon ( ) next to the instance. The instances excluded from auto-protection are displayed with the exclude ( ) icon.

View	Usage	Action
Tags View	Use this option to select the instances for protection based on tags.	1. Click the **Tags View** icon in the top-right corner of the page. 2. Select the checkbox of a tag, and then select Select All Child Objects to include all instances with that tag. **Tag-Based Auto-Protect**: Optionally, you can configure auto-protection based on a tag by selecting the tag checkbox and then choose **Auto Protect This Tag.** You can also exclude the Amazon RDS for MySQL instances from auto-protection within a tag by clicking the auto-protect icon ( ) next to the instance. The instances excluded from auto-protection are displayed with the exclude ( ) icon.

5. Click the **Protect** button above the checkboxes.

   The New Protection dialog box appears.
6. Provide a name for the **Protection Group**. The name can contain alphanumeric characters, underscores, dashes, and periods.
7. The AWS Snapshot-based policy is enabled by default. Create or select an existing policy from the **Policy (AWS Snapshot)** drop-down.
8. Select **More Options** to change or configure any of the advanced settings.
9. Click **Protect**.

Advanced Settings

Section	Setting	Description
Settings	**Start Time**	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
	SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: This option is not applicable. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

Section	Setting	Description
Additional Settings	**Pause Future Runs**	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
	End Date	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
	QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. • **Backup Auto**: This policy achieves similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. The data is written to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
	Alerts	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.

Section	Setting	Description
	Priority	Select a priority for the Protection Group execution. Cohesity Platform supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: • High-priority protection runs • Medium-priority protection runs • Low-priority protection runs
	Description	**Optional**. Enter a brief description about the Protection Group.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.

Manage Amazon RDS for MySQL Backup Configuration

In the Cohesity, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Object(s) to the Protection Group

Depending on the Protection Type you chose while creating the Protection Group, you can add new Amazon RDS for MySQL instances or databases to the existing Protection Group for backup. The newly added object is backed up from the next protection run, and it will be a full backup for the newly added object.

To add object(s) to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had created for Amazon RDS for MySQL.

3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click in the **Objects** section.
5. In the **Objects** section, click the plus icon (**+**) to enter multiple objects that you plan to back up. Click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon RDS for MySQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon RDS for MySQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a recovery run:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. Click the action menu (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all associated local and archived snapshots. Replicated snapshots must be deleted from the remote cluster. Snapshots under DataLock cannot be deleted.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the product UI.

To delete the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon RDS for MySQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Keep the **Delete Snapshots** toggle disabled to delete the Protection Group only.

- Enable the **Delete Snapshots** toggle to delete the Protection Group and all associated snapshots.

5. Type **YES** to confirm that you want to delete the Protection Group.
6. Click **Delete Group**.

Recover Amazon RDS for MySQL at Database Level

You can recover the Amazon RDS for MySQL at database level if you have protected the Amazon RDS for MySQL using the RDS Ingest Protection Type.

> **Note:** We recommend that you review the Amazon RDS for MySQL requirements and considerations.

To recover Amazon RDS for MySQL:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **AWS** > **RDS MySQL**.
3. Search for the database by entering characters of the database name, or by specifying the wildcard character *.
4. From the list of search results, select the database to recover. By default, the latest snapshot of the database is selected for recovery. To recover from a different snapshot, perform the following steps depending on the object selected:

   From the selected lists, mouse over the snapshot, and then click the edit icon. The **Edit recovery point for <*database_name*>** page appears. By default, the option to select the snapshot is displayed in the **List** mode. You can also choose to view the option in Timeline mode by clicking the **Timeline** tab in the top-right corner of the page.

   - To select a snapshot from the **List** mode:
     a. Select the **List** tab from the top-right corner of the **Edit recovery point for <*database_name*>** page. By default, the page displays the snapshots available in the last one month. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.
     b. Select the snapshots to be recovered.
     c. By default, the snapshot is recovered from the local Cohesity cluster.
     d. Click **Select Recovery Point** and then go to step 5.
   - To select a snapshot from the **Timeline** mode:

a. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar.

b. Select the snapshot to be recovered by clicking the corresponding blue dot.

c. By default, the snapshot is recovered from the local Cohesity cluster.

d. Click **Select Recovery Point** and then go to step 5.

5. Click **Next: Recover Options**.
6. In the **Recover To** section, select any one of the following options based on where you want to restore the database and then provide the required information:
   - **Original Location**: Restore the database to the original Amazon RDS for MySQL instance.

     > **Note:** Restoring to the original location overwrites the existing database.

     Type **Yes** to confirm.
   - **New Location**: Restore the database to a different Amazon RDS for MySQL instance within the same AWS account source. Restoring to another region within the same AWS account is supported. However, restoring to a different AWS account is not supported.

     a. From the **Source** drop down, select a registered AWS account and from the instance drop down, select the Amazon RDS for MySQL instance to which you want to restore the database.

     b. To overwrite any existing database with the same name, enable **Overwrite existing database(s)** and type **Yes** to confirm.

     > **Note:** Restoring to a new location also replaces any existing database with the same name in the selected instance.
7. In the **Recovery Options** section, configure the following options:

Options	Description
Rename	Enter a new name for the database if you want to rename it after recovery.
Task Name	Update the default name of the recovery task.

8. Click **Recover**.

Amazon Aurora MySQL

Amazon Aurora MySQL is a fully managed, MySQL-compatible, cloud-based relational database service offered by Amazon Web Services (AWS). Cohesity natively integrates with AWS to provide a simple, fast, and cost-effective solution for backup, recovery, and data management of Amazon Aurora MySQL instances.

Backup Methods

You can protect your Amazon Aurora MySQL using one of the following backup methods:

- **AWS Snapshot methods**: Cohesity uses this option to protect Amazon Aurora MySQL instances. For protecting the Amazon Aurora MySQL instances, Cohesity leverages the AWS native snapshot and stores them in the same AWS account and region as the source Amazon Aurora MySQL instance.
- **Ingest method**: Cohesity uses this option to protect the Amazon Aurora MySQL instance at the database level by ingesting the backup data to the Cohesity cluster.

> **Important:**
> - Cohesity supports the backup and recovery of Amazon Aurora MySQL on DataProtect for cloud in AWS (formerly known as AWS NGCE cluster) at both the instance level (via RDS snapshot-based protection) and the database level (via ingest-based protection).
> - On DataProtect for cloud (legacy) in AWS (formerly known as AWS Cloud Edition cluster), Cohesity supports the backup and recovery of Amazon Aurora only at the instance level.

This topic provides information on how you can protect Amazon Aurora MySQL on DataProtect for cloud in AWS.

Plan and Prepare for Amazon Aurora MySQL

To protect Amazon Aurora MySQL with Cohesity, you must register your AWS account as a source in the Cohesity cluster and perform backup and recovery operations. Ensure you meet the pre-requisites and understand the considerations before registering the AWS account.

Required Permissions for AWS Aurora MySQL Data Protection

IAM User Permissions to Execute CFT

To register an AWS account with the Cohesity cluster, specific IAM roles must be created in AWS to grant required permissions. These roles are created by deploying an AWS

CloudFormation (CFT) stack provided by Cohesity. The CloudFormation template must be executed from the AWS Management Console. The IAM user or role used to deploy the stack must have sufficient permissions to create, manage, and view CloudFormation stacks, as well as to create the required IAM roles and policies.

The table below lists the minimum permissions required for the IAM user or role to successfully run the CloudFormation template.

> **Note:** Ensure to add these permissions manually.

Permission	Purpose
`cloudformation:CreateStack`	Create a new stack.
`cloudformation:UpdateStack`	Modify the stack during updates or re-registration
`cloudformation:DeleteStack`	Delete a stack.
`cloudformation:ValidateTemplate`	Validate the CFT before deployment.
`cloudformation:DescribeStacks`	View the status of stacks.
`cloudformation:ListStacks`	View the status of stacks.
`cloudformation:GetTemplate`	Fetch template for an existing stack.
`cloudformation:GetTemplateSummary`	View a summary of template resources and parameters.
`cloudformation:DescribeStackEvents`	View stack creation progress/errors.
`cloudformation:DescribeStackResources`	View resources created in the stack.
`cloudformation:CreateUploadBucket`	Create a temporary bucket used for uploading artifacts needed by the stack.
`iam:CreateRole`	Create required IAM roles.
`iam:DeleteRole`	Delete IAM roles when cleaning up registrations.
`iam:GetRole`	Retrieve details of existing roles.
`iam:UpdateRole`	Modify existing IAM role configuration.

Permission	Purpose
iam:TagRole	Add tags to IAM roles created by the template.
iam:UntagRole	Remove tags from IAM roles.
iam:PutRolePolicy	Attach inline policies to IAM roles.
iam:DeleteRolePolicy	Delete inline policies from IAM roles.
iam:GetRolePolicy	iam:GetRolePolicy
iam:CreateInstanceProfile	Create instance profiles needed for EC2-based operations.
iam:GetInstanceProfile	Retrieve instance profile details.
iam:AddRoleToInstanceProfile	Attach IAM roles to the instance profile.
iam:RemoveRoleFromInstanceProfile	Detach IAM roles from the instance profile.
iam:DeleteInstanceProfile	Delete instance profiles during cleanup.
iam:AttachRolePolicy	Attach managed policies to IAM roles.
iam:DetachRolePolicy	Remove managed policies from roles.
iam:ListPolicies	List available policies for attachment/validation.
iam:ListRoles	Retrieve all roles to validate role existence.
iam:PassRole	Allow CloudFormation to pass the IAM role to AWS services.
s3:CreateBucket	Create an S3 bucket for storing backup or exported data.
s3:PutObject	Upload objects to an S3 bucket.
s3:GetObject	Retrieve objects from an S3 bucket.
s3:ListBucket	View bucket contents to validate template uploads.

Permissions for Amazon Aurora MySQL Protection

Permissions for AWS Snapshot-based Protection

The following table lists the minimum required permissions included in the CloudFormation template for protecting Amazon Aurora MySQL at the instance level (AWS snapshot-based

protection).

> **Note:** You do not need to add these permissions manually, as they are automatically added when you run the CFT.

Resource	Permissions	Purpose

rds	`rds:AddTagsToResource`
	`rds:CopyDBClusterSnapshot`
	`rds:CopyDBSnapshot`
	`rds:CreateDBClusterSnapshot`
	`rds:CreateDBInstance`
	`rds:CreateDBSnapshot`
	`rds:DeleteDBClusterSnapshot`
	`rds:DeleteDBSnapshot`
	`rds:DescribeDBClusterSnapshots`
	`rds:DescribeDBClusters`
	`rds:DescribeDBInstances`
	`rds:DescribeDBParameterGroups`
	`rds:DescribeDBSnapshots`
	`rds:DescribeDBSubnetGroups`
	`rds:DescribeOptionGroups`
	`rds:DescribeSourceRegions`
	`rds:ModifyDBClusterSnapshotAttribute`
	`rds:ModifyDBSnapshotAttribute`
	`rds:RestoreDBClusterFromSnapshot`
	`rds:RestoreDBInstanceFromDBSnapshot`
	`rds:RestoreDBInstanceToPointInTime`
		These permissions are required to register the AWS account on Cohesity with the IAM role which got created by the Cloud Formation template.
		Once the source is registered with Cohesity, described permissions are needed so Cohesity can identify resources present in the account, which will be used for backups as well as at the time of recovery we use this information to provide a list of options to choose from.
		Cohesity creates snapshots of the Amazon Aurora instances while backing up and storing the different database instance attributes and tags.
		While recovering the database instance, Cohesity creates DB instance/cluster, it also attaches the original tags.
		Cohesity requires the delete snapshots permissions to delete the expired/old snapshots it creates during the backup.
		The modify snapshot attributes permissions are required for shaing the snapshot across accounts if cross-account recovery is attempted.
		`RestoreDBInstanceToPointInTime` and `RestoreDBClusterToPointInTime` is needed to do the point in time recoveries.

Permissions for Ingest-based Protection

The following table lists the minimum required permissions included in the CloudFormation template for protecting Amazon Aurora MySQL at the database level (Ingest-based protection).

> **Note:** You do not need to add these permissions manually, as they are automatically added when you run the CFT.

Resource	Permission	Purpose
rds	`rds:DescribeDBClusters`	List the Aurora clusters.

Authenticate for Ingest-based Protection

If you are planning to protect the Amazon Aurora MySQL using Ingest-based protection method, you must authenticate the Cohesity cluster to discover the databases of the Amazon Aurora MySQL instance using one of the following methods:

- **Username** and **password** of the Amazon Aurora MySQL instances.
- **IAM-authenticated MySQL user**.

  If you choose the IAM-authenticated MySQL user method, ensure the following:

  - The IAM-authenticated user must be created within the MySQL database and must have the following permissions:
    - `SELECT`
    - `INSERT`
    - `UPDATE`
    - `DELETE`
    - `CREATE`
    - `DROP`
    - `RELOAD`
    - `PROCESS`
    - `REFERENCES`
    - `INDEX`
    - `ALTER`
    - `SHOW DATABASES`
    - `LOCK TABLES`
    - `CREATE VIEW`
    - `SHOW VIEW`
    - `CREATE ROUTINE`
    - `ALTER ROUTINE`
    - `SHOW ROUTINE`

- EVENT
- TRIGGER
- SET_USER_ID
- REPLICATION CLIENT

Example:

```
CREATE USER 'iamuser'@'%' IDENTIFIED BY 'StrongPassword!';
GRANT  SELECT, INSERT, UPDATE, DELETE, CREATE, DROP, RELOAD,
PROCESS,         REFERENCES, INDEX, ALTER, SHOW DATABASES, LOCK TABLES,
CREATE  VIEW,    SHOW VIEW, CREATE ROUTINE, ALTER ROUTINE, SHOW
ROUTINE,         EVENT, TRIGGER, SET_USER_ID, REPLICATION CLIENT

ON *.* TO 'iamuser'@'%'

 WITH GRANT OPTION;
 FLUSH PRIVILEGES;
```

- The IAM role attached to the Cohesity cluster nodes (when registering the AWS account) must include the following trust policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "iam.amazonaws.com",
          "rds.amazonaws.com",
          "ec2.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

Network Access Requirement

- The EC2 instance's (The host applications that connect to the Aurora MySQL database.) security group must allow outbound traffic to the Aurora MySQL cluster

endpoint on port 3306, or any custom port configured for the Aurora MySQL database.

- The Aurora MySQL cluster's security group must allow inbound connections from the EC2 instance (or its associated security group).

Considerations for AWS Aurora MySQL Data Protection

Review and understand the following limitations and knows issues before you protect Amazon Aurora MySQL:

- Cohesity performs only full backup of Amazon Aurora MySQL.
- Cohesity protects only the user databases within the Amazon Aurora MySQL. Protection of system databases are not supported.
- The backup and recovery of Amazon Aurora MySQL instance at database level is supported only on AWS DataProtect for cloud.
- You can perform database-level restores of Amazon Aurora MySQL to another region within the same AWS account. However, you cannot restore the database to a different AWS account in another region.
- Restoring a backup taken from a higher Amazon Aurora MySQL database version to a lower version is not supported.
- You cannot perform ingest-based and snapshot-based protections within the same protection Group.
- If you have selected databases for protection, then you cannot choose snapshot-based policy.
- For protection, if you have selected instances with no databases discovered, then you cannot choose ingest-based policy.

Register and Manage AWS Account

To protect your Amazon Aurora MySQL, you need to register AWS account as a source on the Cohesity cluster. After registering your AWS account as a source, you can:

- Update the AWS source configuration.
- Refresh the source details.
- Unregister the AWS source from the Cohesity cluster.

Register AWS Account

Before registering AWS account as a source, make sure you have completed all prerequisite tasks and reviewed the considerations.

To register AWS account as a source:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Register** at the top-right of the page and then select **Cloud Platforms** > **AWS**.

The **Register AWS Source** dialog box appears.

3. Enter the **AWS Account ID**.
4. From the list of **AWS services**, select **RDS**.
5. Click **Next** to generate a CloudFormation Template (CFT), which you will use to complete the AWS source registration.
6. Click **Download** to download the CloudFormation Template.
7. On running the CFT, IAM roles and policies are created.
8. Once the roles and policies are created successfully, click **Register**.

Run CloudFormation Template

To complete the registration of the AWS account with the Cohesity cluster, you must run the CloudFormation Template on the AWS account you are registering. You can download CFT from the product UI as you register the AWS source.

When you execute the CFT, it creates an AWS IAM role and the policies.

Executing the CFT Template

1. In the **AWS Management Console**, navigate to **Services** and search for **CloudFormation**.
2. Click **Create stack** > **With new resources** to create a stack under AWS cloudFormation using the downloaded CloudFormation Template.
    1. In the **Prerequisite - Prepare template** page, select **Choose an existing template** > **Upload a template file**.
    2. Click **Choose File** to browse and upload the JSON Cloudformation template. Click **Next**.
    3. Enter a **Stack name** and specify the AWS Account ID where the Cloud Edition cluster is running.
    4. Select **source_registration** for creating IAM role for registration AWS source.
    5. Click **Next**.
    6. Acknowledge the creation of IAM resources by selecting the checkbox, then click **Create Stack**.
    7. Once the stack creation is successful, view the **Resources** tab to check the created IAM roles.
    8. The following IAM roles and profiles are created:
        - CohesityInstanceRole
        - CohesityInstanceProfile
        - CohesitySourceRegistrationRole

Attaching the IAM Role to Cluster Nodes

To complete registration, attach the **CohesityInstanceProfile** role to all nodes in the cluster:

1. Navigate to **Services** > **EC2** > **Instances**.
2. Select the cluster created. For a multi node, the IAM role must be attached on all nodes.
3. Select **Actions** > **Security** > **Modify IAM Role**.
4. In the **IAM Role** field, enter the name/search for the Instance Profile (*CohesityInstanceProfile*) that was created.
5. Click **Update IAM role**.

   The IAM role is successfully attached to that EC2 instance.

   > **Note:** If any new node is added to the cluster, then this role has to be attached to every newly added node in the cluster as well.

Complete AWS Source Registration

Once the IAM role is attached, complete the AWS source registration on the cluster.

Update AWS Account Source Configuration

You can edit the registered AWS account to add or remove the Amazon services protected by the Cohesity from your AWS account.

To edit the AWS account source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select Edit.
3. In the **Edit AWS Source** page, select or unselect the Amazon services.
4. Click **Update**.

Refresh AWS Account Source

You can refresh the AWS account source configuration and fetch the latest changes on your AWS account.

To refresh the AWS source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select **Refresh**.

Unregister AWS Account Source

If you plan to stop taking the backup of your AWS source, you can unregister the AWS source from the Cohesity cluster.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the AWS source.

To unregister the AWS source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select **Unregister**.

Backup Amazon Aurora MySQL

After registering your AWS account as a source in the Cohesity cluster, it uses the IAM user used for running the CloudFormation Template (CFT) to authenticate with AWS Account.

Once authenticated, depending on the services you selected while registering the source, the Cohesity cluster automatically discovers all supported workloads including Amazon Aurora MySQL associated with the specified AWS account ID. The discovered workloads appear under **Data Protection** > **Sources**. When you open the registered AWS account source, each workload type is displayed on its own tab. Select the **Aurora MySQL** tab to view all discovered instances.

The **Aurora MySQL** tab displays the entity hierarchy for the Amazon Aurora MySQL environment, allowing you to navigate from the account level down to individual databases.

Aurora MySQL Entity Hierarchy

The **Aurora MySQL** tab displays the entity hierarchy for the Aurora MySQL instance, allowing you to navigate from the account level down to individual databases.

The **Aurora MySQL** entity hierarchy in the Cohesity cluster follows this structure:

Structure	Description
AWS Account	The AWS account registered with Cohesity for Aurora MySQL protection.
AWS Region	The AWS region where the Aurora MySQL resources reside.
Availability Zone	The availability zone within the region where the Aurora MySQL instance is deployed.
Aurora MySQL Instance	The specific Aurora MySQL instance within the selected availability zone.
Database	The individual databases hosted within the Aurora MySQL instance.

Backup Scope by Aurora MySQL Hierarchy

The Cohesity cluster allows you to back up Amazon Aurora MySQL at different levels of the entity hierarchy. You can choose to back up:

- **AWS Account** – Protect all Aurora MySQL instances and databases within the registered AWS account.
- **AWS Region** – Protect all Aurora MySQL instances and databases within a specific region of the registered account.
- **Availability Zone** – Protect Aurora MySQL instances and databases within a specific availability zone.
- **Aurora MySQL Instance** – Protect a specific Aurora MySQL instance and all databases hosted on it.
- **Database** – Protect individual databases within an Aurora MySQL instance by providing the database credentials.

Aurora MySQL Backup Methods

Cohesity provides the following Protection Types for the protecting Amazon Aurora MySQL:

- **AWS Snapshot method**: Cohesity uses this option to protect Amazon Aurora MySQL instances. For protecting the Amazon Aurora MySQL instances, Cohesity leverages the AWS native snapshot and stores them in the same AWS account and region as the source Amazon Aurora MySQL instance.
- **Ingest method**: Cohesity uses this option to protect the Amazon Aurora MySQL instance at the database level by ingesting the backup data to the Cohesity cluster.

Supported Backup Types

Cohesity performs only full backup of Amazon Aurora MySQL.

Protect Amazon Aurora MySQL Using Ingest Method

With the Ingest protection method, Cohesity cluster protects the Amazon Aurora MySQL of your AWS account at the database level.

To protect the Amazon Aurora MySQL of your AWS account at the database level using the Ingest method, you must provide the credentials of the Amazon Aurora MySQL instance while creating the protection. By providing the credentials, Cohesity discovers the databases as objects for protection.

To protect your Amazon Aurora MySQL using Ingest method:

1. In **Data Protection**, navigate to **Sources**.
2. Find the registered AWS account and click into it.
3. Click the **Aurora MySQL** tab.

4. Select the Amazon Aurora MySQL for protection using one of the following views listed in the table:

View	Usage	Action
List View	Use this option to select the instances from a flat, searchable list.	1. Click the **List View** icon in the top-right corner of the page. 2. Use the checkboxes to select the Amazon Aurora MySQL instances.
Hierarchy View	Use this option to select instances at various hierarchy levels.	1. Click the **Hierarchy View** icon in the top-right corner of the page. 2. Select the checkbox for a hierarchy level, and then select **Select All Child Objects** to include all instances with that level.
Tags View	Use this option to select the instances based on tags.	1. Click the **Tags View** icon in the top-right corner of the page. 2. Select the checkbox of a tag, and then select **Select All Child Objects** to include all instances with that tag.

5. Click the **lock** icon labeled **Database Credentials** displayed on the right side of the corresponding instance or hierarchy level.

   The Database Credentials for Aurora MySQL dialogue box appears.

6. Select one of the following authentication methods for Cohesity to discover the databases of the Amazon Aurora MySQL instances:

   - **Credentials**: Enter the **Username**, and **Password** for the Amazon Aurora MySQL instances.
   - **IAM Authentication**: Enter the **Username** created within the database for IAM authentication.

   For information on the authentication requirements, see Authenticate for Ingest-based Protection

7. Click **Save**.

   The databases of the of the Amazon Aurora MySQL instances are discovered.

8. Optionally, you can configure auto-protection at the following levels to automatically protect the new databases that are added to the Amazon Aurora MySQL instances.

- **AWS Account level**: Select the AWS account checkbox, then select **Auto Protect This AWS**.
- **AWS Region level**: Select the region checkbox, then select **Auto Protect This Region**.
- **Availability Zone level**: Select the availability zone checkbox, then select **Auto Protect This Availability Zone**.
- **Instance level**: Select the instance checkbox and then select **Auto Protect This Aurora MySQL**.

To auto-protect the databases of the Amazon Aurora MySQL instances based on tags, click the **Tag** icon at the right corner of the page. Select the checkbox of a tag and then select **Auto Protect** This to auto-protect the Amazon Aurora MySQL instances with this tag.

You can also exclude the databases of Amazon Aurora MySQL instances from auto-protection within an account, region, availability zone, instance by clicking the auto-protect icon ( ) next to the database. The databases excluded from auto-protection are displayed with the exclude ( ) icon.

9. Click the **Protect** button above the checkboxes.

   The New Protection dialog box appears.

10. Provide a name for the **Protection Group**. The name can contain alphanumeric characters, underscores, dashes, and periods.
11. The Ingest-based policy is enabled by default. Create or select an existing policy from the **Policy (Cohesity Ingest)** drop-down.
12. Select **More Options** to change or configure any of the advanced settings.
13. Click **Protect**.

Advanced Settings

Section	Setting	Description
Settings	**Start Time**	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
	SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: This option is not applicable. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

Section	Setting	Description
Additional Settings	**Pause Future Runs**	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
	End Date	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
	QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. • **Backup Auto**: This policy achieves similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. The data is written to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
	Alerts	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.

Section	Setting	Description
	Priority	Select a priority for the Protection Group execution. Cohesity Platform supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: • High-priority protection runs • Medium-priority protection runs • Low-priority protection runs
	Description	**Optional**. Enter a brief description about the Protection Group.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.

Protect Amazon Aurora MySQL Using AWS Snapshot Method

With the AWS Snapshot protection method, Cohesity cluster protects the Amazon Aurora MySQL of your AWS account at the instance level.

To protect your Amazon Aurora MySQL instance using AWS snapshot method:

1. In **Data Protection**, navigate to **Sources**.
2. Find the registered AWS account and click into it.
3. Click the **Aurora MySQL** tab.
4. Select the Amazon Aurora MySQL instances for protection using one of the following views listed in the table:

View	Usage	Action
List View	Use this option to select the instances for protection from a flat, searchable list.	1. Click the **List View** icon in the top-right corner of the page. 2. Use the checkboxes to select the Amazon Aurora MySQL instances you want to protect.
Hierarchy View	Use this option to select instances for protection at various hierarchy levels.	1. Click the **Hierarchy View** icon in the top-right corner of the page. 2. Select the checkbox for a hierarchy level, and then select **Select All Child Objects** to protect all the Amazon Aurora MySQL instances under that hierarchy level. **Auto-Protect Options**: Optionally, you can configure auto-protection at the following levels to automatically protect newly added Aurora MySQL instances: • **AWS Account level**: Select the AWS account checkbox, then select **Auto Protect This AWS Account**. • **AWS Region level**: Select the region checkbox, then select **Auto Protect This Region**. • **Availability Zone level**: Select the availability zone checkbox, then select **Auto Protect This Availability Zone**. You can also exclude the Amazon Aurora MySQL instances from auto-protection within an account, region, or availability zone by clicking the auto-protect icon ( ) next to the instance. The instances excluded from auto-protection are displayed with the exclude ( ) icon.

View	Usage	Action
Tags View	Use this option to select the instances for protection based on tags.	1. Click the **Tags View** icon in the top-right corner of the page. 2. **Select the checkbox of a tag, and then select Select All Child Objects to include all instances with that tag.** **Tag-Based Auto-Protect**: Optionally, you can configure auto-protection based on a tag by selecting the tag checkbox and then choose **Auto Protect This Tag.** You can also exclude the Amazon Aurora MySQL instances from auto-protection within a tag by clicking the auto-protect icon ( ) next to the instance. The instances excluded from auto-protection are displayed with the exclude ( ) icon.

5. Click the **Protect** button above the checkboxes.

   The New Protection dialog box appears.
6. Provide a name for the **Protection Group**. The name can contain alphanumeric characters, underscores, dashes, and periods.
7. The AWS Snapshot-based policy is enabled by default. Create or select an existing policy from the **Policy (AWS Snapshot)** drop-down.
8. Select **More Options** to change or configure any of the advanced settings.
9. Click **Protect**.

Advanced Settings

Section	Setting	Description
Settings	**Start Time**	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
	SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: This option is not applicable. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

Section	Setting	Description
Additional Settings	**Pause Future Runs**	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
	End Date	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
	QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. • **Backup Auto**: This policy achieves similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. The data is written to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
	Alerts	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.

Section	Setting	Description
	Priority	Select a priority for the Protection Group execution. Cohesity Platform supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: • High-priority protection runs • Medium-priority protection runs • Low-priority protection runs
	Description	**Optional**. Enter a brief description about the Protection Group.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.

Manage Amazon Aurora MySQL Backup Configuration

In the Cohesity, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Object(s) to the Protection Group

Depending on the Protection Type you chose while creating the Protection Group, you can add new Amazon Aurora for MySQL instances or databases to the existing Protection Group for backup. The newly added object is backed up from the next protection run, and it will be a full backup for the newly added object.

To add object(s) to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had created for Amazon Aurora MySQL.

3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click in the **Objects** section.
5. In the **Objects** section, click the plus icon (**+**) to enter multiple objects that you plan to back up. Click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon Aurora MySQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon Aurora MySQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a recovery run:

1. Navigate to **Data Protection** > **Protection**.
2. Click the action menu (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all associated local and archived snapshots. Replicated snapshots must be deleted from the remote cluster. Snapshots under DataLock cannot be deleted.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the product UI.

To delete the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon Aurora MySQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Keep the **Delete Snapshots** toggle disabled to delete the Protection Group only.

- Enable the **Delete Snapshots** toggle to delete the Protection Group and all associated snapshots.

5. Type **YES** to confirm that you want to delete the Protection Group.
6. Click **Delete Group**.

Recover Amazon Aurora MySQL at Database Level

You can recover the Amazon Aurora MySQL at database level if you have protected the Amazon Aurora MySQL using the Amazon Ingest Protection Type.

> **Note:** We recommend that you review the Amazon Aurora MySQL requirements and considerations.

To recover Amazon Aurora MySQL:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **AWS** > **RDS Aurora MySQL**.
3. Search for the database by entering characters of the database name, or by specifying the wildcard character *.
4. From the list of search results, select the database to recover. By default, the latest snapshot of the database is selected for recovery. To recover from a different snapshot, perform the following steps depending on the object selected:

   From the selected lists, mouse over the snapshot, and then click the edit icon. The **Edit recovery point for <*database_name*>** page appears. By default, the option to select the snapshot is displayed in the **List** mode. You can also choose to view the option in Timeline mode by clicking the **Timeline** tab in the top-right corner of the page.

   - To select a snapshot from the **List** mode:
     a. Select the **List** tab from the top-right corner of the **Edit recovery point for <*database_name*>** page. By default, the page displays the snapshots available in the last one month. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.
     b. Select the snapshots to be recovered.
     c. By default, the snapshot is recovered from the local Cohesity cluster.
     d. Click **Select Recovery Point** and then go to step 5.
   - To select a snapshot from the **Timeline** mode:

a. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar.

b. Select the snapshot to be recovered by clicking the corresponding blue dot.

c. By default, the snapshot is recovered from the local Cohesity cluster.

d. Click **Select Recovery Point** and then go to step 5.

5. Click **Next: Recover Options**.
6. In the **Recover To** section, select any one of the following options based on where you want to restore the database and then provide the required information:
   - **Original Location**: Restore the database to the original Amazon Aurora MySQL instance.

     > **Note:** Restoring to the original location overwrites the existing database.

     Type **Yes** to confirm.
   - **New Location**: Restore the database to a different Amazon Aurora for MySQL instance within the same AWS account source. Restoring to another region within the same AWS account is supported. However, restoring to a different AWS account is not supported.

     a. From the **Source** drop down, select a registered AWS account and from the instance drop down, select the Amazon Aurora MySQL instance to which you want to restore the database.

     b. To overwrite any existing database with the same name, enable **Overwrite existing database(s)** and type **Yes** to confirm.

     > **Note:** Restoring to a new location also replaces any existing database with the same name in the selected instance.
7. In the **Recovery Options** section, configure the following options:

Options	Description
Rename	Enter a new name for the database if you want to rename it after recovery.
Task Name	Update the default name of the recovery task.

8. Click **Recover**.

Amazon Aurora PostgreSQL

Cohesity natively integrates with AWS to provide a simple, fast, and cost-effective solution for backup, recovery, and data management of Amazon Aurora PostgreSQL instances.

Backup Methods

You can protect your Amazon Aurora PostgreSQL using one of the following backup methods:

- **AWS Snapshot methods**: Cohesity uses this option to protect Amazon Aurora PostgreSQL instances. For protecting the Amazon Aurora PostgreSQL instances, Cohesity leverages the AWS native snapshot and stores them in the same AWS account and region as the source Amazon Aurora PostgreSQL instance.
- **Ingest method**: Cohesity uses this option to protect the Amazon Aurora PostgreSQL instance at the database level by ingesting the backup data to the Cohesity cluster.

> **Important:**
> - Cohesity supports the protection of Amazon Aurora PostgreSQL on DataProtect for cloud in AWS (formerly known as AWS NGCE cluster) at both the instance level (via AWS snapshot-based protection) and the database level (via ingest-based protection).
> - On DataProtect for cloud (legacy) in AWS (formerly known as AWS Cloud Edition cluster), Cohesity supports the backup and recovery of Amazon RDS only at the instance level.
> - The backup and recovery of Amazon Aurora PostgreSQL at the database level on DataProtect for cloud in AWS is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

This topic provides information on how you can protect Amazon Aurora PostgreSQL on DataProtect for cloud in AWS.

Plan and Prepare for Amazon Aurora PostgreSQL Protection

To protect Amazon Aurora PostgreSQL with Cohesity, you must register your AWS account as a source in the Cohesity cluster and perform backup and recovery operations. Ensure you meet the pre-requisites and understand the considerations before registering the AWS account.

Required Permissions for AWS Aurora PostgreSQL Data Protection

IAM User Permissions to Execute CFT

To register an AWS account with the Cohesity cluster, specific IAM roles must be created in AWS to grant required permissions. These roles are created by deploying an AWS CloudFormation (CFT) stack provided by Cohesity. The CloudFormation template must be executed from the AWS Management Console. The IAM user or role used to deploy the stack must have sufficient permissions to create, manage, and view CloudFormation stacks, as well as to create the required IAM roles and policies.

The table below lists the minimum permissions required for the IAM user or role to successfully run the CloudFormation template.

> **Note:** Ensure to add these permissions manually.

Permission	Purpose
`cloudformation:CreateStack`	Create a new stack.
`cloudformation:UpdateStack`	Modify the stack during updates or re-registration
`cloudformation:DeleteStack`	Delete a stack.
`cloudformation:ValidateTemplate`	Validate the CFT before deployment.
`cloudformation:DescribeStacks`	View the status of stacks.
`cloudformation:ListStacks`	View the status of stacks.
`cloudformation:GetTemplate`	Fetch template for an existing stack.
`cloudformation:GetTemplateSummary`	View a summary of template resources and parameters.
`cloudformation:DescribeStackEvents`	View stack creation progress/errors.
`cloudformation:DescribeStackResources`	View resources created in the stack.
`cloudformation:CreateUploadBucket`	Create a temporary bucket used for uploading artifacts needed by the stack.
`iam:CreateRole`	Create required IAM roles.
`iam:DeleteRole`	Delete IAM roles when cleaning up registrations.

Permission	Purpose
`iam:GetRole`	Retrieve details of existing roles.
`iam:UpdateRole`	Modify existing IAM role configuration.
`iam:TagRole`	Add tags to IAM roles created by the template.
`iam:UntagRole`	Remove tags from IAM roles.
`iam:PutRolePolicy`	Attach inline policies to IAM roles.
`iam:DeleteRolePolicy`	Delete inline policies from IAM roles.
`iam:GetRolePolicy`	iam:GetRolePolicy
`iam:CreateInstanceProfile`	Create instance profiles needed for EC2-based operations.
`iam:GetInstanceProfile`	Retrieve instance profile details.
`iam:AddRoleToInstanceProfile`	Attach IAM roles to the instance profile.
`iam:RemoveRoleFromInstanceProfile`	Detach IAM roles from the instance profile.
`iam:DeleteInstanceProfile`	Delete instance profiles during cleanup.
`iam:AttachRolePolicy`	Attach managed policies to IAM roles.
`iam:DetachRolePolicy`	Remove managed policies from roles.
`iam:ListPolicies`	List available policies for attachment/validation.
`iam:ListRoles`	Retrieve all roles to validate role existence.
`iam:PassRole`	Allow CloudFormation to pass the IAM role to AWS services.
`s3:CreateBucket`	Create an S3 bucket for storing backup or exported data.
`s3:PutObject`	Upload objects to an S3 bucket.
`s3:GetObject`	Retrieve objects from an S3 bucket.
`s3:ListBucket`	View bucket contents to validate template uploads.

Permissions for Amazon Aurora PostgreSQL Protection

Permissions for AWS Snapshot-based Protection

The following table lists the minimum required permissions included in the CloudFormation template for protecting Amazon Aurora PostgreSQL at the instance level (AWS snapshot-based protection).

> **Note:** You do not need to add these permissions manually, as they are automatically added when you run the CFT.

Resource	Permissions	Purpose

rds	`rds:AddTagsToResource`
	`rds:CopyDBClusterSnapshot`
	`rds:CreateDBClusterSnapshot`
	`rds:DescribeDBInstances`
	`rds:CreateDBInstance`
	`rds:DeleteDBClusterSnapshot`
	`rds:DescribeDBClusterSnapshots`
	`rds:DescribeDBClusters`
	`rds:DescribeDBParameterGroups`
	`rds:DescribeDBSubnetGroups`
	`rds:DescribeSourceRegions`
	`rds:ModifyDBClusterSnapshotAttribute`
	`rds:RestoreDBClusterFromSnapshot`
		These permissions are required to register the AWS account on Cohesity with the IAM role which got created by the Cloud Formation template.
		Once the source is registered with Cohesity, described permissions are needed so Cohesity can identify resources present in the account, which will be used for backups as well as at the time of recovery we use this information to provide a list of options to choose from.
		Cohesity creates snapshots of the Amazon Aurora instances while backing up and storing the different database instance attributes and tags.
		While recovering the database instance, Cohesity creates DB instance/cluster, it also attaches the original tags.
		Cohesity requires the delete snapshots permissions to delete the expired/old snapshots it creates during the backup.
		The modify snapshot attributes permissions are required for shaing the snapshot across accounts if cross-account recovery is attempted.

Permissions for Ingest-based Protection

The following table lists the minimum required permissions included in the CloudFormation template for protecting Amazon Aurora PostgreSQL at the database level (Ingest-based

protection).

> **Note:** You do not need to add these permissions manually, as they are automatically added when you run the CFT.

Resource	Permission	Purpose
rds	`rds:DescribeDBClusters`	List RDS instances.

Authenticate for Ingest-based Protection

To protect Amazon Aurora PostgreSQL using the Ingest-based protection method, you must authenticate the PostgreSQL client running on the Cohesity cluster to discover the databases of the Amazon Aurora PostgreSQL instance. This can be done using one of the following authentication methods:

- **Username** and **password** of the Amazon Aurora PostgreSQL instances.

  Ensure the user has the following permissions:

  - `psql -h instance_fqdn -U postgres`
  - `CREATE USER dbuser WITH PASSWORD '<password>' CREATEDB;`
  - `GRANT rds_superuser TO dbuser;`

- **IAM-authenticated PostgreSQL user**.

  If you choose the IAM-authenticated PostgreSQL user method, ensure the following:

  - Enable IAM DB authentication on the DB instance:
    i. From the AWS Management Console, got to RDS Console.
    ii. Select the DB instance and click **Modify**.
    iii. Scroll to the **Database Authentication section**.
    iv. Enable **Password and IAM database authentication**.
    v. Click **Continue**.
    vi. Choose whether to **Apply Immediately** or during the next maintenance window, and then click **ModifyDBinstance.**
  - Create database user using admin login:
    - `CREATE USER <iamuser> WITH LOGIN;`
  - Grant below role to user

- `GRANT rds_iam TO <iamuser>;`
- `ALTER ROLE <iamuser> WITH LOGIN CREATEDB;`
- `GRANT rds_superuser TO <iamuser>;`

- Attach RDS Policy to IAM Role that will be created once you run the CFT for registering the AWS source:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rds-db:connect"
      ],
      "Resource": [
        "arn:aws:rds-db:<region>:<account>:dbuser:<resource id>/<iamuser>"
      ]
    }
  ]
```

Network Access Requirement

- The EC2 instance's (The host applications that connect to the Aurora PostgreSQL.) security group must allow outbound traffic to the RDS endpoint on port 3306, or any custom port configured for the Aurora PostgreSQL.
- The RDS instance's security group must allow inbound connections from the EC2 instance (or its associated security group).

Considerations for AWS Aurora PostgreSQL Data Protection

Review and understand the following limitations and knows issues before you protect Amazon Aurora PostgreSQL:

- Cohesity performs only full backup of Amazon Aurora PostgreSQL.
- Cohesity protects only the user databases within the Amazon Aurora PostgreSQL. Protection of system databases is not supported.
- Restore of Amazon Aurora PostgreSQL to an EC2 running a PostgreSQL instance is not supported.
- Restoring security privileges is not supported.
- Restore does not fail if the owner or role does not exist on the destination.

- Post restore, the database has the role associated with it, according to the credentialsagainst the destination instance.
- ACLs and permissions for a database are restored only if IAM-authenticated PostgreSQL user is attached to the instance.
- Users need to modify the ownership of databases post-restore.
- The following characters are not supported in the database name in the restore workflow: `, @, \, [,], !, #, %, ^, ., ,, &, *, (,), <, >, ?, /, |, }, {, ~, :, ', ", ;, +, = and -.
- Uppercase username is not supported for new users added after PostgreSQL server creation.
- SCRAM authentication configured on a database instance is not supported.
- If full backup fail with temporary objects, then delete the temporary objects manually and run backup again.
- Restoring a backup taken from a higher Aurora PostgreSQL database version to a lower version is not supported.
- Restoring to another region within the same AWS account is supported. However, restoring to a different AWS account is not supported.
- You cannot perform ingest-based and snapshot-based protections within the same protection Group.
- If you have selected databases for protection, then you cannot choose snapshot-based policy.
- For protection, if you have selected instances with no databases discovered, then you cannot choose ingest-based policy.

Register and Manage AWS Account

To protect your Amazon RDS for PostgreSQL, you need to register AWS account as a source on the Cohesity cluster. After registering your AWS account as a source, you can:

- Update the AWS source configuration.
- Refresh the source details.
- Unregister the AWS source from the Cohesity cluster.

Register AWS Account

Before registering AWS account as a source, make sure you have completed all prerequisite tasks and reviewed the considerations.

To register AWS account as a source:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Register** at the top-right of the page and then select **Cloud Platforms** > **AWS**.

The **Register AWS Source** dialog box appears.

3. Enter the **AWS Account ID**.
4. From the list of **AWS services**, select **RDS**.
5. Click **Next** to generate a CloudFormation Template (CFT), which you will use to complete the AWS source registration.
6. Click **Download** to download the CloudFormation Template.
7. On running the CFT, IAM roles and policies are created.
8. Once the roles and policies are created successfully, click **Register**.

Run CloudFormation Template

To complete the registration of the AWS account with the Cohesity cluster, you must run the CloudFormation Template on the AWS account you are registering. You can download CFT from the product UI as you register the AWS source.

When you execute the CFT, it creates an AWS IAM role and the policies.

Executing the CFT Template

1. In the **AWS Management Console**, navigate to **Services** and search for **CloudFormation**.
2. Click **Create stack** > **With new resources** to create a stack under AWS cloudFormation using the downloaded CloudFormation Template.
    1. In the **Prerequisite - Prepare template** page, select **Choose an existing template** > **Upload a template file**.
    2. Click **Choose File** to browse and upload the JSON Cloudformation template. Click **Next**.
    3. Enter a **Stack name** and specify the AWS Account ID where the Cloud Edition cluster is running.
    4. Select **source_registration** for creating IAM role for registration AWS source.
    5. Click **Next**.
    6. Acknowledge the creation of IAM resources by selecting the checkbox, then click **Create Stack**.
    7. Once the stack creation is successful, view the **Resources** tab to check the created IAM roles.
    8. The following IAM roles and profiles are created:
        - CohesityInstanceRole
        - CohesityInstanceProfile
        - CohesitySourceRegistrationRole

Attaching the IAM Role to Cluster Nodes

To complete registration, attach the **CohesityInstanceProfile** role to all nodes in the cluster:

1. Navigate to **Services** > **EC2** > **Instances**.
2. Select the cluster created. For a multi node, the IAM role must be attached on all nodes.
3. Select **Actions** > **Security** > **Modify IAM Role**.
4. In the **IAM Role** field, enter the name/search for the Instance Profile (*CohesityInstanceProfile*) that was created.
5. Click **Update IAM role**.

   The IAM role is successfully attached to that EC2 instance.

   > **Note:** If any new node is added to the cluster, then this role has to be attached to every newly added node in the cluster as well.

Complete AWS Source Registration

Once the IAM role is attached, complete the AWS source registration on the cluster.

Update AWS Account Source Configuration

You can edit the registered AWS account to add or remove the Amazon services protected by the Cohesity from your AWS account.

To edit the AWS account source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select Edit.
3. In the **Edit AWS Source** page, select or unselect the Amazon services.
4. Click **Update**.

Refresh AWS Account Source

You can refresh the AWS account source configuration and fetch the latest changes on your AWS account.

To refresh the AWS source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select **Refresh**.

Unregister AWS Account Source

If you plan to stop taking the backup of your AWS source, you can unregister the AWS source from the Cohesity cluster.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the AWS source.

To unregister the AWS source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select **Unregister**.

Backup Amazon Aurora PostgreSQL

Depending on the services you selected while registering the source, the Cohesity cluster automatically discovers all supported workloads including Amazon Aurora PostgreSQL associated with the specified AWS account ID. The discovered workloads appear under **Data Protection** > **Sources**. When you open the registered AWS account source, each workload type is displayed on its own tab. Select the **Aurora PostgreSQL** tab to view all discovered instances.

The **Aurora PostgreSQL** tab displays the entity hierarchy for the Amazon Aurora PostgreSQL environment, allowing you to navigate from the account level down to individual databases.

Amazon Aurora PostgreSQL Entity Hierarchy

The **Aurora PostgreSQL** tab displays the entity hierarchy for the Aurora PostgreSQL, allowing you to navigate from the account level down to individual databases.

The **Aurora PostgreSQL** entity hierarchy in the Cohesity cluster follows this structure:

Structure	Description
AWS Account	The AWS account registered with Cohesity for Aurora protection.
AWS Region	The AWS region where the Aurora resources reside.
Availability Zone	The availability zone within the region where the Aurora instance is deployed.
Auora Instance	The specific Aurora PostgreSQL instance within the selected availability zone.

Structure	Description
Database	The individual databases hosted within the Aurora PostgreSQL instance. The database will be listed in the entity hierarchy only if you have provided credentials to discover the databases of the Amazon Aurora PostgreSQL instance.

Backup Scope by Aurora PostgreSQL Hierarchy

The Cohesity cluster allows you to back up Amazon Aurora PostgreSQL at different levels of the entity hierarchy. You can choose to back up:

- **AWS Account** – Protect all Aurora PostgreSQL instances and databases within the registered AWS account.
- **AWS Region** – Protect all Aurora PostgreSQL instances and databases within a specific region of the registered account.
- **Availability Zone** – Protect Aurora PostgreSQL instances and databases within a specific availability zone.
- **Aurora Instance** – Protect a specific Aurora PostgreSQL instance and all databases hosted on it.
- **Database** – Protect individual databases within an Aurora PostgreSQL instance by providing the database credentials.

Aurora PostgreSQL Backup Methods

Cohesity provides the following Protection Types for the protecting Amazon Aurora PostgreSQL:

- **AWS Snapshot method**: Cohesity uses this option to protect Amazon Aurora PostgreSQL instances. For protecting the Amazon Aurora PostgreSQL instances, Cohesity leverages the AWS native snapshot and stores them in the same AWS account and region as the source Amazon Aurora PostgreSQL instance.
- **Ingest method**: Cohesity uses this option to protect the Amazon Aurora PostgreSQL instance at the database level by ingesting the backup data to the Cohesity cluster.

Supported Backup Types

Cohesity performs only full backup of Amazon Aurora PostgreSQL.

Protect Amazon Aurora PostgreSQL Using Ingest Method

With the Ingest protection method, Cohesity cluster protects the Amazon Aurora PostgreSQL of your AWS account at the database level.

Authenticate Cohesity Cluster for Aurora PostgreSQL Protection

To protect the Amazon Aurora PostgreSQL of your AWS account at the database level using the Ingest method, you must provide the credentials of the Amazon Aurora PostgreSQL

instance while creating the protection. By providing the credentials, Cohesity discovers the databases as objects for protection.

Perform the following steps for authenitcation:

1. Navigate to **Data Protection** > **Sources**.
2. Locate the registered AWS account and click into it.
3. Click the **Aurora PostgreSQL** tab.
4. Select the checkbox for the hierarchy level (acount, region, availability zone or instance level), and then click **Database Credentials** above the checkboxes.

   The **Database Credentials for <instance>** appears.
5. Select one of the following authentication methods for Cohesity to discover the databases of the Amazon Aurora PostgreSQL instances:
   - **Credentials**: Enter the **Username**, and **Password** for the Amazon Aurora PostgreSQL instances.
   - **IAM Authentication**: Enter the **Username** for IAM authentication.

     For information on the authentication requirements, see Authenticate for Ingest-based Protection.
6. Click **Save**.

   The databases of the Amazon Aurora PostgreSQL instances are discovered.

Protect Amazon Aurora PostgreSQL Database

To protect your Amazon Aurora PostgreSQL using Ingest method:

1. Navigate to **Data Protection** > **Protection**.
2. Click **Protect** on the top-right of the page and then select **AWS** > **Aurora PostgreSQL**.
3. In the New Protection page, click **Add Objects** and select your registered source or click **Register Source** to add a new one.
4. Select the Amazon Aurora PostgreSQL databases for protection using one of the following views:
   - **List View**: Use this option to select the Aurora PostgreSQL databases for protection from a flat, searchable list.
   - **Hierarchy View**: Use this option to select databases for protection at various hierarchy levels.

     Optionally,
     - You can click the auto-protect icon at the AWS Account level, AWS Region level, Availability Zone level to automatically protect newly added RDS

databases.

- You can also exclude the Amazon Aurora PostgreSQL databases from auto-protection within an account, region, or availability zone by clicking the auto-protect icon ( ) next to the database. The databases excluded from auto-protection are displayed with the exclude ( ) icon.

- **Tags**: Use this option to select the databases for protection based on tags.

  Optionally,

  - You can configure auto-protection based on a tag. You can select the tag checkbox and then choose **Auto Protect This Tag** to automatically protect all newly added Amazon Aurora PostgreSQL databases with this tag.
  - You can exclude the Amazon Aurora PostgreSQL databases from auto-protection within a tag by clicking the auto-protect icon ( ) next to the database. The databases excluded from auto-protection are displayed with the exclude ( ) icon.
  - You can exclude databases with a specific tag from auto-protection by clicking the exclude icon (⊘). The tag excluded from auto-protection are displayed with the exclude icon.

5. Click **Continue**.
6. Provide a name for the **Protection Group**. The name can contain alphanumeric characters, underscores, dashes, and periods.
7. The Ingest-based policy is enabled by default. Create or select an existing policy from the **Policy (Cohesity Ingest)** drop-down.
8. Select **More Options** to change or configure any of the advanced settings.
9. Click **Protect**.

Advanced Settings

Section	Setting	Description
Settings	**Start Time**	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
	SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: This option is not applicable. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

Section	Setting	Description
Additional Settings	**Pause Future Runs**	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
	End Date	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
	QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. • **Backup Auto**: This policy achieves similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. The data is written to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. For best performance, we recommend the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
	Alerts	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.

Section	Setting	Description
	Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: • High-priority protection runs • Medium-priority protection runs • Low-priority protection runs
	Description	**Optional**. Enter a brief description about the Protection Group.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.

Protect Amazon Aurora PostgreSQL Using AWS Snapshot Method

With the AWS Snapshot protection method, Cohesity cluster protects the Amazon Aurora PostgreSQL of your AWS account at the instance level.

To protect your Amazon Aurora PostgreSQL instance using AWS snapshot method:

1. Navigate to **Data Protection** > **Protection**.
2. Click **Protect** on the top-right of the page and then select **AWS** > **Aurora PostgreSQL**.
3. In the New Protection page, click **Add Objects** and select your registered source or click **Register Source** to add a new one.
4. Select the Amazon Aurora PostgreSQL instances for protection using one of the following views:
    - **List View**: Use this option to select the Aurora PostgreSQL instances for protection from a flat, searchable list.

- **Hierarchy View**: Use this option to select instances for protection at various hierarchy levels.

  Optionally,

  - You can click the auto-protect icon at the AWS Account level, AWS Region level, Availability Zone level to automatically protect newly added Aurora instances.
  - You can also exclude the Amazon Aurora PostgreSQL instances from auto-protection within an account, region, or availability zone by clicking the auto-protect icon ( ) next to the instance. The instances excluded from auto-protection are displayed with the exclude ( ) icon.

- **Tags**: Use this option to select the instances for protection based on tags.

  Optionally,

  - You can configure auto-protection based on a tag. You can select the tag checkbox and then choose **Auto Protect This Tag** to automatically protect all newly added Amazon Aurora PostgreSQL instances with this tag.
  - You can exclude the Amazon Aurora PostgreSQL instances from auto-protection within a tag by clicking the auto-protect icon ( ) next to the instance. The instances excluded from auto-protection are displayed with the exclude ( ) icon.

  You can exclude instances with a specific tag from auto-protection by clicking the exclude icon (⊘). The tag excluded from auto-protection are displayed with the exclude icon.

5. Click **Continue**.
6. Provide a name for the **Protection Group**. The name can contain alphanumeric characters, underscores, dashes, and periods.
7. The AWS Snapshot-based policy is enabled by default. Create or select an existing policy from the **Policy (AWS Snapshot)** drop-down.
8. Select **More Options** to change or configure any of the advanced settings.
9. Click **Protect**.

Advanced Settings

Section	Setting	Description
Settings	**Start Time**	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Emails are sent when warning alerts are created. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.

Section	Setting	Description
	Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: • High-priority protection runs • Medium-priority protection runs • Low-priority protection runs
	Description	**Optional**. Enter a brief description about the Protection Group.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.

Manage Amazon Aurora PostgreSQL Backup Configuration

In the Cohesity, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Object(s) to the Protection Group

Depending on the Protection Type you chose while creating the Protection Group, you can add new Amazon Aurora PostgreSQL instances or databases to the existing Protection Group for backup. The newly added object is backed up from the next protection run, and it will be a full backup for the newly added object.

To add object(s) to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had created for Amazon Aurora PostgreSQL.

3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click in the **Objects** section.
5. In the **Objects** section, click the plus icon (**+**) to enter multiple objects that you plan to back up. Click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon Aurora PostgreSQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon Aurora PostgreSQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a recovery run:

1. Navigate to **Data Protection** > **Protection**.
2. Click the action menu (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all associated local and archived snapshots. Replicated snapshots must be deleted from the remote cluster. Snapshots under DataLock cannot be deleted.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the product UI.

To delete the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon Aurora PostgreSQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Keep the **Delete Snapshots** toggle disabled to delete the Protection Group only.

- Enable the **Delete Snapshots** toggle to delete the Protection Group and all associated snapshots.

5. Type **YES** to confirm that you want to delete the Protection Group.
6. Click **Delete Group**.

1. Type **YES** to confirm that you want to delete the Protection Group.
2. Click **Delete Group**.

Recover Amazon Aurora PostgreSQL at Database Level

You can recover the Amazon Aurora PostgreSQL at database level if you have protected the Amazon Aurora PostgreSQL using the RDS Ingest Protection Type.

> **Note:** We recommend that you review the Plan and Prepare for Amazon Aurora PostgreSQL Protection.

To recover Amazon Aurora PostgreSQL:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **AWS** > **Aurora PostgreSQL**.
3. Search for the database by entering characters of the database name, or by specifying the wildcard character *.
4. From the list of search results, select the database to recover. By default, the latest snapshot of the database is selected for recovery. To recover from a different snapshot, perform the following steps depending on the object selected:

   From the selected lists, mouse over the snapshot, and then click the edit icon. The **Edit recovery point for <*database_name*>** page appears. By default, the option to select the snapshot is displayed in the **List** mode. You can also choose to view the option in Timeline mode by clicking the **Timeline** tab in the top-right corner of the page.

   - To select a snapshot from the **List** mode:
     a. Select the **List** tab from the top-right corner of the **Edit recovery point for <*database_name*>** page. By default, the page displays the snapshots available in the last one month. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.
     b. Select the snapshots to be recovered.

c. By default, the snapshot is recovered from the local Cohesity cluster.

d. Click **Select Recovery Point** and then go to step 5.

- To select a snapshot from the **Timeline** mode:

a. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar.

b. Select the snapshot to be recovered by clicking the corresponding blue dot.

c. By default, the snapshot is recovered from the local Cohesity cluster.

d. Click **Select Recovery Point** and then go to step 5.

5. Click **Next: Recover Options**.
6. In the **Recover To** section, select any one of the following options based on where you want to restore the database and then provide the required information:
   - **Original Location**: Restore the database to the original Amazon Aurora PostgreSQL instance.

     > **Note:** Restoring to the original location overwrites the existing database.

     Type **Yes** to confirm.
   - **New Location**: Restore the database to a different Amazon Aurora PostgreSQL instance within the same AWS account source. Restoring to another region within the same AWS account is supported. However, restoring to a different AWS account is not supported.

     a. From the **Source** drop down, select the AWS account and from the instance drop down, select the Amazon Aurora PostgreSQL instance to which you want to restore the database.

     b. To overwrite any existing database with the same name, enable **Overwrite existing database(s)** and type **Yes** to confirm.

     > **Note:** Restoring to a new location also replaces any existing database with the same name in the selected instance.
7. In the **Recovery Options** section, configure the following options:

Options	Description
Rename	Enter a new name for the database if you want to rename it after recovery.
Task Name	Update the default name of the recovery task.

8. Click **Recover**.

Amazon Relational Database Service for PostgreSQL

Cohesity natively integrates with AWS to provide a simple, fast, and cost-effective solution for backup, recovery, and data management of Amazon RDS for PostgreSQL instances.

Backup Methods

You can protect your Amazon RDS for PostgreSQL using one of the following backup methods:

- **AWS Snapshot methods**: Cohesity uses this option to protect Amazon RDS for PostgreSQL instances. For protecting the Amazon RDS for PostgreSQL instances, Cohesity leverages the AWS native snapshot and stores them in the same AWS account and region as the source Amazon RDS for PostgreSQL instance.
- **Ingest method**: Cohesity uses this option to protect the Amazon RDS for PostgreSQL instance at the database level by ingesting the backup data to the Cohesity cluster.

> **Important:**
> - Cohesity supports the protection of Amazon RDS for PostgreSQL on DataProtect for cloud in AWS (formerly known as AWS NGCE cluster) at both the instance level (via AWS snapshot-based protection) and the database level (via ingest-based protection).
> - On DataProtect for cloud (legacy) in AWS (formerly known as AWS Cloud Edition cluster), Cohesity supports the backup and recovery of Amazon RDS only at the instance level.
> - The backup and recovery of Amazon RDS for PostgreSQL at the database level on DataProtect for cloud in AWS is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

This topic provides information on how you can protect Amazon RDS for PostgreSQL on DataProtect for cloud in AWS.

Plan and Prepare for Amazon RDS for PostgreSQL Protection

To protect Amazon RDS for PostgreSQL with Cohesity, you must register your AWS account as a source in the Cohesity cluster and perform backup and recovery operations. Ensure you meet the pre-requisites and understand the considerations before registering the AWS account.

Required Permissions for AWS RDS for PostgreSQL Data Protection

IAM User Permissions to Execute CFT

To register an AWS account with the Cohesity cluster, specific IAM roles must be created in AWS to grant required permissions. These roles are created by deploying an AWS CloudFormation (CFT) stack provided by Cohesity. The CloudFormation template must be executed from the AWS Management Console. The IAM user or role used to deploy the stack must have sufficient permissions to create, manage, and view CloudFormation stacks, as well as to create the required IAM roles and policies.

The table below lists the minimum permissions required for the IAM user or role to successfully run the CloudFormation template.

> **Note:** Ensure to add these permissions manually.

Permission	Purpose
`cloudformation:CreateStack`	Create a new stack.
`cloudformation:UpdateStack`	Modify the stack during updates or re-registration
`cloudformation:DeleteStack`	Delete a stack.
`cloudformation:ValidateTemplate`	Validate the CFT before deployment.
`cloudformation:DescribeStacks`	View the status of stacks.
`cloudformation:ListStacks`	View the status of stacks.
`cloudformation:GetTemplate`	Fetch template for an existing stack.
`cloudformation:GetTemplateSummary`	View a summary of template resources and parameters.
`cloudformation:DescribeStackEvents`	View stack creation progress/errors.
`cloudformation:DescribeStackResources`	View resources created in the stack.

Permission	Purpose
`cloudformation:CreateUploadBucket`	Create a temporary bucket used for uploading artifacts needed by the stack.
`iam:CreateRole`	Create required IAM roles.
`iam:DeleteRole`	Delete IAM roles when cleaning up registrations.
`iam:GetRole`	Retrieve details of existing roles.
`iam:UpdateRole`	Modify existing IAM role configuration.
`iam:TagRole`	Add tags to IAM roles created by the template.
`iam:UntagRole`	Remove tags from IAM roles.
`iam:PutRolePolicy`	Attach inline policies to IAM roles.
`iam:DeleteRolePolicy`	Delete inline policies from IAM roles.
`iam:GetRolePolicy`	iam:GetRolePolicy
`iam:CreateInstanceProfile`	Create instance profiles needed for EC2-based operations.
`iam:GetInstanceProfile`	Retrieve instance profile details.
`iam:AddRoleToInstanceProfile`	Attach IAM roles to the instance profile.
`iam:RemoveRoleFromInstanceProfile`	Detach IAM roles from the instance profile.
`iam:DeleteInstanceProfile`	Delete instance profiles during cleanup.
`iam:AttachRolePolicy`	Attach managed policies to IAM roles.
`iam:DetachRolePolicy`	Remove managed policies from roles.
`iam:ListPolicies`	List available policies for attachment/validation.
`iam:ListRoles`	Retrieve all roles to validate role existence.
`iam:PassRole`	Allow CloudFormation to pass the IAM role to AWS services.

Permission	Purpose
`s3:CreateBucket`	Create an S3 bucket for storing backup or exported data.
`s3:PutObject`	Upload objects to an S3 bucket.
`s3:GetObject`	Retrieve objects from an S3 bucket.
`s3:ListBucket`	View bucket contents to validate template uploads.

Permissions for Amazon RDS for PostgreSQL Protection

Permissions for AWS Snapshot-based Protection

The following table lists the minimum required permissions included in the CloudFormation template for protecting Amazon RDS for PostgreSQL at the instance level (AWS snapshot-based protection).

> **Note:** You do not need to add these permissions manually, as they are automatically added when you run the CFT.

Resource	Permissions	Purpose

rds	`rds:AddTagsToResource`
	`rds:CopyDBClusterSnapshot`
	`rds:CopyDBSnapshot`
	`rds:CreateDBClusterSnapshot`
	`rds:CreateDBInstance`
	`rds:CreateDBSnapshot`
	`rds:DeleteDBClusterSnapshot`
	`rds:DeleteDBSnapshot`
	`rds:DescribeDBClusterSnapshots`
	`rds:DescribeDBClusters`
	`rds:DescribeDBInstances`
	`rds:DescribeDBParameterGroups`
	`rds:DescribeDBSnapshots`
	`rds:DescribeDBSubnetGroups`
	`rds:DescribeOptionGroups`
	`rds:DescribeSourceRegions`
	`rds:ModifyDBClusterSnapshotAttribute`
	`rds:ModifyDBSnapshotAttribute`
	`rds:RestoreDBClusterFromSnapshot`
	`rds:RestoreDBInstanceFromDBSnapshot`
	`rds:RestoreDBInstanceToPointInTime`
		These permissions are required to register the AWS account on Cohesity with the IAM role which got created by the Cloud Formation template.
		Once the source is registered with Cohesity, described permissions are needed so Cohesity can identify resources present in the account, which will be used for backups as well as at the time of recovery we use this information to provide a list of options to choose from.
		Cohesity creates snapshots of the Amazon RDS instances while backing up and storing the different database instance attributes and tags.
		While recovering the database instance, Cohesity creates DB instance/cluster, it also attaches the original tags.
		Cohesity requires the delete snapshots permissions to delete the expired/old snapshots it creates during the backup.
		The modify snapshot attributes permissions are required for shaing the snapshot across accounts if cross-account recovery is attempted.
		`RestoreDBInstanceToPointInTime` and `RestoreDBClusterToPointInTime` is needed to do the point in time recoveries.

Permissions for Ingest-based Protection

The following table lists the minimum required permissions included in the CloudFormation template for protecting Amazon RDS for PostgreSQL at the database level (Ingest-based protection).

> **Note:** You do not need to add these permissions manually, as they are automatically added when you run the CFT.

Resource	Permission	Purpose
rds	`rds:DescribeDBInstances`	List RDS instances.

Authenticate for Ingest-based Protection

To protect Amazon RDS for PostgreSQL using the Ingest-based protection method, you must authenticate the PostgreSQL client running on the Cohesity cluster to discover the databases of the Amazon RDS for PostgreSQL instance. This can be done using one of the following authentication methods:

- **Username** and **password** of the Amazon RDS for PostgreSQL instances.

  Ensure the user has the following permissions:

  - `psql -h instance_fqdn -U postgres`
  - `CREATE USER dbuser WITH PASSWORD '<password>' CREATEDB;`
  - `GRANT rds_superuser TO dbuser;`

- **IAM-authenticated PostgreSQL user**.

  If you choose the IAM-authenticated PostgreSQL user method, ensure the following:

  - Enable IAM DB authentication on the RDS DB instance:
    i. From the AWS Management Console, got to RDS Console.
    ii. Select the DB instance and click **Modify**.
    iii. Scroll to the **Database Authentication** section.
    iv. Enable **Password and IAM database authentication**.
    v. Click **Continue**.
    vi. Choose **Apply Immediately**, and then click **ModifyDBinstance.**
  - Create database user using admin login:
    - `CREATE USER <iamuser> WITH LOGIN;`
  - Grant below role to user
    - `GRANT rds_iam TO <iamuser>;`
    - `ALTER ROLE <iamuser> WITH LOGIN CREATEDB;`
    - `GRANT rds_superuser TO <iamuser>;`
  - Attach RDS Policy to IAM Role that will be created once you run the CFT for registering the AWS source:

```
{
  "Version": "2012-10-17",
```

```
"Statement": [
  {
    "Effect": "Allow",
    "Action": [
      "rds-db:connect"
    ],
    "Resource": [
      "arn:aws:rds-db:<region>:<account>:dbuser:<resource id>/<iamuser>"
    ]
  }
]
```

Network Access Requirement

- The EC2 instance's (The host applications that connect to the RDS for PostgreSQL.) security group must allow outbound traffic to the RDS endpoint on port 3306, or any custom port configured for the RDS for PostgreSQL.
- The RDS instance's security group must allow inbound connections from the EC2 instance (or its associated security group).

Considerations for AWS RDS for PostgreSQL Data Protection

Review and understand the following limitations and knows issues before you protect Amazon RDS for PostgreSQL:

- Cohesity performs only full backup of Amazon RDS for PostgreSQL. Even if you choose an incremental-based policy, Cohesity will always perform a full backup, regardless of the selected policy type.
- Cohesity protects only the user databases within the Amazon RDS for PostgreSQL. Protection of system databases is not supported.
- Restore of Amazon RDS for PostgreSQL to an EC2 running a PostgreSQL instance is not supported.
- Restoring a backup taken from a higher RDS PostgreSQL database version to a lower version is not supported.
- Restoring security privileges is not supported.
- Restore does not fail if the owner or role does not exist on the destination.
- Post restore, the database has the role associated with it, according to the credentialsagainst the destination instance.

- ACLs and permissions for a database are restored only if IAM-authenticated PostgreSQL user is attached to the instance.
- Users need to modify the ownership of databases post-restore.
- The following characters are not supported in the database name in the restore workflow: `, @, \, [,], !, #, %, ^, ., ,, &, *, (,), <, >, ?, /, |, }, {, ~, :, ', ", ;, +, = and -.
- Uppercase username is not supported for new users added after PostgreSQL server creation.
- SCRAM authentication configured on a database instance is not supported.
- If full backup fail with temporary objects, then delete the temporary objects manually and run backup again.
- Restoring to another region within the same AWS account is supported. However, restoring to a different AWS account is not supported.
- You cannot perform ingest-based and snapshot-based protections within the same protection Group.
- If you have selected databases for protection, then you cannot choose snapshot-based policy.
- For protection, if you have selected instances with no databases discovered, then you cannot choose ingest-based policy.

Register and Manage AWS Account

To protect your Amazon RDS for PostgreSQL, you need to register AWS account as a source on the Cohesity cluster. After registering your AWS account as a source, you can:

- Update the AWS source configuration.
- Refresh the source details.
- Unregister the AWS source.

Register AWS Account

Before registering AWS account as a source, make sure you have completed all prerequisite tasks and reviewed the considerations.

To register AWS account as a source:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Register** at the top-right of the page and then select **Cloud Platforms** > **AWS**.

   The **Register AWS Source** dialog box appears.
3. Enter the **AWS Account ID**.
4. From the list of **AWS services**, select **RDS**.

5. Click **Next** to generate a CloudFormation Template (CFT), which you will use to complete the AWS source registration.
6. Click **Download** to download the CloudFormation Template.
7. On running the CFT, IAM roles and policies are created.
8. Once the roles and policies are created successfully, click **Register**.

Run CloudFormation Template

To complete the registration of the AWS account with the Cohesity cluster, you must run the CloudFormation Template on the AWS account you are registering. You can download CFT from the product UI as you register the AWS source.

When you execute the CFT, it creates an AWS IAM role and the policies.

Executing the CFT Template

1. In the **AWS Management Console**, navigate to **Services** and search for **CloudFormation**.
2. Click **Create stack** > **With new resources** to create a stack under AWS cloudFormation using the downloaded CloudFormation Template.
    1. In the **Prerequisite - Prepare template** page, select **Choose an existing template** > **Upload a template file**.
    2. Click **Choose File** to browse and upload the JSON Cloudformation template. Click **Next**.
    3. Enter a **Stack name** and specify the AWS Account ID where the Cloud Edition cluster is running.
    4. Select **source_registration** for creating IAM role for registration AWS source.
    5. Click **Next**.
    6. Acknowledge the creation of IAM resources by selecting the checkbox, then click **Create Stack**.
    7. Once the stack creation is successful, view the **Resources** tab to check the created IAM roles.
    8. The following IAM roles and profiles are created:
        - CohesityInstanceRole
        - CohesityInstanceProfile
        - CohesitySourceRegistrationRole

Attaching the IAM Role to Cluster Nodes

To complete registration, attach the **CohesityInstanceProfile** role to all nodes in the cluster:

1. Navigate to **Services** > **EC2** > **Instances**.
2. Select the cluster created. For a multi node, the IAM role must be attached on all nodes.
3. Select **Actions** > **Security** > **Modify IAM Role**.
4. In the **IAM Role** field, enter the name/search for the Instance Profile (*CohesityInstanceProfile*) that was created.
5. Click **Update IAM role**.

   The IAM role is successfully attached to that EC2 instance.

   > **Note:** If any new node is added to the cluster, then this role has to be attached to every newly added node in the cluster as well.

Complete AWS Source Registration

Once the IAM role is attached, complete the AWS source registration on the cluster.

Update AWS Account Source Configuration

You can edit the registered AWS account to add or remove the Amazon services protected by the Cohesity from your AWS account.

To edit the AWS account source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select Edit.
3. In the **Edit AWS Source** page, select or unselect the Amazon services.
4. Click **Update**.

Refresh AWS Account Source

You can refresh the AWS account source configuration and fetch the latest changes on your AWS account.

To refresh the AWS source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select **Refresh**.

Unregister AWS Account Source

If you plan to stop taking the backup of your AWS source, you can unregister the AWS source from the Cohesity cluster.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the AWS source.

To unregister the AWS source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select **Unregister**.

Backup Amazon RDS for PostgreSQL

Depending on the services you selected while registering the source, the Cohesity cluster automatically discovers all supported workloads including Amazon RDS for PostgreSQL associated with the specified AWS account ID. The discovered workloads appear under **Data Protection** > **Sources**. When you open the registered AWS account source, each workload type is displayed on its own tab. Select the **RDS PostgreSQL** tab to view all discovered instances.

The **RDS PostgreSQL** tab displays the entity hierarchy for the Amazon RDS for PostgreSQL environment, allowing you to navigate from the account level down to individual databases.

RDS PostgreSQL Entity Hierarchy

The **RDS PostgreSQL** tab displays the entity hierarchy for the RDS instance, allowing you to navigate from the account level down to individual databases.

The **RDS PostgreSQL** entity hierarchy in the Cohesity cluster follows this structure:

Structure	Description
AWS Account	The AWS account registered with Cohesity for RDS protection.
AWS Region	The AWS region where the RDS resources reside.
Availability Zone	The availability zone within the region where the RDS instance is deployed.
RDS Instance	The specific RDS PostgreSQL instance within the selected availability zone.
Database	The individual databases hosted within the RDS PostgreSQL instance. The database will be listed in the entity hierarchy only if you have provided credentials to discover the databases of the Amazon RDS for PostgreSQL instance.

Backup Scope by RDS PostgreSQL Hierarchy

The Cohesity cluster allows you to back up Amazon RDS for PostgreSQL at different levels of the entity hierarchy. You can choose to back up:

- **AWS Account** – Protect all RDS PostgreSQL instances and databases within the registered AWS account.
- **AWS Region** – Protect all RDS PostgreSQL instances and databases within a specific region of the registered account.
- **Availability Zone** – Protect RDS PostgreSQL instances and databases within a specific availability zone.
- **RDS Instance** – Protect a specific RDS PostgreSQL instance and all databases hosted on it.
- **Database** – Protect individual databases within an RDS PostgreSQL instance by providing the database credentials.

RDS for PostgreSQL Backup Methods

Cohesity provides the following Protection Types for the protecting Amazon RDS PostgreSQL:

- **AWS Snapshot method**: Cohesity uses this option to protect Amazon RDS for PostgreSQL instances. For protecting the Amazon RDS for PostgreSQL instances, Cohesity leverages the AWS native snapshot and stores them in the same AWS account and region as the source Amazon RDS for PostgreSQL instance.
- **Ingest method**: Cohesity uses this option to protect the Amazon RDS for PostgreSQL instance at the database level by ingesting the backup data to the Cohesity cluster.

Supported Backup Types

Cohesity performs only full backup of Amazon RDS for PostgreSQL.

Protect Amazon RDS for PostgreSQL Using Ingest Method

With the Ingest protection method, Cohesity cluster protects the Amazon RDS PostgreSQL of your AWS account at the database level.

Authenticate for RDS for PostgreSQL Protection

To protect the Amazon RDS PostgreSQL of your AWS account at the database level using the Ingest method, you must provide the credentials of the Amazon RDS PostgreSQL instance while creating the protection. By providing the credentials, Cohesity discovers the databases as objects for protection.

Perform the following steps for authenitcation:

1. Navigate to **Data Protection** > **Sources**.
2. Locate the registered AWS account and click into it.
3. Click the **RDS PostgreSQL** tab.

4. Select the checkbox for the hierarchy level (account, region, availability zone or instance level), and then click **Database Credentials** above the checkboxes.

   The **Database Credentials for <instance>** appears.

5. Select one of the following authentication methods for Cohesity to discover the databases of the Amazon RDS for PostgreSQL instances:

   - **Credentials**: Enter the **Username**, and **Password** for the Amazon RDS for PostgreSQL instances.
   - **IAM Authentication**: Enter the **Username** for IAM authentication.

     For information on the authentication requirements, see Authenticate for Ingest-based Protection.

6. Click **Save**.

   The databases of the Amazon RDS for PostgreSQL instances are discovered.

Protect Amazon RDS for PostgreSQL Database

To protect your Amazon RDS for PostgreSQL using Ingest method:

1. Navigate to **Data Protection** > **Protection**.
2. Click **Protect** on the top-right of the page and then select **AWS** > **RDS PostgreSQL**.
3. In the New Protection page, click **Add Objects** and select your registered source or click **Register Source** to add a new one.
4. Select the Amazon RDS for PostgreSQL databases for protection using one of the following views:

   - **List View**: Use this option to select the RDS for PostgreSQL databases for protection from a flat, searchable list.
   - **Hierarchy View**: Use this option to select databases for protection at various hierarchy levels.

     Optionally,

     - You can click the auto-protect icon at the AWS Account level, AWS Region level, Availability Zone level to automatically protect newly added RDS databases.
     - You can also exclude the Amazon RDS for PostgreSQL databases from auto-protection within an account, region, or availability zone by clicking the auto-protect icon ( ) next to the database. The databases excluded from auto-protection are displayed with the exclude ( ) icon.

   - **Tags**: Use this option to select the databases for protection based on tags.

     Optionally:

- You can configure auto-protection based on a tag. You can select the tag checkbox and then choose **Auto Protect This Tag** to automatically protect all newly added Amazon RDS for PostgreSQL databases with this tag.
- You can exclude the Amazon RDS for PostgreSQL databases from auto-protection within a tag by clicking the auto-protect icon ( ) next to the database. The databases excluded from auto-protection are displayed with the exclude ( ) icon.
- You can exclude databases with a specific tag from auto-protection by clicking the exclude icon (⊘). The tag excluded from auto-protection are displayed with the exclude icon.

5. Click **Continue**.
6. Provide a name for the **Protection Group**. The name can contain alphanumeric characters, underscores, dashes, and periods.
7. The Ingest-based policy is enabled by default. Create or select an existing policy from the **Policy (Cohesity Ingest)** drop-down.
8. Select **More Options** to change or configure any of the advanced settings.
9. Click **Protect**.

Advanced Settings

Section	Setting	Description
Settings	**Start Time**	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
	SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: This option is not applicable. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

Section	Setting	Description
Additional Settings	**Pause Future Runs**	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
	End Date	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
	QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. • **Backup Auto**: This policy achieves similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. The data is written to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. For best performance, we recommend the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
	Alerts	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.

Section	Setting	Description
	Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: • High-priority protection runs • Medium-priority protection runs • Low-priority protection runs
	Description	**Optional**. Enter a brief description about the Protection Group.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.

Protect Amazon RDS for PostgreSQL Using AWS Snapshot Method

With the AWS Snapshot protection method, Cohesity cluster protects the Amazon RDS PostgreSQL of your AWS account at the instance level.

To protect your Amazon RDS for PostgreSQL instance using AWS snapshot method:

1. Navigate to **Data Protection** > **Protection**.
2. Click **Protect** on the top-right of the page and then select **AWS** > **RDS PostgreSQL**.
3. In the New Protection page, click **Add Objects** and select your registered source or click **Register Source** to add a new one.
4. Select the Amazon RDS for PostgreSQL instances for protection using one of the following views:
    - **List View**: Use this option to select the RDS for PostgreSQL instances for protection from a flat, searchable list.

- **Hierarchy View**: Use this option to select instances for protection at various hierarchy levels.

  Optionally,

  - You can click the auto-protect icon at the AWS Account level, AWS Region level, Availability Zone level to automatically protect newly added RDS instances.
  - You can also exclude the Amazon RDS for PostgreSQL instances from auto-protection within an account, region, or availability zone by clicking the auto-protect icon ( ) next to the instance. The instances excluded from auto-protection are displayed with the exclude ( ) icon.

- **Tags**: Use this option to select the instances for protection based on tags.

  Optionally,

  - You can configure auto-protection based on a tag. You can select the tag checkbox and then choose **Auto Protect This Tag** to automatically protect all newly added Amazon RDS for PostgreSQL instances with this tag.
  - You can exclude the Amazon RDS for PostgreSQL instances from auto-protection within a tag by clicking the auto-protect icon ( ) next to the instance. The instances excluded from auto-protection are displayed with the exclude ( ) icon.
  - You can exclude instances with a specific tag from auto-protection by clicking the exclude icon (⊘). The tag excluded from auto-protection are displayed with the exclude icon.

5. Click **Continue**.
6. Provide a name for the **Protection Group**. The name can contain alphanumeric characters, underscores, dashes, and periods.
7. The AWS Snapshot-based policy is enabled by default. Create or select an existing policy from the **Policy (AWS Snapshot)** drop-down.
8. Select **More Options** to change or configure any of the advanced settings.
9. Click **Protect**.

Advanced Settings

Section	Setting	Description
Settings	**Start Time**	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
	SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Not applicable. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: • High-priority protection runs • Medium-priority protection runs • Low-priority protection runs
	Description	**Optional**. Enter a brief description about the Protection Group.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.

Manage Amazon RDS for PostgreSQL Backup Configuration

In the Cohesity, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Object(s) to the Protection Group

Depending on the Protection Type you chose while creating the Protection Group, you can add new Amazon RDS for PostgreSQL instances or databases to the existing Protection Group for backup. The newly added object is backed up from the next protection run, and it will be a full backup for the newly added object.

To add object(s) to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had created for Amazon RDS for PostgreSQL.

3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click in the **Objects** section.
5. In the **Objects** section, click the plus icon (**+**) to enter multiple objects that you plan to back up. Click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon RDS for PostgreSQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon RDS for PostgreSQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a recovery run:

1. Navigate to **Data Protection** > **Protection**.
2. Click the action menu (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all associated local and archived snapshots. Replicated snapshots must be deleted from the remote cluster. Snapshots under DataLock cannot be deleted.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the product UI.

To delete the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon RDS for PostgreSQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Keep the **Delete Snapshots** toggle disabled to delete the Protection Group only.

- Enable the **Delete Snapshots** toggle to delete the Protection Group and all associated snapshots.

5. Type **YES** to confirm that you want to delete the Protection Group.
6. Click **Delete Group**.

Recover Amazon RDS for PostgreSQL at Database Level

You can recover the Amazon RDS for PostgreSQL at database level if you have protected the Amazon RDS for PostgreSQL using the RDS Ingest Protection Type.

> **Note:** We recommend that you review the Plan and Prepare for Amazon RDS for PostgreSQL Protection.

To recover Amazon RDS for PostgreSQL:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **AWS** > **RDS PostgreSQL**.
3. Search for the database by entering characters of the database name, or by specifying the wildcard character *.
4. From the list of search results, select the database to recover. By default, the latest snapshot of the database is selected for recovery. To recover from a different snapshot, perform the following steps depending on the object selected:

   From the selected lists, mouse over the snapshot, and then click the edit icon. The **Edit recovery point for <*database_name*>** page appears. By default, the option to select the snapshot is displayed in the **List** mode. You can also choose to view the option in Timeline mode by clicking the **Timeline** tab in the top-right corner of the page.

   - To select a snapshot from the **List** mode:
     a. Select the **List** tab from the top-right corner of the **Edit recovery point for <*database_name*>** page. By default, the page displays the snapshots available in the last one month. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.
     b. Select the snapshots to be recovered.
     c. By default, the snapshot is recovered from the local Cohesity cluster.
     d. Click **Select Recovery Point** and then go to step 5.
   - To select a snapshot from the **Timeline** mode:

a. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar.

b. Select the snapshot to be recovered by clicking the corresponding blue dot.

c. By default, the snapshot is recovered from the local Cohesity cluster.

d. Click **Select Recovery Point** and then go to step 5.

5. Click **Next: Recover Options**.
6. In the **Recover To** section, select any one of the following options based on where you want to restore the database and then provide the required information:
   - **Original Location**: Restore the database to the original Amazon RDS for PostgreSQL instance.

     > **Note:** Restoring to the original location overwrites the existing database.

     Type **Yes** to confirm.
   - **New Location**: Restore the database to a different Amazon RDS for PostgreSQL instance within the same AWS account source. Restoring to another region within the same AWS account is supported. However, restoring to a different AWS account is not supported.

     a. From the **Source** drop down, select the AWS account and from the instance drop down, select the Amazon RDS for PostgreSQL instance to which you want to restore the database. Cross-account restore is not supported.

     b. To overwrite any existing database with the same name, enable **Overwrite existing database(s)** and type **Yes** to confirm.

     > **Note:** Restoring to a new location also replaces any existing database with the same name in the selected instance.
7. In the **Recovery Options** section, configure the following options:

Options	Description
Rename	Enter a new name for the database if you want to rename it after recovery.
Task Name	Update the default name of the recovery task.

8. Click **Recover**.

Amazon Relational Database Service for Oracle

Amazon Relational Database Service (RDS) for Oracle, a fully managed service offered by Amazon Web Services (AWS) that simplifies the deployment, operation, and scaling of Oracle Database in the cloud. Cohesity natively integrates with AWS to provide a simple, fast, and cost-effective solution for backup, recovery, and data management of Amazon RDS for Oracle.

Backup Methods

You can protect your Amazon RDS for Oracle using one of the following backup methods:

- **AWS Snapshot methods**: For protecting the Amazon RDS for Oracle, Cohesity leverages the AWS native snapshot and stores them in the same AWS account and region as the source Amazon RDS for Oracle.
- **Ingest method**: Cohesity uses this option to protect Amazon RDS for Oracle by ingesting the backup data into the Cohesity cluster. During a restore operation, Cohesity do not rely on connectivity to AWS RDS Service. Instead, restoration requires connectivity only to the Cohesity cluster where the backups resides and the EC2 target VM.

> **Important:**
> - Cohesity supports both AWS snapshot-based protection and ingest-based protection of Amazon RDS for Oracle on DataProtect for cloud in AWS (formerly known as AWS NGCE cluster).
> - On DataProtect for cloud (legacy) in AWS (formerly known as AWS Cloud Edition cluster), Cohesity supports only ingest-based protection of Amazon RDS for Oracle.
> - The ingest-based protection of Amazon RDS for Oracle on DataProtect for cloud in AWS is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

This topic provides information on how you can protect Amazon RDS for Oracle on DataProtect for cloud in AWS.

Plan and Prepare for Amazon RDS for Oracle Protection

To protect Amazon RDS for Oracle with Cohesity, you must register your AWS account as a source in the Cohesity cluster and perform backup and recovery operations. Ensure you meet the pre-requisites and understand the considerations before registering the AWS account.

Required Permissions for AWS RDS for Oracle Data Protection

IAM User Permissions to Execute CFT

To register an AWS account with the Cohesity cluster, specific IAM roles must be created in AWS to grant required permissions. These roles are created by deploying an AWS CloudFormation (CFT) stack provided by Cohesity. The CloudFormation template must be executed from the AWS Management Console. The IAM user or role used to deploy the stack must have sufficient permissions to create, manage, and view CloudFormation stacks, as well as to create the required IAM roles and policies.

The table below lists the minimum permissions required for the IAM user or role to successfully run the CloudFormation template.

> **Note:** Ensure to add these permissions manually.

Permission	Purpose
`cloudformation:CreateStack`	Create a new stack.
`cloudformation:UpdateStack`	Modify the stack during updates or re-registration
`cloudformation:DeleteStack`	Delete a stack.
`cloudformation:ValidateTemplate`	Validate the CFT before deployment.
`cloudformation:DescribeStacks`	View the status of stacks.
`cloudformation:ListStacks`	View the status of stacks.
`cloudformation:GetTemplate`	Fetch template for an existing stack.
`cloudformation:GetTemplateSummary`	View a summary of template resources and parameters.
`cloudformation:DescribeStackEvents`	View stack creation progress/errors.
`cloudformation:DescribeStackResources`	View resources created in the stack.
`cloudformation:CreateUploadBucket`	Create a temporary bucket used for uploading artifacts needed by the stack.
`iam:CreateRole`	Create required IAM roles.
`iam:DeleteRole`	Delete IAM roles when cleaning up registrations.

Permission	Purpose
`iam:GetRole`	Retrieve details of existing roles.
`iam:UpdateRole`	Modify existing IAM role configuration.
`iam:TagRole`	Add tags to IAM roles created by the template.
`iam:UntagRole`	Remove tags from IAM roles.
`iam:PutRolePolicy`	Attach inline policies to IAM roles.
`iam:DeleteRolePolicy`	Delete inline policies from IAM roles.
`iam:GetRolePolicy`	iam:GetRolePolicy
`iam:CreateInstanceProfile`	Create instance profiles needed for EC2-based operations.
`iam:GetInstanceProfile`	Retrieve instance profile details.
`iam:AddRoleToInstanceProfile`	Attach IAM roles to the instance profile.
`iam:RemoveRoleFromInstanceProfile`	Detach IAM roles from the instance profile.
`iam:DeleteInstanceProfile`	Delete instance profiles during cleanup.
`iam:AttachRolePolicy`	Attach managed policies to IAM roles.
`iam:DetachRolePolicy`	Remove managed policies from roles.
`iam:ListPolicies`	List available policies for attachment/validation.
`iam:ListRoles`	Retrieve all roles to validate role existence.
`iam:PassRole`	Allow CloudFormation to pass the IAM role to AWS services.
`s3:CreateBucket`	Create an S3 bucket for storing backup or exported data.
`s3:PutObject`	Upload objects to an S3 bucket.
`s3:GetObject`	Retrieve objects from an S3 bucket.
`s3:ListBucket`	View bucket contents to validate template uploads.

Permissions for Amazon RDS for Oracle Protection

Permissions for AWS Snapshot-based Protection

The following table lists the minimum required permissions included in the CloudFormation template for protecting Amazon RDS for Oracle using AWS snapshot-based protection method.

> **Note:** You do not need to add these permissions manually, as they are automatically added when you run the CFT.

Resource	Permissions	Purpose
rds	`rds:AddTagsToResource`	To add tags to RDS resources.

Resource	Permissions	Purpose
	`rds:CopyDBClusterSnapshot`	To copy an RDS DB cluster snapshot to another region or account.
	`rds:CopyDBSnapshot`	To copy an RDS DB snapshot.
	`rds:CreateDBClusterSnapshot`	To create a manual DB cluster snapshot. Used when protecting Aurora-based or cluster-based Oracle deployments (if applicable).
	`rds:CreateDBSnapshot`	To create a manual DB snapshot. This is the core permission for Oracle snapshot backups.
	`rds:DeleteDBClusterSnapshot`	To delete a DB cluster snapshot.
	`rds:DeleteDBSnapshot`	To delete a DB snapshot.
	`rds:ModifyDBClusterSnapshotAttribute`	To update attributes of a DB cluster snapshot.
	`rds:ModifyDBSnapshotAttribute`	To modify attributes of a DB snapshot.
	`rds:CreateDBInstance`	To create a new RDS DB instance. Required when restoring a DB instance from a snapshot.
	`rds:RestoreDBClusterFromSnapshot`	To restore an RDS DB cluster from a snapshot and create a new cluster.
	`rds:RestoreDBInstanceFromDBSnapshot`	To restore a standalone RDS DB instance from a snapshot.
	`rds:DescribeDBClusterSnapshots`	To list all DB cluster snapshots for discovery and inventory.
	`rds:DescribeDBClusters`	To retrieve information about DB clusters (engine type, settings, etc.).
	`rds:DescribeDBInstances`	To list DB instances and identify Oracle databases configured for backup.
	`rds:DescribeDBParameterGroups`	To read parameter groups associated with RDS instances for configuration awareness.

Resource	Permissions	Purpose
	`rds:DescribeDBSnapshots`	To list DB snapshots for visibility and validation of backups.
	`rds:DescribeDBSubnetGroups`	To retrieve DB subnet groups to ensure compatibility when restoring instances.
	`rds:DescribeOptionGroups`	To list option groups and validate Oracle-specific configuration during restore.
	`rds:DescribeSourceRegions`	To retrieve supported source regions for cross-region snapshot copy operations.

Permissions for Ingest-based Protection

The following table lists the minimum required permissions included in the CloudFormation template for protecting Amazon RDS for Oracle using Ingest-based protection method.

> **Note:** You do not need to add these permissions manually, as they are automatically added when you run the CFT.

Resource	Permissions	Purpose
rds	`rds:DescribeDBClusters`	To list RDS DB clusters for discovery.
	`rds:DescribeDBInstances`	To list RDS DB instances for discovery.
	`rds:DescribeTenantDatabases`	To discover tenant databases.
	`rds:DescribeDBProxies`	To list all RDS proxies.
	`rds:DescribeDBProxyTargets`	To list RDS DB instances associated with a particular proxy.
	`rds:DescribeDBProxyEndpoints`	To list proxy endpoints for a given RDS proxy.
	`rds:ListTagsForResource`	To list tags associated with RDS resources.
	`rds:DescribeOptionGroupOptions`	To list Oracle option group options and verify if export to EFS or S3 is enabled.
	`rds:ModifyOptionGroup`	To modify an option group to add S3 export capability.
ec2	`ec2:DescribeInstanceTypes`	To retrieve available instance types. Used to determine parallelism required for backup and restore operations.
	`ec2:DescribeNetworkInterfaces`	To list network interfaces required for EFS connectivity.
	`ec2:DescribeSubnets`	To list subnets required for EFS connectivity.
	`ec2:CreateNetworkInterface`	To create network interfaces needed for EFS access.

Resource	Permissions	Purpose
s3	`s3:CreateBucket`	To create an S3 bucket required for backups.
	`s3:ListBucket`	To check whether an S3 bucket already exists.
	`s3:GetObjectAcl`	To retrieve ACLs of S3 objects created during backup.
	`s3:GetObject`	To retrieve contents of S3 objects used in backup or restore workflows.
	`s3:DeleteObject`	To delete objects from the S3 bucket during backup operations.
	`s3:PutObject`	To upload data into the S3 bucket during backup workflows.
elasticfilesystem	`elasticfilesystem:DescribeFileSystems`	To list EFS file systems.
	`elasticfilesystem:CreateFileSystem`	To create an EFS file system.
	`elasticfilesystem:DeleteFileSystem`	To delete an EFS file system.
	`elasticfilesystem:DescribeMountTargets`	To list mount targets for the EFS file system.
	`elasticfilesystem:CreateMountTarget`	To create mount targets for EFS.
	`elasticfilesystem:DeleteMountTarget`	To delete EFS mount targets.
	`elasticfilesystem:ClientMount`	To mount the EFS file system on the client.
	`elasticfilesystem:ClientWrite`	To write data to EFS.
	`elasticfilesystem:ClientRootAccess`	To enable root-level access over NFS for EFS operations.
	`AmazonRDSReadOnlyAccess`	To read data placed in RDS directories so it can be exported to EFS or S3.

Authenticate for Ingest-based Protection

To protect Amazon RDS for Oracle using the Ingest-based protection method, you must authenticate by providing the username and password of an Amazon RDS for Oracle instance user. These credentials are required for Cohesity to connect to the Oracle instance and initiate backup operations.

For CDB-enabled databases, Cohesity must connect to one of the PDBs. In this case, the credentials must be provided in the following format:

Username: `{PDB username}@{PDB name}`

Password: Corresponding PDBs password

Example:

- Consider a CDB named **CDB** that contains two PDBs: **PDB1** and **PDB2**. The credentials for these PDBs are as follows:
- **PDB1**: `pdb1admin/Mynameis1pwd`
- **PDB2**: `pdb2admin/Mynameis2pwd`

When adding credentials for the CDB database (**CDB**) while protection, you can choose either of the following:

- `Pdb1admin@PDB1`: In this case use the password `Mynameis1pwd`
- `Pdb2admin@PDB2`: In this case use the password `Mynameis2pwd`

Network Access Requirement

- The EC2 instance's (The host applications that connect to the RDS for Oracle.) security group must allow outbound traffic to the RDS endpoint on port 3306, or any custom port configured for the RDS for Oracle.
- The RDS instance's security group must allow inbound connections from the EC2 instance (or its associated security group).

(Optional) Encrypt Data to be Protected

Optionally, if you want to encrypt the data to be protected, you can enable the NNE (Native Network Encryption) option for RDS Oracle.

Considerations for AWS RDS for Oracle Data Protection

Review and understand the following limitations and knows issues before you protect Amazon RDS for Oracle:

- Cohesity supports only full backups for Amazon RDS for Oracle instances. Even if you choose an incremental-based policy, Cohesity will always perform a full backup, regardless of the selected policy type.
- Incremental and log backups are not supported.

- Do not select a log-backup–based policy, as log backups are not supported. The backup will fail if you select a log-based policy.
- Tune the section size and the number of parallel streams based on the database size for optimal performance.
- Group databases of similar size into the same Protection Group to improve overall performance.

Register and Manage AWS Account

To protect your Amazon RDS for Oracle, you need to register AWS account as a source on the Cohesity cluster. After registering your AWS account as a source, you can:

- Update the AWS source configuration.
- Refresh the source details.
- Unregister the AWS source.

Register AWS Account

Before registering AWS account as a source, make sure you have completed all prerequisite tasks and reviewed the considerations.

To register AWS account as a source:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Register** at the top-right of the page and then select **Cloud Platforms** > **AWS**.

   The **Register AWS Source** dialog box appears.
3. Enter the **AWS Account ID**.
4. From the list of **AWS services**, select **RDS**.
5. Click **Next** to generate a CloudFormation Template (CFT), which you will use to complete the AWS source registration.
6. Click **Download** to download the CloudFormation Template.
7. On running the CFT, IAM roles and policies are created.
8. Once the roles and policies are created successfully, click **Register**.

Run CloudFormation Template

To complete the registration of the AWS account with the Cohesity cluster, you must run the CloudFormation Template on the AWS account you are registering. You can download CFT from the product UI as you register the AWS source.

When you execute the CFT, it creates an AWS IAM role and the policies.

Executing the CFT Template

1. In the **AWS Management Console**, navigate to **Services** and search for **CloudFormation**.
2. Click **Create stack** > **With new resources** to create a stack under AWS cloudFormation using the downloaded CloudFormation Template.
    1. In the **Prerequisite - Prepare template** page, select **Choose an existing template** > **Upload a template file**.
    2. Click **Choose File** to browse and upload the JSON Cloudformation template. Click **Next**.
    3. Enter a **Stack name** and specify the AWS Account ID where the Cloud Edition cluster is running.
    4. Select **source_registration** for creating IAM role for registration AWS source.
    5. Click **Next**.
    6. Acknowledge the creation of IAM resources by selecting the checkbox, then click **Create Stack**.
    7. Once the stack creation is successful, view the **Resources** tab to check the created IAM roles.
    8. The following IAM roles and profiles are created:
        - CohesityInstanceRole
        - CohesityInstanceProfile
        - CohesitySourceRegistrationRole

Attaching the IAM Role to Cluster Nodes

To complete registration, attach the **CohesityInstanceProfile** role to all nodes in the cluster:

1. Navigate to **Services** > **EC2** > **Instances**.
2. Select the cluster created. For a multi node, the IAM role must be attached on all nodes.
3. Select **Actions** > **Security** > **Modify IAM Role**.
4. In the **IAM Role** field, enter the name/search for the Instance Profile (*CohesityInstanceProfile*) that was created.
5. Click **Update IAM role**.

   The IAM role is successfully attached to that EC2 instance.

> **Note:** If any new node is added to the cluster, then this role has to be attached to every newly added node in the cluster as well.

Complete AWS Source Registration

Once the IAM role is attached, complete the AWS source registration on the cluster.

Update AWS Account Source Configuration

You can edit the registered AWS account to add or remove the Amazon services protected by the Cohesity from your AWS account.

To edit the AWS account source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select **Edit**.
3. In the **Edit AWS Source** page, select or unselect the Amazon services.
4. Click **Update**.

Refresh AWS Account Source

You can refresh the AWS account source configuration and fetch the latest changes on your AWS account.

To refresh the AWS source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select **Refresh**.

Unregister AWS Account Source

If you plan to stop taking the backup of your AWS source, you can unregister the AWS source from the Cohesity cluster.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the AWS source.

To unregister the AWS source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select **Unregister**.

Backup Amazon RDS for Oracle

Depending on the services you selected while registering the source, the Cohesity cluster automatically discovers all supported workloads including Amazon RDS for Oracle associated with the specified AWS account ID. The discovered workloads appear under **Data Protection** > **Sources**. When you open the registered AWS account source, each workload type is displayed on its own tab. Select the **RDS Oracle** tab to view all discovered instances.

RDS for Oracle Entity Hierarchy

The **RDS Oracle** entity hierarchy in the Cohesity cluster follows this structure:

Structure	Description
AWS Account	The AWS account registered with Cohesity for RDS protection.
AWS Region	The AWS region where the RDS resources reside.
RDS for Oracle Instance	The specific RDS for Oracle instance within the selected region. You can mouse hover over each database to view the following details: • **Size**: The logical size of the database. • **AWS Region**: The region where the RDS for Oracle instance reside. • **Multi-tenant**: Whether multi-tenancy is enabled on the database. Multi-tenancy enabled implies that the database is Oracle container Database (CDB). • **Pluggable DBs**: The number of pluggable databases on the selected RDS for Oracle. • **Protection Details**: Whether the database is protected or unprotected.

Backup Scope by RDS Oracle Hierarchy

The Cohesity cluster allows you to back up Amazon RDS for Oracle at different levels of the entity hierarchy. You can choose to back up:

- **AWS Account** – Backup all the Amazon RDS for Oracle instances within the registered AWS account.
- **AWS Region** – Backup all the Amazon RDS for Oracle instances within a specific region of the registered account.
- **RDS for Oracle instance** – Backup individual Amazon RDS for Oracle instance.

Supported Backup Types

Cohesity supports only full backups for Amazon RDS for Oracle instances. Incremental and log backups are not supported.

Protect Amazon RDS for Oracle Using Ingest Method

In Cohesity, Amazon RDS for Oracle instances are protected using a Protection Group and a Protection Policy. The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select standard or custom policy to use when creating a Protection Group. For more information, see Manage Policies.

Prerequisites

Choose Stagging Bucket

Before initiating a backup of Amazon RDS for Oracle instances, ensure that an Amazon S3 staging bucket is available in the AWS account where the Amazon RDS for Oracle reside. This bucket is used to temporarily store exported data during the backup process. You can manually create or select an existing S3 bucket in your AWS account, or allow Cohesity to automatically create one when the backup process begins. When creating a Protection Group, you can choose either option based on your preference.

If you choose Auto Create:

Cohesity automatically creates a staging bucket in the same AWS region as the instance when the protection run starts.

If you choose to specify a bucket:

You must specify an S3 bucket that you created or that already exists in the same AWS region as the RDS for Oracle instances being protected.

Authenticate for RDS for Oracle Protection

To protect the RDS for Oracle by ingesting the backup data to the Cohesity cluster, the Cohesity cluster must authenticate to the RDS for Oracle.

Perform the following steps for authenitcation:

1. Navigate to **Data Protection** > **Sources**.
2. Locate the registered AWS account and click into it.
3. Click the **RDS Oracle** tab.
4. Select the checkbox for the hierarchy level (account, region, or instance level), and then click **instance Credentials** above the checkboxes.

   The **instance Credentials for <instance>** appears.
5. Provide the Username and Enter Password of the Amazon RDS for Oracle. For information on the authentication requirements, see Authenticate for Ingest-based Protection.
6. Click **Save**.

Protect Amazon RDS for Oracle Instance Using Ingest Method

Cohesity uses the Ingest Method option to protect the Amazon RDS for Oracle by ingesting the backup data to the Cohesity cluster.

To protect Amazon RDS for Oracle instances:

1. Navigate to **Data Protection** > **Protection**.
2. Click **Protect** on the top-right of the page and then select **AWS** > **RDS Oracle**.
3. In the New Protection page, click **Add Objects** and select your registered source or click **Register Source** to add a new one.
4. Select the Amazon RDS for Oracle instance for protection using one of the following views:
   - **List View**: Use this option to select the RDS for Oracle instances for protection from a flat, searchable list.
   - **Hierarchy View**: Use this option to select instances for protection at various hierarchy levels.

     Optionally,
     - You can click the auto-protect icon at the AWS Account level, AWS Region level to automatically protect newly added instances.
     - You can also exclude the Amazon RDS for Oracle instances from auto-protection within an account or region by clicking the auto-protect icon ( ) next to the RDS for Oracle instance. The instances excluded from auto-protection are displayed with the exclude ( ) icon.
   - **Tags**: Use this option to select the instances for protection based on tags.

     Optionally,
     - You can configure auto-protection based on a tag. You can select the tag checkbox and then choose **Auto Protect This Tag** to automatically protect all newly added Amazon RDS for Oracle instances with this tag.
     - You can exclude the Amazon RDS for Oracle instances from auto-protection within a tag by clicking the auto-protect icon ( ) next to the instance. The instances excluded from auto-protection are displayed with the exclude ( ) icon.
     - You can exclude instances with a specific tag from auto-protection by clicking the exclude icon (⊘). The tag excluded from auto-protection are displayed with the exclude icon.
5. Click **Continue**.
6. Provide a name for the **Protection Group**. The name can contain alphanumeric characters, underscores, dashes, and periods.
7. In the Staging Bucket section, choose one of the following options:

- **Auto Create**: Cohesity automatically creates a temporary AWS S3 staging bucket in the same region as your RDS for Oracle instances selected for backup. The bucket follows the naming format: `cohe-<source-id>-<region-name>`.

  Where:

  - `source-id` is the AWS account ID.
  - `region-name` is the AWS region where the database reside.
- **Specify Bucket to Use**: Enter the S3 stagging bucket that you created or that already exists in the same AWS region as the RDS for Oracle instances being protected.

  After each protection run, Cohesity deletes only the temporary data stored in the staging bucket during backup operations. The staging bucket itself is retained and reused for future backup operations to minimize storage costs and avoid cross-region charges.

> **Note:** Backup will fail if you use a stagging bucket in a different region than the databases being protected.

8. In the Policy section, select **Ingest Method**, and then select a policy from the drop-down.

> **Note:**
> - You must not select a log backup-based policy as log backup is not supported. Backup will fail if you select log backup-based policy.
> - If you select an incremental-based policy, Cohesity will still perform a full backup.

9. Select **More Options** to change or configure any of the advanced settings.
10. Click **Protect**.

Advanced Settings

Section	Setting	Description
Settings	**Start Time**	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
	SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: This option is not applicable. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

Section	Setting	Description
Additional Settings	**Parallel Streams**	Specify the number of parallel streams to be used during backup. The default value is 4.
	Section Size	Define the section size for data transfer during the backup operation. We recommend using 40 GB as the section size, which is set as the default value.
	Pause Future Runs	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
	End Date	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
	QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. • **Backup Auto**: This policy achieves similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. The data is written to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. For best performance, we recommend the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.

Section	Setting	Description
	Alerts	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.
	Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: • High-priority protection runs • Medium-priority protection runs • Low-priority protection runs
	Description	**Optional**. Enter a brief description about the Protection Group.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.

Protect Amazon RDS for Oracle Using AWS Snapshot Method

With the AWS Snapshot protection method, Cohesity cluster protects the Amazon RDS Oracle of your AWS account at the instance level.

To protect your Amazon RDS for Oracle instance using AWS snapshot method:

1. Navigate to **Data Protection** > **Protection**.
2. Click **Protect** on the top-right of the page and then select **AWS** > **RDS Oracle**.
3. In the New Protection page, click **Add Objects** and select your registered source or click **Register Source** to add a new one.
4. Select the Amazon RDS for Oracle instances for protection using one of the following views:
   - **List View**: Use this option to select the RDS for Oracle instances for protection from a flat, searchable list.
   - **Hierarchy View**: Use this option to select instances for protection at various hierarchy levels.

     Optionally,
     - You can click the auto-protect icon at the AWS Account level, AWS Region level, Availability Zone level to automatically protect newly added RDS instances.
     - You can also exclude the Amazon RDS for Oracle instances from auto-protection within an account, region, or availability zone by clicking the auto-protect icon ( ) next to the instance. The instances excluded from auto-protection are displayed with the exclude ( ) icon.
   - **Tags**: Use this option to select the instances for protection based on tags.

     Optionally,
     - You can configure auto-protection based on a tag. You can select the tag checkbox and then choose **Auto Protect This Tag** to automatically protect all newly added Amazon RDS for Oracle instances with this tag.
     - You can exclude the Amazon RDS for Oracle instances from auto-protection within a tag by clicking the auto-protect icon ( ) next to the instance. The instances excluded from auto-protection are displayed with the exclude ( ) icon.
     - You can exclude instances with a specific tag from auto-protection by clicking the exclude icon (⊘). The tag excluded from auto-protection are displayed with the exclude icon.
5. Click **Continue**.

6. Provide a name for the **Protection Group**. The name can contain alphanumeric characters, underscores, dashes, and periods.
7. The AWS Snapshot-based policy is enabled by default. Create or select an existing policy from the **Policy (AWS Snapshot)** drop-down.
8. Select **More Options** to change or configure any of the advanced settings.
9. Click **Protect**.

Advanced Settings

Section	Setting	Description
Settings	**Start Time**	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
	SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: This option is not applicable. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

Section	Setting	Description
Additional Settings	**Parallel Streams**	This option is not applicable for snapshot-based protection.
	Section Size	This option is not applicable for snapshot-based protection.
	Pause Future Runs	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
	End Date	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
	QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. • **Backup Auto**: This policy achieves similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. The data is written to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. For best performance, we recommend the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.

Section	Setting	Description
	Alerts	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.
	Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: • High-priority protection runs • Medium-priority protection runs • Low-priority protection runs
	Description	**Optional**. Enter a brief description about the Protection Group.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.

Manage Amazon RDS for Oracle Backup Configuration

In the Cohesity, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Object(s) to the Protection Group

Depending on the Protection Type you chose while creating the Protection Group, you can add new Amazon RDS for Oracle instances or databases to the existing Protection Group for backup. The newly added object is backed up from the next protection run, and it will be a full backup for the newly added object.

To add object(s) to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had created for Amazon RDS for Oracle.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click in the **Objects** section.
5. In the **Objects** section, click the plus icon (**+**) to enter multiple objects that you plan to back up. Click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon RDS for Oracle.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to

execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon RDS for Oracle.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a recovery run:

1. Navigate to **Data Protection** > **Protection**.
2. Click the action menu (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all associated local and archived snapshots. Replicated snapshots must be deleted from the remote cluster. Snapshots under DataLock cannot be deleted.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the product UI.

To delete the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon RDS for Oracle.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Keep the **Delete Snapshots** toggle disabled to delete the Protection Group only.
    - Enable the **Delete Snapshots** toggle to delete the Protection Group and all associated snapshots.
5. Type **YES** to confirm that you want to delete the Protection Group.
6. Click **Delete Group**.

Recover RDS for Oracle

You can recover RDS for Oracle instance using one of the following methods:

- Recover Amazon RDS for Oracle Using Snapshot Method
- Recover Amazon RDS for Oracle Using Ingest Method

Recover Amazon RDS for Oracle Using Ingest Method

If you are choosing to recover the Amazon RDS for Oracle using the ingest method, then you can recover the Amazon RDS for Oracle instance as a standalone instance on an EC2 instance of the same AWS account or a different AWS account.

Prerequisites

Before recovering an Amazon RDS for Oracle instance as a standalone database on an EC2 instance, ensure the following:

- **Oracle Software Installation**: The target EC2 instance must have Oracle software installed. The Oracle software version must match the version of the source RDS for Oracle instance.
    - If the target Oracle version matches the source version, no additional configuration is required.
    - If the target Oracle version is newer than the source, you may need to manually set the COMPATIBLE parameter in the pfile during recovery. The value should match the source database's compatibility version.
- **Database Instance**: The database instance you are recovering must not already exist on the target EC2 instance.

- **Free Space**: The EC2 instance must have sufficient free space to restore the database.
- **Cohesity Agent**: The Cohesity Agent must be running on the EC2 instance (this applies only to Linux-based Oracle databases).
- **OS Authentication**: If the Cohesity Agent is running as a non-root, non-oracle user, OS authentication must be enabled for that user.

Recover Amazon RDS for Oracle

To recover Amazon RDS for Oracle:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **AWS** > **RDS Oracle**.
3. Select **Ingest** as the **Recovery Task**.
4. Search for the instance by entering characters of the instance name, or by specifying the wildcard character *.
5. From the list of search results, select the instance to recover. By default, the latest snapshot of the instance is selected for recovery. To recover from a different snapshot, perform the following steps depending on the object selected:

   From the selected lists, mouse over the snapshot, and then click the edit icon. The **Edit recovery point for *<instance_name>*** page appears. By default, the option to select the snapshot is displayed in the **List** mode. You can also choose to view the option in Timeline mode by clicking the **Timeline** tab in the top-right corner of the page.

   - To select a snapshot from the **List** mode:
     a. Select the **List** tab from the top-right corner of the **Edit recovery point for *<instance_name>*** page. By default, the page displays the snapshots available in the last one month. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.
     b. Select the snapshots to be recovered.
     c. By default, the snapshot is recovered from the local Cohesity cluster.
     d. Click **Select Recovery Point** and then go to step 5.
   - To select a snapshot from the **Timeline** mode:
     a. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar.

   b. Select the snapshot to be recovered by clicking the corresponding blue dot.
   c. By default, the snapshot is recovered from the local Cohesity cluster.
   d. Click **Select Recovery Point** and then go to step 5.
6. Click **Next: Recover Options**.
7. In the **Recovery To** section, provide the following information:
   a. **Source**: Select the destination AWS Account.
   b. **EC2 Instance:** Type the EC2 instance name to which you want to recover the RDS for Oracle as a standalone database.
   c. **Restore Database Files to**: Specify the path to an existing empty directory. The newly created database files will reside in this path.

      > **Note:** You can restore to an ASM path using this option. Specify just the ASM volume name instead of the entire path. Example: The restore path for ASM volume data1 is +data1. If you specify the entire path, +data1/dbname the restore job will fail.

   d. **Oracle Home**: The ORACLE_HOME value for the host where the database is restored.
   e. **Base Directory**: The directory for the restored database.
   f. **Target Database Name**: The name for the newly restored database.
8. In the **Recovery Options** section, configure the following options:
   a. **Number of Channels**: Specify the number of channels to perform the restore job. The system will run these channels in parallel to improve the restore performance.
   b. **Use NOFILENAMECHECK**: Set this option to **YES** to force RMAN to skip checking whether target datafile names match the source datafile names.

      > **Important:** Use NOFILELNAMECHECK with caution, as this restore can inadvertently clobber the datafiles if restored back to the source host which already reside on the host.

> **Note:** Some restore use case requires restoring the datafiles and/or online logfiles using the same names and file paths as the source database, but to a different host (i.e. not restoring back to the source database host).

For example, using this restore to create a standby database of the source database with exactly the same directory structure on a different host. In this case, it is required to set the 'Use NOFILENAMECHECK' option for this alternate restore.

c. **Enable Archive Log mode for the Database**: Set this option ON if you want to enable the redo log archiving on the recovered database.

d. **BCT File Path**: Specify the Block Change Tracking (BCT) file path to determine where the block change tracking file will be created. If not provided, BCT will not be enabled for the restored database.

e. **Number of Temporary Files to Use**: Enter the number of temp files to rename from the source database.

f. **Redo Log Group Settings**: Provide the number, size, and prefix of redo log groups, along with the redo log group member path for the recovery database. Redo log groups store all changes made to the database and protect against instance failure.

g. **Task Name**: Update the default name of the recovery task.

9. Click **Recover**.

Recover Amazon RDS for Oracle Using Snapshot Method

If you are choosing to recover the Amazon RDS for Oracle using the snapshot method, then you can recover RDS for Oracle instance to the original location or to a different location.

To recover Amazon RDS for Oracle:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **AWS** > **RDS Oracle**.
3. Select **Snapshot** as the **Recovery Task**.
4. Search for the instance by entering characters of the instance name, or by specifying the wildcard character *.
5. From the list of search results, select the instance to recover. By default, the latest snapshot of the instance is selected for recovery. To recover from a different snapshot, perform the following steps depending on the object selected:

   From the selected lists, mouse over the snapshot, and then click the edit icon. The **Edit recovery point for *<instance_name>*** page appears. By default, the option

to select the snapshot is displayed in the **List** mode. You can also choose to view the option in Timeline mode by clicking the **Timeline** tab in the top-right corner of the page.

- To select a snapshot from the **List** mode:
  a. Select the **List** tab from the top-right corner of the **Edit recovery point for *<instance_name>*** page. By default, the page displays the snapshots available in the last one month. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.
  b. Select the snapshots to be recovered.
  c. By default, the snapshot is recovered from the local Cohesity cluster.
  d. Click **Select Recovery Point** and then go to step 5.
- To select a snapshot from the **Timeline** mode:
  a. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar.
  b. Select the snapshot to be recovered by clicking the corresponding blue dot.
  c. By default, the snapshot is recovered from the local Cohesity cluster.
  d. Click **Select Recovery Point** and then go to step 5.

6. Click **Next: Recover Options**.
7. In the **Recover To** section, select any one of the following options based on where you want to restore the instance and then provide the required information:
   - **Original Location**: Restore the instance to the original Amazon RDS for Oracle instance.

     > **Note:** Restoring to the original location overwrites the existing instance.

     Type **Yes** to confirm.
   - **New Location**: Restore the instance to a different Amazon RDS for Oracle instance
     a. From the **Source** drop down, select a registered AWS account and from the instance drop down, select the Amazon RDS for Oracle instance to which you want to restore the instance.

b. To overwrite any existing instance with the same name, enable **Overwrite existing database(s)** and type **Yes** to confirm.

> **Note:** Restoring to a new location also replaces any existing instance with the same name in the selected instance.

8. In the **Recovery Options** section, configure the following options:

Options	Description
Rename	Enter a new name for the instance if you want to rename it after recovery.
Task Name	Update the default name of the recovery task.

9. Click **Recover**.

Amazon Relational Database Service for Microsoft SQL Server

Amazon Relational Database Service (RDS) for SQL Server is a fully managed relational database service offered by Amazon Web Services (AWS) that simplifies the deployment, operation, and scaling of Microsoft SQL Server databases in the cloud. Cohesity natively integrates with AWS to provide a simple, fast, and cost-effective solution for the backup, recovery, and data management Amazon Relational Database Service for Microsoft SQL Server (MS SQL) databases.

Backup Method

Cohesity uses the Ingest method to protect Amazon RDS for MS SQL Server databases. With this approach, Cohesity exports database-level data from Amazon RDS for MS SQL to an Amazon S3 staging bucket, then ingests the data into the Cohesity cluster for backup.

Important:

- Cohesity supports the protection of Amazon RDS for MS SQL on DataProtect for cloud in AWS (formerly known as AWS NGCE cluster) at both the instance level (via AWS snapshot-based protection) and the database level (via ingest-based protection).
- On DataProtect for cloud (legacy) in AWS (formerly known as AWS Cloud Edition cluster), Cohesity supports the backup and recovery of Amazon RDS only at the instance level.
- The backup and recovery of Amazon RDS for MS SQL at the database level on DataProtect for cloud in AWS is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

Plan and Prepare for Amazon RDS for MS SQL Server Protection

To protect Amazon RDS for MS SQL Server databases with Cohesity, you must register your AWS account as a source in the Cohesity cluster and perform backup and recovery operations. Ensure you meet the pre-requisites and understand the considerations before registering the AWS account.

Required Permissions for Amazon RDS for MS SQL Server Data Protection

IAM User Permissions to Execute CFT

To register an AWS account with the Cohesity cluster, specific IAM roles must be created in AWS to grant required permissions. These roles are created by deploying an AWS CloudFormation (CFT) stack provided by Cohesity. The CloudFormation template must be executed from the AWS Management Console. The IAM user or role used to deploy the stack must have sufficient permissions to create, manage, and view CloudFormation stacks, as well as to create the required IAM roles and policies.

The table below lists the minimum permissions required for the IAM user or role to successfully run the CloudFormation template.

Note: Ensure to add these permissions manually.

Permission	Purpose
`cloudformation:CreateStack`	Create a new stack.
`cloudformation:UpdateStack`	Modify the stack during updates or re-registration

Permission	Purpose
`cloudformation:DeleteStack`	Delete a stack.
`cloudformation:ValidateTemplate`	Validate the CFT before deployment.
`cloudformation:DescribeStacks`	View the status of stacks.
`cloudformation:ListStacks`	View the status of stacks.
`cloudformation:GetTemplate`	Fetch template for an existing stack.
`cloudformation:GetTemplateSummary`	View a summary of template resources and parameters.
`cloudformation:DescribeStackEvents`	View stack creation progress/errors.
`cloudformation:DescribeStackResources`	View resources created in the stack.
`cloudformation:CreateUploadBucket`	Create a temporary bucket used for uploading artifacts needed by the stack.
`iam:CreateRole`	Create required IAM roles.
`iam:DeleteRole`	Delete IAM roles when cleaning up registrations.
`iam:GetRole`	Retrieve details of existing roles.
`iam:UpdateRole`	Modify existing IAM role configuration.
`iam:TagRole`	Add tags to IAM roles created by the template.
`iam:UntagRole`	Remove tags from IAM roles.
`iam:PutRolePolicy`	Attach inline policies to IAM roles.
`iam:DeleteRolePolicy`	Delete inline policies from IAM roles.
`iam:GetRolePolicy`	iam:GetRolePolicy
`iam:CreateInstanceProfile`	Create instance profiles needed for EC2-based operations.
`iam:GetInstanceProfile`	Retrieve instance profile details.

Permission	Purpose
`iam:AddRoleToInstanceProfile`	Attach IAM roles to the instance profile.
`iam:RemoveRoleFromInstanceProfile`	Detach IAM roles from the instance profile.
`iam:DeleteInstanceProfile`	Delete instance profiles during cleanup.
`iam:AttachRolePolicy`	Attach managed policies to IAM roles.
`iam:DetachRolePolicy`	Remove managed policies from roles.
`iam:ListPolicies`	List available policies for attachment/validation.
`iam:ListRoles`	Retrieve all roles to validate role existence.
`iam:PassRole`	Allow CloudFormation to pass the IAM role to AWS services.
`s3:CreateBucket`	Create an S3 bucket for storing backup or exported data.
`s3:PutObject`	Upload objects to an S3 bucket.
`s3:GetObject`	Retrieve objects from an S3 bucket.
`s3:ListBucket`	View bucket contents to validate template uploads.

Permissions for Amazon RDS for MS SQL Server Protection

The following table lists the minimum required permissions included in the CloudFormation template for protecting Amazon RDS for MS SQL Server databases.

Resource	Permissions	Purpose
rds	`rds:DescribeDBClusters`	Lists RDS database clusters for discovery
	`rds:DescribeDBInstances`	Lists RDS database instances for discovery.
ec2	`ec2:DescribeInstanceTypes`	Retrieves details of instance types available in a specific location. Used to determine parallelism during RDS backup and restore operations.

Resource	Permissions	Purpose
S3	`s3:CreateBucket`	Creates an S3 bucket required during RDS restore operations.
	`s3:ListBucket`	Checks whether an S3 bucket already exists
	`s3:GetObjectAcl`	Retrieves ACLs for an S3 object stored in a bucket.
	`s3:GetObject`	Retrieves the contents of an S3 object stored in a bucket.
	`s3:PutObject`	Uploads data to an S3 bucket..
	`s3:DeleteObject`	Deletes an object from an S3 bucket

Authentication Requirement

To protect the Amazon RDS for MS SQL Server at database level , you must authenticate the Cohesity cluster to discover the databases of the Amazon RDS for MS SQL Server instance using the credentials of the RDS for MS SQL Server instance. You can provide either the credentials of:

- Admin user, or
- Custom database user

If you are providing the Custom user credentials of RDS for MS SQL Server instance, then ensure the followings:

- The SQL user has the following permissions on the database:

```
-- Create a login on the SQL Server

CREATE LOGIN dbuser WITH PASSWORD = '';

-- Create a database user mapped to the login

CREATE USER [dbuser] FOR LOGIN [dbuser];

-- Add the user to the db_owner role

ALTER ROLE [db_owner] ADD MEMBER [dbuser];
```

- The custom user is not a part of any database deny role such as `db_denydatareader`, `db_denydatawriter`. These roles prevent discovery and backup operations.

AWS S3 Staging Bucket Requirement

Cohesity uses an Amazon S3 staging bucket as temporary storage during the backup and recovery of Amazon RDS for MS SQL Server databases. You can either allow Cohesity to automatically create the staging bucket when you initiate a backup or recovery task, or you can manually create the staging bucket in your AWS account before starting the process. If

you choose to manually create the staging bucket, ensure to create the AWS S3 bucket in the same AWS region as both the database being protected and the target selected for recovery. The bucket type must be S3 Standard.

Configure Option Group

An Option group is required as the RDS for MS SQL Server backup and restore operations use the SQLSERVER_BACKUP_RESTORE option, which enables native backup and restore integration with Amazon S3.

Perform the following steps to configure Option Group:

1. Create an Option Group.
2. Add SQLSERVER_BACKUP_RESTORE Option to the Option group.
3. Create an IAM Role.
4. Associate the Option group to RDS Instances.

Create an Option Group

To create Option group:

1. Login to the Amazon Management Console and navigate to RDS.
2. From the left menu, select **Option groups**.
3. Click **Create Option Group**.
4. Provide the following information:
    a. Name
    b. Description
    c. Engine
    d. Major Engine Version
    e. Click **Create**.

Add SQLSERVER_BACKUP_RESTORE Option to Option Group

The SQLSERVER_BACKUP_RESTORE option needs to be associated with the Option group to perform backup and restore of RDS for MS SQL Server.

To add SQLSERVER_BACKUP_RESTORE option to the Option Group:

1. From the AWS Management console, open the Option Group created.
2. Click **Add Option**.
3. Select **SQLSERVER_BACKUP_RESTORE**.
4. Save the changes.

Create an IAM Role

To enable backup and restore of RDS for MS SQL server from the S3 staging bucket, an IAM role must be created within the AWS account with required permissions attached.

Attach the following AWS-managed permissions

Attach the following permissions to the IAM Role.

- *AWSBackupServiceRolePolicyForRestores*
- *AWSBackupServiceRolePolicyForBackup*
- *SqlNativeBackup*

Attach S3 Permissions (bucket access policy)

Attach the following S3 permissions to the IAM Role for accessing the staging S3 bucket.

```
      "Action" : [ "s3:ListBucket", "s3:GetBucketLocation" ],
      "Resource" : "arn:aws:s3:::*"
    },
    {
      "Effect" : "Allow",
      "Action" : [
        "s3:GetObjectAttributes", "s3:GetObject", "s3:PutObject",
        "s3:ListMultipartUploadParts", "s3:AbortMultipartUpload"
      ],
      "Resource" : "arn:aws:s3:::mybucket-/*"
    }
  ]
}
```

Where `mybucket` is the name of the staging bucket.

Update Trust Relationships

The IAM Role must also have the following trust relationship attached. The trust relationship allows RDS to assume the role:

{

```
{
  "Version" : "2012-10-17", "Statement" : [ {
    "Effect" : "Allow",
    "Principal" : {"Service" : "rds.amazonaws.com"},
    "Action" : "sts:AssumeRole"
  } ]
}
```

Associate the Option Group to RDS Instances

To perform the backup and recovery of an RDS for MS SQL Server instance, it must be associated with the Option group with SQLSERVER_BACKUP_RESTORE option attached.

To associate the Option group to RDS Instances you want to protect:

1. From the AWS Management console.
2. Navigate to **Databases** in RDS.
3. Select your SQL Server instance.
4. Modify the instance.
5. Under **Option group**, select the Option Group you created.
6. Apply the changes.

Considerations for Amazon RDS for MS SQL Data Protection

Review and understand the following limitations and known issues before you protect Amazon RDS for MS SQL Server databases:

- Cohesity supports only full backups for Amazon RDS for MS SQL Server databases. Incremental backups are not supported.
- The staging buckets you create for temporarily storing data during backup and recovery must be located in the same AWS region as both the database being protected and the target selected for recovery.
- The RDS for MS SQL Server must be in an available state for Cohesity to initiate a backup. Backups cannot be initiated if the server is offline or unavailable.
- Restoring a backup taken from a higher RDS for MS SQL database version to a lower version is not supported.
- Restoring to another region within the same AWS account is supported. However, restoring to a different AWS account is not supported.
- You cannot perform ingest-based and snapshot-based protections within the same protection Group.
- If you have selected databases for protection, then you cannot choose snapshot-based policy.
- For protection, if you have selected instances with no databases discovered, then you cannot choose ingest-based policy.

Register and Manage AWS Account

To protect your Amazon RDS for MS SQL Server, you need to register AWS account as a source on the Cohesity cluster. After registering your AWS account as a source, you can:

- Update the AWS source configuration.
- Refresh the source details.
- Unregister the AWS source.

Register AWS Account

Before registering AWS account as a source, make sure you have completed all prerequisite tasks and reviewed the considerations.

To register AWS account as a source:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Register** at the top-right of the page and then select **Cloud Platforms** > **AWS**.

   The **Register AWS Source** dialog box appears.
3. Enter the **AWS Account ID**.
4. From the list of **AWS services**, select **RDS**.
5. Click **Next** to generate a CloudFormation Template (CFT), which you will use to complete the AWS source registration.
6. Click **Download** to download the CloudFormation Template.
7. On running the CFT, IAM roles and policies are created.
8. Once the roles and policies are created successfully, click **Register**.

Run CloudFormation Template

To complete the registration of the AWS account with the Cohesity cluster, you must run the CloudFormation Template on the AWS account you are registering. You can download CFT from the product UI as you register the AWS source.

When you execute the CFT, it creates an AWS IAM role and the policies.

Executing the CFT Template

1. In the **AWS Management Console**, navigate to **Services** and search for **CloudFormation**.
2. Click **Create stack** > **With new resources** to create a stack under AWS cloudFormation using the downloaded CloudFormation Template.
    1. In the **Prerequisite - Prepare template** page, select **Choose an existing template** > **Upload a templatefile**.
    2. Click **Choose File** to browse and upload the JSON Cloudformation template. Click **Next**.
    3. Enter a **Stack name** and specify the AWS Account ID where the Cloud Edition cluster is running.
    4. Select **source_registration** for creating IAM role for registration AWS source.
    5. Click **Next**.
    6. Acknowledge the creation of IAM resources by selecting the checkbox, then click **Create Stack**.
    7. Once the stack creation is successful, view the **Resources** tab to check the created IAM roles.
    8. The following IAM roles and profiles are created:

- CohesityInstanceRole
- CohesityInstanceProfile
- CohesitySourceRegistrationRole

Attaching the IAM Role to Cluster Nodes

To complete registration, attach the **CohesityInstanceProfile** role to all nodes in the cluster:

1. Navigate to **Services** > **EC2** > **Instances**.
2. Select the cluster created. For a multi node, the IAM role must be attached on all nodes.
3. Select **Actions** > **Security** > **Modify IAM Role**.
4. In the **IAM Role** field, enter the name/search for the Instance Profile (*CohesityInstanceProfile*) that was created.
5. Click **Update IAM role**.

   The IAM role is successfully attached to that EC2 instance.

> **Note:** If any new node is added to the cluster, then this role has to be attached to every newly added node in the cluster as well.

Complete AWS Source Registration

Once the IAM role is attached, complete the AWS source registration on the cluster.

Update AWS Account Source Configuration

You can edit the registered AWS account to add or remove the Amazon services protected by the Cohesity from your AWS account.

To edit the AWS account source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select **Edit**.
3. In the **Edit AWS Source** page, select or unselect the Amazon services.
4. Click **Update**.

Refresh AWS Account Source

You can refresh the AWS account source configuration and fetch the latest changes on your AWS account.

To refresh the AWS source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select **Refresh**.

Unregister AWS Account Source

If you plan to stop taking the backup of your AWS source, you can unregister the AWS source from the Cohesity cluster.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the AWS source.

To unregister the AWS source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select **Unregister**.

Attach Permissions to IAM Role for RDS for MS SQL Protection

After completing source registration by running the CloudFormation Template (CFT), the following IAM roles and profiles are created:

- *CohesityInstanceRole*
- *CohesityInstanceProfile*
- *CohesitySourceRegistrationRole*

The *CohesitySourceRegistrationRole* contains the permissions defined in the CFT that allow Cohesity to discover AWS resources in the entity hierarchy within the product UI.

However, to perform backup and recovery operations for RDS for MS SQL, you must attach the permissions listed in the Permissions for Amazon RDS for MS SQL Server Protection section to the *CohesityInstanceRole*.

Attach Permissions

Perform the following steps to attach the permissions to the *CohesityInstanceRole*.

1. In the AWS Management Console, navigate to **IAM** > **Roles**.
2. Search for and open the role *CohesityInstanceRole*.
3. Go to the **Permissions** tab and select **Add permissions** > **Create inline policy**.
4. Switch to the **JSON** tab.
5. Paste the required RDS for MS SQL permissions JSON policy and save it. For the list of permissions, see Permissions for Amazon RDS for MS SQL Server Protection.

Backup Amazon RDS for MS SQL Server

Depending on the services you selected while registering the source, the Cohesity cluster automatically discovers all supported workloads in the specified AWS account ID. The discovered workloads appear under **Data Protection** > **Sources**. When you open the registered AWS account source, each workload type is displayed on its own tab. Select the **RDS MSSQL** tab to to view all discovered RDS MS SQL Instances and databases.

The **RDS MSSQL** tab displays the entity hierarchy Redshift, allowing you to navigate from the account level down to individual databases.

Amazon RDS for Microsoft SQL Server Hierarchy

The Amazon RDS for Microsoft SQL Server entity hierarchy in the Cohesity cluster follows this structure:

Structure	Description
AWS Account	The AWS account registered with Cohesity for protecting Amazon RDS for Microsoft SQL Server databases
AWS Region	The AWS region where the RDS resources reside.
Availability Zone	The availability zone within the region where the RDS instance is deployed.
RDS MS SQL Server Instance	The specific RDS for MS SQL Server instance within the selected availability zone.
RDS MS SQL Server Database	The individual databases hosted within the RDS for MS SQL Server instance. The database will be listed in the entity hierarchy only if you have provided credentials to discover the databases of the Amazon RDS for MS SQL Server instance.

Backup Scope by RDS for Microsoft SQL Server Hierarchy

The Cohesity cluster allows you to back up Amazon RDS for MS SQL Server databases at different levels of the entity hierarchy. You can choose to back up:

- **AWS Account** – Backup all the Amazon RDS for MS SQL Server databases within the registered AWS account.
- **AWS Region** – Backup all the Amazon RDS for MS SQL Server databases within a specific region of the registered account.
- **Availability Zone** – Protect Amazon RDS for MS SQL Server databases within a specific availability zone.

- **RDS MS SQL Server Instance** – Backup all Amazon RDS for MS SQL Server databases within a specific database instance.
- **RDS MS SQL Server Databases** – Backup individual Amazon RDS for MS SQL Server database.

Backup Process

When you initiate a protection run in the Cohesity cluster to back up Amazon RDS for MS SQL Server databases, Cohesity first exports the selected database data to an Amazon S3 staging bucket.

Once the data is successfully exported to the S3 bucket, Cohesity ingests the staged data from the S3 bucket into the Cohesity cluster. Once the ingestion is successful and the data is fully backed up to the cluster, Cohesity automatically deletes the exported data from the staging bucket to free up storage and minimize S3 costs.

Supported Backup Types

Cohesity supports only full backups for Amazon RDS for MS SQL Server databases. Incremental backups are not supported.

Protect Amazon RDS for MS SQL Server

In Cohesity, Amazon RDS for MS SQL Server databases are protected using a Protection Group and a Protection Policy. The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select standard or custom policy to use when creating a Protection Group. For more information, see Manage Policies.

Prerequisites

Choose Stagging Bucket

Before initiating a backup of Amazon RDS for MS SQL Server databases, ensure that an Amazon S3 staging bucket is available in the AWS account where the Amazon RDS for MS SQL Server resources reside. This bucket is used to temporarily store exported data during the backup process. You can manually create or select an existing S3 bucket in your AWS account, or allow Cohesity to automatically create one when the backup process begins. When creating a Protection Group, you can choose either option based on your preference.

If you choose Auto Create:

Cohesity automatically creates a staging bucket in the same AWS region as the database when the protection run starts.

If you choose to specify a bucket:

You must specify an S3 bucket that you created or that already exists in the same AWS region as the RDS for MS SQL Server databases being protected.

Authenticate RDS for MS SQL Server Protection

To protect the RDS for MS SQL Server at database level, the Cohesity cluster must authenticate to the MS SQL Server instance. Once authentication is successful, Cohesity discovers the databases of the MS SQL Server instance for protection.

Perform the following steps for authentication:

1. Navigate to **Data Protection** > **Sources**.
2. Locate the registered AWS account and click into it.
3. Click the **RDS MSSQL** tab.
4. Select the checkbox for the hierarchy level (Account, region, Availability zone or cluster level), and then click **Database Credentials** above the checkboxes.

   The **Database Credentials for <instance>** appears.
5. Provide the **Username** and **Enter Password** of the Amazon RDS for MS SQL Server instances.
6. Click **Save**.
7. Click the **Refresh** icon for the discovered databases to appear on the UI.

The databases corresponding to the selected instance or hierarchy level are discovered.

Protect Amazon RDS for MS SQL Server Database

To protect Amazon RDS for MS SQL Server databases:

1. Navigate to **Data Protection** > **Protection**. Click **Protect** on the top-right of the page and then select **AWS** > **RDS MSSQL**.
2. In the **New Protection** page, click **Add Objects** and select your registered source, or click **Register Source** to add a new one.
3. Select the RDS for MS SQL Server databases using one of the following views or option:
   - **List View**: Use this option to select the RDS for MS SQL Server databases for protection from a flat, searchable list.
   - **Hierarchy View**: Use this option to select RDS for MS SQL Server databases for protection at various hierarchy levels.

     Optionally:
     - You can click the auto-protect icon at the **AWS Account** level, **AWS Region** level, **Availability Zone** level, or **Instance** level to automatically protect newly added RDS for MS SQL Server databases.
     - You can exclude the RDS for MS SQL Server databases from auto-protection within an account, region, availability zone, or instance by

clicking the auto-protect icon ( ) next to the database. The databases excluded from auto-protection are displayed with the exclude ( ) icon.

- **Tags**: Use this option to select the databases for protection based on tags. Select the checkbox of a tag, and then select **Select All Child Objects** to include all databases with that tag for protection.

  Optionally:

  - You can configure auto-protection based on a tag. You can select the tag checkbox and then choose **Auto Protect This Tag** to automatically protect all newly added RDS for MS SQL Server databases with this tag.
  - You can exclude the RDS for MS SQL Server databases from auto-protection within a tag by clicking the auto-protect icon ( ) next to the database. The databases excluded from auto-protection are displayed with the exclude ( ) icon.
  - You can exclude databases with a specific tag from auto-protection by clicking the exclude icon (⊘). The tag excluded from auto-protection are displayed with the exclude icon.

4. Click **Continue.**
5. Provide a name for the **Protection Group**. The name can contain alphanumeric characters, underscores, dashes, and periods.
6. In the **Staging Bucket** section, choose one of the following options:
   - **Auto Create**: Cohesity automatically creates a temporary AWS S3 staging bucket in the same region as your RDS for MS SQL Server databases selected for backup. The bucket follows the naming format: `cohe-<source-id>-<region-name>`.

     Where,

     - `source-id` is the AWS account ID.
     - `region-name` is the AWS region where the Redshift database reside.
   - **Specify Bucket to Use**: Enter the S3 stagging bucket that you created or that already exists in the same AWS region as the RDS for MS SQL Server databases being protected.

     > **Note:** Using a bucket in a different region than the database is not supported.

- After each protection run, Cohesity deletes only the temporary data stored in the staging bucket during backup operations. The staging bucket itself is retained and reused for future backup operations to minimize storage costs and avoid cross-region charges.

  > **Note:** Backup will fail if you use a staging bucket in a different region than the databases being protected.

7. Create or select an existing policy from the **Policy** drop-down.
8. Select **More Options** to change or configure any of the advanced settings.
9. Click **Protect**.

Advanced Settings

Section	Setting	Description
Settings	**Start Time**	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
	SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: This option is not applicable. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

Section	Setting	Description
Additional Settings	**Pause Future Runs**	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
	End Date	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
	QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. • **Backup Auto**: This policy achieves similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. The data is written to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. For best performance, we recommend the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
	Alerts	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.

Section	Setting	Description
	Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: • High-priority protection runs • Medium-priority protection runs • Low-priority protection runs
	Description	**Optional**. Enter a brief description about the Protection Group.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.

Manage Amazon RDS for MS SQL Server Backup Configuration

In the Cohesity, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Object(s) to the Protection Group

Depending on the Protection Type you chose while creating the Protection Group, you can add new Amazon RDS for MS SQL Server database to the existing Protection Group for backup. The newly added object is backed up from the next protection run, and it will be a full backup for the newly added object.

To add object(s) to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had created for Amazon RDS for MS SQL Server database.

3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click in the **Objects** section.
5. In the **Objects** section, click the plus icon (**+**) to enter multiple objects that you plan to back up. Click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon RDS for MS SQL Server database.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon RDS for MS SQL Server database.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a recovery run:

1. Navigate to **Data Protection** > **Protection**.
2. Click the action menu (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all associated local and archived snapshots. Replicated snapshots must be deleted from the remote cluster. Snapshots under DataLock cannot be deleted.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the product UI.

To delete the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon RDS for MS SQL Server database.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Keep the **Delete Snapshots** toggle disabled to delete the Protection Group only.

- Enable the **Delete Snapshots** toggle to delete the Protection Group and all associated snapshots.

5. Type **YES** to confirm that you want to delete the Protection Group.
6. Click **Delete Group**.

Recover Amazon RDS for MS SQL Server

You can restore the Amazon RDS for MS SQL Server database either to its original location or to a different location.

> **Note:** We recommend that you review the Plan and Prepare for Amazon RDS for MS SQL Server Protection section.

Recovery Process

When you initiate a recovery, Cohesity exports the selected database data from the Cohesity cluster to an Amazon S3 staging bucket. You can manually create or select an existing S3 bucket in your AWS account, or allow Cohesity to automatically create one when the recovery process begins.

After the data is successfully exported to the staging bucket, Amazon RDS reads the exported files from the bucket and imports them into the specified Amazon RDS for MS SQL database instance. Once the import completes, Cohesity automatically deletes the exported files from the staging bucket to free up storage and minimize S3 costs.

If you choose Auto Create:

Cohesity automatically creates a staging bucket in the same AWS account and region as the target RDS for MS SQL Server database instance.

If you choose to specify a bucket:

You must specify an S3 bucket that you created or that already exists. The S3 bucket must be in the same AWS region as the target RDS for MS SQL database instance.

Recover Amazon RDS for MS SQL Server Database

To recover Amazon RDS for MS SQL Server database:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **AWS** > **RDS MSSQL**.
3. Search for the database by entering characters of the database name, or by specifying the wildcard character *.
4. From the list of search results, select the database to recover.

- By default, the latest snapshot of the database is selected for recovery.
- To recover from a different snapshot, hover over the snapshot and click the **Edit** icon. The **Edit Recovery Point for <*database_name*>** page appears.
- By default, snapshots are displayed in the List mode. You can switch to the Timeline mode by clicking the **Timeline** tab in the top-right corner of the page.

To select a snapshot from the **List** mode:

a. Select the **List** tab from the top-right corner of the **Edit recovery point for <*database_name*>** page. By default, the page displays the snapshots available in the last one month. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.

b. Select the snapshots to be recovered.

c. By default, the snapshot is recovered from the local Cohesity cluster.

d. Click **Select Recovery Point** and then go to step 5.

To select a snapshot from the **Timeline** mode:

a. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar.

b. Select the snapshot to be recovered by clicking the corresponding blue dot.

c. By default, the snapshot is recovered from the local Cohesity cluster.

d. Click **Select Recovery Point** and then go to step 5.

5. Click **Next: Recover Options**.
6. In the **Recover To** section, select any one of the following options based on where you want to restore the database and then provide the required information:
   - **Original Location**: Restore the database to the original Amazon RDS for MS SQL database instance.

     > **Note:** Restoring to the original location will overwrite any existing database with the same name.

     Type **Yes** to confirm.
   - **New Location**: Restore the database to an Amazon RDS for MS SQL database instance within the same AWS account. Restoring to another region within the same AWS account is supported. However, restoring to a different AWS account is not supported.

a. From the **Source** drop down, select the AWS account and from the **Instance** drop down, select the Amazon RDS for MS SQL database instance to which you want to restore the database.

b. To overwrite any existing database with the same name, enable **Overwrite existing database(s)** and type **Yes** to confirm.

> **Note:** Restoring to a new location also replaces any existing database with the same name in the selected instance.

7. In the **Staging Bucket** section, choose one of the following options:
   - **Auto Create**: Cohesity automatically creates a temporary AWS S3 staging bucket in the same region as your RDS for MS SQL Server databases selected for recovery. The bucket follows the naming format: `cohe-<source-id>-<region-name>`.

     Where:
     - `source-id` is the AWS account ID.
     - `region-name` is the target database AWS region.
   - **Specify Bucket to Use**: Enter the name of the AWS S3 staging bucket you created for temporarily storing the data. Ensure the bucket is in the same region as the target RDS for MS SQL database instance.

   After the recovery task, Cohesity deletes only the temporary data stored in the staging bucket during backup operations. The staging bucket itself is retained and reused for future recovery operations to minimize storage costs and avoid cross-region charges.

   > **Note:** Using a bucket in a different region than the database may incur additional storage costs.

8. In the **Recovery Options** section, configure the following options:

Options	Description
Rename	Enter a new name for the database if you want to rename it after recovery.
Task Name	Update the default name of the recovery task.

9. Click **Recover**.

Amazon Relational Database Service Custom for Oracle

Cohesity supports protecting Relational Database Service (RDS) Custom for Oracle databases using two methods:

- **Ingest method (via Cohesity Oracle Adapter)**: Performs database-level protection by installing the Cohesity Oracle Adapter directly on the RDS Custom instance. This method enables RMAN-based, application-consistent backups and restores with external storage like EC2 VMs as target storage.
- **Snapshot method (via native AWS snapshots)**: Uses AWS's native snapshot capability to capture and restore the RDS Custom instance at the storage layer.

The setup and workflows differ for each method. Choose the method that best suits your protection strategy and operational requirements.

Cohesity enables protection of Amazon RDS Custom for Oracle databases through two supported approaches — ingest-based protection using the Cohesity Oracle Adapter and snapshot-based protection using AWS native snapshots.

With the ingest method, you can use a Protection Group to perform database-level protection for Amazon RDS Custom for Oracle instances. The Cohesity Oracle Adapter, installed directly on the RDS Custom instance, integrates natively with Oracle Recovery Manager (RMAN) to deliver application-consistent backup and recovery for single-instance RDS custom oracle databases.

The snapshot method, on the other hand, leverages AWS native snapshot capabilities to back up and restore the RDS Custom instance at the infrastructure level, offering a fast and storage-efficient alternative for customers preferring snapshot-based workflows.

> **Note:** Cohesity supports the backup and recovery of Amazon RDS Custom for Oracle on DataProtect for cloud in AWS (formerly known as AWS NGCE cluster).

To learn more, see the following topics:

- Plan and Prepare for Amazon RDS Custom for Oracle
- Manage Protection Policy
- Backup Amazon RDS Custom for Oracle

Plan and Prepare for Amazon RDS Custom for Oracle

This topic provides information on minimum permissions, prerequisites, and considerations to protect Amazon RDS Custom for Oracle using both **Ingest** and **Snapshot** methods.

- Ingest method (via Cohesity Oracle Adapter)
- Snapshot method (via native AWS snapshots)

Ingest method (via Cohesity Oracle Adapter)

To protect Amazon Custom RDS for Oracle with Cohesity using the Ingest method, you must register your custom RDS EC2 instance as a source in the Cohesity cluster and perform backup and recovery operations. Ensure you meet the prerequisites and understand the considerations before registering for the AWS account.

Prerequisite

- The Cohesity Oracle adapter has to be installed on the Custom RDS EC2 instance.
- **Non-overlapping backup windows**: Schedule Amazon RDS Custom backup and maintenance windows so they do not overlap with Cohesity backup jobs.
- **Archive log retention**: Configure RDS Custom archive log retention to ensure that archived logs are retained long enough for at least one Cohesity backup cycle to complete successfully.

  For example, create the following configuration file on your RDS Custom instance:

  ```
  sudo mkdir -p /opt/aws/rdscustomagent/config
  sudo vi /opt/aws/rdscustomagent/config/redo_logs_custom_
  configuration.json
  Add the following content:
  {
  "archivedLogRetentionHours": "60"
  }
  ```

  This ensures archived logs are retained for 60 hours, preventing them from being purged before Cohesity backup jobs complete.

  For more details, see Configuring archived log retention for Amazon RDS Custom.
- **Required service endpoints**: The following table lists the service endpoints required for the backup and recovery of AWS Custom RDS databases:

AWS Resource Type	Service Endpoints
IAM	iam.amazonaws.com
KMS	kms.<region>.amazonaws.com
RDS	rds.<region>.amazonaws.com
EC2 (for SBT traffic & agent operations)	ec2.<region>.amazonaws.com
CloudWatch Logs (for monitoring agent activity)	logs.<region>.amazonaws.com

Considerations

- Ingest Backup and recovery of Amazon RDS Custom databases are not supported on Physical clusters or Virtual Edition clusters. To back up and recover Amazon RDS Custom databases, the cluster must be a Next-Gen Cloud Edition (NGCE) cluster.
- Cohesity uses the Oracle Adapter installed on the RDS Custom instance to perform database-level ingest backups and restores. Backup and recovery operations are managed through Oracle RMAN, with Cohesity acting as the backup target.
- Cohesity supports full, incremental, and archivelog backups for RDS Custom databases.
- You can restore backups to the original RDS Custom instance or to an alternate location (such as another RDS Custom instance or an on-premises Oracle environment).
- Cohesity does not support recovery to different accounts with different regions, but recovery to different accounts with the same region, the same account with the same region, and the same account with different regions are supported.
- Point-in-time recovery (PITR) is supported for RDS Custom databases if archive log retention is configured to meet Cohesity backup requirements and AWS automated backups are enabled. PITR allows you to select a specific time within the retention period and restore the database to that point in time.
- Cohesity supports full, incremental, and archived log backups via Oracle RMAN using the Cohesity Adapter.
- Recovery of an RDS Custom database encrypted with the default AWS KMS Customer Managed Key (CMK) to a different account is not supported because AWS does not allow sharing snapshots encrypted with the default KMS key.
- You cannot restore an RDS Custom database to a location (same or alternate) if the target already has a database with the same name. AWS prohibits multiple RDS Custom database instances with identical names.
- Workaround: Assign a unique name to the RDS Custom database instance before performing recovery.
- When creating a protection group for Linux sources, choose either Imagecopy or Backupset (SBT) as the backup type; these types are not interchangeable.

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

Snapshot method (via native AWS snapshots)

To protect Amazon Custom RDS for Oracle with Cohesity, you must register your AWS account as a source in the Cohesity cluster and perform backup and recovery operations.

Ensure you meet the prerequisites and understand the considerations before registering for the AWS account.

Prerequisites

- Non-overlapping backup windows: Schedule Amazon RDS Custom backup and maintenance windows so they do not overlap with Cohesity backup jobs.
- **Archive log retention**: Configure RDS Custom archive log retention to ensure that archived logs are retained long enough for at least one Cohesity backup cycle to complete successfully.

  For example, create the following configuration file on your RDS Custom instance:

  ```
  sudo mkdir -p /opt/aws/rdscustomagent/config
  sudo vi /opt/aws/rdscustomagent/config/redo_logs_custom_
  configuration.json
  Add the following content:
  {
  "archivedLogRetentionHours": "60"
  }
  ```

  This ensures archived logs are retained for 60 hours, preventing them from being purged before Cohesity backup jobs complete.

  For more details, see Configuring archived log retention for Amazon RDS Custom.
- Required Permissions - IAM require the user permissions listed below to execute.

  To register an AWS account with the Cohesity cluster, you need to run the CloudFormation template on the AWS console. The IAM user you use must have the required permissions to run the CloudFormation Template and to create and view the stack. The following table lists the permissions the IAM user must have to run the CloudFormation template.

  > **Note:** Ensure to add these permissions manually.

Hypervisor	Cluster Type
cloudformation:CreateStack	To create a new stack.
cloudformation:DeleteStack	To delete a stack.
cloudformation:ValidateTemplate	To validate the CFT before deployment.
cloudformation:DescribeStacks	To view the status of stacks.

Hypervisor	Cluster Type
cloudformation:ListStacks	To view the status of stacks.
cloudformation:GetTemplate	To fetch template for an existing stack.
cloudformation:DescribeStackEvents	To view stack creation progress/errors.
cloudformation:DescribeStackResources	To see resources created in the stack.

- The following table lists the permissions that are added to the policy of the CloudFormation template.

> **Note:** You do not need to add these permissions manually, as they are automatically added when you run the CFT.

Resource	Permissions	Reason
ebs	ebs: GetSnapshotBlock ebs:ListChangedBlocks ebs:ListSnapshotBlocks	These permissions are required for EBS direct APIs to read & write data from/to EBS snapshots.

Resource	Permissions	Reason
ec2	ec2:AllocateAddress ec2:AssociateSubnetCidrBlock ec2:AssociateVpcCidrBlock ec2:AttachInternetGateway ec2:AttachNetworkInterface ec2:AttachVolume ec2:AttachVpnGateway ec2:AuthorizeSecurityGroupIngress ec2:AuthorizeSecurityGroupEgress ec2:CancelImportTask ec2:CopySnapshot ec2:CreateFleet ec2:CreateImage ec2:CreateInstanceExportTask ec2:CreateKeyPair ec2:CreateNetworkInterface ec2:CreateSecurityGroup ec2:CreateSnapshot ec2:CreateTags ec2:CreateVolume ec2:DeleteNetworkInterface ec2:DeleteSnapshot ec2:DeleteTags ec2:DeleteVolume ec2:DeregisterImage ec2:DescribeAvailabilityZones ec2:DescribeExportTasks ec2:DescribeFleetHistory ec2:DescribeFleetInstances	Required for AWS source registration, and discover the resources present in the account, which will be used for backups. Also needed for recovery to provide list of options to choose from.

Resource	Permissions	Reason
	ec2:DescribeFleets ec2:DescribeImages ec2:DescribeImportImageTasks ec2:DescribeImportSnapshotTasks ec2:DescribeInstanceAttribute ec2:DescribeInstanceCreditSpecifications ec2:DescribeInstances ec2:DescribeInstanceStatus ec2:DescribeKeyPairs ec2:DescribeNetworkInterfaces ec2:DescribeRegions ec2:DescribeReservedInstances ec2:DescribeReservedInstancesListings ec2:DescribeReservedInstancesModifications ec2:DescribeReservedInstancesOfferings ec2:DescribeSecurityGroupReferences ec2:DescribeSecurityGroups ec2:DescribeSnapshotAttribute ec2:DescribeSnapshots ec2:DescribeSubnets ec2:DescribeTags ec2:DescribeVolumeAttribute ec2:DescribeVolumes ec2:DescribeVolumeStatus ec2:DescribeVpcAttribute ec2:DescribeVpcClassicLink ec2:DescribeVpcClassicLinkDnsSupport ec2:DescribeVpcEndpointConnectionNotifications ec2:DescribeVpcEndpointConnections	

Resource	Permissions	Reason
	ec2:DescribeVpcEndpoints ec2:DescribeVpcEndpointServiceConfigurations ec2:DescribeVpcEndpointServicePermissions ec2:DescribeVpcEndpointServices ec2:DescribeVpcPeeringConnections ec2:DescribeVpcs ec2:DetachNetworkInterface ec2:DetachVolume ec2:ImportImage ec2:ImportInstance ec2:ImportKeyPair ec2:ImportSnapshot ec2:ImportVolume ec2:ModifyFleet ec2:ModifyInstanceAttribute ec2:ModifyNetworkInterfaceAttribute ec2:ModifySnapshotAttribute ec2:ModifyVolume ec2:ModifyVolumeAttribute ec2:RegisterImage ec2:RunInstances ec2:StartInstances ec2:StopInstances ec2:TerminateInstances	

Resource	Permissions	Reason
iam	iam:AddRoleToInstanceProfile iam:AttachRolePolicy iam:CreatePolicy iam:CreateRole iam:DeleteRole iam:DeleteRolePolicy iam:GetAccessKeyLastUsed iam:GetInstanceProfile iam:GetPolicy iam:GetRole iam:GetRolePolicy iam:GetUser iam:GetUserPolicy iam:ListAccessKeys iam:ListPolicies iam:ListRolePolicies iam:ListRoles iam:ListRoleTags iam:PassRole iam:PutRolePolicy iam:TagRole iam:UntagRole iam:UpdateRole iam:UpdateUser	

Resource	Permissions	Reason
kms	kms:CreateGrant kms:Decrypt kms:DescribeKey kms:Encrypt kms:GenerateDataKey kms:ListAliases kms:ListKeys kms:ReEncryptFrom kms:ReEncryptTo	`KMS permissions are needed to read data of an encrypted database at the time of backup, as well as write encrypted data to the recovered database. Describe permissions are needed so we can list & identify keys associated with database instances.

Resource	Permissions	Reason
rds	rds:AddTagsToResource rds:CopyDBClusterSnapshot rds:CopyDBSnapshot rds:CreateDBClusterSnapshot rds:CreateDBInstance rds:CreateDBSnapshot rds:DeleteDBClusterSnapshot rds:DeleteDBSnapshot rds:DescribeDBClusterSnapshots rds:DescribeDBClusters rds:DescribeDBInstances rds:DescribeDBParameterGroups rds:DescribeDBSnapshots rds:DescribeDBSubnetGroups rds:DescribeOptionGroups rds:DescribeSourceRegions rds:ModifyDBClusterSnapshotAttribute rds:ModifyDBSnapshotAttribute rds:RestoreDBClusterFromSnapshot rds:RestoreDBInstanceFromDBSnapshot rds:RestoreDBInstanceToPointInTime	These permissions are required to register the AWS account on Cohesity with the IAM role which got created by the Cloud Formation template. Once the source is registered with Cohesity, described permissions are needed so Cohesity can identify resources present in the account, which will be used for backups as well as at the time of recovery we use this information to provide a list of options to choose from. Cohesity creates snapshots of the Amazon RDS & Aurora instances while backing up and storing the different database instance attributes and tags. While recovering the database instance, Cohesity creates DB instance/cluster, it also attaches the original tags. Cohesity requires the delete snapshots permissions to delete the expired/old snapshots it creates during the backup. We need to modify snapshot attributes permission so that we can share the snapshot across accounts if cross-account recovery is attempted. RestoreDBInstanceToPointInTime and RestoreDBClusterToPointInTime is needed to do the point in time recoveries.

Resource	Permissions	Reason
s3	s3:AbortMultipartUpload s3:CreateBucket s3:DeleteBucket s3:DeleteObject s3:DeleteObjectTagging s3:DeleteObjectVersion s3:DeleteObjectVersionTagging s3:GetBucketAcl s3:GetBucketLocation s3:GetBucketNotification s3:GetBucketObjectLockConfiguration s3:GetBucketOwnershipControls s3:GetBucketPolicy s3:GetBucketTagging s3:GetBucketVersioning s3:GetInventoryConfiguration s3:GetLifecycleConfiguration s3:GetObject s3:GetObjectAcl s3:GetObjectAttributes s3:GetObjectTagging s3:GetObjectTorrent s3:GetObjectVersion s3:GetObjectVersionAcl s3:AbortMultipartUpload s3:CreateBucket s3:DeleteBucket s3:DeleteObject s3:DeleteObjectTagging	These permissions are required for the backup and recovery of Amazon S3 objects.

Considerations

- To back up and recover Amazon RDS Custom databases, the cluster must be a Next-Gen Cloud Edition (NGCE) cluster.

- Cohesity uses the Oracle Adapter installed on the RDS Custom instance to perform database-level ingest backups and restores.
- Cohesity supports full, incremental, and archivelog backups for RDS Custom databases.
- You can restore backups to the original RDS Custom instance or to an alternate location (such as another RDS Custom instance or an on-premises Oracle environment).
- Cohesity does not support recovery to different accounts with different regions, but recovery to different accounts with the same region, the same account with the same region, and the same account with different regions is supported.
- Point-in-time recovery (PITR) is supported for RDS Custom databases if archive log retention is configured to meet Cohesity backup requirements and AWS automated backups are enabled. PITR allows you to select a specific time within the retention period and restore the database to that point in time.
- Recovery of an RDS Custom database encrypted with the default AWS KMS Customer Managed Key (CMK) to a different account is not supported because AWS does not allow sharing snapshots encrypted with the default KMS key.
- You cannot restore an RDS Custom database to a location (same or alternate) if the target already has a database with the same name. AWS prohibits multiple RDS Custom database instances with identical names.
- Workaround: Assign a unique name to the RDS Custom database instance before performing recovery.
- If you are protecting an Amazon RDS Custom instance within a private VPC, then you must:
- Register the AWS cloud source using an IAM role with permissions for RDS Custom, EC2, KMS, CloudWatch Logs, and STS. For more information, see Register an AWS Cloud Source using IAM Role.
- Ensure the following service endpoints are accessible from the Cohesity cluster and the RDS Custom EC2 instance:
    - `iam.amazonaws.com`
    - `sts.amazonaws.com (AWS Security Token Service)`
    - `kms.<region>.amazonaws.com`
    - `rds-custom.<region>.amazonaws.com`
    - `ec2.<region>.amazonaws.com`
    - `logs.<region>.amazonaws.com (CloudWatch Logs)`

- Enable AWS Security Token Service (STS) in the default AWS region where the Cohesity cluster is deployed.

Register and Manage Amazon RDS Custom for Oracle

Cohesity supports both ingest-based and snapshot-based backup of Custom Relational Database Service (RDS) databases for Oracle:

- Register Amazon RDS Custom for Oracle using the Ingest Method
- Register Amazon RDS Custom for Oracle using the Snapshot Method

Register Amazon RDS Custom for Oracle Using Ingest Method

To protect your Amazon RDS Custom for Oracle instances using the ingest method, follow the steps below:

1. Navigate to **Data Protection > Sources**.
2. Click **Register** > **Databases** > **Oracle Source**.

   > **Note:** A physical server refers to a bare metal server or a VM running the supported versions of the OS and Oracle Database with the Cohesity agent installed.

3. In the **Select Source Type** drop-down, select **Oracle Standalone Source**.
4. **Enter Host Address**, for an Oracle Standalone server, specify the Hostname, Server IP, or FQDN of the Oracle server.
5. **Authentication Type**, specify the Authentication Type to register the Oracle source.

   When connecting to the Oracle databases, Cohesity can use either the Oracle OS Authentication or Oracle DB Authentication method. If you use DB authentication, provide the database username and password.
6. Click **Register**.
7. Select one of the following options from the **Cohesity Network Interface**:
   - **Auto Select**: If you select this option, the system automatically selects the interface group to use for the VLAN.
   - **Interface Group**: If you select this option, you must select the interface group to use for the source.

   > **Note:** If You select a different interface group from what was selected during the Oracle source registration, the system will use this VLAN for all the objects in the protection job.

Register Amazon RDS Custom for Oracle Using Snapshot Method

To protect your Amazon RDS Custom for Oracle instances, you need to register your AWS account as a source on the Cohesity cluster. After registering your AWS account as a source, you can:

- Update the AWS source configuration
- Refresh the source details
- Unregister the AWS source from the Cohesity cluster

Register AWS Account

Before registering AWS account as a source, make sure you have completed all prerequisite tasks and review the considerations.

To register AWS account as a source:

1. In the Cohesity Dashboard, select **Data Protection** > **Sources**.
2. Click **Register** at the top-right of the page and then select **Cloud Platforms** > **AWS**.

   The **Register AWS Source** dialog box appears.
3. Enter the **AWS Account ID**.
4. Select the AWS Services you want to register:
   - EC2
   - RDS
   - S3
5. (Applies only for Amazon S3 service) Cohesity utilizes the Amazon S3 inventory report to protect the Amazon S3 bucket. Under **Inventory Report Location**, provide the following information to create the inventory report:
   - **S3 buckets ARN**: Enter the ARN of the Amazon S3 bucket where you want to create the inventory report. The ARN you provide must be of only those Amazon S3 buckets that are in the same AWS account and cloud region as the Amazon S3 you want to protect.
   - **Prefix**: Add a prefix value to the name of the inventory report that will be created.
     - The prefix can be of any character and can also include white spaces.
     - For example, Report-Source Bucket.
     - The prefix should not begin or end with a forward slash (/) .
     - The prefix should not contain consecutive forward slashes.
     - You must not upload any files in the prefix of the inventory report.

The inventory report will be created at `<Prefix>/<Path_to_inventoy_report>` when you initiate the protection. Cohesity creates the path to the inventory report on AWS based on the cluster, Amazon S3 bucket, and protection.

6. Click **Next** to generate a CloudFormation Template (CFT), which you will use to complete the AWS source registration.
7. Click **Download** to download the CloudFormation Template.
8. On running the CFT, IAM roles and policies are created.
9. Once the roles and policies are created successfully, the **Register AWS Source** dialog box will indicate the account authentication status as **Confirmed**.
10. Once account authentication is successful, click **Register**.

    If authentication fails, contact Cohesity Support.

Run CloudFormation Template

To complete the registration of the AWS account with the Cohesity cluster, you must run the Cohesity's CloudFormation Template on the AWS account you are registering. You can download CFT from the Cohesity cluster UI as you register the AWS source.

When you execute the CFT, it creates an AWS IAM role and the policies for accessing all IAM roles and KMS keys in your account.

Executing the CFT Template

1. In the **AWS Management Console**, navigate to **Services** and search for **CloudFormation**.
2. Click **Create stack** > **With new resources** to create a stack under AWS cloudFormation using the downloaded CloudFormation Template.
    a. In the **Prerequisite - Prepare template** page, select **Upload a template** file.
    b. Click **Choose File** to browse and upload the JSON Cloudformation template. Click **Next**.
    c. Enter a **Stack name** and specify the AWS Account ID where the Cloud Edition cluster is running.
    d. Select **source_registration** for creating IAM role for registration AWS source.
    e. Click **Next**.
    f. Acknowledge the creation of IAM resources by selecting the checkbox, then click **Create Stack**.
    g. Once the stack creation is successful, view the **Resources** tab to check the created IAM roles.
    h. The following IAM roles and profiles are created:

- CohesityInstanceRole
- CohesityInstanceProfile
- CohesitySourceRegistrationRole

Attaching the IAM Role to Cohesity Nodes

To complete registration, attach the **CohesityInstanceProfile** role to all nodes in the cluster:

1. Navigate to **Services** > **EC2** > **Instances**.
2. Select the cluster created. For a multi node, the IAM role must be attached on all nodes.
3. Select **Actions** > **Instance Settings** > **Attach/Replace IAM Role**.
4. In the **IAM Role** field, enter the name/search for the Instance Profile that was created.

   Example: *CohesityInstanceProfile*
5. Click **Apply**.

   The IAM role is successfully attached to that VM.
6. Click **Close**.

> **Note:** If any new node is added to the cluster, then this role has to be attached to every newly added node in the cluster as well.

Complete AWS Source Registration

Once the IAM role is attached, complete the AWS source registration on the cluster, To register an AWS Cloud Source using IAM Role.

Update AWS Account Source Configuration

You can edit the registered AWS account to add or remove the Amazon services protected by the Cohesity from your AWS account.

To edit the AWS account source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select Edit.
3. In the **Edit AWS Source** page, select or unselect the Amazon services.
4. Click **Update**.

Refresh AWS Account Source

You can refresh the AWS account source configuration and fetch the latest changes on your AWS account.

To refresh the Google Cloud source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select **Refresh**.

Unregister AWS Account Source

If you plan to stop taking the backup of your AWS source, you can unregister the AWS source from the Cohesity Cluster.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the AWS source.

To unregister the AWS source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select **Unregister**.

Backup Amazon RDS Custom for Oracle

Cohesity supports both ingest-based and snapshot-based backup of Custom Relational Database Service (RDS) databases for Oracle:

- Add or Edit a Protection Group for Amazon RDS Custom for Oracle using Ingest Method
- Add or Edit a Protection Group for Amazon RDS Custom for Oracle using Snapshot Method

Protect Amazon RDS Custom for Oracle Using Ingest Method

Cohesity supports ingest-based backup of Custom Relational Database Service (RDS) databases for Oracle.

Before you begin

When you create a Protection Group, you can select an existing source, policy, or storage domain. You can also create them while creating the Protection Group. However, you might find it easier to create them prior to creating the Protection Group, as described in the following topics.

- Register or Edit an Oracle Source
- Create or Edit a Standard Policy

To create a Protection Group for Custom RDS for Oracle:

1. Navigate to **Data Protection > Protection** and do one of the following:
   - To create a Protection Group—Click **Protect** on the top-right of the page and then select the type of Protection Group.
   - To edit a Protection Group—Click the action icon (⋮) next to the Protection Group and select **Edit**.
2. If creating a Protection Group for **Custom RDS**, select **Databases** > **Oracle Database**.
3. **Name**: Enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.
4. **Source**: Select the database you want to protect. You can also register a new source with the Cohesity cluster so you can protect it.
5. Select the source objects to back up or exclude. By default, all objects in the source are excluded as indicated by the unselected check box. Expand the source objects and select the objects you want to include in the Protection Group. A selected check box indicates the object is selected to be backed up.
6. Click the arrow adjacent to the Object (**Expand All**) to expand the entire Object hierarchy. Click the arrow again (**Collapse All**) to collapse the entire Object hierarchy.
7. The graphical representations in the table are described below.

   When creating a new Protection Group, a shield next to the Object name indicates the Object is already been protected by another Protection Group.

   Click the icon to see details about the object.

   If the object name is in red, it is inaccessible, invalid, or orphaned. If the object is in one of the specified states when the Protection Group runs, no snapshot is created. If the object becomes accessible, a snapshot is created the next time the Protection Group runs.
8. Click **Save Selection**.
9. **Policy**: Select an existing protection policy or create a new one by selecting **New Policy**.
10. **Backup Type**: When creating a protection group for Linux sources, choose either Imagecopy or Backupset (SBT) as the backup type. Backup type selection is possible while creation of the protection job. They are not interchangeable.
    a. **Image Copy**: Use this option if you prefer NFS-based backups and require forever incremental backup capability. This is selected by Default.
    b. **Backup Sets**: Use this option to enable encryption in transit using gRPC and to avoid NFS client dependencies.

> **Note:**
> - You must create or select a policy with the **Periodic Full Backup** option set when using Oracle SBT.
> - This is an Early Access feature. Contact your Cohesity account team to enable the feature.

11. **Start Time**: Indicates when the Protection Group should run. The current time is displayed by default, but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting.

    The default time zone is the browser's time zone. You can change the time zone by selecting a different time zone.

12. **End Date**: Optional. Toggle on and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion, even if it completes after this date.

13. **Cancel Runs at Quiet Time Start**: Available only if the selected policy has at least one quiet time period. Toggle it on to specify that all currently executing protection runs should abort if a quiet time period specified for the Protection Group starts. By default, this toggle is off, which means after a protection run starts, it continues to execute even when a quiet time period specified for this protection run starts. However, a new protection run will not start during a quiet time period.

    a. **Success**: Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created.

    b. **Failure**: Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created.

    c. **SLA Violation**: Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created.

    For more information, see Alerts.

14. **Priority**: Select a priority for the Protection Group execution. Cohesity supports concurrent backups, but if the number of Protection Groups exceeds the ability to process them, those with High priority are given the highest priority to execute, Medium the second-highest priority, and Low the lowest priority.

15. **Email Recipients**: You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the Protection Group.

    The connection to the SMTP Server must be enabled to send email notifications. You can enable the SMTP Server connection in the configuration settings page (**Cohesity UI > Settings > Summary > Configure > Enable SMTP Server**).

16. **SLA**: The service-level agreement (SLA) defines the expected time to complete either a full backup or an incremental backup. The backup completion time depends on the Windows volume size on AD, objects changed between incremental backups, network speed, and other Protection Groups running on the Cohesity cluster.
    a. **Incremental**: Enter the number of minutes you expect an incremental protection run to complete. An incremental backup captures only the differences (changed blocks) since the last protection run.
    b. **Full**: Enter the number of minutes you expect a full backup protection run to complete. A full backup captures the entire object (all blocks).
17. **Description**: Optional. Click the plus sign and enter a description for the Protection Group.
18. Click **Protect**.

The Protection page is displayed and includes the new Protection Group.

Protect Amazon RDS Custom for Oracle Using Snapshot Method

Cohesity supports snapshot-based backup of Custom Relational Database Service (RDS) databases for Oracle.

Before you begin

When you create a Protection Group, you can select an existing source, policy, or storage domain. You can also create them while creating the Protection Group. However, you might find it easier to create them prior to creating the Protection Group, as described in the following topics.

- Register or Edit a Hypervisor Source
- Create or Edit a Standard Policy
- Create or Edit Storage Domains

To create a Protection Group for Custom RDS for Oracle:

1. Navigate to **Data Protection > Protection** > **Databases** > **Amazon RDS** and do one of the following:
    1. To create a Protection Group—Click **Protect** on the top-right of the page and then select the type of Protection Group.
    2. To edit a Protection Group—Click the action icon (⋮) next to the Protection Group and select **Edit**.
2. **Source**: Select the database you want to protect. You can also register a new source with the Cohesity cluster so you can protect it.
3. Select the source objects to back up or exclude. By default, all objects in the source are excluded as indicated by the unselected check box. Expand the source objects and select the objects you want to include in the Protection Group. A selected check box

indicates the object is selected to be backed up.

4. Click the arrow adjacent to the Object (**Expand All**) to expand the entire Object hierarchy. Click the arrow again (**Collapse All**) to collapse the entire Object hierarchy.
5. The graphical representations in the table are described below.

   When creating a new Protection Group, a shield next to the Object name indicates the Object is already been protected by another Protection Group.

   Click the icon to see details about the object.

   If the object name is in red, it is inaccessible, invalid, or orphaned. If the object is in one of the specified states when the Protection Group runs, no snapshot is created. If the object becomes accessible, a snapshot is created the next time the Protection Group runs.
6. Click **Save Selection**.
7. **Policy**: Select an existing protection policy or create a new one by selecting **New Policy**.

   > **Note:** You must create or select a policy with the **Periodic Full Backup** option set.

8. **Start Time**: Indicates when the Protection Group should run. The current time is displayed by default, but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting.

   The default time zone is the browser's time zone. You can change the time zone by selecting a different time zone.
9. **SLA**: The service-level agreement (SLA) defines the expected time to complete either a full backup or an incremental backup. The backup completion time depends on the Windows volume size on AD, objects changed between incremental backups, network speed, and other Protection Groups running on the Cohesity cluster.
   a. **Incremental**: Enter the number of minutes you expect an incremental protection run to complete. An incremental backup captures only the differences (changed blocks) since the last protection run.
   b. **Full**: Enter the number of minutes you expect a full backup protection run to complete. A full backup captures the entire object (all blocks).
10. From the Backup Options (Optional), configure the following **Additional Settings**:
    a. **Pause Future Runs**: Toggle on this option to stop protection runs of the Protection Group from executing. Once you enable this option, no protection

runs will be scheduled for this Protection Group.

b. **End Date**: Optional. Toggle on and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion, even if it completes after this date.

c. **Alerts**: Optional. Select one or more of the following settings if you want alerts to be created for the following triggers:

   i. **Success**: Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created.

   i. **Failure**: Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created.

   ii. **SLA Violation**: Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts.

d. **Priority**: Select a priority for the Protection Group execution. Cohesity supports concurrent backups, but if the number of Protection Groups exceeds the ability to process them, those with **High** priority are given the highest priority to execute, **Medium** the second-highest priority, and **Low** the lowest priority.

e. **Description**: Optional. Click the plus sign and enter a description for the Protection Group.

11. Click **Protect**.

The Protection page is displayed and includes the new Protection Group.

Recover Amazon RDS Custom for Oracle

Cohesity supports both ingest-based and snapshot-based recoveries of Custom Relational Database Service (RDS) databases for Oracle:

- Recover Amazon RDS Custom for Oracle Using Ingest Method
- Recover Amazon RDS Custom for Oracle Using Snapshot Method

Recover Amazon RDS Custom for Oracle Using Ingest Method

Cohesity provides the ability to recover the Custom Relational Database Service (RDS) databases for Oracle to its original location or an alternate location. For more information, see:

- Recover Custom RDS to the Original location
- Recover Custom RDS to an Alternate Location
- Create Cohesity View with DB Files - Custom RDS database

Recover Custom RDS to the Original location

To recover the Custom RDS to the original location:

1. In the Cohesity Dashboard, select **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **Databases** > **Oracle Database**.
3. In the Recover page, search for the Oracle database instance that needs to be restored or use a wildcard name to search for a specific database instance.
    a. **CDB**: Search the Oracle CDB that you want to restore.
        1. Select the entire CDB (with all the PDBs) or a CDB and a subset of PDBs associated with that CDB for restore.
        2. Select the CDB and click **Next**.
    b. **PDB**: Search for the Oracle PDB that you want to restore.
        1. You can either search for the parent CDB associated with the PDB or directly search for the PDB.
        2. Select the PDB and click **Next**.
    c. **Oracle Database**: Search for the Oracle Database you want to restore.
4. Accept the latest Recovery Point or click the change icon and select a different recovery point.
    a. **Snapshots**: Select a different recovery point. You can change the time zone before or after selecting a new restore time.
    b. **Point-in-Time**: Use the slide control to adjust the date and time and click **Save**.
5. Click **Next: Recover Options**.
6. From the **Recover To** options, select **Original Location** to recover the Custom RDS database to the original location.

    > **Note:** For PDB overwrite restore, PDB can be rolled back only within the current CDBs set.

7. From the Recovery Options (Optional), configure the following **Additional Settings**:

Field Name	Description
Leave Database in Recovery Mode:	Select the checkbox if you do not want the recovered database to be opened.
Shell Environment	Toggle on the Shell Environment to configure your shell environment that executes the Cohesity restore workflow using this setting. For example, when restoring the Oracle EBS database, the restore environment often needs to define a different TNS_ADMIN value to use a different sqlnet.ora file in the same Oracle Home shared with other databases. You can use the Shell Environment to define your TNS_ADMIN shell variable here to point to a different sqlnet.ora file to be used for your restored target database. For TDE support, the wallet location for your restore target database may depend on a shell variable. This is the case when your restored database wallet location is specified either by the ENCRYPTION_ WALLET_LOCATION or WALLET_LOCATION keyword in your sqlnet.ora file. A typical value for these parameters will reference a shell variable. For Example, ENCRYPTION_WALLET_LOCATION=(SOURCE=(METHOD=FILE) (METHOD_DATA=(DIRECTORY=/etc/ORACLE/WALLETS/$ORACLE_UNIQUE_NAME/))) In this example, you will need to set ORACLE_UNIQUE_NAME in the SHELL ENVIRONMENT setting in the GUI to set up the Cohesity restore shell environment for the Oracle restore to find the Keystore.
Cluster Interface	Select one of the following options to assign the interface group for the recovery job. 1. **Auto Select**: Toggle on this option if you want to use the same interface group that was selected during the Oracle source registration. 2. **Interface Group**: Select the interface group to use for the recovery. If you select a different interface group from what was selected during the Oracle source registration, the system will use this VLAN for the recovery job.
Task Name	(Optional) Provide the name for the recovery task. Click **Recover**.

The recovery process is initiated. You can monitor the recovery task from the Recoveries page.

Recover Custom RDS to the Alternate location

To recover the Custom RDS to the alternate location:

1. In the Cohesity Dashboard, select **Data Protection** > **Recoveries**.
2. Click Recover at the top right of the page and then select **Databases** > **Oracle Database**.

3. In the Recover page, search for the Oracle database instance that needs to be restored or use a wildcard name to search for a specific database instance.
    a. **CDB**: Search the Oracle CDB that you want to restore.
        1. Select the entire CDB (with all the PDBs) or a CDB and a subset of PDBs associated with that CDB for restore.
        2. Select the CDB and click **Next**.
    b. **PDB**: Search for the Oracle PDB that you want to restore.
        1. You can either search for the parent CDB associated with the PDB or directly search for the PDB.
        2. Select the PDB and click **Next**.
    c. **Oracle Database**: Search for the Oracle Database you want to restore.
4. Accept the latest Recovery Point or click the change icon and select a different recovery point.
    a. **Snapshots**: Select a different recovery point. You can change the time zone before or after selecting a new restore time.
    b. **Point-in-Time**: Use the slide control to adjust the date and time and click **Save**.
5. Click **Next: Recover Options**.
6. From the **Recover To** options, select **Alternate CDB/PDB** to recover the Custom RDS database to the new location. From the drop-down menu for target source, select a registered RDS custom Instance to which you want to restore the Custom RDS database:
    1. **Oracle Host**: The host to which to restore the database.
    2. **Configure Channels**: Click these options to configure the following:
        a. **System selects active node**: If you select this option, Cohesity will select the channels for the recovery job.
        b. Select specific nodes:
            i. **Hostname**: Select the hostname to which you want to perform the restore.
            ii. **Node**: Select the node to which you want to perform the restore. This option is valid only in the case of a multi-node cluster.

                In the case of PDB alternate restore it is mandatory to select the node as we have to provide the target CDB instance name.
            iii. **Channels**: Specify the number of channels to perform the restore

job. The system will run these channels in parallel to improve the restore performance.

7. In the **Recovery Option**, enter the following:
   a. **Restore Database Files to**: Specify the path to an existing empty directory. The newly created database files will reside in this path.
   b. **Oracle Home**: The ORACLE_HOME value for the host where the database is restored.
   c. **Base Directory**: The directory for the restored database.
   d. **Target Database Name**: The name for the alternate CDB database.

      If you are restoring a PDB, you must provide the target CDB on which the PDB is restored.

      > **Note:** When recovering to an alternate location, make sure a database with the same name does not exist on the Oracle server instance. Otherwise, the recovery task will fail.

8. In the Recovery Options (Optional), configure the following **Additional Settings**:

Field Name	Description

Pfile Parameters	**Pfile Parameters**: The Pfile parameters option allows you to see the target database parameters before the restore job is initiated. The Pfile inherits some source database parameters to the target database and allows you to edit the target database parameters based on your requirement by specifying the additional parameters as a `key=value` pair.
	
	The Pfile lists the following parameters:
	
	• **Default Parameters**: Default parameters of the target database and you can edit the default
	• **Inherited Parameters**: Parameters from the source database and you can edit the inherited parameters, if required.
	• **Restricted Parameters**: You cannot edit the restricted parameters in the Pfile. The following are the restricted parameters:
	  • INSTANCE_NAME
	  • DB_NAME
	  • DB_UNIQUE_NAME
	  • DB_BLOCK_SIZE
	  • MAX_STRING_SIZE
	  • COMPATIBLE
	
	If you edit the following values in the **Recover Oracle** GUI, You must click the **Reset** button on the top-right corner to reset the Pfile and get the updated parameter values in the Pfile box.
	  • Restore database files to
	  • Oracle Home
	  • Oracle Base
	  • Database Name
	
	Cohesity Platform will create a target database with the specified parameters in the Pfile. For example, if `SGA_TARGET` is specified as a part of the Pfile parameters, the restore operation will use the value specified in the Pfile during the restore.

Rename Database	Rename the database, if required.

Field Name	Description
Enable Archive Log mode for the Database	Select the checkbox if you want to enable the redo log archiving on the recovered database.
BCT File Path	The BCT file path specifies the location where the block change tracking file will be created. If not provided, BCT is not enabled for the restored database.
Number of Temporary Files to Use	Number of temp files to rename from the source database.
Redo Log Group Settings	The Redo log group configuration stores all changes made to the database as they occur. Every instance of an Oracle Database has an associated redo log to protect the database in case of an instance failure. You can provide the number, size, and prefix of redo log groups along with the redo log group member path for the recovery database.
Leave Database in Recovery Mode	Select the checkbox if you do not want the recovered database to be opened.
Shell Environment	Toggle on the Shell Environment to configure your shell environment that executes the Cohesity restore workflow using this setting. For example, when restoring the Oracle EBS database, the restore environment often needs to define a different TNS_ADMIN value to use a different sqlnet.ora file in the same Oracle Home shared with other databases. You can use Shell Environment to define your TNS_ADMIN shell variable here to point to a different sqlnet.ora file to be used for your restored target database. For TDE support, the wallet location for your restore target database may depend on a shell variable. This is the case when your restored database wallet location is specified either by the ENCRYPTION_WALLET_LOCATION or WALLET_LOCATION keyword in your sqlnet.ora file. A typical value for these parameters will reference a shell variable. For Example, ENCRYPTION_WALLET_LOCATION=(SOURCE=(METHOD=FILE) (METHOD_DATA=(DIRECTORY=/etc/ORACLE/WALLETS/$ORACLE_UNIQUE_NAME/))) In this example, you will need to set ORACLE_UNIQUE_NAME in the SHELL ENVIRONMENT setting in the GUI to set up the Cohesity restore shell environment for the Oracle restore to find the Keystore.

Field Name	Description
Cluster Interface	Select one of the following options to assign the interface group for the recovery job. 1. **Auto Select**: Toggle on this option if you want to use the same interface group that was selected during the Oracle source registration. 2. **Interface Group**: Select the interface group to use for the recovery. If you select a different interface group from what was selected during the Oracle source registration, the system will use this VLAN for the recovery job.
Use NOFILENAMECHECK	Using NOFILENAMECHECK forces RMAN to skip checking whether target datafile names are the same as source datafile names.
Customize Destination Paths with SET NEWNAME	Use the SET NEWNAME command to define a new location for individual datafiles, tempfiles, tablespaces, or the whole database. If not specified, Cohesity uses DB_FILE_NAME_CONVERT, if not empty. Otherwise, it uses your input to restore the destination location. Use SET NEWNAME specifications to determine the location of your restored datafiles and logfiles You can specify DB_FILE_NAME_CONVERT together with this option to augment paths that are not affected by DB_FILE_NAME_CONVERT. Syntax Example: SET NEWNAME FOR DATAFILE 1 TO 'u01/home/test_1.dbf';
Task Name	(Optional) Provide the name for the recovery task.

9. Click **Recover**.

The recovery process is initiated. You can monitor the recovery task from the Recoveries page.

Create Cohesity View with DB Files - Custom RDS database

1. In the Cohesity Dashboard, select **Data Protection** > **Recoveries**.
2. Click Recover at the top right of the page and then select **Databases** > **Oracle Database**.
3. In the Recover page, search for the Oracle database instance that needs to be restored or use a wildcard name to search for a specific database instance.

a. **CDB**: Search the Oracle CDB that you want to restore.
    1. Select the entire CDB (with all the PDBs) or a CDB and a subset of PDBs associated with that CDB for restore.
    2. Select the CDB and click **Next**.
b. **PDB**: Search for the Oracle PDB that you want to restore.
    1. You can either search for the parent CDB associated with the PDB or directly search for the PDB.
    2. Select the PDB and click **Next**.
c. **Oracle Database**: Search for the Oracle Database you want to restore.

4. Accept the latest Recovery Point or click the change icon and select a different recovery point.
    a. **Snapshots**: Select a different recovery point. You can change the time zone before or after selecting a new restore time.
    b. **Point-in-Time**: Use the slide control to adjust the date and time and click **Save**.
5. Click **Next: Recover Options**.
6. From the **Recover To** options, select **Create Cohesity View with DB Files** to recover the Custom RDS database to the new location. From the drop-down menu for target source, select a registered Instance to which you want to create a Cohesity View with DB Files:
    1. **Oracle Host**: The host to which to restore the database.
    2. **Configure Channels**: Click these options to configure the following:
        a. **System selects active node**: If you select this option, Cohesity will select the channels for the recovery job.
        b. **Select specific nodes**:
            i. **Hostname**: Select the hostname to which you want to perform the restore.
            ii. **Node**: Select the node to which you want to perform the restore. This option is valid only in the case of a multi-node cluster.

            In the case of PDB alternate restore it is mandatory to select the node as we have to provide the target CDB instance name.
            iii. **Channels**: Specify the number of channels to perform the restore job. The system will run these channels in parallel to improve the restore performance.
7. In the **Recovery Option**, enter the following:

1. **View Name Identifier**: A view will be created with this name as identity.
2. **Cluster Interface**: Select one of the following options to assign the interface group for the recovery job.
    a. **Auto Select**: Toggle on this option if you want to use the same interface group that was selected during the Oracle source registration.
    b. **Interface Group**: Select the interface group to use for the recovery.

    If you select a different interface group from what was selected during the Oracle source registration, the system will use this VLAN for the recovery job.
    c. **Task Name**: (Optional) Provide the name for the recovery task.

8. Click **Recover**.

The recovery process is initiated. You can monitor the recovery task from the Recoveries page.

Recover Amazon RDS Custom for Oracle Using Snapshot Method

Cohesity provides the ability to recover the Custom Relational Database Service (RDS) databases for Oracle to its original location or an alternate location. For more information, see:

- Recover Custom RDS to the Original location
- Recover Custom RDS to an Alternate Location

Recover Custom RDS to the Original location

To recover the Custom RDS to the original location:

1. In the Cohesity Dashboard, select **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **Databases** > **Amazon RDS**.

    The Amazon RDS page appears.
3. Search for the database you want to recover by entering the characters of the database name or by specifying the wildcard character *.

    A list of VMs displays.

    You can optionally filter the search results by Source, Protection Group, Storage Domain, or Date.
4. From the list of search results, select the database you want to recover.

    By default, the latest snapshot is selected for recovery.

5. To recover from a different snapshot, mouse over the snapshot from the selected list, and then click the **edit** icon.

   The Edit recovery point for <VM_name> page appears.

   By default, the option to select the snapshot is displayed in **Timeline** mode. You can also choose to view the option in **List** mode by clicking the **List** tab in the top-right corner of the page.

   - To select a snapshot from the **Timeline** mode:
     a. From the **Choose a date** drop-down, select a date for the recovery point.
     b. The snapshots available on the selected date are displayed in blue dots on the timeline bar.
     c. Select the snapshot to be recovered by clicking the corresponding blue dot on the timeline bar.

        If multiple snapshots are available, then you can choose any point in timeline (Point-in-Time snapshot) between the two snapshots either by adjusting the timeline bar or by selecting the time from the timer field. If you have selected an invalid time, then the nearest valid snapshot will be selected for recovery.
     d. Click **Select Recovery Point** and then go to step 6.
   - To select a snapshot from the List mode:
     a. Select the **List** tab from the top-right corner of the Edit recovery point for <VM_name> page.
     b. By default, the page displays the snapshots available in the last one month.
     c. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.
     d. Select the snapshot to be recovered.
     e. Click **Select Recovery Point** and then go to step 6.
6. Click **Next: Recover Options**.
7. From the **Recover To** options, select **Original Location** to recover the Amazon RDS to the original location.
8. Configure the following Additional Settings:

   The Database Engine field auto-populates the database engine name used for this instance.

   a. **Database Instance Identifier**: Specify the unique key that identifies the database instance that will be recovered.

b. **Database Port**: Specify the TCP/IP port that the DB instance will use for application connections. The connection string of any application connecting to the DB instance must specify the port number of the DB instance. Both the security group applied to the instance and your company's firewalls must allow connections to this port.

c. **Multi A-Z Deployment**: Enable this option if you want the DB instance to be recovered to have a standby instance deployed in another availability zone. This option is disabled by default.

d. **IAM DB Authentication**: Enable this option if you want to manage your database user credentials through AWS IAM users and roles. This option is disabled by default.

e. **Public Accessibility**: Enable this option if you want the DB instance also to have a public IP address in addition to the private IP address. This option is disabled by default.

f. **Copy Tags To Snapshots**: Enable this option for copying tags to snapshots. This option is disabled by default.

g. **Auto Minor Version Upgrade**: Enable this option if you want the DB instance to automatically upgrade when a new minor database engine version is available. This option is disabled by default. Optional. Change the default name of the recovery task in the **Task Name** field.

9. Click **Start Recovery**.

The recovery process is initiated. You can monitor the recovery task from the Recoveries page.

Recover Custom RDS to the Alternate location

To recover the Custom RDS to the alternate location:

1. In the Cohesity Dashboard, select **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **Databases** > **Amazon RDS**.

   The Amazon RDS page appears.
3. Search for the database you want to recover by entering the characters of the database name or by specifying the wildcard character *.

   A list of VMs displays.

   You can optionally filter the search results by Source, Protection Group, Storage Domain, or Date.
4. From the list of search results, select the database you want to recover.

   By default, the latest snapshot is selected for recovery.

5. To recover from a different snapshot, mouse over the snapshot from the selected list, and then click the **edit** icon.

   The Edit recovery point for <VM_name> page appears.

   By default, the option to select the snapshot is displayed in **Timeline** mode. You can also choose to view the option in **List** mode by clicking the **List** tab in the top-right corner of the page.

   - To select a snapshot from the **Timeline** mode:
     a. From the **Choose a date** drop-down, select a date for the recovery point.
     b. The snapshots available on the selected date are displayed in blue dots on the timeline bar.
     c. Select the snapshot to be recovered by clicking the corresponding blue dot on the timeline bar.

        If multiple snapshots are available, then you can choose any point in timeline (Point-in-Time snapshot) between the two snapshots either by adjusting the timeline bar or by selecting the time from the timer field. If you have selected an invalid time, then the nearest valid snapshot will be selected for recovery.
     d. Click **Select Recovery Point** and then go to step 6.
   - To select a snapshot from the List mode:
     a. Select the **List** tab from the top-right corner of the Edit recovery point for <VM_name> page.
     b. By default, the page displays the snapshots available in the last one month.
     c. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.
     d. Select the snapshot to be recovered.
     e. Click **Select Recovery Point** and then go to step 6.
6. Click **Next: Recover Options**.
7. From the **Recover To** options, select **New Location** to recover the Amazon RDS to the original location.
8. From the **Source** drop-down menu, select a registered RDS instance to which you want to restore the Amazon RDS . You can also register a new source by clicking **Register Source** from the **Source** drop-down menu.
9. From the **Region** drop-down menu, select a region to restore the Amazon RDS.
10. Provide the following **Network Settings** information:

a. **VPC**: Select an Amazon Virtual Private Cloud (VPC) to store the recovered RDS.
b. **Subnet**: From the drop-down list, select a subnet in the Amazon VPC to store the recovered Amazon RDS.
c. **Availability Zone**: From the drop-down list, select an availability zone in AWS to recover the RDS.

11. Configure the following **Additional Settings**:

    The **Database Engine** field auto-populates the database engine name used for this instance.

    a. **Database Instance Identifier**: Specify the unique key that identifies the database instance that will be recovered.
    b. **DB Port**: Specify the TCP/IP port that the DB instance will use for application connections. The connection string of any application connecting to the DB instance must specify the port number of the DB instance. Both the security group applied to the instance and your company's firewalls must allow connections to this port.
    c. **DB Option Group**: Select an option group that contains the option you want to attach to the DB instance that will be recovered. If there are not any option groups compatible with the selected engine, a default group will be created at launch.
    d. **DB Parameter Group**: Select the database parameter group to associate with the DB instance.
    e. **Multi A-Z Deployment**: Enable this option if you want the DB instance to be recovered to have a standby instance deployed in another availability zone. This option is disabled by default.
    f. **IAM DB Authentication**: Enable this option if you want to manage your database user credentials through AWS IAM users and roles. This option is disabled by default.
    g. **Public Accessibility**: Enable this option if you want the DB instance to also have a public IP address in addition to the private IP address. This option is disabled by default.
    h. **Copy Tags To Snapshots**: Enable this option for copying tags to snapshots. This option is disabled by default.
    i. **Auto Minor Version Upgrade**: Enable this option if you want the DB instance to automatically upgrade when a new minor database engine version is available. This option is disabled by default.

12. Optional. Change the default name of the recovery task in the **Task Name** field.
13. Click **Start Recovery**.

The recovery process is initiated. You can monitor the recovery task from the Recoveries page.

Amazon Relational Database Service Custom for SQL Server

Cohesity supports protecting Amazon Relational Database Service (RDS) Custom for Microsoft SQL Server. This managed database service provided by AWS offers a balance between the automation of Amazon RDS and the flexibility of self-managing a database on Amazon EC2.

> **Note:** Cohesity supports the backup and recovery of Amazon RDS Custom for SQL Server on DataProtect for cloud in AWS (formerly known as AWS NGCE cluster).

This chapter includes the following topics:

Planning and Preparation for Amazon RDS Custom for SQL Server

The following topics provide guidance that helps you get ready to implement MS SQL Server:

Requirements to Access Amazon RDS Custom for SQL Server

Cohesity DataProtect SQL Server agent must be installed on the corresponding EC2 instance that has the Amazon RDS Custom instance. You can then perform the backup and recovery operations as you would for a standalone SQL Server instance.

You must access Amazon RDS Custom to connect to the underlying EC2 instance and then to the database. Use remote access to the EC2 instance and then client tools to connect to the database.

1. **Prepare the EC2 Instance for Remote Desktop:**
    i. Ensure the VPC security group allows inbound RDP traffic (port 3389) from your source IP.
    ii. Create an RDS instance. For more information, see Creating an Amazon RDS DB Instance.
    The EC2 instance will also be created.
    iii. Configure the Windows firewall on the EC2 instance to allow remote desktop access.
    iv. On the EC2 instance, connect with the **Session Manager**.
    v. Run the following PowerShell command to open firewall:

    ```
    Set-NetFirewallRule -DisplayName "Remote Desktop - User Mode (TCP-In)" -Direction Inbound -LocalAddress Any -Profile Any
    ```

    vi. Retrieve the administrator password for the EC2 instance from AWS Secrets Manager using the key pair information.
    vii. Go to the **Secret Manager** and click on the required **secret name**.

viii. Under the **Secret Value** section, select **Retrieve Secret Value**.

ix. Copy the secret value in plain text.

2. **Connect to the EC2 Instance via RDP:**
   i. Use an RDP client (like Remote Desktop Connection on Windows) to connect to the EC2 instance using its private IP address and the administrator credentials. A jump server in a public subnet is often used for this.
   ii. On the EC2 instance, connect with the **RDP Client**.
   iii. Select **Get Password** at the bottom of the page.
   iv. Paste the secret value into the **Private Key Contents** field and click **Decrypt Password**.
   v. Copy the decrypted password.
   vi. Go back to the jump server and RDP into the ECE instance with the administrator credentials and decrypted password.
3. **Connect to SQL Server:**
   i. From the RDP session on the EC2 instance, use SQL Server Management Studio (SSMS) or other SQL client tools to connect to the SQL Server database endpoint.
   ii. Use this endpoint to register your Microsoft SQL Server as a source on Cohesity DataProtect.

Requirements for Amazon RDS Custom for SQL Server Protection

Supported Software for Microsoft SQL Server Protection

For more information, see Supported Software.

Agent Minimum Permissions for Microsoft SQL Server Protection

You can use either the host LOCAL SYSTEM account or an account that meets the requirements to install the Cohesity agent.

It is recommended to run the Cohesity Agent service with an Active Directory domain user account that is a member of the local administrator of the SQL Server host. The AD domain user account must be a member of the SQL sysadmin server role. The user account must have log-on rights to the SQL Server host in the local security policy of the SQL Server host.

If you do not use the LOCAL SYSTEM account, ensure the following for the chosen account:

- The account must be a member of the local Windows Administrators group. For example, qa01\tme-backup is an Active Directory user account in the data center. If the backup admin plans to use this account, qa01\tme-backup must be part of the local Windows Administrators group on the SQL server.
- The account must have Log on as a service in the User Rights Assignment on the MS SQL server to install the Cohesity agent.
- The account must have the sysadmin role in the MS SQL Server instance.

Ports Used for Communication

- On physical servers or VMs with an ephemeral or installed agent, open the ports 445, 11113, 11117, and 50051. For more information, see Manage Firewall Ports.
- If the Windows Firewall is used:
  - Inbound rules:
    - Add a rule to accept SQL Server traffic and TCP connections on local port 1433.
    - Set Remote Port to All Ports.
  - Outbound rules (for MS SQL Server 2016 running on Windows 2016):

    Update the "Block network access for R local user accounts in SQL server instance MSSQLSERVER" rule by going to General tab > Action window > select "Allow the connection".

Prerequisites for Microsoft SQL Server Protection

- Verify MS SQL Server services are running.
- The **Readable Secondary** field in the Availability Group Properties of the SQL Server Availability Group (AAG) must be set to **Yes** if you have selected **Secondary Only** as the **Backup Preference setting for AAG**.
- MS SQL database and instance names must meet the Microsoft SQL Server naming requirements. Names containing illegal Windows file characters, such as double quotes, pipe symbols, greater than and less than signs (" | > <), a space at the beginning or end of the database name (applicable only for VDI-based backup) are not supported. For more information, see Naming Files, Paths, and Namespaces.
- On the Server's Windows system, Cohesity recommends to set the Power Plan to High performance.

Credentials and Privileges for Microsoft SQL Server Protection

There are three accounts you must consider when installing the Cohesity Agent:

- **Installation Account**: The account you use to log in to the host and run the installer.
- **Service Account**: The account under which the Cohesity Agent service runs on the SQL Server host. (Selected at the time of installation.)
- **SQL Server login account**: The SQL Server account by which the Cohesity Agent has access to the databases. (Configured after installation.)

Installation Account

When installing the Cohesity Agent on a Microsoft Windows host, you must log onto the SQL Server host with an account that has local administrator privileges. This is because the Windows agent installer installs the Cohesity Agent service. Microsoft requires the installation account to have administrator privileges on the host.

Choose the Service Account

The installer gives you the option between two types of service accounts:

- The LocalSystem account.
- A user account. Assigning privileges to the service account will differ depending on which type of account you choose. Cohesity recommends using either the LocalSystem account or an Active Directory Domain User account. See the chart below for a comparison of service account types.

Comparison of Service Account Types

SERVICE ACCOUNT	TYPE	DEFINITION	RECOMMENDATION
LocalSystem (Default)	LocalSystem Account (Built-in Host Account)	The LocalSystem account is a predefined local account on the host computer.	Recommended: The Local System account is a predefined local account used by the service control manager. It has extensive privileges on the local computer, and acts as the computer on the network. Its token includes the NT AUTHORITY\SYSTEM and BUILTIN\Administrators SIDs; these accounts have access to most system objects.
User Account	Domain User Account (Active Directory)	A user whose username and password are stored in Active Directory.	Recommended: A domain user account enables the service to take full advantage of the service security features of Windows and Microsoft Active Directory Domain Services. The service has whatever local and network access is granted to the account, or to any groups of which the account is a member.
	Local User Account (Host account)	In Windows, a local user is one whose username and encrypted password are stored locally, only on the computer itself.	Not recommended: When you log in as a local user, the computer checks its own list of users and its own password file to see if you are allowed to log in to the computer. The computer itself then applies all the permissions and restrictions that are assigned to you for that computer.

> **Note:** If you are unsure which account to use, choose the LocalSystem account. This account already has most of the required permissions. The agent service account can be changed later if needed.

Microsoft SQL Server on Linux OS

Cohesity provides backup and recovery solutions for Microsoft SQL Server databases running on the Linux Operating System.

Requirements

Operating System	Database	Notes
Linux OS RHEL 8 and higher versions **Note:** This is an Early Access feature. Contact Cohesity Support to enable the feature.	Microsoft SQL Server 2019	• Only VDI-based backups are currently supported on Linux OS. • High Availability Microsoft SQL Server configurations like FCI and AG are not supported.

Considerations

- Cross-platform database restores between Windows and Linux are currently not supported.
- For VDI-based backups to work, Microsoft requires the backup application account (Cohesity Agent's service account) and the Microsoft SQL Server service account to be added to each other's primary groups using the usermod command.

  For example:

  sudo usermod -a -G mssql cohesityagent

  sudo usermod -a -G cohesityagent mssql

  where, mssql is the user account of the mssql-server service and cohesityagent is the user account of the Cohesity Agent service.

  Following this, the Microsoft SQL Server and the Cohesity Agent services must be restarted for the changes to take effect.

  > **Note:** The usermod -a -G command may not work for domain accounts.

- Currently, only password-based SQL Server authentication is supported and Active Directory-based authentication is not supported for Linux.

  For supported features of SQL Server 2019 on Linux, see Editions and supported features of SQL Server 2019 on Linux.

Register SQL Server on Linux OS

- In **DataProtect as a Service**, select **Sources**.
- Click **+Register Source > Microsoft SQL > Start Registration**.
- In the **Register Microsoft SQL Server** page, select the **SaaS Connection** and click **Continue**.
- In the **Hostname or IP Address** field, enter the IP address of the server, FQDN of the server, or VIP of the SQL FCI. Cohesity recommends you to provide the FQDN of the server.
- Select the **Server Type** as Linux.
- Provide the username and password for the **Database Authentication**.
- Click **Complete**.

Supported Database Types for Microsoft SQL Server

Before proceeding to deploy the Cohesity agent for SQL data protection, we recommend you correctly identify the type of SQL database you want to protect. Below is a table of SQL database types that are supported by the Cohesity SQL agent, and the recommended protection methods.

To understand the concept of each method, see About Microsoft SQL Server Backup.

Database Types	Definition	Adapter-based Protection Method	
		File-based Protection	VDI-based Protection
Stand Alone	A SQL Server User database.	✅	✅
AG	A database that belongs to an availability group (AG). For each availability database, the availability group maintains a single read-write copy (the primary replica) and one to four read-only copies (secondary replicas). For details, see Always On availability groups: a high-availability and disaster-recovery solution in the Microsoft documentation.	✅	✅
FCI	A database that belongs to a Failover Cluster Instance (FCI), which is a single instance of SQL Server that is installed across Windows Server Failover Clustering (WSFC) nodes.	✅	✅

Database Types	Definition	Adapter-based Protection Method	
		File-based Protection	VDI-based Protection
CDC	A change data capture (CDC) enabled SQL database records activity and is applied to an internal table. This makes the details of the changes available in an easily consumed relational format. For details, see About Change Data Capture (SQL Server) in the Microsoft documentation.	✓	✓
TDE	A Transparent Data Encryption (TDE) enabled SQL database has its data files encrypted, known as encrypting data at rest. TDE performs real-time I/O encryption and decryption of the data and log files. For details, see Transparent Data Encryption (TDE) in the Microsoft documentation. **NOTE**: Cohesity does not manage the keys associated with the TDE database.	✓	✓
File Stream	A Filestream enabled SQL Database is a database that contains a table that stores its data outside the database on the host file system. SQL Filestream leverages the OS file system's ability to handle large objects like images, PDFs, Binary, Bmp, Docs, and other unstructured data. For details, see FILESTREAM (SQL Server) in the Microsoft documentation.	✗	✓
SQL System	SQL Server maintains a set of four system-level databases (*master, model, msdb, tempdb*), which are essential for the operation of a server instance. System databases must be backed up after every significant update. The system databases that you must always back up include msdb, master, and model. System databases are not supported for log backups. For details, see Backup & restore: system databases (SQL Server) in the Microsoft documentation.	✓	✓

Now that you can identify the type of SQL database you want to protect, you can register it as a Cohesity source.

Microsoft SQL Server Dashboard

Access the MS SQL Dashboard by going to **Dashboard** and from the drop-down, select **MS SQL**.

The page's upper portion displays information such as metrics, status and recovery history. In the page's lower portion, you can start the different actions from the Hosts tab and the Databases tab. The MS SQL Dashboard displays local MS SQL databases only. To restore or clone replicated or CloudRetrieved databases, use their respective restore or clone workflows.

From the Hosts tab, mouse over the actions menu for the following actions (some actions are available for physical servers only):

- **Protect Databases** ( )—Create a Protection Group using this server.
- **Unregister MS SQL** ( )—Unregister the MS SQL application. The server remains registered with the Cohesity cluster.
- **Edit** ( )—Configure the settings of a registered MS SQL server.
- **Unregister** ( )—Unregister this server from the Cohesity cluster.
- **Refresh** ( )—Manually force a refresh of the object hierarchy.
- **Upgrade Agents** ( )—Upgrade the Cohesity agent on the server if an upgrade is available.

From the Databases tab, mouse over the actions menu for the following actions (some actions are not available for system databases):

- **Protect** ( )—Create a Protection Group using this database.
- **Run Now** ( )—Start a run of this Protection Group. You have the option to back up one or more objects.

  If the policy associated with the Protection Group is configured with replication and archive targets, you can select those targets. If the policy supports multiple backup types, you can select an incremental, full or log backup.

  VM MS SQL Protection Groups do not support selecting individual databases for run now; only the entire VM is selectable.
- **Pause Future Runs/Resume Future Runs** ( )
  - Select **Pause Future Runs** to stop new runs of this Protection Group from executing. However, if the job is currently executing a run, the current run continues to execute and only future runs of this job are paused.

    - Select **Resume Future Runs** to restore the Protection Group to a running state. The runs resume as specified in the schedule defined in the policy associated with this job.

- **Cancel this Protection Group Run** ( )—Cancel the current run of this Protection Group. (This option is only available when a Protection Group run is executing.) This cancellation only affects the current run of the Protection Group and not future runs.
- **Clone** ( )—Make a copy of the database. The clone database is a unique copy of the original database taken from the backup.
- Follow the instructions provided in Clone Microsoft SQL Server Databases.
- **Recover** ( )—Restore a database. Follow the instructions provided in Recover Amazon RDS Custom for SQL Server.
- **Migrate** ( )—Migrate a database. Follow the instructions provided in Migrate Microsoft SQL Server Databases.

Database Recover and Clone Actions

In the Databases tab click a protected database to display available recover and clone actions.

To recover or clone the latest snapshot, click the arrow next to the **Protect** button at the top right corner and select an action.

By default, the latest snapshot is selected. You can optionally choose to restore from a different snapshot by clicking Edit ( ).

You can also provide a specific time to restore to if transaction logs are available.

Click a date on the calendar to select a snapshot from that date. The default point selected will be the latest log transaction or the latest full or incremental, whichever is the latest. The slider also displays available points in time and displays snapshots as circles. Manually select a point on the slider if you want to restore to a specific point in time. Selecting an invalid time from the slider automatically changes to the closest available snapshot. If your manual selection is within 10 minutes of a snapshot, your selection automatically snaps to it. You can also select a specific point in time by entering it in the time fields.

After selecting the desired recover point, click **Recover**. You can choose to clone the selected recover point by clicking the arrow adjacent to recover and selecting **Clone**.

In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

Register and Manage Amazon RDS Custom for SQL Server

To start protecting SQL Server databases, you need to register the SQL Server as a source in Cohesity. The following topics provide guidance that helps you register and manage SQL Server:

Auto-discover Microsoft SQL Server Topology when Registering Microsoft SQL Server

To register an MS SQL Server, MS SQL FCI, or an MS SQL AG of a Windows cluster, you can provide the IP address of the server, FQDN of the server, or VIP of the SQL FCI. The Cohesity cluster discovers the entire MS SQL topology on the Windows cluster and displays the relevant subset based on the MS SQL address you provide while registering. From the topology list, you can select the servers you want to register with the Cohesity cluster. To display the entire MS SQL topology, use the Windows Cluster IP/FQDN.

Prerequisites

Before you register the MS SQL, ensure to meet the following:

- MS SQL prerequisites. For more information, see Requirements for Amazon RDS Custom for SQL Server Protection.
- Download and Install the Agent.

Download and Install the Agent

Install the Cohesity agent on each SQL server that you want Cohesity to protect.

1. Select **Data Protection > Sources**.
2. Click **Download Cohesity Agent**. Ensure the agent has been downloaded to the appropriate server.
3. As an administrator with local system privileges on that server, run the executable and complete the installation using the following steps:
4. **Volume CBT (Changed Block Tracker):** Install this component to leverage Cohesity's built-in CBT technology. Without this component, only full backups can be performed. Installing this component requires a one-time reboot to load the Cohesity CBT driver. Until a reboot, only full backups can be performed.

   File System CBT (Changed Block Tracker): Install this component to perform MS SQL file-based protection.

   > **Note:** Installing the Volume CBT or File System CBT is not necessary for MS SQL VDI-based protection.

5. **Service Account Credentials:** You can use either the LOCAL SYSTEM account or an account that meets the requirements to install the Cohesity agent.

   If you do not use the LOCAL SYSTEM account, ensure the following:

   - The account must be a member of the local Windows Administrators group. For example, qa01\tme-backup is an Active Directory user account in the data center. If the backup admin plans to use this account, qa01\tme-backup must be part of the local Windows Administrators group on the SQL server.

- The account must have Log on as a service in the User Rights Assignment on the MS SQL server to install the Cohesity agent.

6. Wait for the installation to finish.

   In the SQL Server Management Studio (SSMS), ensure that the account used to install the Cohesity agent has **Server Roles: sysadmin** in the SQL server instances.
7. The agent starts automatically.
8. Reboot the machine if you have installed the Volume CBT component.
9. Repeat the agent installation process on each SQL server you want to protect. This includes any standalone MS SQL servers and Microsoft SQL Server nodes with AGs.

Register MS SQL Server

1. Select **Data Protection > Sources**.
2. Click **Register** > **Databases** > **MS SQL Server (early access: auto-detect)**.

   The Register an MS SQL Server page appears.

   > **Note:** Ensure that the agent is installed on all the nodes that are part of the Always on Availability Group (AG) and Failover Cluster Instance (FCI). For more details, Download and Install the Agent.
3. In the **Hostname or IP Address** field, enter the IP address of the server, FQDN of the server, or VIP of the SQL FCI. Cohesity recommends you to provide the FQDN of the server.
4. Select the **Server Type**: Windows or Linux.

   For Linux, provide the username and password for the Database Authentication.

   > **Note:** This is an Early Access feature. Contact Cohesity Support to enable the feature.
5. Click **Register**.

   The Cohesity cluster auto-discovers the entire MS SQL topology on the cluster. Based on the MS SQL address you provide while registering, the Cohesity cluster displays the relevant subset of that MS SQL server. The Cohesity cluster also displays which version of the Cohesity agent is running on each of the servers.

   For AG and FCI, ensure to register all the nodes that are part of the AG and FCI.
6. From the topology list, select the entities you want to register with the Cohesity cluster and select **Complete Registration**.

   The selected entities are registered with the Cohesity cluster and are displayed on the source page of the Cohesity cluster UI.

AG is registered as a source, and the databases are listed under AG on the Sources page.

Set Up Standalone Microsoft SQL Server or Microsoft SQL Server AGs

This topic describes how to set up standalone MS SQL servers and MS SQL Server Always On Availability Groups (AGs) to be protected by a Cohesity cluster.

> **Note:** The **Readable Secondary** field in the Availability Group Properties of the SQL Server Availability Group (AG) must be set to "Yes" or "Read-intent only".

The following are the different methods to register your physical or virtual MS SQL Servers allowing you to protect your MS SQL server databases:

- **Registering a SQL Server using the Cohesity SQL Agent**:

  This option is the preferred method to protect your MS SQL server databases on physical or virtual hardware. This option can be used to protect any SQL server configurations such as MS MSQL standalone, FCI, and AG. For more information, see Set Up MS SQL on Virtual or Physical Servers using the Agent.

  To set up an MS SQL FCI, follow the steps described in Set Up Microsoft SQL Server FCI.

- **Registering a Hypervisor for SQL Server**:

  Cohesity provides an additional option to protect your MS SQL server at the hypervisor level. While this option is available, it is not the preferred method to protect your SQL server databases. Following are the two available registration methods:

  - **Persistent Agent**—For more information, see Set Up MS SQL on VMs as a VMware vCenter application with the Installed Agent.
  - **Auto-Deployed Agent (non-Persistent)**—For more information, see Set Up MS SQL on VMs as a VMware vCenter application with the Auto-deployed Agent.

Ensure Prerequisites are Met

Ensure the prerequisites listed in Prerequisites for Microsoft SQL Server Protection are met.

Set Up MS SQL on Virtual or Physical Servers using the Agent

This option can be used for both physical or virtual servers that are in standalone or AG configurations. Cohesity recommends you use this method to protect the MS SQL Servers with the Cohesity cluster. For more information, see Set Up MS SQL on Virtual or Physical Servers using the Agent.

Download and Install the Agent

Install the Cohesity agent on each SQL server that you want Cohesity to protect.

1. Select **Data Protection > Sources**.
2. Click **Download Cohesity Agent**. Ensure the agent has been downloaded to the appropriate server.
3. As an administrator with local system privileges on that server, run the executable and complete the installation using the following steps:
4. **Volume CBT (Changed Block Tracker):** Install this component to leverage Cohesity's built-in CBT technology. Without this component, only full backups can be performed. Installing this component requires a one-time reboot to load the Cohesity CBT driver. Until a reboot, only full backups can be performed.

   File System CBT (Changed Block Tracker): Install this component to perform MS SQL file-based protection.

   > **Note:** Installing the Volume CBT or File System CBT is not necessary for MS SQL VDI-based protection.

5. **Service Account Credentials:** You can use either the LOCAL SYSTEM account or an account that meets the requirements to install the Cohesity agent.

   If you do not use the LOCAL SYSTEM account, ensure the following:

   - The account must be a member of the local Windows Administrators group. For example, qa01\tme-backup is an Active Directory user account in the data center. If the backup admin plans to use this account, qa01\tme-backup must be part of the local Windows Administrators group on the SQL server.
   - The account must have Log on as a service in the User Rights Assignment on the MS SQL server to install the Cohesity agent.

6. Wait for the installation to finish.

   In the SQL Server Management Studio (SSMS), ensure that the account used to install the Cohesity agent has **Server Roles: sysadmin** in the SQL server instances.
7. The agent starts automatically.
8. Reboot the machine if you have installed the Volume CBT component.
9. Repeat the agent installation process on each SQL server you want to protect. This includes any standalone MS SQL servers and Microsoft SQL Server nodes with AGs.

Register a Physical MS SQL Server

> **Important:** If the server contains one or more databases that belong to an Always On Availability Group (AAG), all remaining servers within the AAG must also be registered with the Cohesity cluster as MS SQL Server in order to be backed up. Navigate to **Data Protection > Sources > click on the required source > All Objects > Show AAG Nodes** to display the registered AAG nodes and any warnings about unregistered servers. If a replica is added to an existing AAG, the replica is automatically backed up by the next Protection Group run that protects that AAG, even if the AAG node list does not display it.

1. Select **Data Protection > Sources**.
2. Click **Register** > **Physical Server**.
3. Specify the hostname (FQDN) or server IP of the server to register. Cohesity recommends using the FQDN.
4. Select the **Server Type**: Windows or Linux.

   For Linux, provide the username and password for the Database Authentication.

   > **Note:** This is an Early Access feature. Contact Cohesity Support to enable the feature.

5. Click **Register**.

   When registration finishes, a new entry appears in the physical section of the Sources page.

6. Next to the newly added physical server, mouse over the actions menu (⋮) and click **Register as MS SQL Server**.

   When registration finishes successfully, the MS SQL Server information is displayed when you click the icon.

> **Note:**
> You can throttle the CPU capacity on the MS SQL physical servers (running on Windows 2012R2 and later) you registered with the Cohesity cluster. Throttling optimizes the CPU capacity utilized when a Protection Group with source-side deduplication is run on the server. However, for MS SQL Protection Group, source-side deduplication is not enabled by default. You must contact Cohesity Support for enabling the source-side deduplication for a Protection Group. CPU throttling does not affect the MS SQL Server if source-side deduplication in a SQL Protection Group is not enabled. For more information on enabling CPU throttling, see Network Bandwidth and CPU Throttling for Physical Server.

> **Note:**
> - AGs discovered on the registered standalone physical hosts or failovercluster are registered as sources internally.
> - After registration, databases belonging to an AG will appear only under the AG listed in Sources and not under the registered SQL host (which is an AG replica). SQL host lists only the local databases.

Set Up MS SQL on VMs as a VMware vCenter application with the Installed Agent

This method must be used only when you are registering SQL Server at the hypervisor-level. You can use this option for standalone SQL or SQL servers in AG running on the VMware vCenter.

Download and Install the Agent

Before registering the MSSQL server at the hypervisor-level, you must first install the Cohesity agent on each SQL server that you want Cohesity to protect.

You can optionally use the auto-deployed Cohesity agent, which does not require agent installation. Cohesity, however, recommends installing the agent because this avoids additional configuration such as disabling Windows User Account Control (UAC). If you still want to use the auto-deployed agent, follow the steps described in Set Up MS SQL on VMs as a VMware vCenter application with the Auto-deployed Agent.

1. Select **Data Protection > Sources**.
2. Click **Download Cohesity Agent**. Ensure the agent has been downloaded to the appropriate server.
3. As an administrator with local system privileges on that server, run the executable and complete the installation wizard.

4. You do not need to install any components. Backups leverage VMware VADP CBT or Hyper-V 2016 RCT.
5. **Service Account Credentials:** You can use either the LOCAL SYSTEM account or an account that meets the requirements to install the Cohesity agent.

   If you do not use the LOCAL SYSTEM account, ensure the following:

   - The account must be a member of the local Windows Administrators group. For example, qa01\tme-backup is an Active Directory user account in the data center. If the backup admin plans to use this account, qa01\tme-backup must be part of the local Windows Administrators group on the SQL server.
   - The account must have Log on as a service in the User Rights Assignment on the MS SQL server to install the Cohesity agent.
6. Wait for the installation to finish.

   In the SQL Server Management Studio (SSMS), ensure that the account used to install the Cohesity agent has **Server Roles: sysadmin** in the SQL server instances.
7. The agent starts automatically.
8. Repeat the agent installation process on each SQL server you want to protect. This includes any standalone MS SQL servers and MS SQL Server nodes with AGs.

Register MS SQL

> **Important:** If the server contains one or more databases that belong to an Always On Availability Group (AAG), all remaining servers within the AAG must also be registered with the Cohesity cluster as MS SQL Server in order to be backed up. Navigate to **Data Protection > Sources > click on the required source > All Objects > Show AAG Nodes** to display the registered AAG nodes and any warnings about unregistered servers. If a replica is added to an existing AAG, the replica is automatically backed up by the next Protection Group run that protects that AAG, even if the AAG node list does not display it.

1. Select **Data Protection > Sources**.
2. Navigate the hierarchy to the server that is running MS SQL.
3. Mouse over the server's actions menu (⋮) and click **Register Applications**.
4. Select **Installed Agent**.

   If the agent is not already installed, registration fails.
5. Select MS SQL.
6. Click **Register**.

The agent starts automatically.

The server's MS SQL and agent information display when you click the icon.

Set Up MS SQL on VMs as a VMware vCenter application with the Auto-deployed Agent

> **Important:** If the server contains one or more databases that belong to an Always On Availability Group (AAG), all remaining servers within the AAG must also be registered with the Cohesity cluster as MS SQL Server in order to be backed up. Navigate to **Data Protection > Sources > click on the required source > All Objects > Show AAG Nodes** to display the registered AAG nodes and any warnings about unregistered servers. If a replica is added to an existing AAG, the replica is automatically backed up by the next Protection Group run that protects that AAG, even if the AAG node list does not display it.

1. Select **Data Protection > Sources**.
2. Navigate the hierarchy to the server that is running MS SQL.
3. Mouse over the server's actions menu ( ) and click **Register Applications**.
4. Select **Auto-Deployed Agent**.

   Enter the Windows administrator **Username** and **Password** for the server that is running MS SQL. Windows administrator privileges are required. Ensure that the user account used for auto-deploying the agent is added to all the MS SQL server's SQL instances' **Security > Logins** with Windows Integrated Authentication.

   Disable the UAC property Admin Approval Mode

   1. Click **Start**, type secpol.msc in the Search programs and files box, and then press Enter.
   2. If the User Account Control dialog box appears, confirm that the action it displays is what you want, and then click **Yes**.
   3. In the console tree, expand Local Policies, and click **Security Options**.
   4. In the details pane, scroll down and double-click the **Group Policy** setting that you want to change. This opens the UAC policy settings that a local administrator can modify.
   5. Disable **User Account Control: Run all administrators in Admin Approval Mode** for the Administrator account.
   6. Ensure that **User Account Control: Admin Approval Mode for Built-in Administrator Account** is set to Disabled.
   7. Ensure that **User Account Control: Behavior of elevation prompt for administrators in Admin Approval Mode** is set to Elevate without Prompting.

8. Restart/reboot the Windows server for the changes to take effect.
9. Provide the Administrator/Domain Administrator user that has Admin Approval Mode disabled.

5. Select MS SQL.
6. Click **Register**.

The server's MS SQL information displays when you click the icon.

Upgrade the Cohesity Agent and Add the File System CBT Component

If necessary, you can upgrade the agent and add the File System Changed Block Tracking (CBT) manually. Start the upgrade and select the option to include the File System CBT component in the upgrade.

Troubleshoot

- The log backup of AG MS SQL Server fails with the following error if there is a break in the log chain.

  ```
  Log chain break error: Discovered a break in the log chain for
  <Database Names>
  ```

  Resolution: To resolve this issue, ensure that no other third-party applications are running a log backup, and then perform a full backup run to reset the log chain.

- The log backup of the AG MS SQL Server fails with the following error if a database is added or removed from the AG MS SQL Server.

  ```
  AG relationship error: Discovered a AG relationship error for database
  <Database Names>
  ```

  Resolution: To resolve this error, perform a full backup run.

For more troubleshooting information, see the following KB article:

- Collecting troubleshooting information for MS SQL issues

Log in to the Cohesity Support Portal to see more KB articles.

Set Up Microsoft SQL Server FCI

This topic describes how to set up an MS SQL Failover Cluster Instance (FCI) to be protected by a Cohesity cluster. To set up a standalone MS SQL Server or MS SQL AG, follow the steps described in Set Up Standalone Microsoft SQL Server or Microsoft SQL Server AGs.

MS SQL FCI - Overview

An MS SQL FCI is an MS SQL instance installed on a Windows server that is part of a Windows Server Failover Cluster (WSFC or simply Windows Cluster for short). The SQL instance physically exists on (and is accessible from) only one node of the WSFC at any given time. If the FCI's current node goes down, the FCI moves to another node in the

WSFC. The FCI is addressed by a Virtual IP (VIP) which points to the physical IP of the node on which it currently resides.

Set Up MS SQL FCI Overview

MS SQL FCI setup has the following steps:

1. Ensure Prerequisites Are Met
2. Download and Install the Agent on Each Node
3. Register an MS SQL FCI as a Source
4. Register an MS SQL FCI as MS SQL

Ensure Prerequisites Are Met

Ensure the prerequisites listed in Prerequisites for Microsoft SQL Server Protection are met.

Download and Install the Agent on Each Node

Before registering an MS SQL Server FCI, you must download and install the Cohesity agent on each node within the MS SQL FCI.

1. Select **Data Protection > Sources**.
2. Click **Download Cohesity Agent**. Ensure the agent has been downloaded to the appropriate server.
3. As an administrator with local system privileges on that server, run the executable and complete the installation using the following steps:
4. **Volume CBT (Changed Block Tracker):** Install this component to leverage Cohesity's built-in CBT technology. Without this component, only full backups can be performed. Installing this component requires a one-time reboot to load the Cohesity CBT driver. Until a reboot, only full backups can be performed.

   File System CBT (Changed Block Tracker): Install this component to perform MS SQL file-based protection.

   > **Note:** Installing the Volume CBT or File System CBT is not necessary for MS SQL VDI-based protection.

5. **Service Account Credentials:** You can use either the LOCAL SYSTEM account or an account that meets the requirements to install the Cohesity agent.

   If you do not use the LOCAL SYSTEM account, ensure the following:

   - The account must be a member of the local Windows Administrators group. For example, qa01\tme-backup is an Active Directory user account in the data center. If the backup admin plans to use this account, qa01\tme-backup must be part of the local Windows Administrators group on the SQL server.

- The account must have Log on as a service in the User Rights Assignment on the MS SQL server to install the Cohesity agent.

6. Wait for the installation to finish.

   In the SQL Server Management Studio (SSMS), ensure that the account used to install the Cohesity agent has **Server Roles: sysadmin** in the SQL server instances.
7. The agent starts automatically.
8. Reboot the machine if you have installed the Volume CBT component.
9. Repeat the agent installation process on each node within the MS SQL FCI.

   After you install the agent on each node within the FCI, the MS SQL FCI can be registered as a source with the Cohesity cluster.

Register an MS SQL FCI as a Source

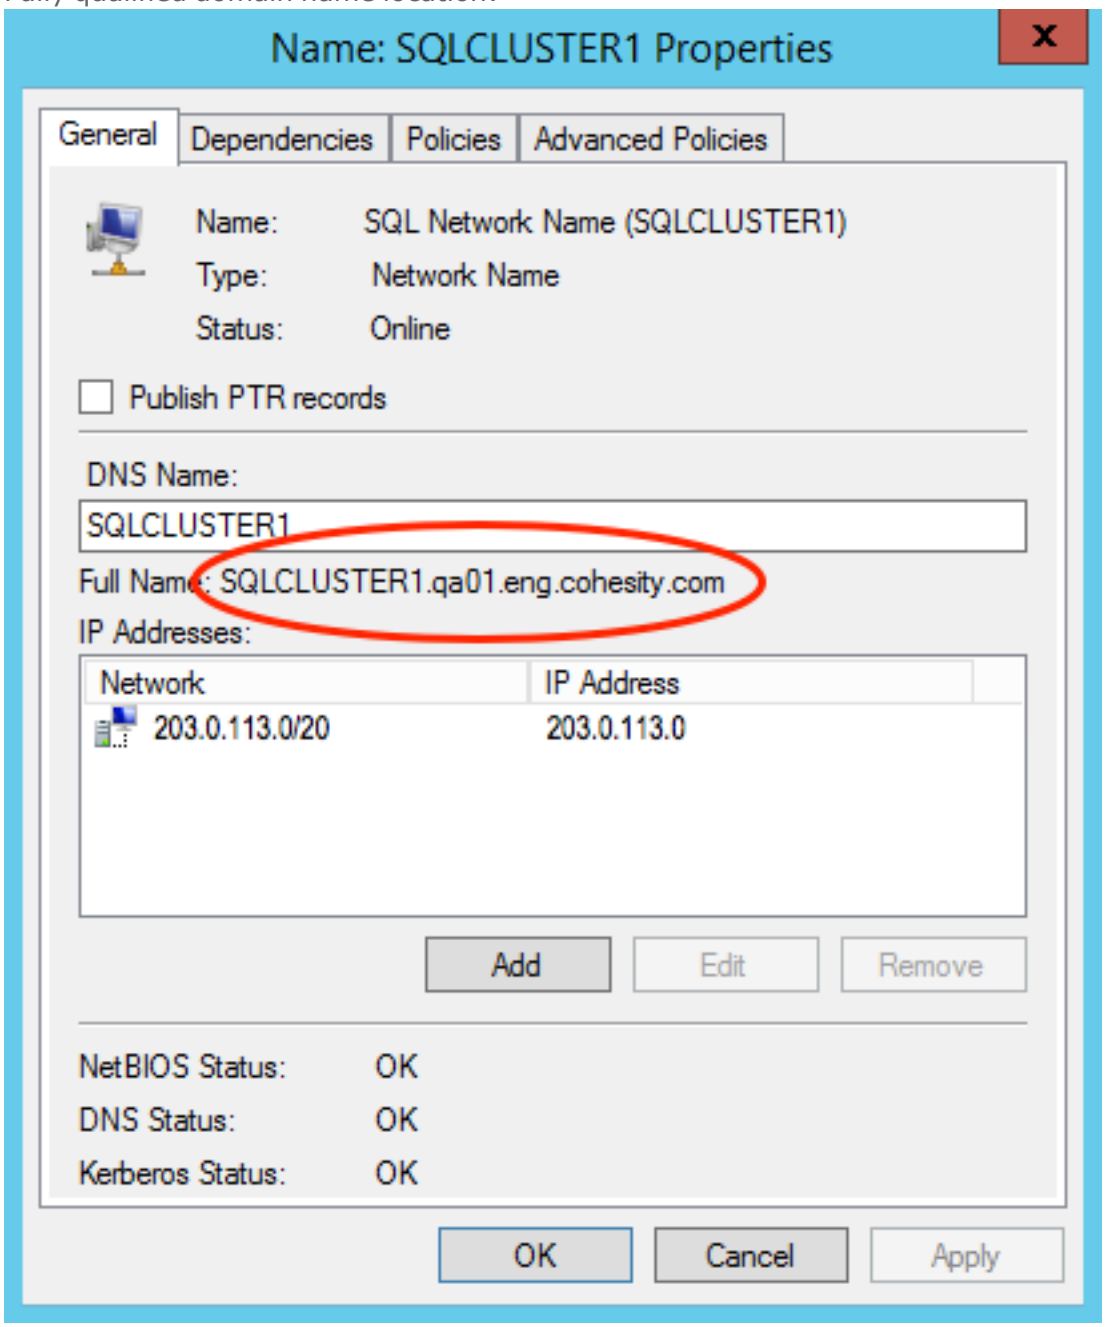
This registration step makes an MS SQL FCI visible to the Cohesity cluster so that its content is eligible to be protected or backed up.

> **Note:**
> - An MS SQL FCI can be registered with only one Cohesity cluster at a time.
> - Each MS SQL FCI must be registered separately.

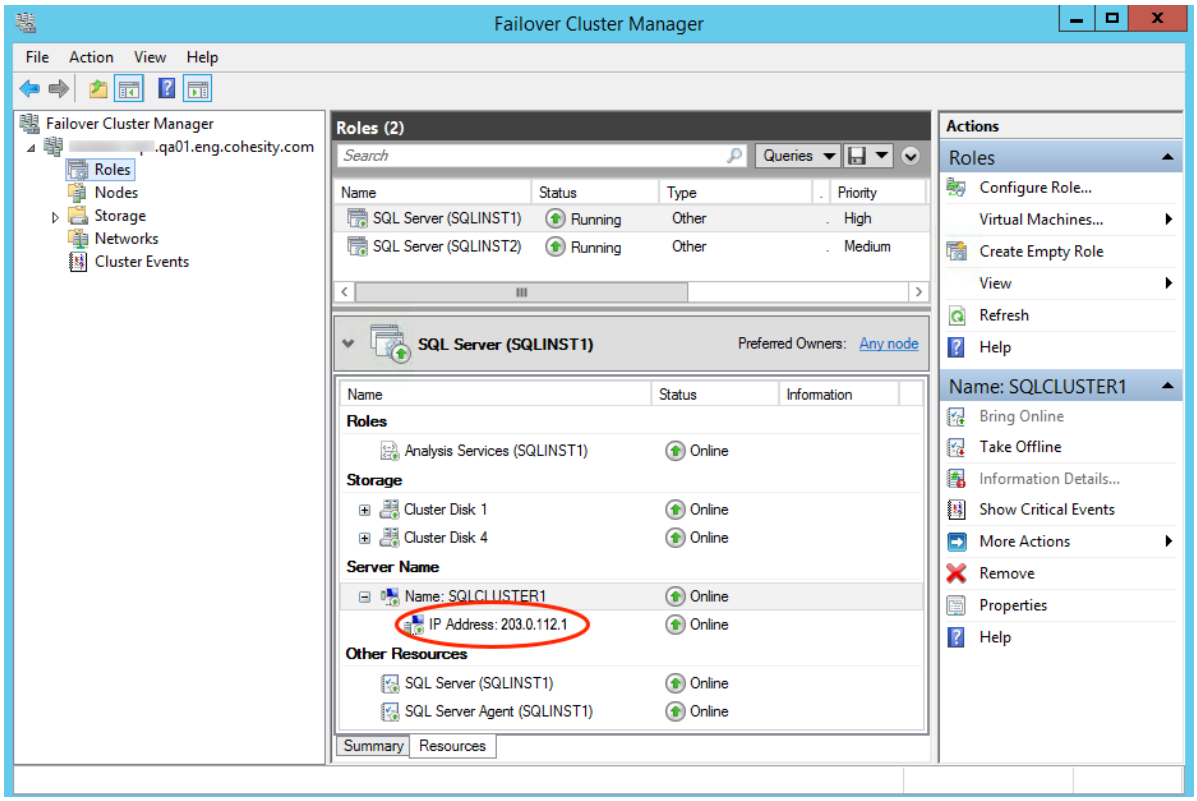
1. Select **Data Protection > Sources**.
2. Click **Register** > **Databases** > **MS SQL Cluster**.
3. Enter the **Hostname**.

   Cohesity recommends that you specify the fully qualified domain name of the MS SQL FCI to register. Or you can specify the virtual IP address (VIP) of the MS SQL FCI present under SQL Role.

Fully qualified domain name location:



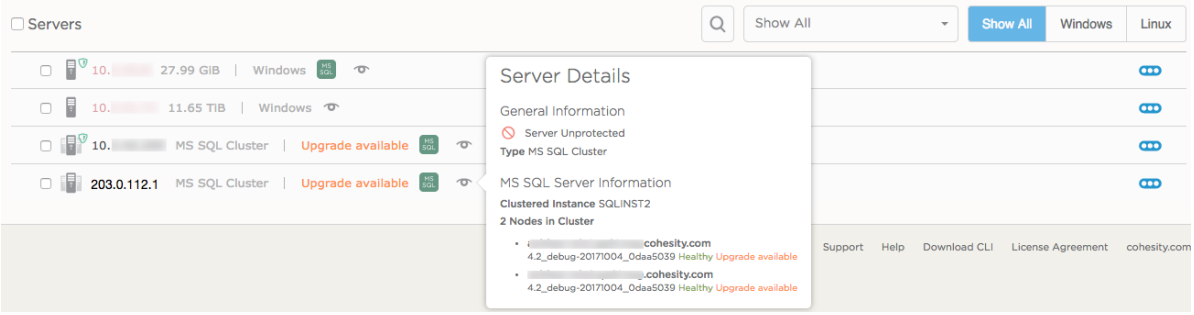
Virtual IP address location:



> **Note:** If the MS SQL FCI is not registered using an FQDN and all its nodes are not configured with FQDNs (for example, it is a test environment), changing the IP address of a registered node or adding/removing nodes may not update the FCI's registration configuration information, which could prevent some Cohesity SQL workflows. If you change the configuration information or add/remove nodes under these conditions, Cohesity recommends that you unregister and then reregister the MS SQL FCI. MS SQL FCIs that are registered using an FQDN do not have limitations when updating configuration information such as node IP address changes or adding/removing nodes.

4. Click **Register**.

   When registration finishes, a new entry appears in the physical section on the Sources page.



The MS SQL FCI is now registered as a physical server.

Register an MS SQL FCI as MS SQL

This registration step takes an MS SQL FCI source that is already visible (as a physical server) to the Cohesity cluster and registers it as MS SQL Server.

Next to the newly added MS SQL FCI (displayed as a physical server), mouse over the MS SQL FCI's actions menu and click **Register as MS SQL Server**.

When registration finishes successfully, MS SQL Server information displays when you click the icon.

FCI Standalone Multi-Registration

You can register and back up a Windows Server that participates in an MS SQL FCI. You can separately register the FCI clusters and their standalone nodes. This allows you to backup local drives for physical server backups.

Prerequisites

- Ensure that all the SQL agents are upgraded.
- Ensure that the following unsupported protection groups are not present:
  - A protection group that auto-protects a standalone SQL host participating in a WSFC.
  - A protection group that explicitly protects FCI databases on a SQL server participating in an MS SQL FCI.

Error Messages

- The following error message is displayed when unsupported protection groups are present:
  Error
  FCI-node multi-registration cannot proceed, please correct the following protection groups:

- <protectiongroupname1>, <protectiongroupname2> - jobs that autoprotect Windows Cluster node(s).
- <protectiongroupname1>, <protectiongroupname2> - jobs that explicitly back up some FCI databases from Windows Cluster node(s).

Solution

Either delete or fix the protection groups such that they no longer fit the unsupported criteria, and continue the procedure.

- The following error message is displayed when the agent on the Windows cluster node has not been upgraded to a version that supports this feature:
  Error
  Agents on the following sources do not support FCI-node multi-registration: <server1>, <server2>
  Solution
  Upgrade the agent on the Windows cluster node to a version that supports this feature.

Best Practices for Microsoft SQL Server

Cohesity recommends the following best practices when protecting MS SQL:

- Cohesity recommends triggering a full backup whenever a database file (.mdf, .ndf, .ldf) is added or removed from the database.
- Multiple Cohesity clusters concurrently backing up an MS SQL VM is not recommended because the jobs will interfere with the other's log chain.
- For MS SQL point in time restores, the Full Recovery Model is recommended as a best practice. For more information, see Choosing the Recovery Model for a Database.
- Set MS SQL Server to autostart.
- To accurately report the size of transaction log data read/written during log backups, the Windows local or domain Administrator account that is registered with Cohesity for backup must be added as a user to the 'model' system database. Use the following query:

```
-- Configures accurate reporting of the size of transaction log data
read/written during log backup
USE [model]
GO
CREATE USER [HOSTNAME\Administrator] FOR LOGIN [HOSTNAME\Administrator]

GO
```

  Where HOSTNAME is the hostname of the SQL server.
  This assumes that the Administrator account used to register MS SQL is already registered in the SQL server instance's Security Logins and has the "sysadmin" role per documentation. If privileges are not correct, the logical bytes read stat ("Size" column on the Job's details page) for MS SQL log backups will be the same as the

physical bytes read stat ("Read" column on the Job's details page). If privileges are correct, then the size reported will be the sum of the sizes of all the .ldf files for the database.

Considerations for Microsoft SQL Server

General

- For file-based Protection Group, object-level granularity is not supported for Role-based access control (RBAC), such as setting access to objects through Active Directory and roles.
- If using native or third-party backup software to back up an application (such as MS SQL), note that the following behavior breaks the differential chain for the application on that server:
  - Performing an app-consistent backup on a VMware SQL VM.
  - You are allowed to run a file-based physical server Protection Group with a SQL Protection Group or 3rd party SQL protection tools.
    This is a Microsoft limitation. For more information, see Various Causes of Log Chains Breaking Issue in SQL Server.
- The SQL Server VDI log backup and restore operations require Sysadmin privileges which is a Microsoft requirement. For more details, see Microsoft Documentation on SQL Server VDI backup.
- Cohesity cluster uses the Encrypted Network Block Device (NBDSSL) transport method for the vSphere Storage APIs for Data Protection (VADP) workflow. NBDSSL uses SSL to encrypt the data. SAN transport mode operation is not supported.

Protection

- Ensure that all AG databases you want to protect are selected from the respective replica.
- For file-based backups, Cohesity operations rely on default MS SQL file extensions (.mdf, .ndf, .ldf).
- SQL Database and logs residing on SMB/NFS can be protected using the MS SQL Native method.
- SQL Database and logs residing on Clustered Shared Volumes (CSV) can be protected using the MS SQL Native and MS SQL VDI methods.
- CBT information does not persist after a reboot for the file-based backup method.
- As per Microsoft requirements, VDI backups executed on secondary replicas are copy-only full backups. Copy-only backups on secondary replicas do not impact the log

chain. For more information, see Offload supported backups to secondary replicas of an availability group.

- Overwriting Filestream database is not supported; this may prevent the completion of recovery.

Recovery

- Performing a point-in-time restore of an Always On Availability Group replica requires full backups from that replica.

  Log backups are merged across all replicas; full backups are not. During restore, the user sees multiple results for the same database from different replicas. Each replica shows a set of Snapshots for full backups done on that particular replica. For point in time restore to a specific replica, the user must select a full backup Snapshot from that replica only. If a full backup does not exist, point in time restore is not possible.

  Restore the database to the desired MS SQL Server instance on a replica that has a full backup.

- Using the "Restore to Original SQL Server instance" option is not supported if any of the following occurs:
  - The Windows host name changed and you attempt to restore a snapshot that was taken before the host name change.
  - Granular DB restore performed from a higher SQL Server version to a lower version. This is a Microsoft limitation.

  You can, toggle off "**Restore to Original SQL Server Instance**" and perform a database restore.

  For more information, see Rename computer hosting instance - SQL Server.

  Restoring a snapshot taken after the name change or upgrade is supported.

- Restoring MS SQL Server from backups of dynamic disks to the same machine is not supported.
- Use File-based or VDI-based backup methods to protect TDE databases. Follow the Microsoft TDE best practices for key and cert management.
- If multiple restore tasks are run on the same target host, the restore tasks will be serialized.
- **For system database recovery**:
  - Recovering the system database to an alternate instance is not supported.
  - When recovering to the original database, the original database is deleted before the recovery. Therefore, a recovery failure will also lead to the loss of the original database.

    - If you are recovering the system databases individually, then the recovery of the system database must be in the following order:
        1. Master
        2. MSDB
        3. Model
    - You cannot recover a system database along with a user database.
    - If you are recovering more than one system databases in a recovery task, then the recovery point for the selected system databases must be the same.
- For recovering a database to an Amazon RDS Custom SQL Server, the recovery destination path must be under the **D:\rdsdbdata** folder.

Clone

- Cloning an MS SQL database and renaming the database via SSMS can leave the cloned database in the "Recovery Pending" state during a clone teardown task. This is because the Cohesity cluster database clone operation assumes the cloned database name and files are associated with the original clone operation. To prevent a disconnect between the Cohesity cluster and SQL Server operation, it is recommended to clone a new database with the intended database name rather than rename a cloned database.

Migration

- Cohesity does not support the migration of MS SQL FILESTREAM databases.
- Once a migration task is configured and created, the target SQL Server or database paths cannot be modified for the existing migration task.
- Cohesity does not detect changes/deletions to the target database with a running migration task. Changes made external to the migration task before finalizing can cause the migration task to fail.
- Cohesity does not support the migration of MS SQL databases that are replicated to an alternate Cohesity cluster.

General Recommendations for Microsoft SQL Server Backup Methods

FILESTREAM databases can be protected using the VDI-based approach.

Normal databases can be protected using the following approaches, listed in the order of recommendation:

- File-based
- VDI-based

The following table can help you select the appropriate backup type:

	File-based Backup	VDI-based Backup
Microsoft Approach	Leverages Microsoft VSS approach	Leverages Microsoft SQL Server native backup and restore commands through API calls
Built-in Change Block Tracking (CBT)	Leverages Cohesity's built-in CBT technology	Leverages SQL server's differential backups
Database clone from backup	Supported	Not Supported
Recovery: Cross-domain AD without trust	Supported (GRPC is used to transfer data)	Supported (GRPC is used to transfer data)
Database clone: Cross-domain AD without trust	Not Supported (Clone uses SMB and cross-domain trust is required for SMB access)	-
Implicit Full backup after SQL host restart	The first backup after the SQL server reboot will be a full backup (incremental backup automatically switches to full backup)	-
Memory Optimized Filestream Database	Not Supported	Supported
SQL server-side compression	Not Supported	Supported but not recommended to use, since it may cause low deduplication rate on the Cohesity clusters, which leads to high storage utilization on the Cohesity cluster.
Parallel Log Backup to Full/ Incremental Backup	Supported	Supported
Fast Backup (multi-node)	Supported	Supported
Fast Restore (multi-node)	Supported	Supported
Database-level recovery from archived backup	Supported (Beta till 7.0)	Supported (Beta till 7.0)

	File-based Backup	VDI-based Backup
CAD Policy	Supported	Supported
Transparent Data Encryption (TDE) Databases	Supported	Supported
Database on ReFS volumes	Supported	Supported
Quiesce Support	SQL Database goes through quiesce (freeze/thaw)	Not required. The SQL server performs consistent backup
Free Space on SQL Host (VSS shadow storage requirement)	At least 10% is recommended for each volume on the SQL host by MSFT. Large databases with high IO rates may require additional space.	-
Must-Have	-	Must have Full and incremental (differential). NOTE: Setting extended retention is required for full backup to avoid expiry before the incremental backup expiry.
Parallel run-now backups (same type) for the same job	When the host is already part of a previous run-now submitted, the backup is queued until the previous submitted run is complete.	Backup of the selected database runs in parallel with the existing run-now request.
Known Issues that lead to backup failure	Very High transaction rate on databases may occur resulting in backup failure. This is due to Microsoft's VSS system provider not being able to maintain the VSS snapshot on SQL host with very high transactions. This is very rare. Configuring the shadow storage on volume with no/less IO helps to mitigate the issue.	Agent/SQL host may restart during backup.
Known Issues that lead to incremental backup converting to full backup	First backup after SQL server reboot will be a full backup (incremental backup automatically switches to full backup)	If no explicit policy is available for full backup, incremental backup is converted to full backup after 7 days.

	File-based Backup	VDI-based Backup
Known issues that lead to PIT clone failure	-	-
FortKnox	Supported	Supported

> **Note:** REFS is supported by VDI-based and File-based SQL server.

Backup Amazon RDS Custom for SQL Server

The following topics provide guidance to help you protect MS SQL databases:

For more information on MS SQL deployments, See Protect SQL Server with Cohesity—Deployment Considerations Guide.

About Microsoft SQL Server Backup

Cohesity supports the following MS SQL Server backups:

- File-based Backup
- VDI-based Backup

Cohesity also supports VM-based Backup and SQL Native Backup.

File-based Backup

A Cohesity cluster MS SQL file-based backup protects only the MS SQL databases you choose. It captures only the database files for those selected databases. The Cohesity cluster captures full database server backups and can optionally back up database transaction logs, so you can roll forward to any point in time.

The advantage of a file-based backup is that a smaller amount of data is captured, which allows the Protection Group to run more quickly.

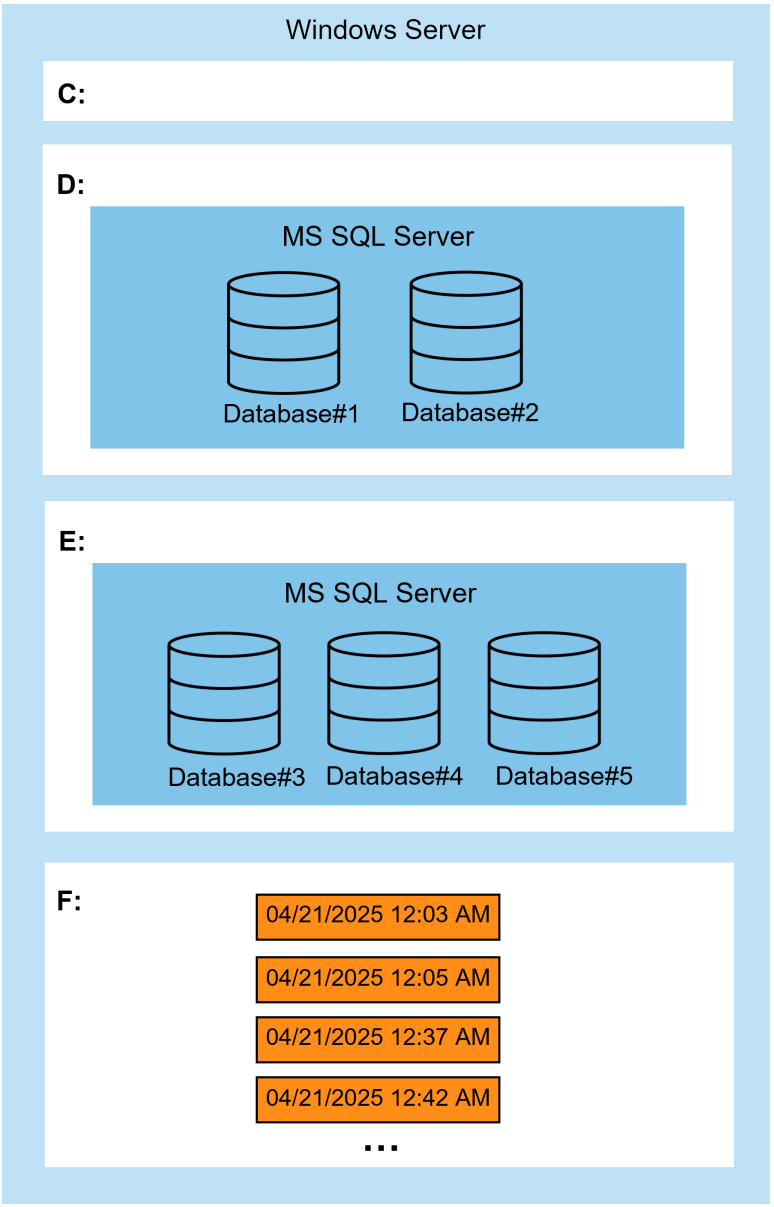
> **Note:** To enable file-based backup, you must install the File System CBT component during Cohesity agent installation.

For information on performing MS SQL file-based backup, see Microsoft SQL Server (File-based).

All configurations are for illustrative purposes only. Cohesity recommends following MS SQL best practices.

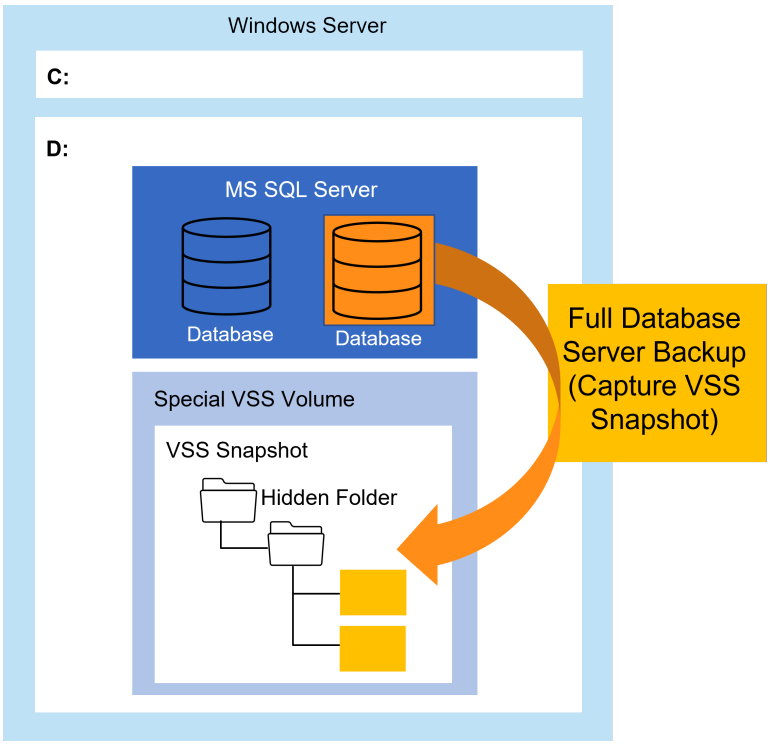
An example of MS SQL running on a Windows server that contains the following:

- Multiple volumes, C, D, E and F in the figure below
- Volume D is running two MS SQL databases
- Volume E is running three MS SQL databases
- Volume F contains database logs

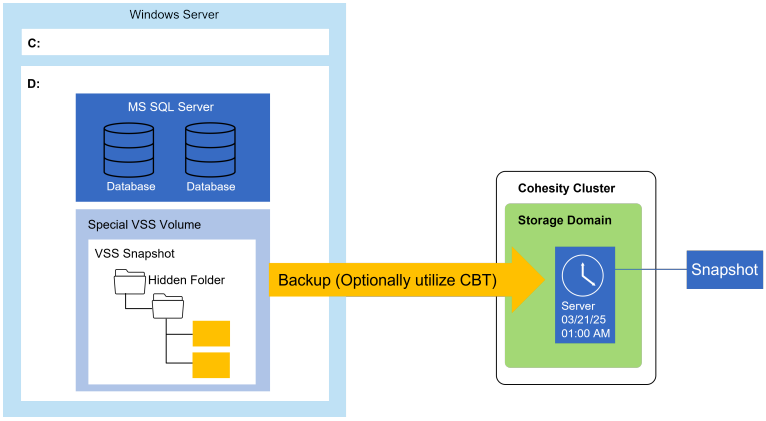


The MS SQL file-based backup task consists of the following actions:

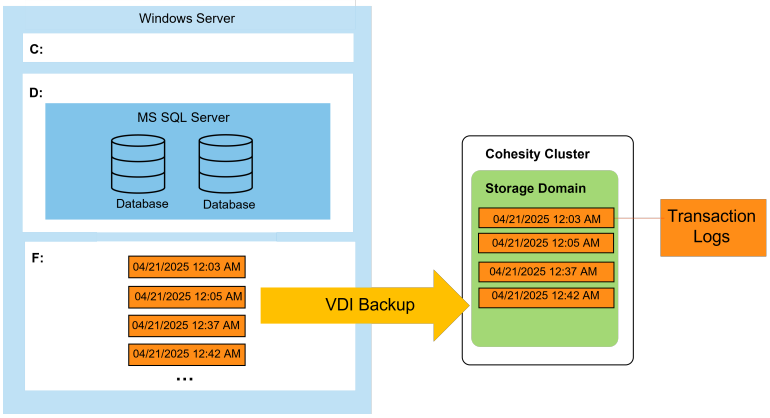
1. During SQL database protection run, a VSS snapshot of the specified MS SQL databases is captured using Volume Shadow Copy Service (VSS). The VSS snapshot resides on the local drive as a special VSS volume. This VSS snapshot is a full database server backup.



2. The snapshot is captured and saved on the Cohesity cluster with a date and time stamp. You can optionally choose for the Cohesity cluster to utilize Change Block Tracking (CBT) when backing up the snapshot. VMware VMs leverage VMware CBT to back up the snapshot. Physical servers leverage Cohesity CBT to back up the snapshot.



3. Backups of database transaction logs use MS SQL Server Virtual Device Interface (VDI) and are stored on the Cohesity cluster. The logs allow you to roll back to a specific point in time. MS SQL Server automatically truncates the SQL logs after a successful SQL log backup and marks the Virtual Log Files (VLFs) for reuse.



VDI-based Backup

A Cohesity cluster MS SQL VDI-based backup captures the native MS SQL server backups. It captures VDI-based backups of a specific database on a SQL Server instance running on a VMware or physical server.

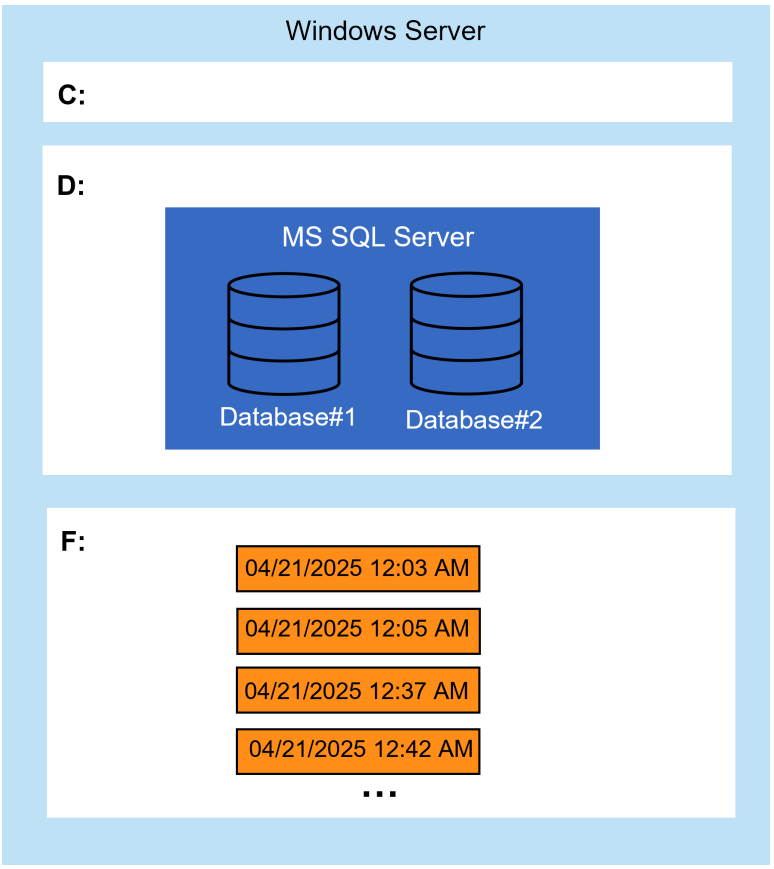
The Virtual Device Interface (VDI) is a Microsoft interface that allows the Cohesity agent to execute SQL Server Native backup and restore commands. This backup type produces a standard SQL Server Native backup of type (.BAK), transaction logs, (.TRN), and differentials, (.DIFF). These backup files are stored on a Cohesity View and take advantage of View compression, deduplication, encryption, replication, and archiving features.

For information on performing MS SQL VDI-based backup, see Backup Microsoft SQL Server (VDI-based).

All configurations are for illustrative purposes only. Cohesity recommends following MS SQL best practices.

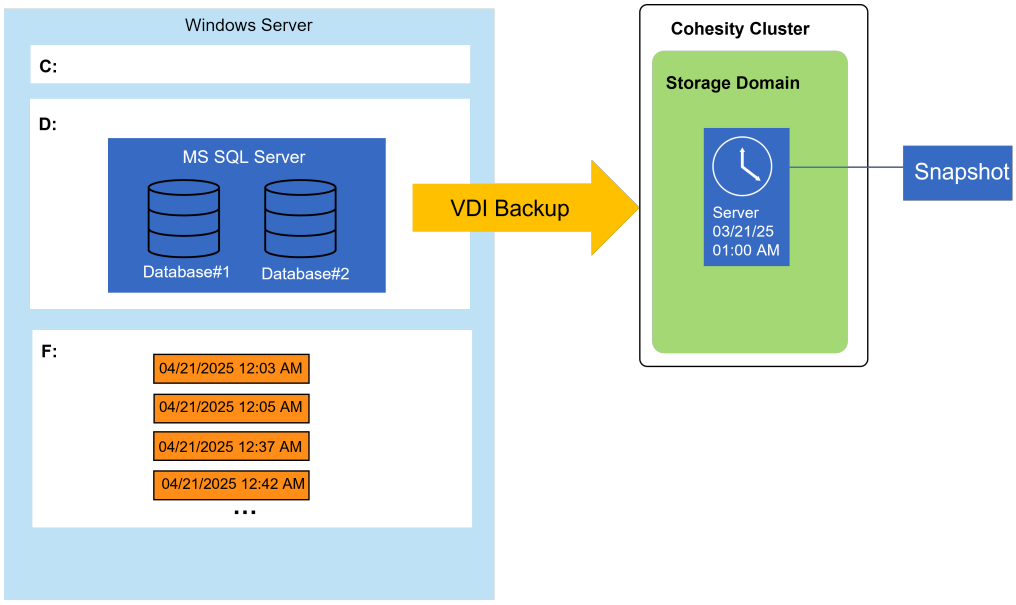
An example of MS SQL running on a Windows server that contains the following:

- Multiple volumes, C, D and F in the figure below
- Volume D is running multiple MS SQL databases
- Volume F contains database logs

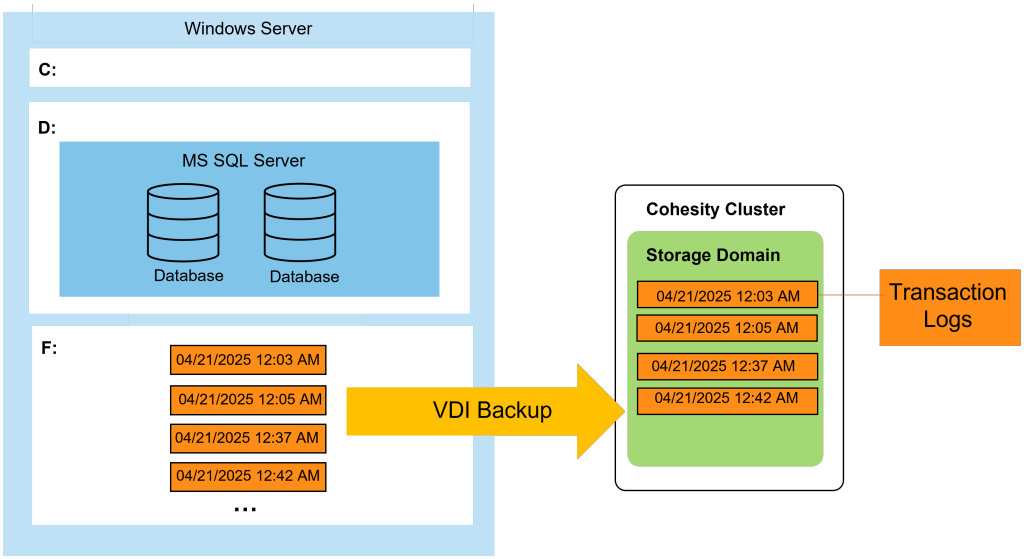


The MS SQL VDI-based backup task consists of the following actions:

1. During an MS SQL protection run, a "BACKUP DATABASE" command for the specified MS SQL databases is initiated using MS SQL Server Virtual Device Interface (VDI). The generated backup file is saved on the Cohesity cluster with a date and time stamp.



2. If the policy is configured to take incremental database backups, it translates to differential backups in case of VDI-based backup.
3. If transaction log backups are specified in the policy, the database transaction logs are backed up to the Cohesity cluster using MS SQL Server Virtual Device Interface (VDI). The logs allow you to roll back to a specific point in time. MS SQL Server automatically truncates the SQL logs after a successful SQL log backup and marks the Virtual Log Files (VLFs) for reuse.



Compare File-Based and VDI-Based Backup Methods

The following table compares the implications of each method.

Cohesity Facet	File-based backup	VDI-based backup
Technology Employed	Cohesity Agent uses Vss and Cohesity technology for file CBT, and VDI for T-logs.	Cohesity agent uses SQL Native backup commands.
What does it capture?	Captures database files.	Captures the database in a SQL Server standard .BAK, .TRN, or .Diff file.
Logs	Yes. Captures a SQL log backup of the database.	Yes. Captures a SQL Server native log backup of the database.
Cohesity Source Registration	Register as a SQL Server application.	Register as a SQL Server application.

Cohesity Facet	File-based backup	VDI-based backup
Compatibility with SQL Server High Availability Features	**Windows Failover Cluster**: **Yes**, backup will succeed if a failover occurs. Must be registered as a Cohesity "SQL Cluster" source. **AG**: **Yes**, backup on the correct replica will succeed after an AG failover occurs. **Mirroring**: **Yes** Each SQL instance must have its own Protection Group. **Log Shipping**: **Yes**. Each SQL instance must have its own Protection Group. **Note:** While Cohesity currently does not include specific features for mirroring and log shipping, it does not conflict with these SQL Server features. **Note:** Log shipping via SQL Server Management Studio supports only full/incremental backup and not log backup since it can break the log chain.	**Windows Failover Cluster**: **Yes**, backup will succeed if a failover occurs. Must be registered as a Cohesity "SQL Cluster" source. **AG**: **Yes**, backup on the correct replica will succeed after an AG failover occurs. Mirroring: No. Log Shipping: No
Method	This is an MS SQL Server database backup at the **file level**. Allows for FULL SQL Server backups with logs, but only the database files are captured. The Cohesity Agent uses Vss, the Cohesity File CBT, and VDI to take an application-consistent snapshot of the volumes on that server. Faster because it's not backing up extraneous files.	This is a native MS SQL Server database backup at the **file level**. Allows for FULL SQL Server backups with logs and Differentials, but only the database is captured. Agent uses SQL Server native backup and restore commands , to take an application-consistent backup of the database.
Recovery/Restore	The database host server should be backed up and restored via a different protection group. Supports Point-in-Time (PIT) restore of the database from across the entire backup history.	

Cohesity Facet	File-based backup	VDI-based backup
Cloning	**Yes**. Can produce a representative database. *Advantage*: Applications can be tested with data that is as close to the production environment as possible: Can reproduce a database. *Advantage*: Applications can be tested with databases that can be destroyed and re-created on demand. No load on Production servers. The backup is NOT modified and therefore always safe. A successful clone is immediate validation of the backup's integrity. Uses storage resources on Cohesity cluster.	**Cloning is scheduled as a future enhancement.**
Source-side deduplication	Supported	Not supported
Archival	**CloudArchive**: Cohesity supports the ability to send backups to public cloud providers like AWS, Azure, and Google Cloud Platform. It also supports search and restore from them, back to the local site when needed.	
Replication	**Managing Copies of backups on another Cohesity cluster**: Backups, files, and volumes can be replicated to a second Cohesity cluster.	

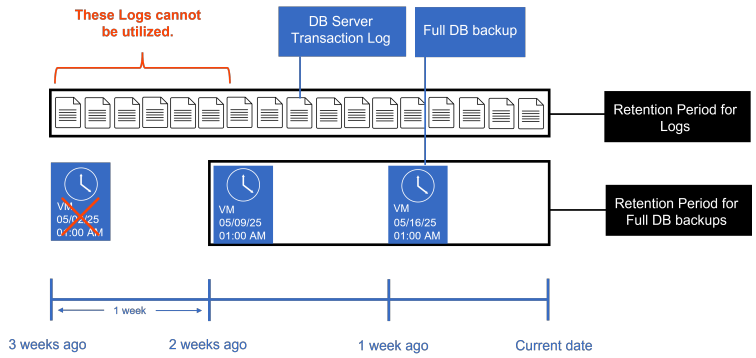
About Log and Full DB Backup Retention Periods

The retention periods of log files and full database server backups are independent of each other. Consider the following examples to help determine the best retention periods for your database server backups. These retention guidelines also apply to full database server and log replication schedules. Retention periods of log files and full database backups must adhere to Microsoft rules for restoring databases.

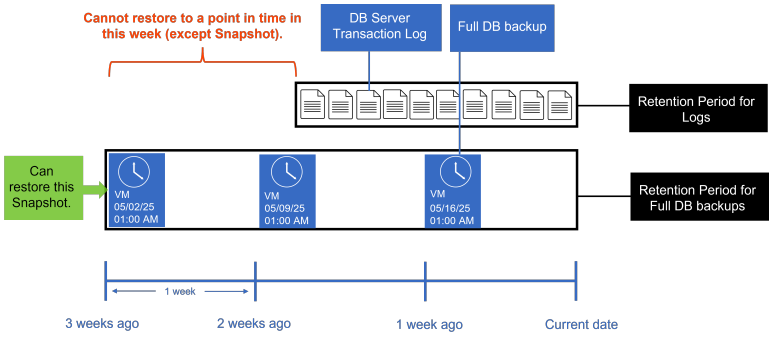
1. A point-in-time restore using SQL log backups is dependent on a full backup because a full database server backup must also be available to apply the logs.

   When the Cohesity cluster restores to a specific point in time, it must first restore a full database server backup and then apply the appropriate set of logs. If a full database server backup is not available because the retention period of the full database server backup is too short, the Cohesity cluster cannot restore to a point in time within the specified log retention period. For example if the log retention period

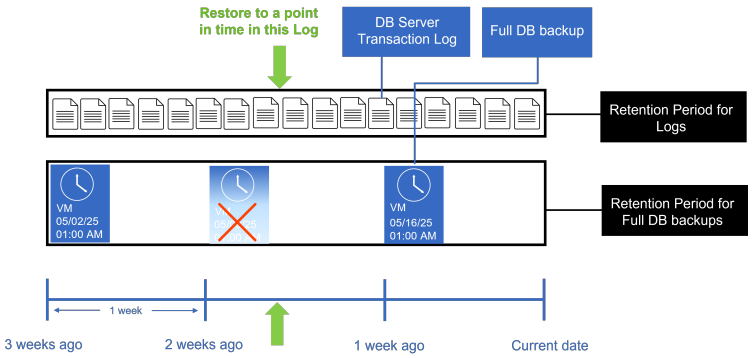
is three weeks and the full database server backup captures snapshots weekly with a retention period of two weeks, the Cohesity cluster will not be able to restore to any point in time from three weeks ago. In addition, the logs from three weeks ago cannot be utilized and are using disk space.



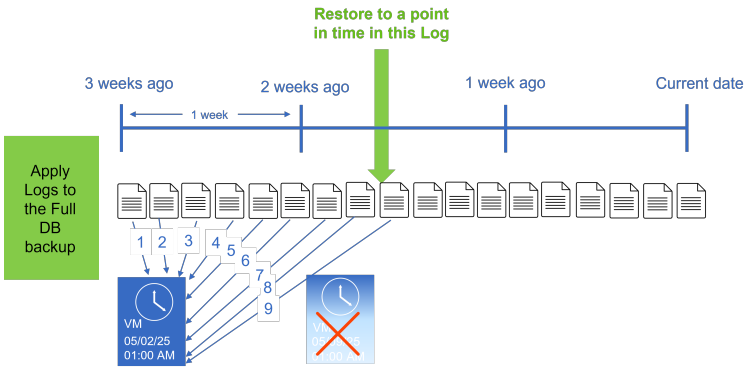
2. If the log retention period is shorter than the full database server backup retention period, the Cohesity cluster cannot restore to a point in time where the logs are not saved. For example, if the log retention period is two weeks and the full database server backup captures snapshots weekly with a retention period of three weeks, the Cohesity cluster will not be able to restore to any point in time between two and three weeks ago. The Cohesity cluster can, however, restore to the snapshot from three weeks ago.



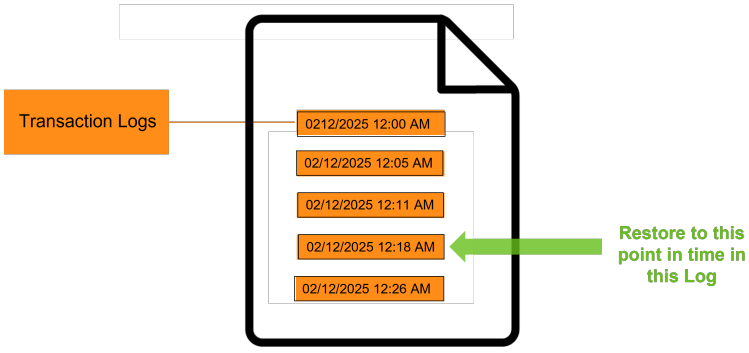
3. Cohesity recommends specifying a log retention period with extra time to allow for failed full database server backups as demonstrated by the following example. A full database server backup is scheduled weekly with a three-week retention period for both full database server and logs. If the full database server backup failed two weeks ago, the Cohesity cluster can still restore to the point in time from the log indicated by the green arrow.



The Cohesity cluster restores full database server backup from three weeks ago and applies the appropriate logs to restore the state to a point.



You can restore to a specific transaction in the log.



> **Note:** A full database backup is not a transaction log backup. Ensure that your SQL Server protection policy has transaction log backup for full and bulk-logged recovery model requirements.

Microsoft SQL Server (File-based)

This topic describes how to protect MS SQL with a file-based Protection Group. File-based Protection Groups protect only the specific MS SQL databases that you select.

MS SQL Protection Group Support

The following table describes supported job types for MS SQL running on physical servers and VMs.

	File-based Jobs	Volume-based Jobs	VDI-based Jobs	Both Job Types Using the Same Server but Protecting Distinct Databases
Physical MS SQL	Multiple file-based jobs protecting all or a subset of DBs	One volume-based job protecting all or a subset of DBs	Multiple VDI-based jobs protecting all or a subset of databases	Supported
SQL Server Virtual Machine Backup	NA	Volume-base with Hypervisor to provide application-consistent backup	NA	NA

Protect MS SQL Overview

Perform the following steps in the Cohesity cluster to protect SQL Server:

1. Register the SQL Server you want to protect as a source with the Cohesity cluster. See Set Up Standalone Microsoft SQL Server or Microsoft SQL Server AGs or Set Up Microsoft SQL Server FCI.
2. Select **Dashboard** and from the drop-down, select **MS SQL**.
3. From the **Hosts** tab, you can protect all databases on a host. Select **Protect Databases** from the host's actions menu.

   From the **Databases** tab, you can protect a single database. Select **Protect** from the database's actions menu.

   You can change which objects you want to protect when creating the job.

You can also protect MS SQL by performing the following steps:

1. Navigate to **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then select **Databases** > **MS SQL Server**.
3. Select the objects to protect.

Create a File-based MS SQL Protection Group

Perform the following to create a file-based SQL Server Protection Group:

1. Navigate to **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then select **Databases** > **MS SQL Server**.
3. In the **New Protection** pop-up, do one of the following:
   - Protect MS SQL by specifying a subset of options such as objects, protection group and policy by clicking the edit icon corresponding to the following options:
     i. **Add Objects**: Select the registered MS SQL source or click Register Source to register an MS SQL source. Select the objects to protect.
     ii. **Protection Group**: Specify a name for the Protection Group.
     iii. **Policy**: Select an existing policy or click **Create Policy** to create a new protection policy.
     iv. **Storage Domain**: Select the appropriate storage domain.

     > **Note:** This option is visible on the **New Protection** pop-up only if there is more than one storage domain.

     v. **Backup Type**: From the drop-down, select **File-based**.
     vi. Click **Protect**.
   - To protect MS SQL by specifying all the options, click **More Options**.
4. **Source:** Select the objects to protect.

   Select the source objects to back up or exclude. By default, all objects in the source are excluded as indicated by the unselected check box. Expand the source objects and select the objects you want to include in the Protection Group. A selected check box ( ) indicates the object is selected to be backed up.

   > **Note:** If you have registered a physical server that is a part of the registered MS SQL Failover Cluster, then the MS SQL Failover Cluster Instance will not appear as a source in the object list of the registered physical server.

   If appropriate for your organization, enable Auto Protect.

   Click to turn on **Auto Protect**. By enabling this option:
   - All the SQL databases that are added to the SQL server in the future are automatically added to the Protection Group and are protected from the next

protection run.

- All the SQL databases that are removed from the SQL server in the future are automatically removed from the Protection Group and are not protected from the next protection run. The existing backup for the user is preserved until the snapshot expires.

For example, you create a Protection Group that backs up a SQL Server. The Protection Group runs for two weeks and then a new database is added to the SQL Server. The next time the Protection Group runs, if the object hierarchy has been refreshed on the Cohesity cluster, the new database is also backed up even though the new database has not been explicitly selected to be included in the Protection Group. The object hierarchy is automatically refreshed every four hours.

To manually refresh the object hierarchy, select **Data Protection > Sources**, find the source in the list and click .

Considerations

Consider the following when using the **Auto Protect** option on the backup job

- If new databases are added to the host, the existing filters are applied to the newly added databases. For example, if the exclude filter matches the newly added databases then these databases will be excluded in the backup job.
- If any system databases are excluded by the filters in an SQL server, it will exclude all the system databases belonging to that SQL server.
- When defining filters to exclude AG databases, ensure that the filters are configured on all the AG hosts. For example, to exclude an AG database and if the AG database has 4 hosts, then ensure that the filters are defined on all the four AG hosts.
- Auto protect functionality is supported only for physical SQL jobs (file-based and native)
- To selectively exclude a SQL database from the protection job, you must upgrade all the cluster nodes to version 6.5.1 and later.

If MS SQL belongs to an AG network, selecting that server displays options for protecting the AG.

- Select all servers that belong to this AG network.

> **Note:** If backing up VMs within an AG, protecting the AG databases requires that all servers within the AG are registered with the Cohesity cluster and are selected for protection. Otherwise AG databases are skipped and only local databases will be backed up. New servers added to AG are not automatically protected.

When using this option when there are multiple AGs, only interlinked AG nodes are automatically selected. For example:

- If there are AGs that use only Node1 and Node2 and other AGs that use Node3 and Node4, if you select Node2 as a source, only Node1 is added automatically.
- If AG1 uses Node1 and Node2, AG2 uses Node2 and Node4, AG3 uses Node3 and Node5. If you select Node2, then these nodes are selected: Node1, Node2 and Node4. Node3 and Node5 are not selected.

When adding nodes to an AG that is protected by Cohesity, ensure you register the node with Cohesity and add it to the Protection Group. Otherwise the AG databases will not be protected.

When removing nodes from an AG that is protected by Cohesity, you can remove it from the Protection Group or keep it; the AG databases remain protected in either case. If the removed node remains in the Protection Group, only its local databases are backed up. If you do not want to back up the removed node, you can safely remove it.

- Select only this server.

Click **Select**.

Click **Add**.

5. If appropriate, set options for specific objects by clicking (**Edit Server Options**) next to the object. A successful SQL log backup automatically truncates the SQL logs.
6. **Name:** Enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.

> **Note:** This page displays registered MS SQL objects only, so only MS SQL servers are selected regardless of the other servers within the source object hierarchy.

7. **Policy:** Select an existing protection policy or create a new one by selecting **New Policy**.
8. **Storage Domain:** Select an existing storage domain or create a new one by selecting **New Storage Domain**.

> **Note:** Once you create a Protection Group, you cannot change the Storage Domain you selected for that job.

The selected storage domain stores the snapshots and logs created by this Protection Group.

9. **Backup Method:** Select **File-based**. This method protects only the specific MS SQL databases that you select.
10. **Make Full Backup Copy-only:** Toggle on if you want full backups to be copy-only backups so they do not affect the differential base.

    Copy-only full backups do not take log backups even if they are scheduled by the policy.
11. **Log Chain Break Auto-Trigger Out of Band Incremental Backup:** When toggled ON, the out of band incremental backup will be triggered at the end of the log backup when the log chain is broken.

    If a scheduled backup is already running for the protection group, the out of band incremental backup will be triggered after the scheduled backup.
12. **New Database Auto-Trigger Out of Band Incremental Backup:** When toggled ON, the out of band incremental backup will be triggered at the end of the log backup when the new database is detected.

    If a scheduled backup is already running for the protection group, the out of band incremental backup will be triggered after the scheduled backup.
13. **User Databases:** Does not apply to file-based Protection Groups. Only selected databases are backed up.
14. **AG Backup Preferences:** Select this option if AG databases will be backed up.
    - **Use Server Preferences** uses MS SQL preferences.
    - **Override Preferences** enables you to override MS SQL's preferences with your selection.

    AAG replica preference for MS SQL backups

    Cohesity uses "replica priority" to select the best replica when more than one qualified replica matches the backup preference. For the following AAG Backup Preference settings, Cohesity uses replicas in the indicated order of preference to back up MS SQL databases:

Backup Preference Setting	Replica Used for MS SQL Backup
Prefer Secondary or Any	1. Sync Secondary Replica 2. Async Secondary Replica 3. Primary Replica
Secondary Only*	1. Sync Secondary Replica 2. Async Secondary Replica
Primary Only	1. Primary Replica

* If the AAG uses the **Secondary Only** Backup Preference setting, ensure the AAG replicas are set to "**Readable secondary**=**Yes**". If all replicas are set to "**Readable secondary**=**No**" with **Secondary Only** as the Backup Preference setting, then the backup of AAG databases fails with "*unavailable_for_vss*".

You can set the **Readable Secondary** field to **No** if the Backup Preference Setting is set to **Prefer Secondary or Any** or **Primary Only**.

> **Note:** You must apply the exclusion filter on each AAG replica to ensure the database is excluded when an SQL Server failover occurs.

15. **System Databases:** Does not apply to file-based Protection Groups. Only selected databases are backed up. When you select any system database, however, all system databases are selected automatically.
16. **Start Time:** Indicates when the Protection Group should run. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting.

    The default time zone is the browser's time zone. You can change the time zone by selecting a different time zone.
17. **End Date:** Optional. Toggle on and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
18. **QoS Policy:** Select an appropriate quality of service (QoS) policy.

    > **Note:** Cohesity recommends specifying **Backup HDD**, which is the default.

    - **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group.
    - **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups.
    - **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy.
    - **TestAndDev High:** The Cohesity cluster writes the data to an SSD drive for this Protection Group. The I/Os with this QoS policy are given higher priority compared to other QoS policies. Use this policy for workloads that require lower I/O latency.

19. **Cancel Runs at Quiet Time Start:** Available only if the selected policy has at least one quiet time period. Toggle it on to specify that all currently executing protection runs should abort if a quiet time period specified for the Protection Group starts. By default this toggle is off, which means after a protection run starts, it continues to execute even when a quiet time period specified for this protection run starts. However, a new protection run will not start during a quiet time period.
20. **Pre & Post Scripts:** Edit this option to run scripts on the protected server before and/or after a Protection Group runs. If configured, the scripts are run every time an object is backed up by a Protection Group run.

    For configuration details, see Configure Pre & Post Scripts.
21. **Indexing:** Indexing is enabled by default and required for file recovery. The Cohesity cluster will scan all the files in the Protection Group and create an internal index that can be used later by a recover task to locate files by name.

    For information about customizing indexing, see Customize Indexing.

    Indexing is not supported for file-based Protection Groups. Without indexing, file/folder-level recovery and searching are not supported.
22. **Alerts:** Optional. Select one or more of the following settings if you want alerts to be created for the following triggers:
    - **Success:** Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created.
    - **Failure:** Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created.
    - **SLA Violation:** Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created.

    For more information, see Alerts.
23. **Priority:** Select a priority for the Protection Group execution. Cohesity supports concurrent backups, but if the number of Protection Groups exceeds the ability to process them, those with **High** priority are given the highest priority to execute, **Medium** the second-highest priority, and **Low** the lowest priority.
24. **Email Recipients**: You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the Protection Group.

> **Note:**
> The connection to the SMTP Server must be enabled to send email notification. You can enable the SMTP Server connection in the configuration settings page (Cohesity UI > **Settings** > **Summary** > **Configure** > **Enable SMTP Server**).

25. **SLA:** The service-level agreement (SLA) defines the expected time to complete either a full backup or incremental backup. The backup completion time depends on the Windows volume size on AD, objects changed between incremental backups, network speed, and other Protection Groups running on the Cohesity cluster.
    - **Incremental:** Enter the number of minutes you expect an incremental protection run to complete. An incremental backup captures only the differences (changed blocks) since the last protection run.
    - **Full:** Enter the number of minutes you expect a full backup protection run to complete. A full backup captures the entire object (all blocks).
26. Click **Protect**.

    The Protection page is displayed and includes the new Protection Group.

Edit an MS SQL Protection Group

Perform the following to edit a SQL Server Protection Group:

1. Select **Data Protection > Protection**.
2. Locate the Protection Group you want to edit.
3. Mouse over the action icon (⋮) next to the Protection Group and select one of the following:
    1. **Run Now** - Start a run of this Protection Group. You have the option to back up one or more objects.
        1. **Backup all Objects in the Protection Group** - Select this option to backup all the databases in the protection group. Any databases excluded from the backup will not be included in the protection run.
        2. **Backup only Selected Objects in the Protection Group** - you can manually select the databases to be backed up at the Protection Group level.
           If the host (parent of the selected database) is already part of a previous run-now submitted, the backup will be queued until the previous run submitted is complete.

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

2. **Pause Future Runs**
    1. Select **Pause Future Runs** to stop new runs of this Protection Group from executing. However, if the Protection Group is currently executing a run, the current run continues to execute and only future runs of this Protection Group are paused.
    2. Select **Resume Future Runs** to restore the Protection Group to a running state. The runs resume as specified in the schedule defined in the policy associated with this Protection Group.
3. **Edit** - Edit the Protection Group settings of the protection group and click Protect.
4. **Delete** - Deletes the protection group.

4. Save the Protection Group settings by clicking **Protect**.

Backup Microsoft SQL Server (VDI-based)

This topic describes how to protect MS SQL with a VDI-based Protection Group.

MS SQL Protection Group Support

The following table describes supported job types for MS SQL running on physical servers and VMs.

	File-based Jobs	Volume-based Jobs	VDI-based Jobs	Both Job Types Using the Same Server but Protecting Distinct Databases
Physical MS SQL	Multiple file-based jobs protecting all or a subset of DBs	One volume-based job protecting all or a subset of DBs	Multiple VDI-based jobs protecting all or a subset of databases	Supported
SQL Server Virtual Machine Backup	NA	Volume-base with Hypervisor to provide application-consistent backup	NA	NA

Protect MS SQL Overview

Perform the following steps in the Cohesity cluster to protect SQL Server:

1. Register the SQL Server you want to protect as a source with the Cohesity cluster. See Set Up Standalone Microsoft SQL Server or Microsoft SQL Server AGs or Set Up Microsoft SQL Server FCI.
2. Select **Dashboard** and from the drop-down, select **MS SQL**.
3. From the **Hosts** tab, you can protect all databases on a host. Select **Protect Databases** from the host's actions menu.

   From the **Databases** tab, you can protect a single database. Select **Protect** from the database's actions menu.

   You can change which objects you want to protect when creating the job.

You can also protect MS SQL by performing the following steps:

1. Navigate to **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then select **Databases** > **MS SQL Server**.
3. Select the objects to protect.

Create a VDI-based MS SQL Protection Group

Perform the following to create a VDI-based SQL Server Protection Group:

1. Navigate to **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then select **Databases** > **MS SQL Server**.
3. In the **New Protection** pop-up, do one of the following:
   - Protect MS SQL by specifying a subset of options such as objects, protection group and policy by clicking the edit icon corresponding to the following options:
     i. **Add Objects**: Select the registered MS SQL source or click Register Source to register an MS SQL source. Select the objects to protect.
     ii. **Protection Group**: Specify a name for the Protection Group.
     iii. **Policy**: Select an existing policy or click **Create Policy** to create a new protection policy.
     iv. **Storage Domain**: Select the appropriate storage domain.

     > **Note:** This option is visible on the **New Protection** pop-up only if there is more than one storage domain.

     v. **Backup Type**: From the drop-down, select **VDI-based**.

vi. Click **Protect**.

- To protect MS SQL by specifying all the options, click **More Options**.

4. **Source:** Select the objects to protect.

   Select the source objects to back up or exclude. By default, all objects in the source are excluded as indicated by the unselected check box. Expand the source objects and select the objects you want to include in the Protection Group. A selected check box ( ) indicates the object is selected to be backed up.

   > **Note:** If you have registered a physical server that is a part of the registered MS SQL Failover Cluster, then the MS SQL Failover Cluster Instance will not appear as a source in the object list of the registered physical server.

   If appropriate for your organization, enable Auto Protect.

   Click to turn on **Auto Protect**. By enabling this option:

   - All the SQL databases that are added to the SQL server in the future are automatically added to the Protection Group and are protected from the next protection run.
   - All the SQL databases that are removed from the SQL server in the future are automatically removed from the Protection Group and are not protected from the next protection run. The existing backup for the user is preserved until the snapshot expires.

   For example, you create a Protection Group that backs up a SQL Server. The Protection Group runs for two weeks and then a new database is added to the SQL Server. The next time the Protection Group runs, if the object hierarchy has been refreshed on the Cohesity cluster, the new database is also backed up even though the new database has not been explicitly selected to be included in the Protection Group. The object hierarchy is automatically refreshed every four hours.

   To manually refresh the object hierarchy, select **Data Protection > Sources**, find the source in the list and click . To exclude an object from Auto Protect, click .

   - Indicates an Auto Protected object.
   - Use this option to exclude SQL databases from the protection group. Excluded objects are not protected. The icon indicates that an ancestor of the object is Auto Protected but this object is explicitly excluded.

To exclude a database from the protection group, specify the absolute path of the database to be excluded from the backup at a protection job level. You can optionally use:

- **Wildcard Exclusion** - You can optionally use the Wildcard * in any location in the search string to exclude all the matching databases from the backup at a protection job level.
- **Regex Exclusion** - You can use the RegEx string name match and manual user selection to exclude DBs from backup at a protection job level.

> **Note:** You can use the exclude SQL database feature only if Auto Protect is enabled for a backup job.

Protection of dismounted databases, recovery database types, and deleted databases are automatically skipped by the Protection Group.

After defining the filer click **Apply** to save the selection.

The following table lists the examples for excluding objects in an MS SQL database:

Sample Configuration		
10.2.157.20 (Host)		
*** SQL2012**	*** SQL2014**	*** MSSQLSERVER**
(SQL Server Instance)	(SQL Server Instance)	(SQL Server Instance)
- UserDB1	- UserDB3	- ProdDB1
- UserDB2	- UserDB4	- ProdDB2
- TestDB1	- TestDB3	
- TestDB2	- TestDB4	

Example of Absolute Path

- **10.2.157.20/SQL2012/UserDB1** - Excludes the database 'UserDB1' from the SQL server instance 'SQL2012' on the host 10.2.157.20.
- **10.2.157.20/SQL2012/** - Excludes the 'SQL2012' from the SQL server instance and its databases.

> **Note:** The absolute instance path must end with '/' and the plain text instance path must contain two or more slashes.

Example of Wildcard Exclusion

- **10.2.157.20/SQL2012/User*** - Excludes the databases 'UserDB1' and 'UserDB2' from the SQL server instance 'SQL2012' on the host 10.2.157.20.

Sample Configuration

- **10.2.157.20/SQL201?/*** - Excludes the SQL server instances 'SQL2012' and 'SQL2014' from the host 10.2.157.20.

Example of Regex Exclusion

10.2.157.20/SQL.*/.* - Excludes the SQL server instances 'SQL2012' and 'SQL2014' from the host 10.2.157.20.

Considerations

Consider the following when using the **Auto Protect** option on the backup job

- If new databases are added to the host, the existing filters are applied to the newly added databases. For example, if the exclude filter matches the newly added databases then these databases will be excluded in the backup job.
- If any system databases are excluded by the filters in an SQL server, it will exclude all the system databases belonging to that SQL server.
- When defining filters to exclude AG databases, ensure that the filters are configured on all the AG hosts. For example, to exclude an AG database and if the AG database has 4 hosts, then ensure that the filters are defined on all the four AG hosts.
- Auto protect functionality is supported only for physical SQL jobs (file-based and native)
- To selectively exclude a SQL database from the protection job, you must upgrade all the cluster nodes to version 6.5.1 and later.

If MS SQL belongs to an AG network, selecting that server displays options for protecting the AG.

- Select all servers that belong to this AG network.

  > **Note:** If backing up VMs within an AG, protecting the AG databases requires that all servers within the AG are registered with the Cohesity cluster and are selected for protection. Otherwise AG databases are skipped and only local databases will be backed up. New servers added to AG are not automatically protected.

  When using this option when there are multiple AGs, only interlinked AG nodes are automatically selected. For example:

  - If there are AGs that use only Node1 and Node2 and other AGs that use Node3 and Node4, if you select Node2 as a source, only Node1 is added automatically.

- If AG1 uses Node1 and Node2, AG2 uses Node2 and Node4, AG3 uses Node3 and Node5. If you select Node2, then these nodes are selected: Node1, Node2 and Node4. Node3 and Node5 are not selected.

When adding nodes to an AG that is protected by Cohesity, ensure you register the node with Cohesity and add it to the Protection Group. Otherwise the AG databases will not be protected.

When removing nodes from an AG that is protected by Cohesity, you can remove it from the Protection Group or keep it; the AG databases remain protected in either case. If the removed node remains in the Protection Group, only its local databases are backed up. If you do not want to back up the removed node, you can safely remove it.

- Select only this server.

Click **Select**.

Click **Add**.

5. If appropriate, set options for specific objects by clicking (**Edit Server Options**) next to the object. A successful SQL log backup automatically truncates the SQL logs.
6. **Name:** Enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.

> **Note:** This page displays registered MS SQL objects only, so only MS SQL servers are selected regardless of the other servers within the source object hierarchy.

7. **Policy:** Select an existing protection policy or create a new one by selecting **New Policy**. Cohesity recommends you schedule periodic full backups for MS SQL VDI-based protection. For more information, see Create or Edit a Standard Policy.

   Storage Domain: Select an existing storage domain or create a new one by selecting **New Storage Domain**.

> **Note:** Once you create a Protection Group, you cannot change the Storage Domain you selected for that job.

   The selected storage domain stores the snapshots and logs created by this Protection Group.
8. **Backup Method:** Select **VDI-based**. This method protects only the specific MS SQL databases that you select.

9. **WITH Clause:** Define the With clause that you want to use to customize the backup. For more information, see BACKUP (Transact-SQL).
10. **Number of Streams:** Define the number of Cohesity nodes that will be used for the backup process. Using multiple nodes provides more throughput for the backup process.
11. **Log Chain Break Auto-Trigger Out of Band Incremental Backup:** When toggled ON, the out of band incremental backup will be triggered at the end of the log backup when the log chain is broken.

    If a scheduled backup is already running for the protection group, the out of band incremental backup will be triggered after the scheduled backup.
12. **New Database Auto-Trigger Out of Band Incremental Backup:** When toggled ON, the out of band incremental backup will be triggered at the end of the log backup when the new database is detected.

    If a scheduled backup is already running for the protection group, the out of band incremental backup will be triggered after the scheduled backup.
13. **Make Full Backup Copy-only:** Toggle on if you want full backups to be copy-only backups so they do not affect the differential base.

    Copy-only full backups do not take log backups even if they are scheduled by the policy.
14. **User Databases:** Select how to handle AG databases during the backup.
15. **AG Backup Preferences:** Select this option if AG databases will be backed up.
    - **Use Server Preferences** uses MS SQL preferences.
    - **Override Preferences** enables you to override MS SQL's preferences with your selection.

    AAG replica preference for MS SQL backups

    Cohesity uses "replica priority" to select the best replica when more than one qualified replica matches the backup preference. For the following AAG Backup Preference settings, Cohesity uses replicas in the indicated order of preference to back up MS SQL databases:

Backup Preference Setting	Replica Used for MS SQL Backup
Prefer Secondary or Any	1. Sync Secondary Replica 2. Async Secondary Replica 3. Primary Replica

Backup Preference Setting	Replica Used for MS SQL Backup
Secondary Only*	1. Sync Secondary Replica 2. Async Secondary Replica
Primary Only	1. Primary Replica

* If the AAG uses the **Secondary Only** Backup Preference setting, ensure the AAG replicas are set to "**Readable secondary**=**Yes**". If all replicas are set to "**Readable secondary**=**No**" with **Secondary Only** as the Backup Preference setting, then the backup of AAG databases fails with "*unavailable_for_vss*".

You can set the **Readable Secondary** field to **No** if the Backup Preference Setting is set to **Prefer Secondary or Any** or **Primary Only**.

> **Note:** You must apply the exclusion filter on each AAG replica to ensure the database is excluded when an SQL Server failover occurs.

> **Note:** AG secondary replicas do not support regular full backups, and differential backups. If the policy is configured to take regular full backups, or differential backups, then select override preferences to backup only from the primary replica. All other AG backup preferences are only available if the policy is configured to take copy-only full backups, and log backups. Incremental backups are not supported on the AG secondary nodes. For more details, see Backup Types Supported on Secondary Replicas.

16. **System Databases:** Does not apply to VDI-based Protection Groups. Only selected databases are backed up. When you select any system database, however, all system databases are selected automatically.
17. **Start Time:** Indicates when the Protection Group should run. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting.

    The default time zone is the browser's time zone. You can change the time zone by selecting a different time zone.
18. **End Date:** Optional. Toggle on and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
19. **QoS Policy:** Select an appropriate quality of service (QoS) policy.

> **Note:** Cohesity recommends specifying **Backup HDD**, which is the default.

- **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group.
- **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups.
- **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy.
- **TestAndDev High:** The Cohesity cluster writes the data to an SSD drive for this Protection Group. The I/Os with this QoS policy are given higher priority compared to other QoS policies. Use this policy for workloads that require lower I/O latency.

20. **Cancel Runs at Quiet Time Start:** Available only if the selected policy has at least one quiet time period. Toggle it on to specify that all currently executing protection runs should abort if a quiet time period specified for the Protection Group starts. By default this toggle is off, which means after a protection run starts, it continues to execute even when a quiet time period specified for this protection run starts. However, a new protection run will not start during a quiet time period.
21. **Pre & Post Scripts:** Edit this option to run scripts on the protected server before and/or after a Protection Group runs. If configured, the scripts are run every time an object is backed up by a Protection Group run.

    For configuration details, see Configure Pre & Post Scripts.
22. **Indexing:** Indexing is enabled by default and required for file recovery. The Cohesity cluster will scan all the files in the Protection Group and create an internal index that can be used later by a recover task to locate files by name.

    For information about customizing indexing, see Customize Indexing.

    Indexing is not supported for VDI-based Protection Groups. Without indexing, file/folder-level recovery and searching are not supported.
23. **Alerts:** Optional. Select one or more of the following settings if you want alerts to be created for the following triggers:
    - **Success:** Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created.
    - **Failure:** Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created.

- **SLA Violation:** Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created.

For more information, see Alerts.

24. **Priority:** Select a priority for the Protection Group execution. Cohesity supports concurrent backups, but if the number of Protection Groups exceeds the ability to process them, those with **High** priority are given the highest priority to execute, **Medium** the second-highest priority, and **Low** the lowest priority.
25. **Email Recipients**: You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the Protection Group.

> **Note:**
> The connection to the SMTP Server must be enabled to send email notification. You can enable the SMTP Server connection in the configuration settings page (Cohesity UI > **Settings** > **Summary** > **Configure** > **Enable SMTP Server**).

26. **SLA:** The service-level agreement (SLA) defines the expected time to complete either a full backup or incremental backup. The backup completion time depends on the Windows volume size on AD, objects changed between incremental backups, network speed, and other Protection Groups running on the Cohesity cluster.
    - **Incremental:** Enter the number of minutes you expect an incremental protection run to complete. An incremental backup captures only the differences (changed blocks) since the last protection run.
    - **Full:** Enter the number of minutes you expect a full backup protection run to complete. A full backup captures the entire object (all blocks).
27. Click **Protect**.

    The Protection page is displayed and includes the new Protection Group.

Edit an MS SQL Protection Group

Perform the following to edit a SQL Server Protection Group:

1. Select **Data Protection > Protection**.
2. Locate the Protection Group you want to edit.
3. Mouse over the action icon (⋮) next to the Protection Group and select one of the following:
    1. **Run Now** - Start a run of this Protection Group. You have the option to back up one or more objects.

1. **Backup all Objects in the Protection Group** - Select this option to backup all the databases in the protection group. Any databases excluded from the backup will not be included in the protection run.
2. **Backup only Selected Objects in the Protection Group** - you can manually select the check box for the databases to be backed up at the Protection Group level.
   This backup of the selected database runs in parallel with the existing run-now request. However, if a subset of the selected database includes a run-now/scheduled backup already active, these databases will be skipped from the run-now being submitted.

   > **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

2. **Pause Future Runs**
   1. Select **Pause Future Runs** to stop new runs of this Protection Group from executing. However, if the Protection Group is currently executing a run, the current run continues to execute and only future runs of this Protection Group are paused.
   2. Select **Resume Future Runs** to restore the Protection Group to a running state. The runs resume as specified in the schedule defined in the policy associated with this Protection Group.
3. **Edit** - Edit the Protection Group settings of the protection group and click Protect.
4. **Delete** - Deletes the protection group.
   Delete only the protection group and keep the snapshots or delete the snapshots also.

4. Save the Protection Group settings by clicking **Protect**.

Backup Microsoft SQL Server FILESTREAM Databases

This topic describes how to protect MS SQL FILESTREAM databases.

MS SQL Protection Group Support

The following table describes supported job types for MS SQL running on physical servers and VMs.

	File-based Jobs	VDI-based Jobs	Both Job Types Using the Same Server but Protecting Distinct Databases
Physical MS SQL	Not supported	Multiple VDI-based jobs protecting all or a subset of databases	Supported
VM MS SQL	Not supported	Not supported	Not supported

> **Note:** Protecting a FILESTREAM database (in general and not specific to memory-optimized) is performed only using VDI-based backup.

Protect MS SQL Overview

Perform the following steps in the Cohesity cluster to protect SQL Server:

1. Register the SQL Server you want to protect as a source with the Cohesity cluster. See Set Up Standalone Microsoft SQL Server or Microsoft SQL Server AGs or Set Up Microsoft SQL Server FCI.
2. Select **Dashboard** and from the drop-down, select **MS SQL**.
3. From the **Hosts** tab, you can protect all databases on a host. Select **Protect Databases** from the host's actions menu.

   From the **Databases** tab, you can protect a single database. Select **Protect** from the database's actions menu.

   You can change which objects you want to protect when creating the job.

You can also protect MS SQL by performing the following steps:

1. Navigate to **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then select **Databases** > **MS SQL Server**.
3. Select the objects to protect.

Create an MS SQL Protection Group

1. **Name:** Enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.

   > **Note:** This page displays registered MS SQL objects only, so only SQL servers are selected regardless of the other servers within the source object hierarchy.

2. **Source:** Select the objects to protect.

   Select the source objects to back up or exclude. By default, all objects in the source are excluded as indicated by the unselected check box. Expand the source objects and select the objects you want to include in the Protection Group. A selected check box ( ) indicates the object is selected to be backed up.

   If MS SQL belongs to an AG network, selecting that server displays options for protecting the AG.

   - Select all servers that belong to this AG network.

     > **Note:** If backing up VMs within an AG, protecting the AG databases requires that all servers within the AG are registered with the Cohesity cluster and are selected for protection. Otherwise AG databases are skipped and only local databases will be backed up. New servers added to AG are not automatically protected.

     When using this option when there are multiple AGs, only interlinked AG nodes are automatically selected. For example:

     - If there are AGs that use only Node1 and Node2 and other AGs that use Node3 and Node4, if you select Node2 as a source, only Node1 is added automatically.
     - If AG1 uses Node1 and Node2, AG2 uses Node2 and Node4, AG3 uses Node3 and Node5. If you select Node2, then these nodes are selected: Node1, Node2 and Node4. Node3 and Node5 are not selected.

     When adding nodes to an AG that is protected by Cohesity, ensure you register the node with Cohesity and add it to the Protection Group. Otherwise the AG databases will not be protected.

     When removing nodes from an AG that is protected by Cohesity, you can remove it from the Protection Group or keep it in the job; the AG databases remain protected in either case. If the removed node remains in the Protection Group, only its local databases are backed up. If you do not want to back up the removed node, you can safely remove it.

   - Select only this server.

   Click **Select**.

   Click **Add**.

3. If appropriate, set options for specific objects by clicking (**Edit Server Options**) next to the object. A successful SQL log backup automatically truncates the SQL logs.

4. **Policy:** Select an existing protection policy or create a new one by selecting **New Policy**.

   Storage Domain: Select an existing storage domain or create a new one by selecting **New Storage Domain**.

   > **Note:** Once you create a Protection Group, you cannot change the Storage Domain you selected for that job.

   The selected storage domain stores the snapshots and logs created by this Protection Group.
5. **Backup Method:** Select **VDI-based**. VDI-based jobs can backup FILESTREAM databases.
6. **Make Full Backup Copy-only:** Ensure this is toggled off to ensure log backups are taken for FILESTREAM databases.
7. **User Databases:** Select how to handle AG databases during backup.
8. **System Databases:** Select whether to back up or skip system databases.
9. **Start Time:** Indicates when the Protection Group should run. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting.

   The default time zone is the browser's time zone. You can change the time zone by selecting a different time zone.
10. **End Date:** Optional. Toggle on and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
11. **QoS Policy:** Select an appropriate quality of service (QoS) policy.

    > **Note:** Cohesity recommends specifying **Backup HDD**, which is the default.

    - **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group.
    - **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups.
    - **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy.

- **TestAndDev High:** The Cohesity cluster writes the data to an SSD drive for this Protection Group. The I/Os with this QoS policy are given higher priority compared to other QoS policies. Use this policy for workloads that require lower I/O latency.

12. **Cancel Runs at Quiet Time Start:** Available only if the selected policy has at least one quiet time period. Toggle it on to specify that all currently executing protection runs should abort if a quiet time period specified for the Protection Group starts. By default this toggle is off, which means after a protection run starts, it continues to execute even when a quiet time period specified for this protection run starts. However, a new protection run will not start during a quiet time period.
13. **Pre & Post Scripts:** Edit this option to run scripts on the protected server before and/or after a Protection Group runs. If configured, the scripts are run every time an object is backed up by a Protection Group run.

    For configuration details, see Configure Pre & Post Scripts.
14. **Indexing:** Indexing is enabled by default and required for file recovery. The Cohesity cluster will scan all the files in the Protection Group and create an internal index that can be used later by a recover task to locate files by name.

    For information about customizing indexing, see Customize Indexing.
15. **Alerts:** Optional. Select one or more of the following settings if you want alerts to be created for the following triggers:
    - **Success:** Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created.
    - **Failure:** Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created.
    - **SLA Violation:** Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created.

    For more information, see Alerts.
16. **Priority:** Select a priority for the Protection Group execution. Cohesity supports concurrent backups, but if the number of Protection Groups exceeds the ability to process them, those with **High** priority are given the highest priority to execute, **Medium** the second-highest priority, and **Low** the lowest priority.
17. **Email Recipients**: You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the Protection Group.

> **Note:**
> The connection to the SMTP Server must be enabled to send email notification. You can enable the SMTP Server connection in the configuration settings page (Cohesity UI > **Settings** > **Summary** > **Configure** > **Enable SMTP Server**).

18. **SLA:** The service-level agreement (SLA) defines the expected time to complete either a full backup or incremental backup. The backup completion time depends on the Windows volume size on AD, objects changed between incremental backups, network speed, and other Protection Groups running on the Cohesity cluster.
    - **Incremental:** Enter the number of minutes you expect an incremental protection run to complete. An incremental backup captures only the differences (changed blocks) since the last protection run.
    - **Full:** Enter the number of minutes you expect a full backup protection run to complete. A full backup captures the entire object (all blocks).
19. Click **Protect**.

    The Protection page is displayed and includes the new Protection Group.

Edit an MS SQL Protection Group

1. Select **Data Protection > Protection**.
2. Locate the Protection Group you want to edit.
3. Mouse over the action icon (⋮) next to the job and select one of the following:
    1. **Run Now** - Start a run of this Protection Group. You have the option to back up one or more objects.
        1. **Backup all Objects in the Protection Group** - Select this option to backup all the databases in the protection group. Any databases excluded from the backup will not be included in the protection job run.
        2. **Backup only Selected Objects in the Protection Group** - you can manually select the databases to be backed up at the protection job level. However, the selection of the database that is excluded at the backup job level is not supported.

    You can run log backups in parallel with existing log backup runs. This helps reduce storage buildup on the primary SQL Server when multiple large backups are in progress.

    This feature is supported only for file-based, VDI-based, and Filestream (backed up using VDI-based method) backups.

> **Note:** When you run a log backup for a database backup job, any preceding backup job for the same database may skip the log backup if the new backup job is completed before the previous backup job for the database is started.

2. **Pause Future Runs**
    1. Select **Pause Future Runs** to stop new runs of this Protection Group from executing. However, if the job is currently executing a run, the current run continues to execute and only future runs of this job are paused.
    2. Select **Resume Future Runs** to restore the Protection Group to a running state. The runs resume as specified in the schedule defined in the policy associated with this job.
3. **Edit** - Edit job settings of the protection group and click Protect.
4. **Delete** - Deletes the protection group.

4. Save the job settings by clicking **Protect**.

Configure Microsoft SQL Server T-log Backup

Cohesity enhances the SQL Server T-log backup and restoration performance by splitting the T-log backup into multiple backup files and ingesting them in parallel through the Cohesity nodes.

This feature is applicable for File-based and VDI-based backups.

Follow the below steps to configure the T-log backup settings for a Protection Group:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. Click **Protect > Databases > MS SQL Server**.
3. Click **Objects** and select the required objects to be protected.
4. In the **Policy** drop-down list, select a policy that includes Log Backup (Database). The **Log Backup Settings** option will be enabled.
5. Optionally configure the following details:
    - **WITH Clause**: Define the WITH clause that you want to use to customize the backup. For more information, see BACKUP (Transact-SQL). The default WITH clause is "*WITH MAXTRANSFERSIZE = 4194304, BUFFERCOUNT = 16*".

> **Important:** The WITH clause text box allows you to invoke the SQL Server general options during backups and restores. The text field accepts any SQL Server general backup or restore option like "ENCRYPTION". Note that specifying an option could add to the overall duration of the backup or restore process.

- **Number of Streams**: Define the number of Cohesity nodes that will be used for the backup process. Using multiple nodes provides more throughput for the backup process. The default number of streams is *1*.

  For details on other settings, see Backup Microsoft SQL Server (VDI-based).

6. Click **Protect**.

> **Note:**
> - Ensure that the agents pre-installed on the SQL VMware source are upgraded to the latest version.
> - If a replication job is configured for the SQL VMware log backup, ensure that the replication cluster is upgraded to the latest version to enable seamless recovery.

Requirements

Ensure the following requirements are met for using SQL log backups:

- The Cohesity cluster's VIPs on **port 11117** must be reachable from the SQL source.
- In a multi-tenant environment, the Hybrid Extender IPs on **port 11117** must be reachable from the SQL source.

> **Note:** If the required port is unreachable, the log backup will fail to start, especially after upgrading from a version lower than 7.2.

Recover Amazon RDS Custom for SQL Server

Cohesity provides the ability to recover the MS SQL databases protected by a Protection Group.

- Recover Microsoft SQL Server Database Over the Original Database.
- Recover Microsoft SQL Server Database as a New Database in the Original Microsoft SQL Server Instance.

- Recover Microsoft SQL Server Database as a New Database in an Alternate Microsoft SQL Server Instance.

Prerequisites

- Before you can restore MS SQL databases, a full backup must exist.
- Cohesity cluster VIPs must be reachable (DNS) and accessible (Ping) from the target MS SQL server.
- For recovery, the server and the cluster must be on the same VLAN.

The following topics provide guidance to help you restore MS SQL databases:

About Restoring Microsoft SQL Server Databases

A restore task copies a database from the backup copy and optionally applies transaction logs depending on the options you choose. Cohesity provides the ability to restore individual databases to a specific point in time.

The following options are supported when restoring an individual database:

- Restore to the original MS SQL server and original instance and overwrite the database.
- Restore to the original MS SQL server and original instance and rename the database.
- Restore to the original MS SQL server and an alternate instance as a specified database name.
- Restore to an alternate MS SQL server and instance as a specified database name.

Restoring physical server to physical server only is supported.

MS SQL DB Restore Example

The following example depicts restoring an individual MS SQL database running on a physical server to its original location and overwriting the existing database. The example assumes the following about the database:

- Failure has already occurred.
- Its MS SQL server is registered as MS SQL on the cluster.
- It was backed up by a Cohesity Protection Group that includes transaction logs.

The action steps in the following procedure are represented in the figure below with blue numbered time squares:

.

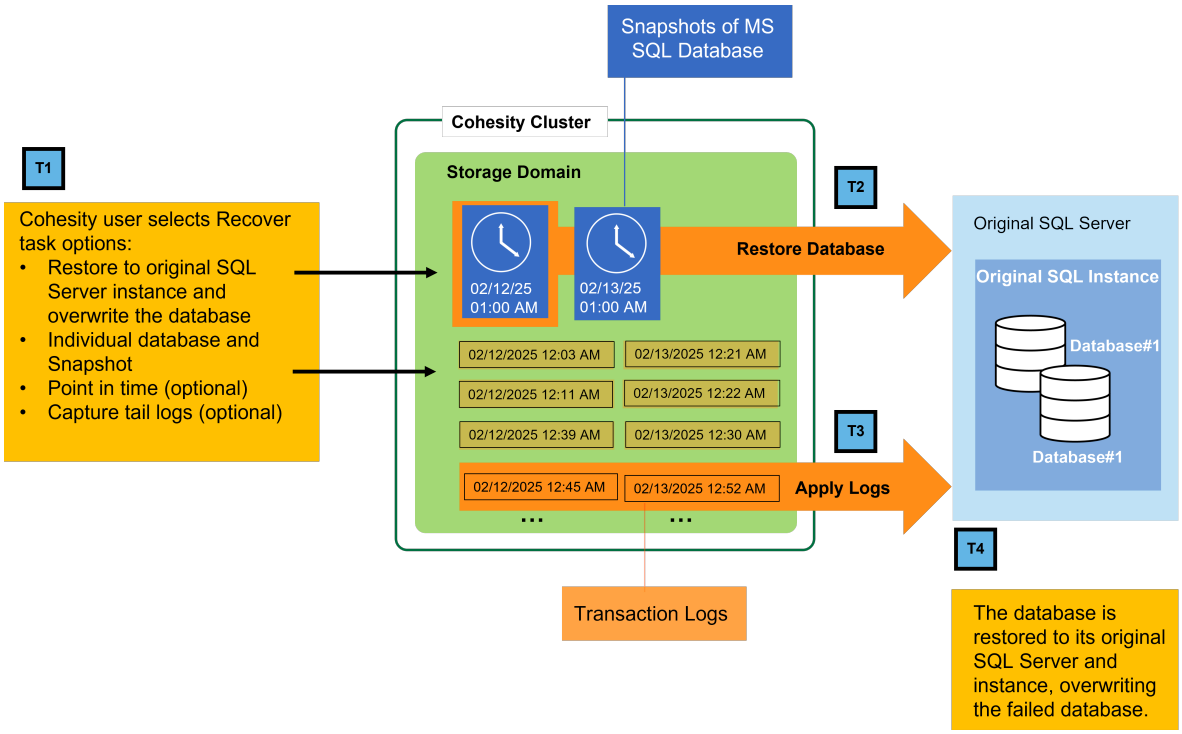
T1) The Cohesity user must select the following task options:
- Restore to the original SQL server and instance and overwrite the database
- An MS SQL database and snapshot

- Point in time (optional)
- Capture tail logs (optional)

T2) The Cohesity cluster copies the database files from the specified snapshot to the original location.

T3) If applicable, transaction logs are applied to the database for the specified point in time.

T4) The database is then brought online.



Resume MS SQL Database Recovery After Failure

You can resume a failed MS SQL Database recovery for databases in the following scenarios:

- If the databases are recovered using the WITH NORECOVERY option
- If the previous restore operation failed and the database remains in the restoring state.

This feature improves the RTO for database restore operations and is applicable only for point-in-time (PIT) restore operations.

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

Recover Microsoft SQL Server System Databases

System databases can be restored in case of system failures. The system databases are restored from the same instance and location where the system databases were backed up. You can also overwrite the existing system database files.

> **Note:**
> Restoring system databases to a different instance is not supported for the VM-based backup method.

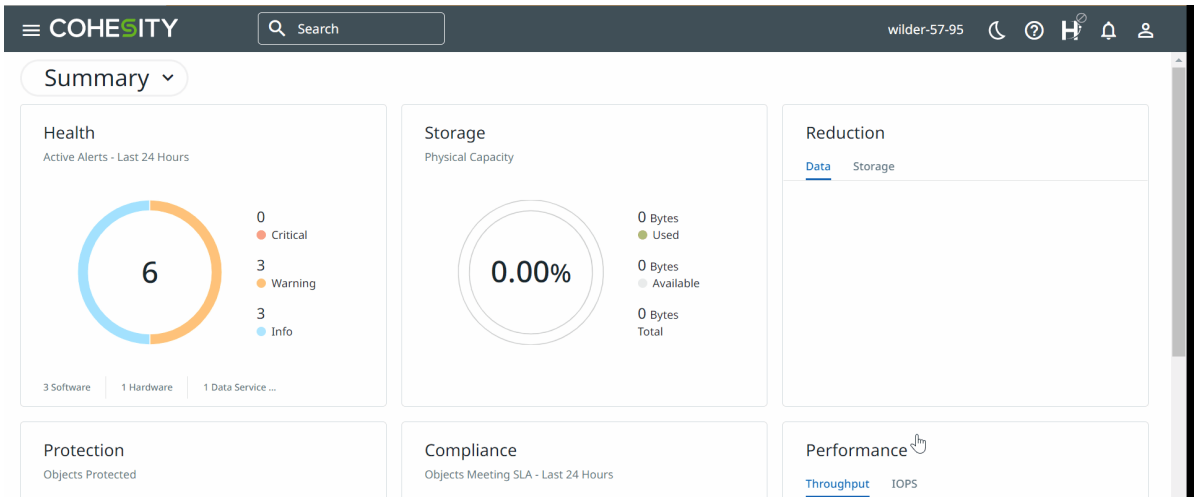
The SQL Server system databases are recovered in the following order:

1. Master
2. MSDB
3. Model

Recovery Workflow

You can recover the system databases to the original SQL Server instance.

The following animated image shows how to recover the system databases to the original server instance:



For the detailed steps on recovering system databases, see:

- Recover Microsoft SQL Server Database Over the Original Database

Consideration

- Recovering the system database to an alternate instance is not supported.
- When recovering to the original database, the original database is deleted before the recovery. Therefore, a recovery failure will also lead to the loss of the original

database.

- If you are recovering the system databases individually, then the recovery of the system database must be in the following order:
  1. Master
  2. MSDB
  3. Model
- You cannot recover a system database along with a user database.
- If you are recovering more than one system database in a recovery task, then the recovery point for the selected system databases must be the same.

Recover Microsoft SQL Server Database Over the Original Database

Recovering an MS SQL database over the original database overwrites the original database. The recovered database will have the original database name.

> **Note:** The original database is deleted before the recovery. Therefore a recovery failure will also lead to the loss of the original database.

To recover the database to the original database:

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Click **Recover** located at the top right of the page and then select **Databases** > **MS SQL**.

   The Restore SQL page appears.
3. Search for the databases you want to recover from by entering the characters of the database name, Protection Group name, or by specifying the wildcard character *.

   A list of databases is displayed with details like Cohesity Cluster, Protection Group, Physical Server, and Create Date. The Create Date option indicates the date and timestamp when the database was created.

   > **Note:** Operations like rename may update the creation date at the SQL Server.
4. From the list of search results, select one or more databases you want to recover. You can select multiple MS SQL databases only if they are protected by the same protection group.

> **Note:** The option to select multiple databases in a recovery task is an Early Access feature. Contact Cohesity Support for enabling this feature.

By default, the latest recovery point is selected. To select a different recovery point, from the selected lists, mouse over the recovery point, and then click the edit icon.

The Edit recovery point for <database_name> page appears.

By default, the option to select the recovery point is displayed in **Timeline** mode. You can also choose to view the option in **List** mode by clicking the **List** tab in the top-right corner of the page. The **Timeline** mode displays the full backups (recovery points) captured at the scheduled time and the CDP-based data available for point-in-time restore. The **List** tab displays only the full backups captured at a scheduled time.

- To select a recovery point from the Timeline mode:
    a. From the **Choose a date** drop-down, select a date.

       The recovery points available on the selected date are displayed in blue dots on the timeline bar and the point-in-time for restore is displayed in a solid green line on the timeline bar.
    b. To recover from a full backup, click the corresponding blue dot. For point-in-time restore, specify the exact point-in-time recovery by sliding the timeline bar.
    c. By default, the data is recovered from the local cluster. You can also select a recovery point archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.
    d. Click **Select Recovery Point** and then go to step 5.
- To select a recovery point from the List mode:
    a. Select the **List** tab from the top-right corner of the Edit recovery point for <database_name> page.

       By default, the page displays the recovery points available for the last 30 days.
    b. You can also select a recovery point from a different date range by selecting the date range from the Date drop-down list. The page displays the available recovery points in the specified range.
    c. Select the recovery points to be recovered.
    d. By default, the data is recovered from the local cluster. You can also select a recovery point archived to the cloud by clicking the cloud (

) icon if available in the **Location** option.

e. Click **Select Recovery Point** and then go to step 5.

5. Click **Next: Recover Options**.
6. From the **Targets** option, select **Overwrite Original Database** to recover the database to the original location.

> **Note:** The original database is deleted before the recovery. Therefore a recovery failure will also lead to the loss of the original database.

7. Specify the following **Recovery Options**:

Recovery Options	Description
VDI Restore Settings	Enable this option to specify the WITH clause that you want to use for the restore. **Note:** • This option is available only for restoring the databases that are protected using Protect MS SQL (VDI-based). • This option is not available for system database restore.
Keep CDC	Enable this option to restore a protected database that has the change data capture (CDC) enabled. If the protected database is not CDC enabled and the user tries to restore it with Keep CDC then, the database will be restored without CDC. **Note:** • This option is available only if the database is restored with recovery. • This option is not available for system database restore.
Cluster Interface	By default, the **Auto Select** option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the **Interface Grou**p drop-down.
Task Name	Change the default name of the recovery task.

Recovery Options	Description
Capture Tail Logs	Enable this option to capture records that have not yet been protected. They are captured to ensure all transactions are protected before restoring the database. **Note:** This option is not available for system database restore.

8. Click **Start Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Microsoft SQL Server VDI-based Recovery Recommendations

The Virtual Device Interface (VDI) is a Microsoft interface that allows the Cohesity agent to execute SQL Server Native backup and restore commands. This backup type produces a standard SQL Server Native backup of type (.BAK), transaction logs, (.TRN), and differentials, (.DIFF). These backup files are stored on a Cohesity View and take advantage of View compression, deduplication, encryption, replication, and archiving features.

The aim of the SQL DBA is to have a combination of backups so that the database can be restored to any point in time. A good combination of backups consists of having a full backup, differential (in Cohesity, incremental) backups, and log backups. For example, all SQL database restores must begin with a full database backup, secondly, a differential can then be applied to the full, and finally, log backups can be applied in sequence to complete the database restore.

When the backups are applied during the database restore process, you are sequentially adding the captured changes to the database: FULL+DIFF+Log1+Log2+Log3 = Restored Database.

All Microsoft VDI backups, their differentials, and their logs are dependent on a full backup to perform a database restore. Microsoft requires that in order to restore a SQL database, you must start with a full backup, then its transaction logs can be applied. This means your backup retention policy must keep a full backup along with its log backups in order to successfully restore a database.

Simply put, a SQL VDI-based database restore requires a full backup to seed the database, then differential and/or log backups are applied to the specified point in time.

We recommend retaining two sets of full backups with their differential and log backups.

> **Note:** A good backup plan always includes a combination of full, differential, and log backups.

Recover Microsoft SQL Server Database as a New Database in the Original Microsoft SQL Server Instance

To recover the database as a new database in the original MS SQL server instance:

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Click **Recover** located at the top right of the page and then select **Databases** > **MS SQL**.

   The Restore SQL page appears.
3. Search for the databases you want to recover from by entering characters of the database name, Protection Group name, or by specifying the wildcard character *. A list of databases is displayed with details like Cohesity Cluster, Protection Group, Physical Server, and Create Date. The Create Date option indicates the date and timestamp when the database was created.

   > **Note:** Operations like rename may update the creation date at the SQL Server.
4. From the list of search results, select one or more databases you want to recover. You can select multiple MS SQL databases only if they are protected by the same protection group.

   > **Note:** The option to select multiple databases in a recovery task is an Early Access feature. Contact Cohesity Support for enabling this feature.

   By default, the latest recovery point is selected. To select a different recovery point, from the selected lists, mouse over the recovery point, and then click the edit icon.

   The Edit recovery point for <database_name> page appears.

   By default, the option to select the recovery point is displayed in **Timeline** mode. You can also choose to view the option in **List** mode by clicking the **List** tab in the top-right corner of the page. The **Timeline** mode displays the full backups (recovery points) captured at the scheduled time and the CDP-based data available for point-in-time restore. The **List** tab displays only the full backups captured at a scheduled time.

   - To select a recovery point from the Timeline mode:
     a. From the **Choose a date** drop-down, select a date.

        The recovery points available on the selected date are displayed in blue dots on the timeline bar and the point-in-time for restore is displayed in a solid green line on the timeline bar.

     b. To recover from a full backup, click the corresponding blue dot. For point-in-time restore, specify the exact point-in-time recovery by sliding the timeline bar.

     c. By default, the data is recovered from the local cluster. You can also select a recovery point archived to the cloud by clicking the cloud (

) icon if available in the **Location** option.

d. Click **Select Recovery Point** and then go to step 5.

- To select a recovery point from the List mode:

a. Select the **List** tab from the top-right corner of the Edit recovery point for <database_name> page.

By default, the page displays the recovery points available for the last 30 days.

b. You can also select a recovery point from a different date range by selecting the date range from the Date drop-down list. The page displays the available recovery points in the specified range.

c. Select the recovery points to be recovered.

d. By default, the data is recovered from the local cluster. You can also select a recovery point archived to the cloud by clicking the cloud (

) icon if available in the **Location** option.

e. Click **Select Recovery Point** and then go to step 5.

5. Click **Next: Recover Options**.
6. From the **Targets** option, select **Recover as a new Database** to recover the database as a new database.
7. Enable the **Restore to Original SQL Server Instance** option to restore the database in the original MS SQL Server instance.
8. In the **Data Files** field, specify the path to an existing directory. The newly created database files will reside in this path.

> **Note:** If the database file names to be restored have a conflict with the existing database files of the database to which files are restored, then Cohesity resolves the conflict by appending a number to the file names.

9. In the **Log Files** field, provide the full path location to which the log files can be restored.
10. (Optional) Click **Add File Path Rules** to add custom rules for the data files.

    You can provide a full path or pattern for the original files and a location to restore to. When providing a location, use the standard path format. For example, use C:\path for Windows instead of the extended path format \\?\c:\path.

    Accept the file patterns and examples:

- Wildcard character used for file matching such as *
  - **.ndf* - All ndf files. Useful if you want every ndf file to go to the same folder
  - *m:*.ndf* - Every ndf file on drive m:
  - *c:*1.ndf* - Every ndf file on drive c: that contains 1.ndf
- Regex pattern
  - *.*\.ndf* - All files with the ndf extension
  - *^.*foo1.*\.ndf$* - All files with the word foo1 and the extension ndf
- Full path to a source database file

Database files that have non-default file extensions or that do not match a specified filename or pattern are restored to the data file restore location.

Click **Add File Path Rule** to add multiple custom rules.

11. Specify the following **Recovery Options**:

Recovery Options	Description
Rename	Select one of the following options: • **Bulk Rename**: Select this option if you want to rename the restored databases in bulk. You can specify a string in the **Suffix** field. The restored databases will be renamed by adding this suffix string with the original database names. • **Rename Individual Objects**: Select this option if you want to individually rename the restored databases. You can specify the new name of the databases in the **New Name** field.
WITH RECOVERY	Disable the option to perform a restore WITH NO RECOVERY (the database will be offline when restored). By default, this option is enabled and the database is restored with recovery (the database will be online when restored).
VDI Restore Settings	Enable this option to specify the WITH clause that you want to use for the restore. **Note:** This option is available only for restoring the databases that are protected using Backup Microsoft SQL Server (VDI-based).

Recovery Options	Description
Keep CDC	Enable this option to restore a protected database that has the change data capture (CDC) enabled. If the protected database is not CDC enabled and the user tries to restore it with Keep CDC then, the database will be restored without CDC. **Note:** This option is available only if the database is restored with recovery.
Overwrite Alternate Database	Enable this option to recover the database by overwriting the existing database.
Cluster Interface	By default, the **Auto Select** option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the **Interface Grou**p drop-down.
Task Name	Change the default name of the recovery task.

12. Click **Start Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Recover Microsoft SQL Server Database as a New Database in an Alternate Microsoft SQL Server Instance

To recover the database as a new database in an alternate MS SQL server instance:

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Click **Recover** located at the top right of the page and then select **Databases** > **MS SQL**.

   The Restore SQL page appears.
3. Search for the databases you want to recover from by entering characters of the database name, Protection Group name, or by specifying the wildcard character *. A list of databases is displayed with details like Cohesity Cluster, Protection Group, Physical Server, and Create Date. The Create Date option indicates the date and timestamp when the database was created.

   > **Note:** Operations like rename may update the creation date at the SQL Server.

4. From the list of search results, select one or more databases you want to recover. You can select multiple MS SQL databases only if they are protected by the same protection group.

By default, the latest recovery point is selected. To select a different recovery point, from the selected lists, mouse over the recovery point, and then click the edit icon.

The Edit recovery point for <database_name> page appears.

By default, the option to select the recovery point is displayed in **Timeline** mode. You can also choose to view the option in **List** mode by clicking the **List** tab in the top-right corner of the page. The **Timeline** mode displays the full backups (recovery points) captured at the scheduled time and the CDP-based data available for point-in-time restore. The **List** tab displays only the full backups captured at a scheduled time.

- To select a recovery point from the Timeline mode:
    a. From the **Choose a date** drop-down, select a date.

       The recovery points available on the selected date are displayed in blue dots on the timeline bar and the point-in-time for restore is displayed in a solid green line on the timeline bar.

    b. To recover from a full backup, click the corresponding blue dot. For point-in-time restore, specify the exact point-in-time recovery by sliding the timeline bar.

    c. By default, the data is recovered from the local cluster. You can also select a recovery point archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.

    d. Click **Select Recovery Point** and then go to step 5.
- To select a recovery point from the List mode:
    a. Select the **List** tab from the top-right corner of the Edit recovery point for <database_name> page.

       By default, the page displays the recovery points available for the last 30 days.

    b. You can also select a recovery point from a different date range by selecting the date range from the Date drop-down list. The page displays the available recovery points in the specified range.

    c. Select the recovery points to be recovered.

    d. By default, the data is recovered from the local cluster. You can also select a recovery point archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.

    e. Click **Select Recovery Point** and then go to step 5.

5. Click **Next: Recover Options**.

6. From the **Targets** option, select **Recover as a new Database** to recover the database as a new database.
7. Disable the **Restore to Original SQL Server Instance** option to restore the database to an alternate SQL Server instance.
8. From the **MS SQL Instance** drop-down, select an alternate SQL server instance.
9. In the **Data Files** field, specify the path to an existing directory. The newly created database files will reside in this path.

   > **Note:**
   > - If the database file names to be restored have a conflict with the existing database files of the database to which files are restored, then Cohesity resolves the conflict by appending a number to the file names.

10. In the **Log Files** field, provide the full path location to which the log files can be restored.
11. (Optional) Click **Add File Path Rules** add custom rules for the data files.

    You can provide a full path or pattern for the original files and a location to restore to. When providing a location, use the standard path format. For example, use C:\path for Windows instead of the extended path format \\?\c:\path.

    This is only used for the destination path in a custom rule and not the source. File path rules are case sensitive. Partial file name or extension (not only directory path) are required for a match to be identified.

    > **Note:** For VDI based backup, use two backslashes after the drive. For example, C:\\path.

    Accept the file patterns and examples:

    - Wildcard character used for file matching such as *
      - **.ndf* - All ndf files. Useful if you want every ndf file to go to the same folder
      - *m:*.ndf* - Every ndf file on drive m:
      - *c:*1.ndf* - Every ndf file on drive c: with a suffix of 1.ndf
    - Regex pattern
      - *.*\.ndf* - All files with the ndf extension
      - *^.*foo1.*\.ndf$* - All files with the word foo1 and the extension ndf
    - Full path to a source database file

Database files that have non-default file extensions or that do not match a specified filename or pattern are restored to the data file restore location.

Click **Add File Path Rule** to add multiple custom rules.

12. Specify the following **Recovery Options**:

Recovery Options	Description
Rename	Optional. Enable the Rename option and select one of the following options to rename the restored databases: • **Bulk Rename**: Select this option if you want to rename the restored databases in bulk. You can specify a string in the **Suffix** field. The restored databases will be renamed by adding this suffix string with the original database names. • **Rename Individual Objects**: Select this option if you want to individually rename the restored databases. You can specify the new name of the databases in the **New Name** field.
WITH RECOVERY	Disable the option to perform a restore WITH NO RECOVERY (the database will be offline when restored). By default, this option is enabled and the database is restored with recovery (the database will be online when restored). **Note:** When restoring a database to an alternate MS SQL server instance with no recovery, a staging directory is created under the database files and logs file directories. To overcome the filename conflict with existing files in the database, the recovered files are saved in this staging directory.
VDI Restore Settings	Enable this option to specify the WITH clause that you want to use for the restore. **Note:** • This option is available only for restoring the databases that are protected using Backup Microsoft SQL Server (VDI-based).

Recovery Options	Description
Keep CDC	Enable this option to restore a protected database that has the change data capture (CDC) enabled. If the protected database is not CDC enabled and the user tries to restore it with Keep CDC then, the database will be restored without CDC. **Note:** • This option is available only if the database is restored with recovery. • This option is not available for system database restore.
Overwrite Alternate Database	Enable this option to recover the database by overwriting the existing database.
Cluster Interface	By default, the **Auto Select** option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the **Interface Grou**p drop-down.
Task Name	Change the default name of the recovery task.

13. Click **Start Recovery**.

The recovery task is initiated. You can monitor the recovery task from the recoveries page.

Recover Microsoft SQL Server FILESTREAM Databases

Before you can restore MS SQL FILESTREAM databases, a snapshot must exist.

Restore Database Overview

1. Select **Dashboard** and from the drop-down, select **MS SQL**.
2. Click **Databases**.
3. Select **Recover** from the database's actions menu.
4. Set restore options.

You can also start a restore task by navigating to **Data Protection > Recoveries** > **Recover** > **Databases** > **MS SQL** and selecting a database to restore.

Set Restore Options

1. **Task Name:** Optionally change the default name for the task.
2. **Restore to Original SQL Server Instance:** Toggle on if you want to restore the database to its original instance.

   Overwriting a FILESTREAM database is not supported and prevents the restore from completing.

a. Select a **SQL Host** and **SQL Instance** if restoring to an alternate MS SQL instance.

> **Note:** Local MS SQL instances that are running within an MS SQL FCI do not display. You can, however, manually enter the local SQL instance name to restore to.

b. Provide the full path location to restore all database files.

You can optionally restore data files and log files to different locations. Click **Add Alternative Log File Locations and Custom Rules** to provide locations for data and log files and any custom rules. For data files, you can provide a full path or pattern for the original files and a location to restore to. When providing a location, use the standard path format. For example, use C:\path for Windows instead of the extended path format \\?\c:\path.

This is only used for the destination path in a custom rule and not the source.

Accept the file patterns and examples:

- Wildcard character used for file matching such as *
  - **.ndf* - All ndf files. Useful if you want every ndf file to go to the same folder
  - *m:*.ndf* - Every ndf file on drive m:
  - *c:*1.ndf* - Every ndf file on drive c: with a suffix of 1.ndf
- Regex pattern
  - *.*\.ndf* - All files with the ndf extension
  - *^.*foo1.*\.ndf$* - All files with the word foo1 and the extension ndf
- Full path to a source database file

Database files that have non-default file extensions or that do not match a specified filename or pattern are restored to the data file restore location.

Click **Add Another Custom Rule** to add multiple custom rules.

> **Note:** Ensure to follow the standard regular expression rules. Specify a dot '.' before asterisk '*' to match all characters, for example, L:.*.ndf.

c. Provide a **Database Name** for the restored database.

3. By default, the latest snapshot is selected. You can optionally choose to restore from a different snapshot by clicking Edit ( ).

You can also provide a specific time to restore to if transaction logs are available.

Click a date on the calendar to select a snapshot from that date. The default point selected will be the latest log transaction or the latest full or incremental, whichever is the latest. The slider also displays available points in time and displays snapshots as circles. Manually select a point on the slider if you want to restore to a specific point in time. Selecting an invalid time from the slider automatically changes to the closest available snapshot. If your manual selection is within 10 minutes of a snapshot, your selection automatically snaps to it. You can also select a specific point in time by entering it in the time fields.

After selecting the desired recover point, click **Recover**. You can choose to clone the selected recover point by clicking the arrow adjacent to recover and selecting **Clone**.

In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

4. By default, an MS SQL restore WITH RECOVERY is performed. You can optionally toggle this off to perform a restore WITH NORECOVERY.
5. **Auto Select:** When enabled, the recovery task automatically selects the correct VLAN.

   > **Note:** If using VLANs and the cluster is joined to an AD domain—One of the machine accounts must be a DNS hostname for a virtual IP (VIP) of a VLAN configured on the cluster in order to recover to servers within that VLAN.

6. **Capture tail logs:** This option is available only when overwriting a database in its original location. This option is unavailable if the database's Protection Group has been paused or deleted.

   Tail logs capture records that have not yet been backed up. They are captured to ensure all transactions are backed up before restoring the database.

7. Click **Recover** to start the task.

SQL Server Maintenance Mode

You can enable maintenance mode for SQL Server instances and databases. Enabling maintenance mode skips any scheduled or manually initiated protection runs.

To place a SQL Server instance or database in maintenance mode:

1. Navigate to **Data Protection > Sources**.
2. Click on the action menu (⋮) of the source and select **Maintenance**.
3. You can initiate the maintenance mode immediately or later.

   To initiate the maintenance mode immediately:

1. Select **Start Now**. The **Start Maintenance Now** dialog displays the list of Protection Groups available in the source.
2. Review the list of Protection Groups and enter **Yes** to confirm.
3. Optionally, you can enter a note.
4. Click **Confirm**.

To schedule the maintenance mode:

1. Select **Schedule**.
2. On the **Schedule Maintenance** dialog, enter the start date and time and the end date and time.
3. Optionally, you can enter a note.
4. Click **Save**.

The SQL Server instance or database will be set in maintenance mode accordingly.

AG in Maintenance Mode

When maintenance mode is enabled for a SQL instance hosting the AG database, the replica hosting the instance is not considered for the AG backup plan. This behavior is common to both legacy (non-first-class citizen) and first-class citizen features.

For legacy AG backup, only the replica for which maintenance mode is enabled will be skipped. You must enable maintenance mode on all the replicas to skip the entire backup.

Migrate Microsoft SQL Server

The following topics provide guidance to help you migrate MS SQL databases:

About Migrating Microsoft SQL Server Databases

You can use MS SQL database migration for the following use cases:

- Back up and migrate a database from a single pane of glass.

  Leverage database backup to achieve database migration. No more shipping logs across multiple sites or multiple data centers.

  Upgrade the MS SQL Server version while minimizing application downtime and maintaining the ability to restore to any point in time.
- Staging a database on the target server for faster recovery with Cohesity's database migration.

  Stage a database on the target SQL server and perform only incremental updates at the file level to improve RPO.

Database migration for file-based MS SQL backups consists of the following actions, which must be initiated manually:

1. Perform the initial copy of database files to the target MS SQL server.
2. Sync forward to the latest incremental/full snapshot available on the cluster. You can trigger multiple syncs.

   For each sync, Cohesity performs incremental file updates to database files on the target MS SQL server. Syncs ensure files are up to date. The files are not attached to the database until you complete the finalized workflow. This ensures that the database is up to date when finalization occurs.
3. Finalize the migration. Finalizing is available only if the target database is synced to the latest snapshot.

   This brings the database online. After the database is online and the finalize step succeeds, the recovery task is completed successfully. You cannot perform syncs after this point because the migration workflow is complete.

Migrate Microsoft SQL Server Databases

Before you migrate an MS SQL database, ensure that a file-based snapshot exists on the cluster.

Migrate MS SQL Database

This section lists the steps to migrate an MS SQL database.

1. Select **Dashboard** and from the drop-down, select **MS SQL**.
2. Select **Migrate** from the database's actions menu.

   You can also start a restore task by navigating to **Data Protection > Recoveries> Recover > Migrate Database (MS SQL only)**.
3. Search for an MS SQL server or database. Enter characters of the name and a list of items displays. You can optionally specify the wildcard character *. You can also optionally narrow the search results by specifying filter criteria, for example, you can filter the search results by a specific Protection Group. Click the **Add Filters** icon, specify the filter and click **Add**.
4. Select a database and set the migration options for the MS SQL database you want to migrate.
   1. **Task Name:** Optionally change the default name for the task.
   2. **Objects Being Recovered**: This displays the database to be migrated.
   3. **Sync Options**: Specify the sync options for the database to be migrated.

      > **Note:** Transaction log backup is not synced. Only the incremental and full backup is synced.

- **Auto Sync Databases**: This option automatically keeps the database in sync with the latest available snapshot until you finalize the database and bring it online.
- **Manually Sync Databases**: Once the initial database migration is completed, you can sync the migrated database files with newer snapshots available until you finalize the database and bring it online.

4. **Recover Point:** This displays the selected recover point for the migration.
5. **Settings:** Specify the **SQL Host** and **SQL Instance** to migrate the database to.

   Provide the full path location to restore all database files.

   You can optionally restore data files and log files to different locations. Click **Add Alternative Log File Locations and Custom Rules** to provide locations for data and log files and any custom rules. For data files, you can provide a full path or pattern for the original files and a location to restore to. When providing a location, use the standard path format. For example, use C:\path for Windows instead of the extended path format \\?\c:\path.

   This is only used for the destination path in a custom rule and not the source.

   Accept the file patterns and examples:

   - Wildcard character used for file matching such as *
     - **.ndf* - All ndf files. Useful if you want every ndf file to go to the same folder
     - *m:*.ndf* - Every ndf file on drive m:
     - *c:*1.ndf* - Every ndf file on drive c: with a suffix of 1.ndf
   - Regex pattern
     - *.*\.ndf* - All files with the ndf extension
     - *^.*foo1.*\.ndf$* - All files with the word foo1 and the extension ndf
   - Full path to a source database file

   Database files that have non-default file extensions or that do not match a specified filename or pattern are restored to the data file restore location.

   Click **Add Another Custom Rule** to add multiple custom rules.

   > **Note:** Ensure to follow the standard regular expression rules. Specify a dot '.' before asterisk '*' to match all characters, for example, L:.*.ndf.

5. By default, an MS SQL restore WITH RECOVERY is performed. You can optionally toggle this off to perform a restore WITH NO RECOVERY.

6. Click **Start Migration**.

   The initial file copy task starts. This is the first step in the migration process.

7. After the file copy task is completed, the options available for the next migration step are displayed.

   - **Finalize** - Available if the target database is synchronized to the latest snapshot.
   - **Sync** - Available if there is a snapshot that is more recent than the target database.

   If you select the **Auto Sync Databases** option in Step 4, the **Auto Sync to latest** toggle is enabled by default. You can manually disable this option if required.

> **Note:** Database migration is not supported for AG databases.

Cancel Migration

You can cancel an in-progress migration task. Canceling the migration prevents syncing or finalizing the database and may leave it in an unusable state. Delete the database files manually and then start another migration task as needed.

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Find the migration task in the list and click the task name to display its detail page.
3. Click the **Cancel** button located at the top right of the page.
4. Respond to the confirmation prompt.

Amazon DocumentDB

Amazon DocumentDB is a fully managed, MongoDB API–compatible document database service. Cohesity natively integrates with AWS to provide simple, fast, and cost-effective backup, recovery, and data management for both Instance-based DocumentDB Clusters and Elastic DocumentDB Clusters in your AWS account.

> **Important:** The backup and recovery of Amazon DocumentDB is supported only on DataProtect for cloud in AWS (formerly known as AWS NGCE cluster). This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

Register AWS Account

To protect Amazon sources with Cohesity, you must register your AWS account as a source in the Cohesity cluster and perform backup and recovery operations.

You can register AWS account using one of the following methods:

- Register AWS Account Using IAM Role Method
- Register AWS Account Using IAM User Method

Register AWS Account Using IAM Role Method

If you are choosing to register the AWS account using the IAM role method, then you will execute a CloudFormation template (CFT) provided by Cohesity to automate the creation of necessary AWS resources, such as IAM roles and policies, which are required for Cohesity to access and protect your AWS services. Executing the CFT ensures all required permissions and roles are set up correctly, enabling secure backup and recovery operations from Cohesity.

Prerequisites

IAM User Permissions to Execute CFT

The IAM user you use to run the CloudFormation Template and to create and view the stack must have the required permissions. The following table lists the permissions the IAM user must have to run the CloudFormation template.

> **Note:** Ensure to add these permissions manually.

Permission	Purpose
`cloudformation:CreateStack`	Create a new stack.
`cloudformation:UpdateStack`	Modify the stack during updates or re-registration
`cloudformation:DeleteStack`	Delete a stack.
`cloudformation:ValidateTemplate`	Validate the CFT before deployment.
`cloudformation:DescribeStacks`	View the status of stacks.
`cloudformation:ListStacks`	View the status of stacks.
`cloudformation:GetTemplate`	Fetch template for an existing stack.
`cloudformation:GetTemplateSummary`	View a summary of template resources and parameters.
`cloudformation:DescribeStackEvents`	View stack creation progress/errors.

Permission	Purpose
`cloudformation:DescribeStackResources`	View resources created in the stack.
`cloudformation:CreateUploadBucket`	Create a temporary bucket used for uploading artifacts needed by the stack.
`iam:CreateRole`	Create required IAM roles.
`iam:DeleteRole`	Delete IAM roles when cleaning up registrations.
`iam:GetRole`	Retrieve details of existing roles.
`iam:UpdateRole`	Modify existing IAM role configuration.
`iam:TagRole`	Add tags to IAM roles created by the template.
`iam:UntagRole`	Remove tags from IAM roles.
`iam:PutRolePolicy`	Attach inline policies to IAM roles.
`iam:DeleteRolePolicy`	Delete inline policies from IAM roles.
`iam:GetRolePolicy`	iam:GetRolePolicy
`iam:CreateInstanceProfile`	Create instance profiles needed for EC2-based operations.
`iam:GetInstanceProfile`	Retrieve instance profile details.
`iam:AddRoleToInstanceProfile`	Attach IAM roles to the instance profile.
`iam:RemoveRoleFromInstanceProfile`	Detach IAM roles from the instance profile.
`iam:DeleteInstanceProfile`	Delete instance profiles during cleanup.
`iam:AttachRolePolicy`	Attach managed policies to IAM roles.
`iam:DetachRolePolicy`	Remove managed policies from roles.
`iam:ListPolicies`	List available policies for attachment/validation.
`iam:ListRoles`	Retrieve all roles to validate role existence.

Permission	Purpose
`iam:PassRole`	Allow CloudFormation to pass the IAM role to AWS services.
`s3:CreateBucket`	Create an S3 bucket for storing backup or exported data.
`s3:PutObject`	Upload objects to an S3 bucket.
`s3:GetObject`	Retrieve objects from an S3 bucket.
`s3:ListBucket`	View bucket contents to validate template uploads.

Permissions Required for DocumentDB Protection

The following table lists the minimum required permissions included in the CloudFormation template for protecting Amazon DocumentDB databases.

> **Note:** You do not need to add these permissions manually, as they are automatically added when you run the CFT.

Resource	Permissions	Purpose
iam	`iam:GetUser`	Required to validate the IAM identity used for account registration.
rds	`rds:DescribeDBClusters`	Required to discover Amazon DocumentDB instance-based clusters.
ec2	`ec2:DescribeRegions`	Required for region discovery.

Register AWS Account Using IAM Role Method

To register AWS account as a source:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Register** at the top-right of the page and then select **Cloud Platforms** > **AWS**.

   The **Register AWS Source** dialog box appears.
3. Enter the **AWS Account ID**.
4. From the list of **AWS services**, select **DocumentDB**.
5. Click **Next** to generate a CloudFormation Template (CFT), which you will use to complete the AWS source registration.

6. Click **Download** to download the CloudFormation Template.
7. On running the CFT, IAM roles and policies are created.
8. Once the roles and policies are created successfully, click **Register**.

Run CloudFormation Template

To complete the registration of the AWS account with the Cohesity cluster, you must run the CloudFormation Template on the AWS account you are registering. You can download CFT from the product UI as you register the AWS source.

When you execute the CFT, it creates an AWS IAM role and the policies.

Executing the CFT Template

1. In the **AWS Management Console**, navigate to **Services** and search for **CloudFormation**.
2. Click **Create stack** > **With new resources** to create a stack under AWS cloudFormation using the downloaded CloudFormation Template.
    1. In the **Prerequisite - Prepare template** page, select **Choose an existing template** > **Upload a templatefile**.
    2. Click **Choose File** to browse and upload the JSON Cloudformation template. Click **Next**.
    3. Enter a **Stack name** and specify the AWS Account ID where the Cloud Edition cluster is running.
    4. Select **source_registration** for creating IAM role for registration AWS source.
    5. Click **Next**.
    6. Acknowledge the creation of IAM resources by selecting the checkbox, then click **Create Stack**.
    7. Once the stack creation is successful, view the **Resources** tab to check the created IAM roles.
    8. The following IAM roles and profiles are created:
        - CohesityInstanceRole
        - CohesityInstanceProfile
        - CohesitySourceRegistrationRole

Attaching the IAM Role to Cluster Nodes

To complete registration, attach the **CohesityInstanceProfile** role to all nodes in the cluster:

1. Navigate to **Services** > **EC2** > **Instances**.
2. Select the cluster created. For a multi node, the IAM role must be attached on all nodes.
3. Select **Actions** > **Security** > **Modify IAM Role**.
4. In the **IAM Role** field, enter the name/search for the Instance Profile (*CohesityInstanceProfile*) that was created.
5. Click **Update IAM role**.

   The IAM role is successfully attached to that EC2 instance.

   > **Note:** If any new node is added to the cluster, then this role has to be attached to every newly added node in the cluster as well.

Complete AWS Source Registration

Once the IAM role is attached, complete the AWS source registration on the cluster.

Register AWS Account Using IAM User Method

The IAM User method allows you to register an AWS account using user credentials instead of IAM roles. You manually create a policy, create an IAM user with the required permissions, and provide the user's access keys during registration.

Prerequisites

For registering using IAM User method, you must first create an AWS policy with required permissions, and then create an IAM user with this policy attached. The permissions required are provided in the following procedure.

1. Create an AWS Policy
2. Create an IAM User

Create an AWS Policy

To restrict Cohesity's access to your AWS resources, Cohesity recommends creating a policy with permissions required for authenticating the Cohesity to perform backup and recovery of DocumentDB. The permissions are provided in the following procedure.

To create a new policy with permissions to create the cluster:

1. Log in to the Amazon AWS console using your AWS account with admin privileges.
2. In the top left of the menu bar, select **Services**.
3. Under **Security, Identity & Compliance**, select **IAM**.

4. In the left frame, click **Policies**.
5. Click **Create policy**.
6. In the **Create policy** page, select the **JSON** tab.
7. Delete the default JSON code.
8. Copy and paste the following JSON code.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "iam:GetUser",
                "rds:DescribeDBClusters",
                "ec2:DescribeRegions",
                "docdb-elastic:ListClusters"
            ],
            "Resource": "*"
        }
    ]
}
```

9. Click **Review policy**.
10. In the Name field, enter a name of this policy, such as `CohesityDocumentDBPolicy` and click **Create policy**.
11. Enter a name, such as `CohesityDocumentDBPolicy` , and an optional description for the policy and click **Create Policy**.

Create an IAM User

Once you create a policy with the required permissions, you can create a new IAM user and attach the policy that you created previously.

To create an IAM user:

1. Log in to the Amazon AWS console using your AWS account with admin privileges.
2. In the top left of the menu bar, select **Services**.
3. Under Security, Identity & Compliance, select **IAM**.
4. In the left frame, click **Users**.
5. Click **Add users**.
6. In the User name field, enter a user name such as `CohesityCE`.
7. For **Access type**, select Programmatic access and click **Next: Permissions**.
8. Click **Attach existing policies directly**, then search for the name of the policy you created previously and select that policy.
9. Click **Next: Tags**.

10. Optionally, enter tags for the policy and then click **Next: Review**.
11. Review your choices and then click **Create User**.
12. In the **Secret access key** column, click **Show**.
13. Copy and paste the **Access key ID** and the Secret access key into a text file or click **Download .csv** to save the information onto your desktop or a corporate share.

    These keys are required when registering AWS Source with the Cohesity cluster.
14. Click **Close**.

Manage AWS Account

After registering your AWS account as a source, you can:

- Update the AWS source configuration.
- Refresh the source details.
- Unregister the AWS source from the Cohesity cluster.

Update AWS Account Source Configuration

You can edit the registered AWS account to add or remove the Amazon services protected by the Cohesity from your AWS account.

To edit the AWS account source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select **Edit**.
3. In the **Edit AWS Source** page, select or unselect the Amazon services.
4. Click **Update**.

Refresh AWS Account Source

You can refresh the AWS account source configuration and fetch the latest changes on your AWS account.

To refresh the AWS source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select **Refresh**.

Unregister AWS Account Source

If you plan to stop taking the backup of your AWS source, you can unregister the AWS source from the Cohesity cluster.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the AWS source.

To unregister the AWS source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select **Unregister**.

Plan and Prepare for Amazon DocumentDB Protection

Supported Amazon DocumentDB Cluster Types

Cohesity supports database-level protection for the following DocumentDB cluster types in your AWS account:

- Instance-based DocumentDB clusters
- DocumentDB Elastic Clusters

Requirements for Amazon DocumentDB Instance-based Cluster Protection

To protect Amazon DocumentDB Instance-based Cluster, you can register AWS account using both **IAM User** and **IAM Role** methods.

Supported versions

The following table lists the DocumentDB Instance-based Cluster versions that are supported based on the registration method you choose.

Registration Method	Supported DocumentDB Versions
IAM User registration	Version 5.x and below
IAM Role registration	Version 5.x

Authentication Requirements

To protect Amazon DocumentDB at the database level, the Cohesity cluster must authenticate to the DocumentDB primary instance using one of the following methods:

- **Username and Password Authentication**: Username and password of the Amazon DocumentDB Cluster instances. Provide the DocumentDB Cluster's database username and password.
- **IAM-authenticated DocumentDB User**: This option is available only if the AWS account is registered using the IAM Role method.

If you choose the **IAM-authenticated DocumentDB** user method, ensure the following:

- DocumentDB supports the MongoDB AWS authentication mechanism ((MONGODB-AWS).
- The database user must be created inside the Amazon DocumentDB cluster.
- The database username must be the ARN of the IAM Role attached to the Cohesity cluster nodes (when registering the AWS account).
- The IAM Role must allow the `sts:AssumeRole` flow for MONGODB-AWS authentication.

To create the IAM-Authenticated DocumentDB User:

1. Connect to the DocumentDB cluster using **mongosh**.
2. Switch to the external authentication database:

```
use $external;
```

3. Create the user with appropriate roles:

```
db.createUser({
    user: "<ARN of IAM Role attached to EC2/NGCE>",
    mechanisms: ["MONGODB-AWS"],
    roles: [
        { db: "readWriteDB", role: "readWrite"},
        { db: "admin", role: "readWriteAnyDatabase"},
        { db: "admin", role: "userAdmin"},
        { db: "admin", role: "dbAdminAnyDatabase"}
    ]
});
```

Requirements for Amazon DocumentDB Elastic Cluster Protection

To protect Amazon DocumentDB Elastic Cluster, you must register the AWS account using the **IAM User** method.

Authentication Requirements

To protect Amazon DocumentDB Elastic Clusters at the database level, authentication must be performed using the username and password of the DocumentDB Elastic cluster.

Considerations for Amazon DocumentDB Protection

Review and understand the following limitations and knows issues before you protect Amazon DocumentDB database:

- Cohesity performs only full backup of Amazon DocumentDB.
- DocumentDB Version 8 for instance-based clusters is not supported for protection.

- IAM-authentication using DocumentDB User is not supported for DocumentDB Elastic Cluster.
- Restoring DocumentDB to an alternate AWS account and region is not supported.
- Restoring DocumentDB Elastic Cluster databases to DocumentDB instance-based cluster and vice-versa are not supported.
- Restoring a backup taken from a higher DocumentDB database version to a lower version is not supported.

Backup Amazon DocumentDB

Depending on the services you selected while registering the source, the Cohesity cluster automatically discovers all supported workloads in the specified AWS account ID. The discovered workloads appear under **Data Protection** > **Sources**. When you open the registered AWS account source, each workload type is displayed on its own tab. Select the **DocumentDB** tab to view all discovered databases.

The DocumentDB tab displays the entity hierarchy for Amazon DocumentDB, allowing you to navigate from the account level down to individual databases.

Amazon DocumentDB Entity Hierarchy

The Amazon DocumentDB entity hierarchy in the Cohesity cluster follows this structure:

Structure	Description
AWS Account	The AWS account registered with Cohesity for DocumentDB protection.
AWS Region	The AWS region where the AWS resources reside.
DocumentDB Cluster	The specific Amazon DocumentDB cluster within the selected region.
DocumentDB Database	The individual databases hosted within the DocumentDB cluster. The database will be listed in the entity hierarchy only if you have provided credentials to discover the databases of the Amazon DocumentDB cluster.

Backup Scope by Amazon DocumentDB Hierarchy

The Cohesity cluster allows you to back up Amazon DocumentDB databases at different levels of the entity hierarchy. You can choose to back up:

- **AWS Account** – Backup all the Amazon DocumentDB databases within the registered AWS account.
- **AWS Region** – Backup all the Amazon DocumentDB databases within a specific region of the registered account.

- **DocumentDB Cluster** – Backup all Amazon DocumentDB databases within a specific database instance.
- **DocumentDB Databases** – Backup individual Amazon DocumentDB database by providing the database credentials.

Supported Backup Types

Cohesity supports only full backups for Amazon DocumentDB databases. Incremental backups are not supported.

Protect Amazon DocumentDB

In Cohesity, Amazon DocumentDB databases are protected using a Protection Group and a Protection Policy. The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select standard or custom policy to use when creating a Protection Group. For more information, see Manage Policies.

Prerequisites for Amazon DocumentDB Protection

Authenticate for DocumentDB Protection

To protect the Amazon DocumentDB at database level, you must authenticate the DocumentDB primary instance. Once authentication is successful, Cohesity discovers the databases of the DocumentDB for protection.

Perform the following steps for authentication:

1. Navigate to **Data Protection** > **Sources**.
2. Locate the registered AWS account and click into it.
3. Click the **DocumentDB** tab.
4. Select the checkbox for the hierarchy level (Account, region, or cluster level), and then click Database Credentials above the checkboxes.

   The **Database Credentials** for AWS DocumentDB dialog appears.
5. Select one of the following authentication methods for Amazon DocumentDB database-level discovery:
   1. **Credentials**: Enter the Username, and Password for the Amazon DocumentDB cluster.

      > **Note:** This option is supported for both Instance-based DocumentDB

> clusters and Elastic DocumentDB clusters.

2. **IAM Authentication**: Enter the Username for IAM authentication.

   For more information, see Authentication Requirements.

   This option is supported only if:

   - The DocumentDB cluster is an instance-based cluster.
   - The cluster runs DocumentDB version 5.
   - The AWS account was registered in Cohesity using the IAM role method.

   The databases corresponding to the selected DocumentDB cluster or hierarchy level are discovered.

6. Click **Save**.
7. Click the **Refresh** icon to discover the databases.

Protect Amazon DocumentDB Database

To protect Amazon DocumentDB databases:

1. Navigate to **Data Protection** > **Protection**. Click **Protect** on the top-right of the page and then select **AWS** > **DocumentDB**.
2. In the **New Protection** page, click **Add Objects** and select your registered source, or click **Register Source** to add a new one.
3. Select the DocumentDB databases using one of the following views or option:
   - **List View**: Use this option to select the DocumentDB databases for protection from a flat, searchable list.
   - **Hierarchy View**: Use this option to select DocumentDB databases for protection at various hierarchy levels.

     Optionally:

     - You can click the auto-protect icon at the **AWS Account**, **AWS Region**, and **DocumentDB Cluster** level to automatically protect newly added DocumentDB databases.
     - You can exclude the Amazon DocumentDB databases from auto-protection within an account orregion by clicking the auto-protect icon ( ) next to the database. The databases excluded from auto-protection are displayed with the exclude ( ) icon.
   - **Tags**: Use this option to select the database for protection based on tags. Select the checkbox of a tag, and then select **Select All Child Objects** to

include all DocumentDB databases with that tag for protection.

Optionally:

- You can configure auto-protection based on a tag. You can select the tag checkbox and then choose **Auto Protect This Tag** to automatically protect all newly added DocumentDB databases with this tag.
- You can exclude the Amazon DocumentDB databases from auto-protection within a tag by clicking the auto-protect icon ( ) next to the database. The DocumentDB databases excluded from auto-protection are displayed with the exclude ( ) icon.
- You can exclude DocumentDB databases with a specific tag from auto-protection by clicking the exclude icon (⊘). The tag excluded from auto-protection are displayed with the exclude icon.

4. Click **Continue.**
5. Provide a name for the **Protection Group**. The name can contain alphanumeric characters, underscores, dashes, and periods.
6. From the **Policy** drop-down, create or select and existing policy.
7. Select **More Options** to change or configure any of the advanced settings.
8. Click **Protect**.

Advanced Settings

Section	Setting	Description
Settings	**Start Time**	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
	SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: This option is not applicable. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

Section	Setting	Description
Additional Settings	**Pause Future Runs**	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
	End Date	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.

Section	Setting	Description
	QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. • **Backup Auto**: This policy achieves similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. The data is written to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. For best performance, we recommend the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.

Section	Setting	Description
	Alerts	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.
	Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: • High-priority protection runs • Medium-priority protection runs • Low-priority protection runs
	Description	**Optional**. Enter a brief description about the Protection Group.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.

Manage Amazon DocumentDB Backup Configuration

In the Cohesity, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Object(s) to the Protection Group

Depending on the Protection Type you chose while creating the Protection Group, you can add new Amazon DocumentDB databases to the existing Protection Group for backup. The newly added object is backed up from the next protection run, and it will be a full backup for the newly added object.

To add object(s) to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had created for DocumentDB databases.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click in the **Objects** section.
5. In the **Objects** section, click the plus icon (**+**) to enter multiple objects that you plan to back up. Click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon DocumentDB databases.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon DocumentDB databases.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a recovery run:

1. Navigate to **Data Protection** > **Protection**.
2. Click the action menu (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all associated local and archived snapshots. Replicated snapshots must be deleted from the remote cluster. Snapshots under DataLock cannot be deleted.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the product UI.

To delete the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for DocumentDB databases.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
   - Keep the **Delete Snapshots** toggle disabled to delete the Protection Group only.
   - Enable the **Delete Snapshots** toggle to delete the Protection Group and all associated snapshots.
5. Type **YES** to confirm that you want to delete the Protection Group.
6. Click **Delete Group**.

Recover Amazon DocumentDB

You can recover the Amazon DocumentDB database either to its original location or to a different location.

You can also perform PITR when restoring to the original AWS account where the backups were created. Restoring to an alternate AWS account using PITR is not supported.

> **Note:** We recommend that you review the Plan and Prepare for Amazon DocumentDB Protection topic.

Recover Amazon DocumentDB Database

To recover Amazon DocumentDB database:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **AWS** > **DocumentDB**.
3. Search for the database by entering characters of the database name, or by specifying the wildcard character *.
4. From the list of search results, select the database to recover.
   - By default, the latest snapshot of the database is selected for recovery.
   - To recover from a different snapshot, hover over the snapshot and click the **Edit** icon. The **Edit Recovery Point for <*database*_name>** page appears.
   - By default, snapshots are displayed in the **List** mode. You can switch to the Timeline mode by clicking the **Timeline** tab in the top-right corner of the page.

   To select a snapshot from the **List** mode:

   a. Select the **List** tab from the top-right corner of the **Edit recovery point for <*database_name*>** page. By default, the page displays the snapshots available in the last one month. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.

   b. Select the snapshots to be recovered.

   c. By default, the snapshot is recovered from the local Cohesity cluster.

   d. Click **Select Recovery Point** and then go to step 5.

   To select a snapshot from the **Timeline** mode:

   a. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar.

   b. Select the snapshot to be recovered by clicking the corresponding blue dot. For point-in-time restore, specify the exact point-in-time recovery by sliding the timeline bar.

   c. By default, the snapshot is recovered from the local Cohesity cluster.

   d. Click **Select Recovery Point** and then go to step 5.
5. Click **Next: Recover Options**.
6. In the **Recover To** section, select any one of the following options based on where you want to restore the database and then provide the required information:
   - **Original Location**: Restore the database to the original Amazon DocumentDB Cluster.

> **Note:** Restoring to the original location overwrites the existing database.

Type **Yes** to confirm.

- **New Location:** Restore the database to an Amazon DocumentDB Cluster within the same region and AWS account. Restoring to another region in the same AWS account and restoring to a different AWS account are not supported.
  a. From the **Source** drop-down, select the AWS account and from the **Cluster** drop-down, select the Amazon DocumentDB Cluster to which you want to restore the database.
  b. To overwrite any existing database with the same name, enable Overwrite existing database(s) and type **Yes** to confirm.

> **Note:**
> Restoring to a new location also replaces any existing database with the same name in the selected instance.

7. In the **Recovery Options** section, configure the following options:

Options	Description
Rename	Click the Edit icon and enter a New Name for the database if you want to rename it after recovery.
Task Name	Update the default name of the recovery task.

8. Click **Recover**.

Amazon DynamoDB

Amazon DynamoDB is a fully managed NoSQL database service provided by AWS, designed for high performance at scale. In DynamoDB, data is stored in tables. Cohesity natively integrates with AWS to provide a simple, fast, and cost-effective solution for the backup, recovery, and data management of both the DynamoDB Standard table class and the DynamoDB Standard-Infrequent Access (DynamoDB Standard-IA) table class in your AWS account.

> **Important:** The backup and recovery of Amazon DynamoDB is supported only on DataProtect for cloud in AWS (formerly known as AWS NGCE cluster). This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

Plan and Prepare for Amazon DynamoDB Protection

To protect Amazon DynamoDB tables with Cohesity, you must register your AWS account as a source in the Cohesity cluster and perform backup and recovery operations. Ensure you meet the pre-requisites and understand the considerations before registering the AWS account.

Required Permissions for Amazon DynamoDB Data Protection

IAM User Permissions to Execute CFT

To register an AWS account with the Cohesity cluster, specific IAM roles must be created in AWS to grant required permissions. These roles are created by deploying an AWS CloudFormation (CFT) stack provided by Cohesity. The CloudFormation template must be executed from the AWS Management Console. The IAM user or role used to deploy the stack must have sufficient permissions to create, manage, and view CloudFormation stacks, as well as to create the required IAM roles and policies.

The table below lists the minimum permissions required for the IAM user or role to successfully run the CloudFormation template.

> **Note:** Ensure to add these permissions manually.

Permission	Purpose
`cloudformation:CreateStack`	Create a new stack.
`cloudformation:UpdateStack`	Modify the stack during updates or re-registration
`cloudformation:DeleteStack`	Delete a stack.
`cloudformation:ValidateTemplate`	Validate the CFT before deployment.
`cloudformation:DescribeStacks`	View the status of stacks.
`cloudformation:ListStacks`	View the status of stacks.

Permission	Purpose
`cloudformation:GetTemplate`	Fetch template for an existing stack.
`cloudformation:GetTemplateSummary`	View a summary of template resources and parameters.
`cloudformation:DescribeStackEvents`	View stack creation progress/errors.
`cloudformation:DescribeStackResources`	View resources created in the stack.
`cloudformation:CreateUploadBucket`	Create a temporary bucket used for uploading artifacts needed by the stack.
`iam:CreateRole`	Create required IAM roles.
`iam:DeleteRole`	Delete IAM roles when cleaning up registrations.
`iam:GetRole`	Retrieve details of existing roles.
`iam:UpdateRole`	Modify existing IAM role configuration.
`iam:TagRole`	Add tags to IAM roles created by the template.
`iam:UntagRole`	Remove tags from IAM roles.
`iam:PutRolePolicy`	Attach inline policies to IAM roles.
`iam:DeleteRolePolicy`	Delete inline policies from IAM roles.
`iam:GetRolePolicy`	iam:GetRolePolicy
`iam:CreateInstanceProfile`	Create instance profiles needed for EC2-based operations.
`iam:GetInstanceProfile`	Retrieve instance profile details.
`iam:AddRoleToInstanceProfile`	Attach IAM roles to the instance profile.
`iam:RemoveRoleFromInstanceProfile`	Detach IAM roles from the instance profile.
`iam:DeleteInstanceProfile`	Delete instance profiles during cleanup.
`iam:AttachRolePolicy`	Attach managed policies to IAM roles.

Permission	Purpose
`iam:DetachRolePolicy`	Remove managed policies from roles.
`iam:ListPolicies`	List available policies for attachment/validation.
`iam:ListRoles`	Retrieve all roles to validate role existence.
`iam:PassRole`	Allow CloudFormation to pass the IAM role to AWS services.
`s3:CreateBucket`	Create an S3 bucket for storing backup or exported data.
`s3:PutObject`	Upload objects to an S3 bucket.
`s3:GetObject`	Retrieve objects from an S3 bucket.
`s3:ListBucket`	View bucket contents to validate template uploads.

Permissions for DyamoDB Protection

The following table lists the minimum required permissions included in the CloudFormation template for protecting Amazon DynamDB tables.

> **Note:** You do not need to add these permissions manually, as they are automatically added when you run the CFT.

Resource	Permissions	Purpose
IAM	`iam:PassRole`	Allow passing an IAM role to AWS services (e.g., EC2, Lambda) for resource access.

kms	`kms:CreateGrant`
	`kms:DescribeKey`
	`kms:Decrypt`
	`kms:Encrypt`
	`kms:ListAliases`
	`kms:ListKeys`
		Enable reading encrypted data during backup and writing encrypted data during recovery. Also allows listing and identifying keys associated with database instances.

Resource	Permissions	Purpose

dynamodb	`dynamodb:BatchWriteItem`
	`dynamodb:DeleteItem`
	`dynamodb:GetItem`
	`dynamodb:PutItem`
	`dynamodb:Query`
	`dynamodb:RestoreTableToPointInTime`
	`dynamodb:Scan dynamodb:UpdateItem`
	`dynamodb:CreateTable`
	`dynamodb:UpdateTable`
	`dynamodb:DescribeContinuousBackups`
	`dynamodb:DescribeExport`
	`dynamodb:DescribeImport`
	`dynamodb:DescribeTable`
	`dynamodb:ExportTableToPointInTime`
	`dynamodb:ImportTable`
	`dynamodb:ListTables`
	`dynamodb:ListTagsOfResource`
	`dynamodb:TagResource`
	`dynamodb:UpdateContinuousBackups`
		Required for backing up and recovering Amazon DynamoDB tables, including reading, writing, restoring, and managing table metadata and tags.

Resource	Permissions	Purpose

s3	`s3:CreateBucket`
	`s3:GetBucketLocation`
	`s3:PutBucketTagging`
	`s3:DeleteBucket`
	`s3:AbortMultipartUpload`
	`s3:DeleteObject`
	`s3:GetBucketVersioning`
	`s3:GetObject`
	`s3:GetObjectTagging`
	`s3:GetObjectVersion`
	`s3:ListBucket`
	`s3:ListBucketMultipartUploads`
	`s3:ListMultipartUploadParts`
	`s3:PutObject`
	`s3:PutObjectTagging`
		Manage S3 buckets and objects for storing, tagging, and retrieving backup/exported data during DynamoDB protection operations.

glue	`glue:CreateJob`
	`glue:TagResource`
	`glue:DeleteJob`
	`glue:StartJobRun`
	`glue:GetJobRun`
		Manage AWS Glue jobs for data transformation and movement as part of backup/recovery workflows.

CloudWatch	`logs:DescribeLogGroups`
	`logs:CreateLogGroup`
	`logs:CreateLogStream`
	`logs:DescribeLogStreams`
	`logs:GetLogEvents`
	`logs:PutLogEvents`
		Create and manage log groups and streams, retrieve and publish log events for auditing and monitoring backup/recovery operations.

Considerations for Amazon DynamoDB Protection

Review and understand the following limitations and known issues before you protect Amazon DynamoDB:

- Protection of DynamoDB tables that contain float values in the partition key, sort key, or both is not supported.
- Tables in Amazon DynamoDB can be protected across all regions in your AWS account.
- During recovery, you can restore Amazon DynamoDB tables to their original region. However, you cannot restore a table if another table with the same name already exists in that region—the restore operation will fail.
- To restore a table using its original name, you must first manually delete the existing table. Then, perform the recovery without specifying any prefix or suffix for the table name.
- For a protected DynamoDB table, the following AWS charges may apply:
  - **AWS Glue job costs**: For data transformation and movement during backup or recovery.
  - **Export table costs**: For exporting table data to S3.
  - **Egress costs**: For data transferred out of AWS.
- Cohesity enables Point-in-Time Recovery (PITR) for Amazon DynamoDB tables, allowing you to restore data to any specific point in time within the past 35 days.

  > **Note:** PITR is only available when restoring to the original AWS account where the backups were created. Restoring to an alternate AWS account using PITR is not supported.

- After you unprotect a DynamoDB table, you must manually disable PITR on that table in order to avoid unnecessary PITR retention and associated AWS costs.
- Manually turning off Point-in-Time Recovery (PITR) for a table after a full backup will break the backup chain. As a result, subsequent incremental backups cannot be performed until a new full backup is completed.
- For DynamoDB tables larger than 2.5 TB, you must increase the default Max task DPUs per account in the AWS region where the AWS Glue job runs. Contact Cohesity Support to request an increase in the Max task DPUs per account.
- Restoring to another region in the same AWS account and restoring to a different AWS account are not supported.
- Restoring a backup taken from a higher DynamoDB version to a lower version is not supported.
- Restore of Local Secondary Indexes (LSIs) is not supported when using snapshot-based protection. This is an AWS consideration for importing DynamoDB tables from Amazon S3.

Register and Manage AWS Account

To protect your Amazon DynamoDB, you need to register AWS account as a source on the Cohesity cluster. After registering your AWS account as a source, you can:

- Update the AWS source configuration.
- Refresh the source details.
- Unregister the AWS source.

Register AWS Account

Before registering AWS account as a source, make sure you have completed all prerequisite tasks and reviewed the considerations.

To register AWS account as a source:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Register** at the top-right of the page and then select **Cloud Platforms** > **AWS**.

   The **Register AWS Source** dialog box appears.
3. Enter the **AWS Account ID**.
4. From the list of **AWS services**, select **DynamoDB**.
5. Click **Next** to generate a CloudFormation Template (CFT), which you will use to complete the AWS source registration.
6. Click **Download** to download the CloudFormation Template.
7. On running the CFT, IAM roles and policies are created.
8. Once the roles and policies are created successfully, click **Register**.

Run CloudFormation Template

To complete the registration of the AWS account with the Cohesity cluster, you must run the CloudFormation Template on the AWS account you are registering. You can download CFT from the product UI as you register the AWS source.

When you execute the CFT, it creates an AWS IAM role and the policies.

Executing the CFT Template

1. In the **AWS Management Console**, navigate to **Services** and search for **CloudFormation**.
2. Click **Create stack** > **With new resources** to create a stack under AWS cloudFormation using the downloaded CloudFormation Template.
    1. In the **Prerequisite - Prepare template** page, select **Choose an existing template** > **Upload a templatefile**.

2. Click **Choose File** to browse and upload the JSON Cloudformation template. Click **Next**.
3. Enter a **Stack name** and specify the AWS Account ID where the Cloud Edition cluster is running.
4. Select **source_registration** for creating IAM role for registration AWS source.
5. Click **Next**.
6. Acknowledge the creation of IAM resources by selecting the checkbox, then click **Create Stack**.
7. Once the stack creation is successful, view the **Resources** tab to check the created IAM roles.
8. The following IAM roles and profiles are created:
    - CohesityInstanceRole
    - CohesityInstanceProfile
    - CohesitySourceRegistrationRole

Attaching the IAM Role to Cluster Nodes

To complete registration, attach the **CohesityInstanceProfile** role to all nodes in the cluster:

1. Navigate to **Services** > **EC2** > **Instances**.
2. Select the cluster created. For a multi node, the IAM role must be attached on all nodes.
3. Select **Actions** > **Security** > **Modify IAM Role**.
4. In the **IAM Role** field, enter the name/search for the Instance Profile (*CohesityInstanceProfile*) that was created.
5. Click **Update IAM role**.

   The IAM role is successfully attached to that EC2 instance.

> **Note:** If any new node is added to the cluster, then this role has to be attached to every newly added node in the cluster as well.

Complete AWS Source Registration

Once the IAM role is attached, complete the AWS source registration on the cluster.

Update AWS Account Source Configuration

You can edit the registered AWS account to add or remove the Amazon services protected by the Cohesity from your AWS account.

To edit the AWS account source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select Edit.
3. In the **Edit AWS Source** page, select or unselect the Amazon services.
4. Click **Update**.

Refresh AWS Account Source

You can refresh the AWS account source configuration and fetch the latest changes on your AWS account.

To refresh the AWS source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select **Refresh**.

Unregister AWS Account Source

If you plan to stop taking the backup of your AWS source, you can unregister the AWS source from the Cohesity cluster.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the AWS source.

To unregister the AWS source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select **Unregister**.

Backup Amazon DynamoDB

Depending on the services you selected while registering the source, the Cohesity cluster automatically discovers all supported workloads in the specified AWS account ID. The discovered workloads appear under **Data Protection** > **Sources**. When you open the registered AWS account source, each workload type is displayed on its own tab. Select the **DynamoDB** tab to view all discovered databases.

The **DynamoDB** tab displays the entity hierarchy DynamoDB, allowing you to navigate from the account level down to individual tables.

Amazon DynamoDB Entity Hierarchy

The **DynamoDB** tab displays the entity hierarchy for DynamoDB, allowing you to navigate from the account level down to individual tables. The **DynamoDB** entity hierarchy in the Cohesity cluster follows this structure:

Structure	Description
AWS Account	The AWS account registered with Cohesity for DynamoDB protection.
AWS Region	The AWS region where the DynamoDB resources reside.
DynamoDB Tables	The DynamoDB tables that can be selected for backup and recovery.

Backup Scope by Amazon DynamoDB Hierarchy

The Cohesity cluster allows you to back up Amazon DynamoDB at different levels of the entity hierarchy. You can choose to back up:

- **AWS Account** – Backup all the AWS DynamoDB tables within the registered AWS account.
- **AWS Region** – Backup all AWS DynamoDB tables within a specific region of the registered account.
- **DynamoDB Tabled** – Backup individual DynamoDB tables.

Backup Process

When you initiate a protection run for DynamoDB tables, Cohesity performs a DynamoDB API call to export the table data to a temporary AWS S3 staging bucket . This S3 bucket is created by Cohesity in the same AWS account and region where the DynamoDB table to be backed up resides.

Once the data is successfully exported to the S3 bucket, Cohesity ingests the exported data from the S3 bucket to the Cohesity cluster. Once the data is fully backed up to the Cohesity cluster, the data on the staging bucket is deleted to free up storage space.

During the first full backup, Cohesity also enables AWS Point-In-Time Recovery (PITR) for the DynamoDB table. This allows you to perform PITR restores, enabling recovery to a specific point in time within the past 35 days by default.

Supported Backup Types

Cohesity supports both full and Incremental backups for Amazon DynamoDB.

Although Cohesity does not support log backups for DynamoDB, it enables Amazon DynamoDB Point-In-Time Recovery (PITR) to provide point-in-time restore capability. This allows Cohesity to perform point-in-time recovery of DynamoDB tables back to the original location using AWS-managed PITR snapshots.

Protect Amazon DynamoDB Tables

In Cohesity, Amazon DynamoDB tables are protected using a Protection Group and a Protection Policy. The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select standard or custom policy to use when creating a Protection Group. For more information, see Manage Policies.

To protect Amazon DynamoDB tables:

1. Navigate to **Data Protection** > **Protection**. Click **Protect** on the top-right of the page and then select **AWS** > **DynamoDB**.
2. In the **New Protection** page, click **Add Objects** and select your registered source, or click **Register Source** to add a new one.
3. Select the DynamoDB tables using one of the following views or option:
    - **List View**: Use this option to select the DynamoDB tables for protection from a flat, searchable list.
    - **Hierarchy View**: Use this option to select DynamoDB tables for protection at various hierarchy levels.

      Optionally:

        - You can click the auto-protect icon at the **AWS Account** level and **AWS Region** level to automatically protect newly added DynamoDB tables.
        - You can exclude the Amazon DynamoDB tables from auto-protection within an account orregion by clicking the auto-protect icon ( ) next to the table. The tables excluded from auto-protection are displayed with the exclude ( ) icon.
    - **Tags**: Use this option to select the tables for protection based on tags. Select the checkbox of a tag, and then select **Select All Child Objects** to include all tables with that tag for protection.

      Optionally:

        - You can configure auto-protection based on a tag. You can select the tag checkbox and then choose **Auto Protect This Tag** to automatically protect all newly added DynamoDB tables with this tag.
        - You can exclude the Amazon DynamoDB tables from auto-protection within a tag by clicking the auto-protect icon ( ) next to the table. The DynamoDB tables excluded from auto-protection are displayed with the exclude ( ) icon.
        - You can exclude DynamoDB tables with a specific tag from auto-protection by clicking the exclude icon (⊘). The tag excluded from auto-protection are displayed with the exclude icon.
4. Click **Continue.**

5. Provide a name for the **Protection Group**. The name can contain alphanumeric characters, underscores, dashes, and periods.
6. Since the data is ingested to the Cohesity cluster from the AWS S3 staging bucket, Ingest based policy is enabled by default. From the **Ingest Method** of Policy, create or select and existing policy
7. Select **More Options** to change or configure any of the advanced settings.
8. Click **Protect**.

Advanced Settings

Section	Setting	Description
Settings	**Start Time**	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
	SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: This option is not applicable. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

Section	Setting	Description
Additional Settings	**Pause Future Runs**	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
	End Date	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
	QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. • **Backup Auto**: This policy achieves similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. The data is written to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
	Alerts	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.

Section	Setting	Description
	Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: • High-priority protection runs • Medium-priority protection runs • Low-priority protection runs
	Description	**Optional**. Enter a brief description about the Protection Group.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.

Manage Amazon DynamoDB Backup Configuration

In the Cohesity, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Object(s) to the Protection Group

Depending on the Protection Type you chose while creating the Protection Group, you can add new Amazon DynamoDB tables to the existing Protection Group for backup. The newly added object is backed up from the next protection run, and it will be a full backup for the newly added object.

To add object(s) to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had created for DynamoDB tables.

3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click in the **Objects** section.
5. In the **Objects** section, click the plus icon (**+**) to enter multiple objects that you plan to back up. Click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon DynamoDB tables.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon DynamoDB tables.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a recovery run:

1. Navigate to **Data Protection** > **Protection**.
2. Click the action menu (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all associated local and archived snapshots. Replicated snapshots must be deleted from the remote cluster. Snapshots under DataLock cannot be deleted.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the product UI.

To delete the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon DynamoDB tables.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Keep the **Delete Snapshots** toggle disabled to delete the Protection Group only.

- Enable the **Delete Snapshots** toggle to delete the Protection Group and all associated snapshots.

5. Type **YES** to confirm that you want to delete the Protection Group.
6. Click **Delete Group**.

Recover Amazon DynamoDB

After protecting your Amazon DynamoDB tables in the Cohesity cluster, you can recover them to either their original region or a different region. Cohesity recovers the table as a new table within the location you choose. When you restore a table, all the tags that were present on the original table at the time of backup are automatically added to the restored table. Additionally, any new tags specified in the custom recovery options are also applied to the restored table.

You can also perform PITR when restoring to the original AWS account where the backups were created. Restoring to an alternate AWS account using PITR is not supported.

> **Note:** We recommend that you review the Plan and Prepare for Amazon DynamoDB Protection topic.

Recovery Process

When you initiate a recovery, Cohesity exports the selected Redshift data from the Cohesity cluster back into the Amazon S3 staging bucket that was used during the original backup. After the data is successfully exported to the staging bucket, Amazon Redshift reads the exported files from the bucket and imports them into the specified Redshift target location. Once the import completes, Cohesity automatically deletes the exported files from the staging bucket to free up storage and minimize S3 costs.

Depending on the target location for recovery, Cohesity supports the following recovery methods for Amazon DynamoDB:

- **Point-in-Time Recovery (PITR)**:

  Cohesity uses PITR when restoring the DynamoDB table to the same region and account as the original DynamoDB table.

  By default, Cohesity uses PITR method for recovering to the same region and account as the original DynamoDB table.

  If PITR is not enabled or available for the table, Cohesity automatically falls back to snapshot-based recovery.

- **Snapshot-based Recovery**:

  Cohesity uses this method when restoring the DynamoDB table to an alternate location (different AWS account or region).

  When snapshot-based recovery is initiated:

1. Cohesity exports the selected table data from the Cohesity cluster to an Amazon S3 staging bucket. This bucket is created by Cohesity in the same AWS region as the target DynamoDB table.
2. After the data export completes, Amazon DynamoDB imports the data directly from the S3 staging bucket into the target table.
3. Once the import is finished, Cohesity automatically deletes the exported files from the staging bucket to free up storage and reduce S3 costs.

Recover Amazon DynamoDB Tables

To recover Amazon DynamoDB:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **AWS** > **DynamoDB**.
3. Search for the table by entering characters of the table name, or by specifying the wildcard character *.
4. From the list of search results, select the table to recover.
   - By default, the latest snapshot of the table is selected for recovery.
   - To recover from a different snapshot, hover over the snapshot and click the **Edit** icon. The **Edit Recovery Point for <*table*_name>** page appears.
   - By default, snapshots are displayed in the **List** mode. You can switch to the Timeline mode by clicking the **Timeline** tab in the top-right corner of the page.

   To select a snapshot from the **List** mode:

   a. Select the **List** tab from the top-right corner of the **Edit recovery point for <*table_name*>** page. By default, the page displays the snapshots available in the last one month. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.

   b. Select the snapshots to be recovered.

   c. By default, the snapshot is recovered from the local Cohesity cluster.

   d. Click **Select Recovery Point** and then go to step 5.

   To select a snapshot from the **Timeline** mode:

   a. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar.

   b. Select the snapshot to be recovered by clicking the corresponding blue dot. For point-in-time restore, specify the exact point-in-time recovery by sliding the timeline bar.

   c. Click **Select Recovery Point** and then go to step 5.
5. Click **Next: Recover Options**.

6. In the **Recover To** section, select any one of the following options based on where you want to restore the table and then provide the required information:
   - **Original Location**: Restore the DynamoDB table within the same region and account as the original DynamoDB table.
   - **New Location:** Restore the DynamoDB table to a new region within the same AWS account or to a different AWS account.
     a. From the **Source** drop down, select a registered AWS account or register a new AWS account by selecting the **Register Source** option.
     b. From the **Region** drop down, select a destination AWS region.

> **Note:**
> You cannot restore a table if another table with the same name already exists in that region—the restore operation will fail.
>
> To restore a table using its original name, you must first manually delete the existing table. Then, perform the recovery without specifying any prefix or suffix for the table name.

7. In the **Recovery Options** section, configure the following options:

Options	Description

Encryption	Select the encryption type for the table to be recovered:
	• **DynamoDB**: The AWS KMS key is owned and managed by DynamoDB. This option is selected by default.
	• **AWS Managed**: The AWS KMS key is stored in your account and managed by AWS Key Management Service.
	• **Self Managed**: The AWS KMS key is stored in your account and managed by you. Provide the following information:
	  • **KMS Key Location**: From the drop-down, select whether you want to use the KMS key from the Same AWS Account where you are recovering to or from a Different AWS Account.
	  • **KMS Key**: If you are using the KMS key from the Same AWS Account, then from the drop-down, select the KMS Key. If you are using the KMS key from a Different AWS Account, then enter the KMS Key ARN in the following format: `arn:<partition>:kms:<region>:<accountid>:key/<key-id>`.

Options	Description
Custom AWS Resource Tags	Provide tags (key-value pairs) to attach to the recovered table. You can add multiple key-value pairs by clicking the **Add i**con.
Rename	Provide a prefix and/or suffix to the name of the table being recovered.
Task Name	Update the default name of the recovery task.

8. Click **Recover**.

Amazon Redshift Cluster

Amazon Redshift cluster is a fully managed, petabyte-scale cloud data warehouse service offered by AWS to efficiently analyze large datasets using standard SQL and existing business intelligence (BI) tools. Cohesity natively integrates with AWS to provide solution for the backup, recovery, and data management of Amazon Redshift databases in your AWS account.

> **Important:** The backup and recovery of Amazon Redshift cluster is supported only on DataProtect for cloud in AWS (formerly known as AWS NGCE cluster). This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

Plan and Prepare for Amazon Redshift

To protect Amazon Redshift databases with Cohesity, you must register your AWS account as a source in the Cohesity cluster and perform backup and recovery operations. Ensure you meet the pre-requisites and understand the considerations before registering the AWS account.

Required Permissions for Amazon Redshift Data Protection

IAM User Permissions to Execute CFT

To register an AWS account with the Cohesity cluster, specific IAM roles must be created in AWS to grant required permissions. These roles are created by deploying an AWS CloudFormation (CFT) stack provided by Cohesity. The CloudFormation template must be executed from the AWS Management Console. The IAM user or role used to deploy the stack must have sufficient permissions to create, manage, and view CloudFormation stacks, as well as to create the required IAM roles and policies.

The table below lists the minimum permissions required for the IAM user or role to successfully run the CloudFormation template.

> **Note:** Ensure to add these permissions manually.

Permission	Purpose
`cloudformation:CreateStack`	Create a new stack.
`cloudformation:UpdateStack`	Modify the stack during updates or re-registration
`cloudformation:DeleteStack`	Delete a stack.
`cloudformation:ValidateTemplate`	Validate the CFT before deployment.
`cloudformation:DescribeStacks`	View the status of stacks.
`cloudformation:ListStacks`	View the status of stacks.
`cloudformation:GetTemplate`	Fetch template for an existing stack.
`cloudformation:GetTemplateSummary`	View a summary of template resources and parameters.
`cloudformation:DescribeStackEvents`	View stack creation progress/errors.
`cloudformation:DescribeStackResources`	View resources created in the stack.
`cloudformation:CreateUploadBucket`	Create a temporary bucket used for uploading artifacts needed by the stack.
`iam:CreateRole`	Create required IAM roles.
`iam:DeleteRole`	Delete IAM roles when cleaning up registrations.
`iam:GetRole`	Retrieve details of existing roles.
`iam:UpdateRole`	Modify existing IAM role configuration.
`iam:TagRole`	Add tags to IAM roles created by the template.
`iam:UntagRole`	Remove tags from IAM roles.
`iam:PutRolePolicy`	Attach inline policies to IAM roles.
`iam:DeleteRolePolicy`	Delete inline policies from IAM roles.

Permission	Purpose
`iam:GetRolePolicy`	iam:GetRolePolicy
`iam:CreateInstanceProfile`	Create instance profiles needed for EC2-based operations.
`iam:GetInstanceProfile`	Retrieve instance profile details.
`iam:AddRoleToInstanceProfile`	Attach IAM roles to the instance profile.
`iam:RemoveRoleFromInstanceProfile`	Detach IAM roles from the instance profile.
`iam:DeleteInstanceProfile`	Delete instance profiles during cleanup.
`iam:AttachRolePolicy`	Attach managed policies to IAM roles.
`iam:DetachRolePolicy`	Remove managed policies from roles.
`iam:ListPolicies`	List available policies for attachment/validation.
`iam:ListRoles`	Retrieve all roles to validate role existence.
`iam:PassRole`	Allow CloudFormation to pass the IAM role to AWS services.
`s3:CreateBucket`	Create an S3 bucket for storing backup or exported data.
`s3:PutObject`	Upload objects to an S3 bucket.
`s3:GetObject`	Retrieve objects from an S3 bucket.
`s3:ListBucket`	View bucket contents to validate template uploads.

Permissions for Amazon Redshift Protection

The following table lists the minimum required permissions included in the CloudFormation template for protecting Amazon Redshift databases.

Resource	Permissions	Purpose
IAM	`iam:GetRole`	Access IAM roles

Resource	Permissions	Purpose
redshift	`redshift:ListDatabases`	To list databases of a Redshift cluster. Retrieve information about database names and their metadata. This permission is for cluster level.
	`redshift:GetClusterCredentialsWithIAM`	To connect to Redshift cluster database using IAM.
	`redshift:DescribeClusters`	For getting properties of Redshift clusters.
	`redshift:GetClusterCredentials`	To connect to Redshift cluster database.
redshift-data	`redshift-data:ExecuteStatement`	To run a query in a Redshift cluster database.
	`redshift-data:ListDatabases`	To list databases of a Redshift cluster via redshift-data API which is a different endpoint than redshift API endpoint. This permission is required for redshift without a server.
	`redshift-data:GetStatementResult`	To fetch temporarily cached result of an SQL statement executed on Redshift cluster databases.
	`redshift-data:CancelStatement`	For canceling a query executed on Redshift cluster database used during Protection Group cancellation.
	`redshift-data:DescribeStatement`	Required to get the details about a specific instance when a query is run by the Amazon Redshift Data API.

Resource	Permissions	Purpose
S3	`s3:CreateBucket`	To create an S3 bucket for storing backup or exported data.
	`s3:ListBucket`	To list objects within an S3 bucket.
	`s3:GetBucketLocation`	To get location of the S3 bucket.
	`s3:GetObjectAcl`	To retrieve the ACL of S3 objects used during backup or export workflows.
	`s3:GetObject`	To retrieve objects from an S3 bucket (e.g., exported data).
	`s3:PutObject`	To upload objects to an S3 bucket.
	`s3:DeleteObject`	To delete objects from the S3 bucket to free up storage and manage lifecycle costs.

AWS S3 Staging Bucket Requirement

Cohesity uses an Amazon S3 staging bucket as temporary storage during the backup and recovery of Amazon Redshift databases. You can either allow Cohesity to automatically create the staging bucket when you initiate a backup or recovery task, or you can manually create the staging bucket in your AWS account before starting the process.

You must use the same bucket for both backup and recovery. If you choose to manually create the staging bucket, ensure to create the AWS S3 bucket of type, S3 Standard in the same AWS region as the Redshift database selected for backup and restore.

Considerations for Amazon Redshift Data Protection

Review and understand the following limitations and known issues before you protect Amazon Redshift databases:

- **Restore Scope**: Cohesity does not support restoring Amazon Redshift databases to a different region or account. Restores can only be performed to the original account within the same region.
- **FIPS Certification**: Backup and recovery operations for Redshift databases using Cohesity are not FIPS-certified.
- Database Coverage: Only user databases are supported for protection. System databases within Redshift are not supported for backup or recovery.

- **Cluster State Requirement**: The Redshift cluster must be in an available state for Cohesity to initiate a backup. Backups cannot be initiated if the cluster is offline or unavailable.
- **Empty Tables**: It is not recommended to back up databases that contain empty tables.
- **Table Format**: Tables with names that use double quotes or are case-sensitive will
- not be restored.
- **Crash-Consistent Backup**: Cohesity provides crash-consistent protection for Amazon Redshift databases. Before initiating a backup, review your application's activity and requirements to determine if it is necessary to perform a checkpoint or quiesce the application.
- **Tag Restore**: Cohesity does not support restoring tags for Amazon Redshift clusters since the protection is at database level.
- **AWS S3 Staging Bucket**: You must use the same AWS S3 staging bucket for both backup and recovery. Recovery may fail if you do not use the same staging bucket that was used during the backup operation.
- **Version Downgrade Not Supported**: Restoring a backup taken from a higher Redshift database version to a lower version is not supported.

Register and Manage AWS Account

To protect your Amazon Redshift, you need to register AWS account as a source on the Cohesity cluster. After registering your AWS account as a source, you can:

- Update the AWS source configuration.
- Refresh the source details.
- Unregister the AWS source from the Cohesity cluster.

Register AWS Account

Before registering AWS account as a source, make sure you have completed all prerequisite tasks and reviewed the considerations.

To register AWS account as a source:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Register** at the top-right of the page and then select **Cloud Platforms** > **AWS**.

   The **Register AWS Source** dialog box appears.
3. Enter the **AWS Account ID**.
4. From the list of **AWS services**, select **Redshift**.
5. Click **Next** to generate a CloudFormation Template (CFT), which you will use to complete the AWS source registration.

6. Click **Download** to download the CloudFormation Template.
7. On running the CFT, IAM roles and policies are created.
8. Once the roles and policies are created successfully, click **Register**.

Run CloudFormation Template

To complete the registration of the AWS account with the Cohesity cluster, you must run the CloudFormation Template on the AWS account you are registering. You can download CFT from the product UI as you register the AWS source.

When you execute the CFT, it creates an AWS IAM role and the policies.

Executing the CFT Template

1. In the **AWS Management Console**, navigate to **Services** and search for **CloudFormation**.
2. Click **Create stack** > **With new resources** to create a stack under AWS cloudFormation using the downloaded CloudFormation Template.
    1. In the **Prerequisite - Prepare template** page, select **Choose an existing template** > **Upload a templatefile**.
    2. Click **Choose File** to browse and upload the JSON Cloudformation template. Click **Next**.
    3. Enter a **Stack name** and specify the AWS Account ID where the Cloud Edition cluster is running.
    4. Select **source_registration** for creating IAM role for registration AWS source.
    5. Click **Next**.
    6. Acknowledge the creation of IAM resources by selecting the checkbox, then click **Create Stack**.
    7. Once the stack creation is successful, view the **Resources** tab to check the created IAM roles.
    8. The following IAM roles and profiles are created:
        - CohesityInstanceRole
        - CohesityInstanceProfile
        - CohesitySourceRegistrationRole

Attaching the IAM Role to Cluster Nodes

To complete registration, attach the **CohesityInstanceProfile** role to all nodes in the cluster:

1. Navigate to **Services** > **EC2** > **Instances**.
2. Select the cluster created. For a multi node, the IAM role must be attached on all nodes.
3. Select **Actions** > **Security** > **Modify IAM Role**.
4. In the **IAM Role** field, enter the name/search for the Instance Profile (*CohesityInstanceProfile*) that was created.
5. Click **Update IAM role**.

   The IAM role is successfully attached to that EC2 instance.

   > **Note:** If any new node is added to the cluster, then this role has to be attached to every newly added node in the cluster as well.

Complete AWS Source Registration

Once the IAM role is attached, complete the AWS source registration on the cluster.

Update AWS Account Source Configuration

You can edit the registered AWS account to add or remove the Amazon services protected by the Cohesity from your AWS account.

To edit the AWS account source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select Edit.
3. In the **Edit AWS Source** page, select or unselect the Amazon services.
4. Click **Update**.

Refresh AWS Account Source

You can refresh the AWS account source configuration and fetch the latest changes on your AWS account.

To refresh the AWS source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select **Refresh**.

Unregister AWS Account Source

If you plan to stop taking the backup of your AWS source, you can unregister the AWS source from the Cohesity cluster.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the AWS source.

To unregister the AWS source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the AWS account source and select **Unregister**.

Attach Permissions to IAM Role for Redshift Protection

After completing source registration by running the CloudFormation Template (CFT), the following IAM roles and profiles are created:

- *CohesityInstanceRole*
- *CohesityInstanceProfile*
- *CohesitySourceRegistrationRole*

The *CohesitySourceRegistrationRole* contains the permissions defined in the CFT that allow Cohesity to discover AWS resources in the entity hierarchy within the product UI.

However, to perform backup and recovery operations for Amazon Redshift, you must:

1. Attach the permissions listed in the Permissions for Amazon Redshift Protection section to the *CohesityInstanceRole*.
2. Update the trust relationship for *CohesityInstanceRole*.

Attach Permissions

Perform the following steps to attach the permissions to the *CohesityInstanceRole:*

1. In the AWS Management Console, navigate to **IAM** > **Roles**.
2. Search for and open the role *CohesityInstanceRole*.
3. Go to the **Permissions** tab and select **Add permissions** > **Create inline policy**.
4. Switch to the **JSON** tab.
5. Paste the required Redshift permissions JSON policy and save it. For the list of permissions, see Permissions for Amazon Redshift Protection.

Update Trust Relationships

Perform the following steps to update the trust relationship for *CohesityInstanceRole*:

1. In the AWS Management Console, navigate to **IAM** > **Roles**.
2. Search for and open the role *CohesityInstanceRole*.
3. Under **Trust relationships** tab, click **Edit trust policy**.
4. Copy and paste the below content, and then click **Update Policy**.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "redhift.amazonaws.com",
          "ec2.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

Backup Amazon Redshift

Depending on the services you selected while registering the source, the Cohesity cluster automatically discovers all supported workloads in the specified AWS account ID. The discovered workloads appear under **Data Protection** > **Sources**. When you open the registered AWS account source, each workload type is displayed on its own tab. Select the **Redshift** tab to view all discovered Redshift clusters and databases.

The **Redshift** tab displays the entity hierarchy Redshift, allowing you to navigate from the account level down to individual databases.

Amazon Redshift Entity Hierarchy

The Amazon Redshift entity hierarchy in the Cohesity cluster follows this structure:

Structure	Description
AWS Account	The AWS account registered with Cohesity for protecting Amazon Redshift databases.
AWS Region	The AWS region where the Redshift resources reside.
Redshift Cluster	A Redshift Cluster hosts one or more Redshift databases.
Redshift Database	The individual Redshift databases hosted within the Redshift cluster.

Backup Scope by Amazon Redshift Hierarchy

The Cohesity cluster allows you to back up Amazon Redshift at different levels of the entity hierarchy. You can choose to back up:

- **AWS Account** – Backup all the AWS Redshift databases within the registered AWS account.
- **AWS Region** – Backup all the AWS Redshift databases within a specific region of the registered account.
- **Redshift Cluster** – Backup all AWS Redshift databases within a specific Redshift cluster.
- **Redshift Database** – Backup individual Redshift database.

Backup Process

When you initiate a protection run in the Cohesity cluster to back up Amazon Redshift databases, Cohesity first exports the selected Redshift data to an Amazon S3 staging bucket.

Once the data is successfully exported to the S3 bucket, Cohesity ingests the staged data from the S3 bucket into the Cohesity cluster. Once the ingestion is successful and the data is fully backed up to the Cohesity cluster, Cohesity automatically deletes the exported data from the staging bucket to free up storage and minimize S3 costs.

Supported Backup Types

Cohesity supports only full backups for Redshift databases. Incremental backups are not supported.

Protect Amazon Redshift

In Cohesity, Amazon Redshift databases are protected using a Protection Group and a Protection Policy. The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select standard or custom policy to use when creating a Protection Group. For more information, see Manage Policies.

Prerequisites

Before initiating a backup of Amazon Redshift databases, ensure that an Amazon S3 staging bucket is available in the AWS account where the Redshift resources reside. This bucket is used to temporarily store exported data during the backup process. You can manually create or select an existing S3 bucket in your AWS account, or allow Cohesity to automatically create one when the backup process begins. When creating a Protection Group, you can choose either option based on your preference.

If you choose Auto Create:

Cohesity automatically creates a staging bucket in the same AWS region as the database when the protection run starts.

If you choose to specify a bucket:

You must specify an S3 bucket that exists in the same AWS account and region as the Redshift cluster being protected.

Protect Amazon Redshift Database

To protect Amazon Redshift databases:

1. Navigate to **Data Protection** > **Protection**. Click **Protect** on the top-right of the page and then select **AWS** > **Redshift**.
2. In the **New Protection** page, click **Add Objects** and select your registered source, or click **Register Source** to add a new one.
3. Select the Redshift databases using one of the following views or option:
    - **List View**: Use this option to select the Redshift databases for protection from a flat, searchable list.
    - **Hierarchy View**: Use this option to select Redshift databases for protection at various hierarchy levels.

      Optionally:

        - You can click the auto-protect icon at the **AWS Account** level, **AWS Region** level, and **Redshift cluster** level to automatically protect newly added Redshift databases.
        - You can exclude the Amazon Redshift databases from auto-protection within an account, region, or cluster by clicking the auto-protect icon ( ) next to the database. The databases excluded from auto-protection are displayed with the exclude ( ) icon.
    - **Tags**: Use this option to select the databases for protection based on tags. Select the checkbox of a tag, and then select **Select All Child Objects** to include all databases with that tag for protection.

      Optionally:

        - You can configure auto-protection based on a tag. You can select the tag checkbox and then choose **Auto Protect This Tag** to automatically protect all newly added Redshift databases with this tag.
        - You can exclude the Amazon Redshift databases from auto-protection within a tag by clicking the auto-protect icon ( ) next to the database. The databases excluded from auto-protection are displayed with the

exclude ( ) icon.

- You can exclude databases with a specific tag from auto-protection by clicking the exclude icon (⊘). The tag excluded from auto-protection are displayed with the exclude icon.

4. Click **Continue.**
5. Provide a name for the **Protection Group**. The name can contain alphanumeric characters, underscores, dashes, and periods.
6. In the **Staging Bucket** section, choose one of the following options:
   - **Auto Create**: Cohesity automatically creates a temporary AWS S3 staging bucket in the same region as your Redshift databases selected for backup. The bucket follows the naming format: `cohe-<source-id>-<region-name>`.

     Where:

     - `source-id` is the AWS account ID.
     - `region-name` is the AWS region where the Redshift database reside.
   - **Specify Bucket to Use**: Enter the name of the AWS S3 staging bucket you created for temporarily storing the data.

   After each protection run, Cohesity deletes only the temporary data stored in the staging bucket during backup operations. The staging bucket itself is retained and reused for future backup operations.

   > **Note:** Using a bucket in a different region than the database is not supported.

7. Create or select an existing policy from the **Policy** drop-down.
8. Select **More Options** to change or configure any of the advanced settings.
9. Click **Protect**.

Advanced Settings

Section	Setting	Description
Settings	**Start Time**	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
	SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: This option is not applicable. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

Section	Setting	Description
Additional Settings	**Pause Future Runs**	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
	End Date	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
	QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. • **Backup Auto**: This policy achieves similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. The data is written to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. For best performance, we recommend the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
	Alerts	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.

Section	Setting	Description
	Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: • High-priority protection runs • Medium-priority protection runs • Low-priority protection runs
	Description	**Optional**. Enter a brief description about the Protection Group.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.

Manage Amazon Redshift Backup Configuration

In the Cohesity, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Object(s) to the Protection Group

Depending on the Protection Type you chose while creating the Protection Group, you can add new Amazon Redshift databases to the existing Protection Group for backup. The newly added object is backed up from the next protection run, and it will be a full backup for the newly added object.

To add object(s) to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had created for Redshift database.

3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click in the **Objects** section.
5. In the **Objects** section, click the plus icon (**+**) to enter multiple objects that you plan to back up. Click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon Redshift database.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon Redshift database.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a recovery run:

1. Navigate to **Data Protection** > **Protection**.
2. Click the action menu (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all associated local and archived snapshots. Replicated snapshots must be deleted from the remote cluster. Snapshots under DataLock cannot be deleted.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the product UI.

To delete the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Amazon Redshift database.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Keep the **Delete Snapshots** toggle disabled to delete the Protection Group only.

- Enable the **Delete Snapshots** toggle to delete the Protection Group and all associated snapshots.

5. Type **YES** to confirm that you want to delete the Protection Group.
6. Click **Delete Group**.

Recover Amazon Redshift

Cohesity does not support restoring Amazon Redshift databases to a different region or account. Restores can only be performed to the original account within the same region.

> **Note:** We recommend that you review the Considerations for Amazon Redshift Data Protection.

Recovery Process

When you initiate a recovery, Cohesity exports the selected Redshift data from the Cohesity cluster back into the Amazon S3 staging bucket that was used during the original backup. After the data is successfully exported to the staging bucket, Amazon Redshift reads the exported files from the bucket and imports them into the specified Redshift target location. Once the import completes, Cohesity automatically deletes the exported files from the staging bucket to free up storage and minimize S3 costs.

Recover Redshift Database

To recover Amazon Redshift database:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **AWS** > **Redshift**.
3. Search for the database by entering characters of the database name, or by specifying the wildcard character *.
4. From the list of search results, select the database to recover.
   - By default, the latest snapshot of the database is selected for recovery.
   - To recover from a different snapshot, hover over the snapshot and click the **Edit** icon. The **Edit Recovery Point for <*database_name*>** page appears.
   - By default, snapshots are displayed in the List mode. You can switch to the Timeline mode by clicking the **Timeline** tab in the top-right corner of the page.

   To select a snapshot from the **List** mode:

   a. Select the **List** tab from the top-right corner of the **Edit recovery point for <*database_name*>** page. By default, the page displays the snapshots available in the last one month. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page

displays the available snapshots in the specified range.

b. Select the snapshots to be recovered.

c. By default, the snapshot is recovered from the local Cohesity cluster.

d. Click **Select Recovery Point** and then go to step 5.

To select a snapshot from the **Timeline** mode:

a. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar.

b. Select the snapshot to be recovered by clicking the corresponding blue dot.

c. By default, the snapshot is recovered from the local Cohesity cluster.

d. Click **Select Recovery Point** and then go to step 5.

5. Click **Next: Recover Options**.
6. In the **Recover To** section, select any one of the following options based on where you want to restore the database and then provide the required information:
   - **Original Location**: Restore the database to the original Amazon Redshift cluster.

     > **Note:** Restoring to the original location will overwrite any existing database with the same name.

     Type **Yes** to confirm.
   - **New Location**: Restore the database to an Amazon Redshift cluster within the same region of the same AWS account. Restoring to different AWS account or to a different region within the same account is not supported.
     a. From the **Source** drop down, select the AWS account and from the **Cluster** drop down, select the Amazon Redshift cluster to which you want to restore the database
     b. To overwrite any existing database with the same name, enable **Overwrite existing database(s)** and type **Yes** to confirm.

     > **Note:** Restoring to a new location also replaces any existing database with the same name in the selected cluster.
7. In the **Staging Bucket** section, choose one of the following options:

- **Auto Create**:

  Select this option if you chose **Auto Create** for the staging bucket during the backup process.

- **Specify Bucket to Use**:

  Select this option if you created a staging bucket during the backup process. Ensure to specify the **same S3 bucket** that was used for the backup.

  > **Important:** Recovery may fail if you do not use the same staging bucket that was used during the backup operation.

  Cohesity deletes only the temporary data stored in the staging bucket during each recovery operation. The bucket itself is retained and reused for future recovery operations.

8. Click the **Edit** icon of the **Rename** field and enter a **New Name** for the database if you want to recover with a new name.
9. In the **Task Name** field, update the default name of the recovery task.
10. Click **Recover**.

Azure

Cohesity natively integrates with Microsoft Azure to provide a simple, fast, and cost-effective solution for backup, recovery, and data management of Azure Services, such as virtual machines, databases and so on.

This chapter includes the following topics:

Azure Virtual Machines

Cohesity provides a simple and fast backup, recovery, and data management solution for Microsoft Azure Virtual Machines.

This chapter includes the following topics:

Plan and Prepare for Azure Protection

Review the following prerequisites and considerations of Azure.

Prerequisites

- Azure agent must be installed on the Windows VMs if you need to CloudSpin the VMs to Azure. For more information, see Windows VM Agent.
- The Cohesity cluster must be able to resolve the following URLs by name:

    - Login.windows.net
    - management.azure.com
    - *.blob.core.windows.net

      Ensure to whitelist *.blob.storage.azure.net.
- All storage accounts associated with the subscription must have the relevant permissions, not just the account used to register Azure.
- Before registering Azure with the Cohesity cluster, you must perform the following steps:
    a. Register an application with Azure AD and create a service principal. For information, see the Azure documentation.
    b. Create an application secret key for setting up authentication for the service principal. For information, see the Azure documentation.
    c. Create a custom role at the subscription level with the required permissions for backup and recovery.

       For information about creating a custom role, see the Azure documentation.
    d. Assign the custom role to the Azure AD application created in step 1.

       The application ID and application secret key are required when you register the Azure source with the Cohesity cluster.

Considerations

- When converting and cloning snapshots of VMs containing independent disks, the independent disks are not converted. If the boot disk of the VM is an independent disk, converting and cloning snapshots of this VM is not supported. This applies to all the following Cloud Edition convert, clone or copy VMs use cases:
    - Clone VMs from On-Premises to Azure Cloud Service (On Demand CloudSpin)
    - Replicate and Clone VMs in Azure Cloud Edition
    - Back Up VMs to On-Prem, Replicate and Failover to Azure Cloud
    - Back Up Azure Cloud VMs, Replicate to On-Prem and Failback to Hypervisor Server
    - Clone VMs to Azure Cloud Using CloudSpin
- Cohesity now supports the backup and restore of UEFI boot mode enabled Azure VMs running on the following guest operating systems:
    - Windows 2012, 2016, 2019
    - Ubuntu 14, 16,18, 20
    - RHEL 6.x, 7.x, 8.x
    - Centos 6.x, 7.x
- File-level recovery is not supported for Azure VMs with XFSv5 file system.

- Recovery of an Azure VM with a disk containing more than 50 tags may fail with the following error:

```
Unable to complete the task. RPC status: 400, Azure response: {"error":
{"code":"InvalidTags","message":"Too many tags specified. Requested tag
count - '51'. Maximum number of tags allowed - '50'."}}
```

- Review the following considerations of Azure Native snapshotting:
  - Backup of the Azure VM having Ephemeral Volumes is not supported.
  - Cohesity does not support the backup of Azure VMs with shared managed disks.
  - VMs with static IP will not be recovered back with static IP.
  - The restored Azure VM does not support login using username and password present in the backed-up VM. Login using SSH keys is supported. When the restored VM boots up for the first time, Azure images are pre-installed with cloud-init software that locks user accounts as per the default behavior. **Workaround** - Create an admin user from the Azure portal or log in through the root account if it was enabled in the source VM. Reinstate the user accounts using the following command.

    ```
    passwd -u username
    ```

  - VMs encrypted through ADE cannot be restored to a different location unless user replicates the keys which were used to encrypt the VM to the new location. VMs encrypted using Azure SSE do not have this issue.
  - Managed disk VMs in turn-off state are shown as 0 bytes in size, in entity hierarchy of Azure Source. However, backup and recovery of the VM is supported in turned-off state.
  - Recovery of the unmanaged disk with different SKU types will depend on the storage container where the recovery is done.
  - Recovery of managed disk VM to the same location, scans for the same resource group, storage account, storage container & blobs created during backup. If these resources are deleted, the restore will fail.
  - Recovery of the VMs from Availability set to different locations will not have the Availability set parameters.
  - LDM for OS disk is not supported.
  - App consistent backup is not supported.
  - Cloning is not supported.
  - File download is supported.
- Cohesity does not support file-level recovery for Azure vaults if Life Cycle Management policy is enabled on Azure storage.

Workaround: Disable the Life Cycle Management policy on Azure storage and move the data to either the cold or hot tier and then perform file-level recovery.

- All disk sizes on the VM must be a multiple of 1MB because Azure only allows creating disks whose size is a multiple of 1MB. You can make the disk size a multiple of 1MB but failback to the on-premises vCenter may fail.
- Hyper-V to Azure CloudSpin supports both BIOS and UEFI boot. For UEFI boot, generation 2 VMs are created and are only supported on managed disks.
- File/folder recovery and download are not supported if Life Cycle Management (LCM) is enabled on the external targets (Azure Hot Tier).
- Recovery of Azure files and folders for encrypted VMs is not supported.
- You can perform files and folder recovery to an Azure VM Linux instance only if the Azure VM Linux instance is of x86_64 architecture
- The **Private Endpoint** option is not supported for the VMs selected using auto-protect. To use a private endpoint, you must manually select the VMs for protection.
- The disk size limit of an Azure VM using a private endpoint is 32 TB.
- When browsing files or folders for recovery, Cohesity does not display files or folders with an absolute path length exceeding approximately 3,500 characters. To recover these files or folders, select the parent directory.
- The following are the configurations supported for Native snapshot-based API:
  - Managed disks - Standard_LRS, Premium_LRS, StandardSSD_LRS, Premium_ZRS, or StandardSSD_ZRS.
  - Unmanaged disks.

Azure Permissions

The following tables list the permissions required for Azure cloud services.

> **Note:** To create custom roles using the Azure Portal, use the format provided here.
> To create custom roles using the Azure PowerShell, use the format provided here.

CloudSpin Policy Based

Action	Resource Provider	Operation Name
Policy based CloudSpin	Microsoft.Resources	Microsoft.Resources/subscriptions/resourceGroups/read Microsoft.Resources/deployments/read Microsoft.Resources/deployments/write

Azure Availability Sets

Cohesity supports Azure availability sets. Availability sets provide VM redundancy and availability. For more information about availability sets, see Microsoft Azure documentation.

You can specify the availability set in the following workflows:

- Azure public cloud—Clone and recover VMs
- Azure public cloud using CloudSpin—Clone VMs
- Azure public cloud using Convert and Deploy—Clone VMs
- Azure Stack Hub—Recover VMs

If the VM was part of an availability set during backup and if the VM is cloned or restored to the same location then the new VM is created in the same availability set.

Related Topics

- Set Clone Options—Azure Subscription Source
- Recover VMs to a New Location—Azure
- Clone VMs to Cloud Using Policy Based CloudSpin—Launch VM from the Cohesity Dashboard:

Register Azure Source

You can register Azure source with the Cohesity cluster using the following ways:

- Register an Azure Cloud Source at Subscription Level
- Register an Azure Cloud Source at Tenant Level

Registering Azure source at tenant level is supported only on DataProtect for cloud in Azure.

Register an Azure Cloud Source at Subscription Level

A Cohesity cluster supports registering an Azure Cloud Source for the following functionality:

- **Converting, cloning, and copying Snapshots of VMware VMs**—For this functionality, the registered Azure Cloud Source is where the VM Snapshots are cloned or copied to. Converting, cloning or copying VM Snapshots occurs during the following use cases:
  - Clone VMs from On-Premises to Azure Cloud Service (On Demand CloudSpin)
  - Clone VMs to Azure Cloud Using CloudSpin
  - Replicate and Clone VMs in Azure Cloud Edition
- **Backing up Azure infrastructure** — For this functionality, the registered Azure Cloud source contains the Azure VMs to back up.

To register an Azure Cloud Source:

> **Note:** Before registering the Azure Cloud Source with the Cohesity cluster, ensure you have met the prerequisites and reviewed the considerations.

1. Select **Data Protection > Sources**.
2. Select **Register > Virtual Machines** and select **Azure: Azure Subscription** from

the Source drop-down.

3. Enter the information described below and click **Register Source**.

Field Name	Description
Category	Select one of the following options: • **Standard**–Standard Azure. • **Gov**–Azure Government. • **Stack**–Azure Stack Hub. You must specify the authentication type, region, and the domain name. For more information, see Azure Stack Hub.
Subscription ID	This is the subscription ID from which you want to back up data. Log in to the Azure portal. In the left panel, click **Subscriptions**. Copy the SUBSCRIPTION ID from the table.
Application ID	The Application ID assigned by Azure during the service principal creation process. For instructions see Get application ID and authentication key in the Microsoft Azure documentation.
Application Key	The Azure Application key generated using Legacy App Registration during the service principal creation process that is used for authentication. For instructions see Get application ID and authentication key in the Microsoft Azure documentation.
Tenant ID	The unique tenant ID assigned by Azure. For instructions see Get tenant ID in the Microsoft Azure documentation. > **Note:** The **Tenant ID** field is not displayed for Azure Stack Hub Active Directory Federation Services (AD FS) authentication type.
Stack Type	If you select Stack, select the authentication type: • Azure Active Directory • Active Directory Federation Services Azure Stack Hub uses either Azure Active Directory or AD FS for authentication. AD FS is mostly used for disconnected deployments of Azure Stack Hub. For more information, see Microsoft Azure Stack Hub documentation.
Region	If you select **Stack**, specify the Azure Stack Hub region. For instructions, see Region management in Azure Stack Hub in the Microsoft Azure documentation.
Domain Name	If you select **Stack**, specify the Azure Stack Hub domain name.

Support for HTTP Proxy Server

Cohesity cluster supports HTTP proxy for Azure connectors for performing the following workflows:

- On-demand CloudSpin
- Policy-based CloudSpin
- Cloud-native backup and recovery
- Disaster recovery failback workflows

Register an Azure Cloud Source at Tenant Level

In DataProtect for cloud in Azure, you can register an Azure Cloud Source at tenant level.

To register an Azure Cloud Source at tenant level:

> **Note:** Before registering the Azure Cloud Source with the Cohesity cluster, ensure you have met the prerequisites and reviewed the considerations.

1. Navigate to **Data Protection > Sources**.
2. Click **Register** at the top-right of the page and then select **Cloud Platforms > Azure**.
3. The **Register Azure Source** dialog box appears.

   In the **Source Details** page,

   a. In the **Domain Name** field, provide the unique tenant ID assigned by Azure. For information on getting the tenant ID, see Get tenant ID.

   b. In the **Azure Workloads** section, under **Virtual Machines**, select **Azure VM**.

   c. Click **Continue**.
4. In the **Azure Apps** page,

   a. In the **Application ID** field, enter the application ID assigned by Azure during the service principal creation process. For instructions see Get application ID and authentication key in the Microsoft Azure documentation.

   b. In the **Application Secret Key** field, enter the application secret key for setting up authentication for the service principal.

   c. Click **Continue**.
5. In the **Subscriptions** page,

   a. In the **Subscription ID** field, enter the subscription IDs of the subscriptions where the Virtual Machine you want to protect belongs to.
   You can add multiple subscription IDs by clicking the + icon. The subscriptions

must be manually added and will not be automatically discovered.

b. Click **Register**.

6. Manual creation of Azure App requires significantly more effort and time. It involves several steps within Microsoft Azure configuration.

   a. Click **Continue**.

The source will be registered and displayed under the Azure section in the **Data Protection > Sources** page. You can click on the source and navigate to the **Azure** tab to view the entity tree of the VMs.

Manage Azure Source

After registering your Azure as a source with Cohesity cluster, you can:

Update Azure Source Configuration

Refresh Azure Source

Unregister Azure Source

Update Azure Source Configuration

You can update the registered Azure source to add or remove the Azure services, and subscriptions protected by Cohesity from your Azure source.

To edit an Azure source:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure sources and select **Edit**.
3. In the **Edit Azure Source** form, select or unselect the Azure services you need and click **Continue** to update Azure Application ID, Azure secret key, or add or remove subscriptions.
4. Once you edit the Azure Source, click **Update**.

Refresh Azure Source

You can refresh the Azure source configuration and fetch the latest changes on your Azure environment.

To refresh the Azure source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure source and select **Refresh**.

Unregister Azure Source

If you plan to stop backing up your Azure source, you can unregister the Azure source from Cohesity cluster.

> **Note:** Before you unregister an Azure source from Cohesity cluster, you must unprotect all the protected objects in that Azure source.

To unregister the Azure source:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure source and select **Unregister**.
3. In the **Unregister Source** dialog, click **Unregister**.

> **Note:** When you unregister a source, all the objects in the source will be unprotected. Any new protection after the re-registration of the source will trigger a full backup and not an incremental backup.

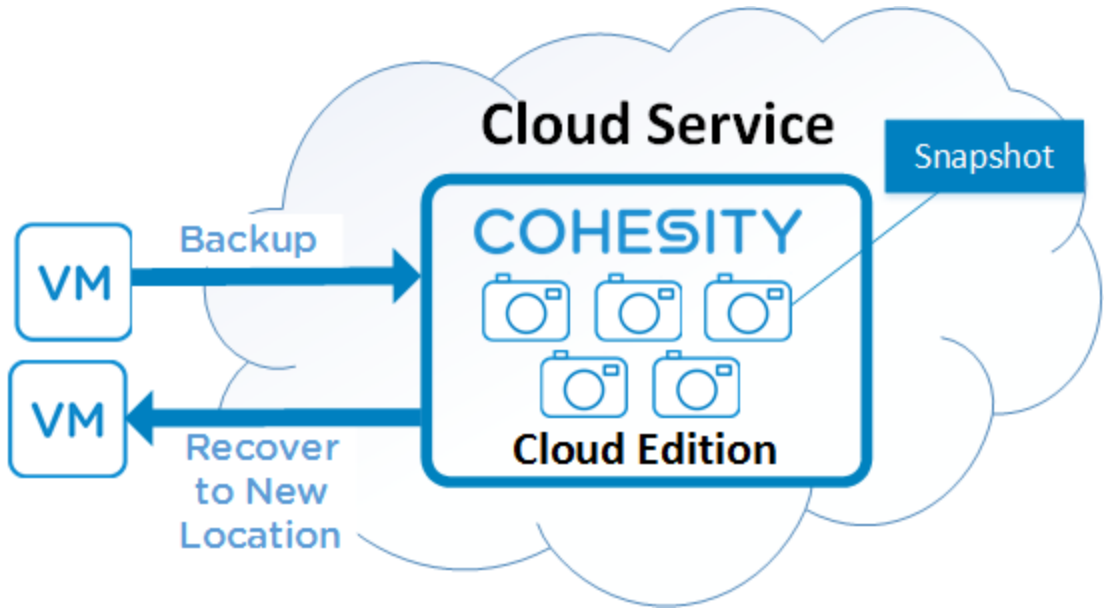
Backup Azure Virtual Machines

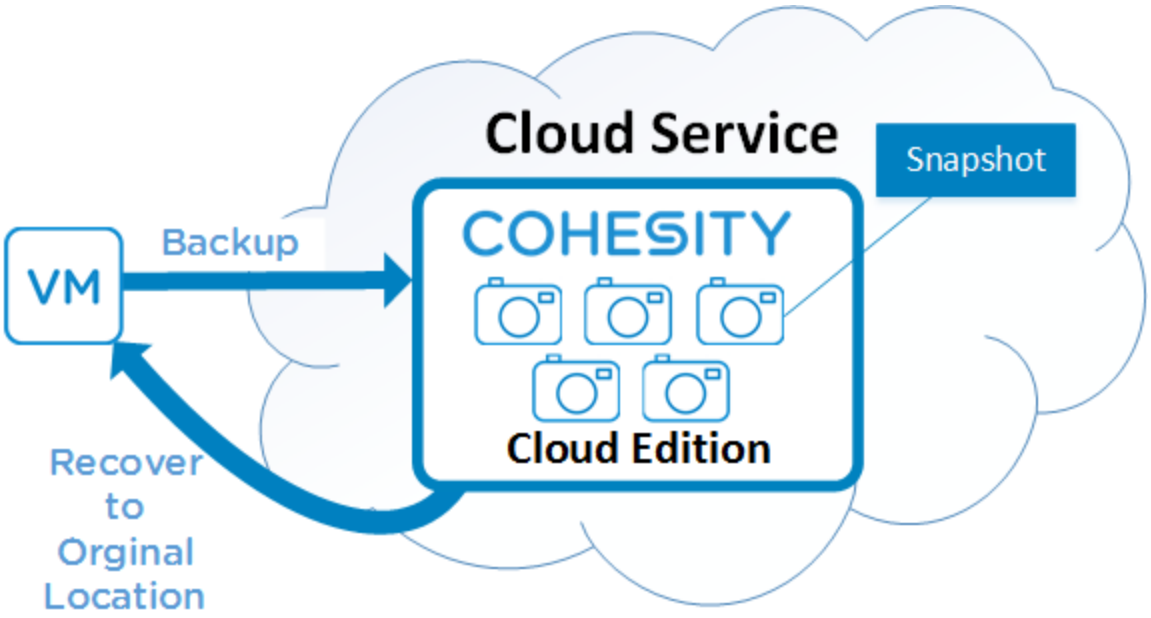
This chapter includes the following topics:

Back Up and Recover VMs from Azure Cloud Edition

Cloud Edition supports the backup and recovery of Virtual Machines (such as a VM in a vCenter server) to a Cohesity clusterCloud Edition running in Azure Cloud service.

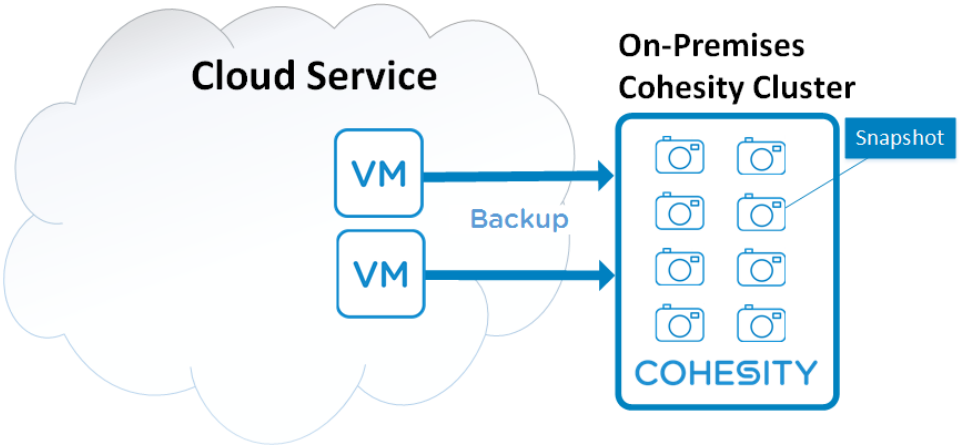
VMs can be recovered to a new location or back to the original location as shown in the following figures.





Back Up Azure Cloud VMs to On-Premises Cluster Using Native Snapshot API

As shown by the figure below, the Cohesity cluster supports backing up virtual servers using the native snapshot API of the cloud service. For example, a virtual server Protection Group backs up VMs from Azure to an on-premises Cohesity cluster. The result of this backup is a snapshot on the on-premises Cohesity cluster. You can recover the VMs from the snapshot on the Cohesity cluster to the cloud service as described in Recover VMs.



Configure the Backup of a Cloud VM Using Cloud Native APIs

Prerequisites

- Azure Commercial Native Snapshot backup requires the following URLs to be allowlisted in the firewall:

    - Login.windows.net
    - management.azure.com
    - *.blob.core.windows.net
- If you are using a disk private endpoint, then ensure to meet the following prerequisites:
    - The Cohesity cluster must have network connectivity to the subnet used for SAS URL private endpoints.
    - If your Cohesity cluster is located in an on-prem data center, then you must set up VPN or use the Azure express route. If you are using the Cohesity Cloud edition cluster, you must ensure network connectivity between the Cloud edition subnet and the subnet used for SAS URL private endpoints.
    - If you are using a proxy server for the backup of Azure VM using disk private endpoint, then you must perform the following steps:
        1. Create a private DNS zone and link to the virtual network of the proxy server.
        2. Contact Cohesity support and provide the Private DNS Zone name.
        3. Azure does not support SAS URI creation of a snapshot with a private endpoint if the size of Azure disk is more than 32 TB.

To configure the backup of Azure VMs using cloud-native APIs, perform the following steps:

1. Register the Azure cloud source. For more information, see Register an Azure Cloud Source at Subscription Level.
2. Create a Protection Group and select **Native Snapshot** as the Protection Group type. While configuring the job, select a cloud source. For detailed instructions, see Add a Protection Group for Azure VM.
3. You can recover the VMs from the snapshot on the Cohesity cluster to the cloud service as described in Recover VMs.

Native Snapshot Process for Creating a Snapshot

Creating a Snapshot for Managed Disks

Default method:

The following is the default native snapshot process for creating a snapshot:

1. A snapshot of each managed disk is taken.
2. (*Applicable only for private endpoint-enabled backup*) A disk access resource with a private endpoint linked is created.

3. (*Applicable only for private endpoint-enabled backup*) The disk access is then attached to the snapshot of the managed disk.

   > **Note:** The disk access resource can be shared only by five disks. For every backup, depending on the disk access availability, Cohesity creates a new disk access or uses an existing disk access to attach it to the disk snapshot.

4. A SAS URI (Uniform Resource Identifier) is generated for the created snapshot.
5. The snapshot is then copied to the Cohesity cluster.
   For managed disks, Azure does not provide APIs to perform incremental backups. The entire data is downloaded onto the Cohesity cluster each time you run a Protection Group.

Alternative method:

You can also use the following process for creating the snapshot:

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

1. A snapshot (S1) of each managed disk is taken.
2. (*Applicable only for private endpoint-enabled backup*) A disk access resource with a private endpoint linked is created and is then attached to the snapshot (S1).

   > **Note:** The disk access resource can be shared by up to five disks. For each backup, depending on disk access availability, Cohesity either creates a new disk access or reuses an existing one to attach to the disk snapshot.

3. A SAS URI is generated for the snapshot (S1).
4. Using the SAS URI, the snapshot (S1) is copied to the Cohesity cluster for the first backup, which will be a full backup.

   (*Applicable only for private endpoint-enabled backup*) The disk access resource attached to the snapshot (S1) is deleted.

   This snapshot (S1) on Azure is retained after the first protection run.
5. In the next protection run, a new snapshot (S2) of each managed disk is taken.
6. (*Applicable only for private endpoint-enabled backup*) A disk access resource with a private endpoint linked is created and is then attached to the new and the previous snapshots (S1 and S2).

> **Note:** Since each disk access resource can be shared by only five disks, multiple disk access resources may be created if there are more than five snapshots.

7. A SAS URI is generated for the new and previous snapshots.
8. The changes between the previous snapshot (S1) and the new snapshot (S2) are calculated and then downloaded to the Cohesity cluster.
9. The SAS URI of both the snapshots is revoked.
10. The previous snapshot (S1) on Azure is deleted. The new snapshot (S2) is retained on Azure for the next incremental protection run.

> **Important:** Multiple Protection Groups can share disk access. However, if no Protection Group has used it for the past 20 minutes, Cohesity will delete it.

Creating a Snapshot for Unmanaged Disks

1. A snapshot of an unmanaged disk is stored as a page blob.
2. The incremental changes between the previous and the current snapshot are calculated and then downloaded to a Cohesity cluster.
3. The previous snapshot is then deleted.

> **Note:** Only one outstanding snapshot (which reflects the latest complete snapshot) is always maintained and therefore to take an incremental backup, the current snapshot is compared with the previous outstanding snapshot and the incremental changes are only considered for backup. The older snapshots are deleted so that the system always maintains only one outstanding snapshot at any time.

Considerations

Review the following considerations of Azure native snapshotting:

- App consistent backup is not supported.
- Cloning is not supported.
- Disks cannot be excluded when using Azure Native Snapshot API.

Back Up Azure Cloud VMs to Cloud Edition Cluster Using Native Snapshot API

Cohesity Cloud Edition supports backing up Virtual Servers using the native snapshot API of the cloud service. For example, a Virtual Server Protection Group backs up VMs in a cloud service to a Cloud Edition Cohesity cluster running in the same cloud service. The result of this backup is Snapshots on the Cloud Edition cluster. You can recover the VMs from the snapshot on the Cohesity cluster to the cloud service as described in Recover VMs.

Review the following considerations of Azure native snapshotting:

- App consistent backup is not supported.
- Cloning is not supported.
- Disks cannot be excluded when using Azure Native Snapshot API.

Configure the Backup of a Cloud VM Using Cloud Native APIs

Prerequisites

Verify the following requirements prior to backing up the VMs:

- Azure Commercial Native Snapshot backup requires the following URLs to be allowlisted in the firewall:
  - Login.windows.net
  - management.azure.com
  - *.blob.core.windows.net
- If you are using a disk private endpoint, then ensure to meet the following prerequisites:
  - The Cohesity cluster must have network connectivity to the subnet used for SAS URL private endpoints.
  - If your Cohesity cluster is located in an on-prem data center, then you must set up VPN or use the Azure express route. If you are using the Cohesity Cloud edition cluster, you must ensure network connectivity between the Cloud edition subnet and the subnet used for SAS URL private endpoints.
  - If you are using a proxy server for the backup of Azure VM using disk private endpoint, then you must perform the following steps:
    1. Create a private DNS zone and link to the virtual network of the proxy server.
    2. Contact Cohesity support and provide the Private DNS Zone name.
    3. Azure does not support SAS URI creation of a snapshot with a private endpoint if the size of Azure disk is more than 32 TB.

To configure the backup of Azure VMs using cloud native APIs , perform the following steps:

1. Register the Azure cloud source. For more information, see Register an Azure Cloud Source at Subscription Level.
2. Create a Protection Group and select **Native Snapshot** as the Protection Group type. While configuring the job, select a cloud source. For detailed instructions, see Add a Protection Group for Azure VM.
3. You can recover the VMs from the snapshot on the Cohesity cluster to the cloud service as described in Recover VMs.

Native Snapshot Process for Creating a Snapshot

> **Note:** By default, every backup run is a full backup. Please contact Cohesity Support to enable incremental backup.

Creating a Snapshot for Managed Disks

Default method:

The following is the default native snapshot process for creating a snapshot:

1. A snapshot of each managed disk is taken.
2. (*Applicable only for private endpoint-enabled backup*) A disk access resource with a private endpoint linked is created.
3. (*Applicable only for private endpoint-enabled backup*) The disk access is then attached to the snapshot of the managed disk.
4. A SAS URI (Uniform Resource Identifier) is generated for the created snapshot.
5. The snapshot is then copied to the Cohesity cluster.
   For managed disks, Azure does not provide APIs to perform incremental backups. The entire data is downloaded onto the Cohesity cluster each time you run a Protection Group.

Alternative method:

You can also use the following process for creating the snapshot:

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

1. A snapshot (S1) of each managed disk is taken.
2. (*Applicable only for private endpoint-enabled backup*) A disk access resource with a private endpoint linked is created and is then attached to the snapshot (S1).
3. A SAS URI is generated for the snapshot (S1).

4. Using the SAS URI, the snapshot (S1) is copied to the Cohesity cluster for the first backup, which will be a full backup.

   (*Applicable only for private endpoint-enabled backup*) The disk access resource attached to the snapshot (S1) is deleted.

   This snapshot (S1) on Azure is retained after the first protection run.
5. In the next protection run, a new snapshot (S2) of each managed disk is taken.
6. (*Applicable only for private endpoint-enabled backup*) A disk access resource with a private endpoint linked is created and is then attached to the new and the previous snapshots (S1 and S2) .

   > **Note:** Multiple disk access resource may exist if the there are more than five snapshots.
7. A SAS URI is generated for the new and previous snapshots.
8. The changes between the previous snapshot (S1) and the new snapshot (S2) are calculated and then downloaded to the Cohesity cluster.
9. The SAS URI of both the snapshots are revoked.
10. The previous snapshot (S1) on Azure is deleted. The new snapshot (S2) is retained on Azure for the next incremental protection run.

Creating a Snapshot for Unmanaged Disks

1. A snapshot of an unmanaged disk is stored as a page blob.
2. The incremental changes between the previous and the current snapshot are calculated and then downloaded to a Cohesity cluster.
3. The previous snapshot is then deleted.

   > **Note:** Only one outstanding snapshot (which reflects the latest complete snapshot) is always maintained and therefore to take an incremental backup, the current snapshot is compared with the previous outstanding snapshot and the incremental changes are only considered for backup. The older snapshots are deleted so that the system always maintains only one outstanding snapshot at any time.

Back Up Azure Cloud VMs Using Cloud Snapshot Management

Cohesity cluster uses Cloud Snapshot Management (CSM) APIs to backup the Azure VMs (Managed VMs) and AWS Cloud services to the same cloud. To enable this feature, you must select the Snapshot Manager as the job type while creating the Virtual Server Protection

Group. When this Protection Group is executed, the VMs' snapshots are created on the same cloud service. The CSM snapshots are stored in the same Azure subscription, but can be used to recover to a different subscription.

Cloud Snapshot Management Process for Creating the Snapshot

For Azure Managed Disks:

1. Fetch the information about the VM using the GET API.

   This API takes `subscriptionId`, `resourceGroupName`, and `vmName` as an argument and returns the information about the VM (such as disks, network interfaces, and so on).
2. After the VM information is fetched, snapshots of the VM's disk is created on the same cloud service using the Snapshots API.

You can also recover these snapshots. For more information, see Recover VMs.

Considerations

- The backup of unmanaged VMs is not supported.
- Incremental snapshot of managed disks is not supported
- App consistent backup is not supported.
- Cloning is not supported.
- File download is not supported.

Configure the Back Up of a Cloud VM Using CSM

1. Register the Azure cloud source. For more information, see Register an Azure Cloud Source at Subscription Level.
2. Create a Protection Group and select **Snapshot Manager** as the Protection Group type. While configuring the job, select a cloud source. For detailed instructions, see Add a Protection Group for Azure VM.
3. You can recover the VMs from the snapshot on the Cohesity cluster to the cloud service as described in Recover VMs.

Cohesity creates a snapshot of VMs for Azure on the same Cloud service.

Add a Protection Group for Azure VM

In Cohesity, Azure VMs are protected using a Protection Group and a Protection Policy. A Protection Group uses the schedules and settings defined in the policy to determine when and how backups are captured, archived, or replicated.

A Protection Policy is a reusable set of settings that define how and when objects are protected and replicated. You can select which standard or custom policy to use when creating a Protection Group.

To protect Azure VMs:

1. Select **Data Protection** > **Protection**.
2. Click **Protect** on the top-right of the page and then select **Virtual Machines**.
3. Click **Add Objects** and from the **Registered Source** drop-down list, select the Azure source you want to back up. You can also register a new Azure source with the Cohesity cluster by clicking **Register Source**. For more information, see Register an Azure Cloud Source at Subscription Level.
4. In the **Objects** section, choose the Azure VM using one of the following views:
   - **List View**: Use this option to select the Azure VMs for protection from a flat, searchable list.
   - **Hierarchy View**: Use this option to select Azure VMs for protection at various hierarchy levels (Tenant level, Subscription level, resource group level).

     Optionally:

     a. You can click the auto-protect icon at the **Tenant** level, **Subscription level, Resource group** level to automatically protect newly added VMs.

     b. You can exclude VMs from auto-protection within an account, region, or cluster by clicking the auto-protected icon ( ) next to the VM. The VMs excluded from auto-protection are displayed with the exclude ( ) icon.
   - **Tags**: Use this option to select the VMs for protection based on tags. Select the checkbox of a tag, and then select Select All Child Objects to include all tables with that tag for protection.

     Optionally:

     - You can configure auto-protection based on a tag. You can select the tag checkbox and then choose **Auto Protect This Tag** to automatically protect all newly added VMs with this tag.
     - You can exclude the Azure VMs from auto-protection within a tag by clicking the auto-protect icon ( ) next to the table. The VMs excluded from auto-protection are displayed with the exclude ( ) icon.
     - You can exclude VMs with a specific tag from auto-protection by clicking the exclude icon (⊘). The tag excluded from auto-protection are displayed with the excluded icon.
5. (*Supported only on DataProtect for cloud in Azure*) Optionally, you can exclude any disk of the Azure VM from protection. To exclude a disk:
   1. Click the **All Volumes** edit icon displayed next to the VM of which you want to exclude the disk.
   2. Unselect the disks that you want to exclude from protection.

> **Note:** You cannot exclude the root disk from protection.

3. Click **Save** > **Continue**.

> **Note:** You cannot exclude disk at the object level for auto-protected VMs. To exclude disk for auto-protect VMs, use the **Volume Exclusion Settings** option in the Additional Settings.

6. Provide a name for the **Protection Group**. The name can contain alphanumeric characters, underscores, dashes, and periods.
7. In the **Protection Group** field, enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.
8. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, see Create or Edit a Standard Policy.
9. If you want to change or configure any of the additional settings, then select **More Options** and perform the below steps or else, click **Protect**.
10. Select a **Protection Group Type**:
    - **Native Snapshot**—Back up VMs in a cloud service using the native snapshot API of the cloud service.
    - **Snapshot Manager**—Backup VMs in a cloud service using the Cloud Snapshot Manager APIs of the cloud service.
11. Optionally, from the **Policy** drop-down list, you can change the policy you selected earlier policy or create a new Protection Policy. For more information, see Create or Edit a Standard Policy.
12. In the **Storage Domain** field, select the storage domain where you want to store the snapshots.
13. In the **Start Time** field, the default time zone is the browser's time zone. You can change the time zone of the job by selecting a different time zone.
14. In the **SLA** field, select how long the administrator expects a Protection Group run to take.
    - **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).
    - **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run.

15. If you need to change any of the advanced settings on the Protection Group page, click the down arrow icon next to **Additional Settings** and click **Edit** on the right. For more information, see Additional Settings.
16. Click **Protect**.

The protection of Azure VMs is now active and running.

Additional Settings

If you select..	Then..
Pause Future Runs	Toggle on this option to stop protection runs of the Protection Group from executing. Once you enable this option, no protection runs will be scheduled for this Protection Group.
End Date	Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts prior to this date runs until completion even if it completes after this date.

If you select..	Then..

Azure SAS URL Type
 	
Note: This option is available only if you have selected the **Native Snapshot** option as the Protection Group Type.
	For the backup of Azure VMs, Cohesity uses the snapshots of Azure managed disks that are accessible through SAS URLs. Select one of the following endpoint options to access data from the SAS URL:
	
	• **Public Endpoint**: Select this option to access snapshots over a public network.
	• **Private Endpoint**: Select this option to access snapshots using a private IP address from your virtual network. Provide the following details for configuring the private endpoint:
	  • **Region**: Select the region of the VM you have selected for backup.
	  • **Virtual Network**: Select a virtual network in Azure. Ensure this virtual network is connected to the Cohesity cluster.
	  • **Subnet**: Select a subnet of the virtual network.
	
	Note:
	• In the native snapshot backup process for managed disks, a disk access resource is created and attached to the snapshot. Since the disk access requires an IP address, ensure that the selected subnet has sufficient IP availability. For more see Back Up Azure Cloud VMs to On-Premises Cluster Using Native Snapshot API
	• If you have selected VMs from multiple regions, then you must select at least one virtual network and subnet per region. Click the add icon to add regions and their virtual networks and subnets.
	• The Private Endpoint option is not supported for the VMs selected using auto-protect. To use a private endpoint, you must manually select the VMs for protection.
	• The disk size limit of an Azure VM using a private endpoint is 32 TB.
	
	Cohesity recommends using dedicated subnets for Azure SAS URL endpoint.

If you select..	Then..
QoS	Select an appropriate quality of service (QoS) policy. Cohesity recommends specifying Backup HDD, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups. Backup SSD policy and reduces the SSD wear-out compared to the Backup SSD policy. • **Backup Auto**: (Applicable only for C6K Platform) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve similar backup performance as the • **TestAndDev High**: The Cohesity cluster writes the data to an SSD drive for this Protection Group. The I/Os with this QoS policy are given higher priority compared to other QoS policies. Use this policy for workloads that require lower I/O latency.
Indexing	This option is toggled on by default to index the data of the Protection Group. Indexing improves files and folders search. Cohesity performs incremental indexing where only the data that has changed since the previous snapshot is scanned and indexed.

If you select..	Then..
Volume Exclusion Settings (*Supported only on DataProtect for cloud in Azure*)	Use the following tag keys to construct a boolean expression for excluding disks based on disk tags: • Name • automation • cohesity::helios::uuid • email • environment • expiry • location • non-business-hrs • purpose • rigel • squad • test • user • weekend For example, the expression, `(name = net_volume AND environment IN (qa, dev)) OR sqaud = eng`, excludes all disks from protection for which the disk tags meet the above condition. **Note:** Exclusion of disks enabled at the object level will take precedence over the exclusion configured here.
Cancel Run at Quite Start Time	Available only if the selected policy has at least one quiet time period. Toggle it on to specify that all currently executing protection runs should abort if a quiet time period specified for the Protection Group starts. If the option is toggled off, then after a protection run starts, it continues to execute even when a quiet time period specified for this Protection Group starts. However, a new protection run will not start during a quiet time period.

If you select..	Then..
Alerts	Optional. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts.
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of jobs exceeds the ability to process jobs, this will be the priority of implementation of the jobs: a. High b. Medium c. Low
Description	Enter a brief description about the Protection Group.

Azure Stack Hub

Cohesity supports image-level backups of VMs in Azure Stack Hub. Cohesity supports the following Azure Stack Hub versions:

- 2102
- 2008
- 2005

Note the following terminology:

- Source cluster—Cohesity cluster on which the Azure Stack Hub VM is registered and protected.
- Target cluster—Remote Cohesity cluster to which the Azure Stack Hub VM backup data is replicated. For more information about replication, see About Replication Setup.

You can perform the following tasks:

- Back up and restore Azure Stack Hub VMs.
- Restore an individual file from the backup. You must install the Cohesity agent on the VM to perform file-level recovery.
- Replicate and archive backups. You can restore VMs, files, or folders only from replicated or archived copies.
- Back up and restore Azure Stack Hub infrastructure data.
- Restore Azure Stack Hub VMs
    - On one Cohesity cluster, you can restore VMs from:
        - Azure Stack Hub to Azure Standard
        - Azure Standard to Azure Stack Hub
        - Azure Stack Hub that uses AD to Azure Stack Hub that uses AD FS
        - Azure Stack Hub that uses AD FS to Azure Stack Hub that uses AD
    - You can restore VMs from:
        - Azure Stack Hub in the source cluster to Azure Standard in the target cluster
        - Azure Standard in the source cluster to Azure Stack Hub in the target cluster
        - Azure Stack Hub that uses AD in the source cluster to Azure Stack Hub that uses AD FS in the target cluster
        - Azure Stack Hub that uses AD FS in the source cluster to Azure Stack Hub that uses AD in the target cluster
- Failover Azure Stack Hub VMs
    - On one Cohesity cluster, you can failover VMs from:
        - Azure Stack Hub to Azure Standard
        - Azure Standard to Azure Stack Hub
    - You can failover VMs from:
        - Azure Stack Hub in the source cluster to Azure Standard in the target cluster
        - Azure Standard in the source cluster to Azure Stack Hub in the target cluster
- Migrate Azure Stack Hub VMs
    - On one Cohesity cluster, you can migrate VMs from:
        - Azure Stack Hub to Azure Standard
        - Azure Standard to Azure Stack Hub

- You can migrate VMs from:
  - Azure Stack Hub in the source cluster to Azure Standard in the target cluster
  - Azure Standard in the source cluster to Azure Stack Hub in the target cluster

When registering or editing an Azure Cloud source, specify the authentication type, region, and domain name for Azure Stack Hub. For more information, see the following topics:

- Register an Azure Cloud Source at Subscription Level
- Azure

Protect Azure Stack Hub Infrastructure

Cohesity enables you to manage Azure Stack Hub infrastructure backups. You can backup and restore the data to an existing Azure Stack Hub or another Azure Stack Hub in case of a disaster. Azure Stack Hub administrators can backup Azure Stack Hub infrastructure data to an SMB share. For more information, see Recover data in Azure Stack Hub with the Infrastructure Backup Service in the Microsoft Azure documentation.

To protect Azure Stack Hub infrastructure data, complete the following steps:

1. Create a View to backup Azure Stack Hub infrastructure data. For more information, see Create Views Using a Predefined Template.
2. Create a protection job for the View. For more information, see Add or Edit a Protection Group for a View.

Considerations

- Incremental backup is not supported.
- Direct upload to Azure managed disks is not supported.
- Generation 2 VMs and encrypted VMs are not supported.
- Cloning of Hyper-V VMs to Azure Stack Hub is not supported.

Recover Azure Virtual Machines

This chapter includes the following topics:

Recover Files or Folders for Azure Native Snapshots to the New Server

Prerequisites

- Firewall port 50051 must be open on the target VM. For more information, see Manage Firewall Ports
- The target VM must be reachable with private IP.
- The Azure agent must be installed on the source VM.

> **Note:** You can perform files and folder recovery to an Azure VM Linux instance only if the Azure VM Linux instance is of x86_64 architecture.

> **Note:** Files and folder recovery of Azure VM is an Early Acces feature on DataProtect for cloud in Azure. Contact your Cohesity account team to enable the feature.

Recover Files and Folders to New Server

Perform the following steps to recover files and folders to the new server:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** at the top right of the page and then select **Files or Folders**.

   The Recover Files or Folders page appears.
3. Select any one of the following options to search for the file or folder:
   - **Files and Folders**: Allows you to search and recover files using file or folder names from any backup available on Cohesity.
   - **Browse or Specify Path for Search**: Allows you to search and recover files using the name of the server or Protection Group from any backup available on Cohesity.

If you select..	Then..
Files and Folders	a. Enter characters of the file name, path, or by specifying the wildcard character *. A list of items displays. You can optionally filter the search results by object type, source, object, Protection Group, Storage Domain, files only, or folders only. b. From the list of search results, select the required files or folders to recover. c. By default, the latest snapshot is selected for recovery. To recover from a different snapshot: i. From the selected list, mouse over the snapshot, and then click the **edit** icon. The Edit recovery point page appears. ii. By default, only the snapshots that are indexed are displayed. To display all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. iii. Select a date range and the snapshot point for recovery. By default, the snapshot is recovered from the local cluster. d. Go to step 4.

If you select..	Then..
Browse	1. Enter the full or partial server or Protection Group name. You can by specify the wildcard character *. You can also optionally filter the search results by object type, source, object, Protection Group, Storage Domain. 2. From the list of search results, select the object whose files or folders are to be recovered. 3. By default, the latest snapshot is selected for recovery. To recover from a different snapshot, click the snapshots drop-down in the top-left corner and select the snapshot you need. 4. **Browse on Indexed Data**: Toggle on this setting to browse the indexed data. It helps to speed up browsing of recovery data. By default, it only displays the files and folders that are indexed. Hidden files, folders, paths such as /usr, /var, /sys , /Windows, /ProgramData etc. are excluded from indexing. To display all the available files and folders, including hidden files and folders toggle off the **Browse on Indexed Data** setting. **Note:** • Changing the snapshot after selecting the items (files or folder) removes the selected items from the cart. • Enabling or disabling the **Browse on Indexed Data** option after selecting the items (files or folder) removes the selected items from the cart. • Deleted snapshots may be displayed as valid recovery points for a brief period until they are removed from the search index by a background process. 5. Browse to the file or folder that you want to recover by clicking a folder and subfolders. 6. Click **Save**. 7. After saving the selection, if you want to recover from a different snapshot or change the location from where the snapshot is recovered, perform the following steps: 1. From the selected list, mouse over the snapshot, and click the edit icon. The Edit recovery point page appears. 2. By default, only the snapshots that are indexed are displayed. To display

If you select..	Then..
	all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. 3. Select a date range and the snapshot point for recovery. By default, the snapshot is recovered from the local cluster. 8. Go to step 4.

The Cohesity cluster attempts to index all files and folders to a drive on both Windows and Linux systems. If the Cohesity cluster is unable to find mount point information about files or directories, it indexes and displays these files and directories in the `lvol_N` directory, where `N` is a unique number such as `1`.

On Windows systems, if the Cohesity cluster finds the mount point information about files and directories, it indexes and displays these files and directories with a drive letter such as `C:`.

On Linux systems, how files and directories are indexed and displayed is dependent on the conditions specified in the following table.

Server Type	Volume Type	

Linux Virtual Machine	Simple Volume	The Cohesity cluster detects mount points for entries in the `/etc/fstab` file with the following formats:
		`UUID=ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc /mnt ext4 auto 0`
		`UUID="ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc" /mnt ext4 auto 0`
		If the Cohesity cluster can detect a mount point, it indexes and displays files and directories in the volume with the mount point that was specified in the `/etc/fstab` file. For these example entries, files and directories are indexed with the `/mnt` mount path, such as `/mnt/example/test.txt`.
		If the Cohesity cluster cannot detect a mount point, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

Server Type	Volume Type	

Linux Virtual Machine	LVM Volume	The Cohesity cluster detects mount points for entries in the `/etc/fstab` file with the following formats:
		`UUID=ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc /mnt ext4 auto 0`
		`/dev/mapper/VG1-root /mnt ext4 defaults 1 1`
		`/dev/VG1/root /mnt ext4 defaults 1 1`
		If the Cohesity cluster can detect a mount point, it indexes and displays files and directories in the volume with the mount point specified in the `/etc/fstab` file. For these example entries, files and directories are indexed with the `/mnt` mount path, such as `/mnt/example/test.txt`.
		If the Cohesity cluster cannot detect a mount point, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

Linux Physical	LVM Volume	The Cohesity agent can only return mount data when the volume is mounted on the Linux physical Server. If the volume is mounted, the Cohesity cluster indexes and displays files and directories in the volume with the mount point such as `/mnt/example/test.txt`. If the volume is not mounted, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

4. Once you select the files and folder to recover, select one of the following options:
   - **Next: Recover Options**: If you select this option, then continue with the step 5 to configure the file recovery options.
   - **Download Files**: If you are recovering a single file, this option downloads the file to your browser's download folder. For all other selections, this creates a recovery task. When the task completes, from the Recoveries page, click the task name and then click **Download Files** to download the generated zip file.

     Character replacement explanation for : and \ in file and directory names in zip files

     If the original file or directory name contains a ':', it is replaced with '_COLON_' in the archive.
     Example:

- The original name is "a:b" then the archived name is "a_COLON_b"
- The original name is "a:b:c" then the archived name is "a_COLON_b_COLON_c"

If the original file or directory name contains a '\', it is replaced with '_BACK_SLASH_' in the archive.
Example:

- The original name is "x\y" then the archived name is "x_BACK_SLASH_y"
- The original name is "x\y\z" then the archived name is "x_BACK_SLASH_y_BACK_SLASH_z"

5. From the **Recover To**, select **New Server** to recover the files or folders to a new server.
6. **Source**: From the **Source** drop-down menu, select a registered server to which you want to recover the files and folders. You can also register a new source by clicking **Register Source**.
7. **Target**: From the Target (for VM and physical server) or Volume (for NAS) drop-down menu, select a VM or volume to which the files and files are to be recovered.

   > **Note:** For recovering files and folders of a VMware VM, ensure that VMware Tools are installed and running on the target VM. The target list displayed includes only VMs with VMware Tools installed and running.

8. **Recover to**: In the **Recover to** field, change the default location to which the files or folders are recovered. By default, the files and folders are recovered to the /**tmp**/ directory for VMs.

   For NAS, an example path on an alternate location could be /tmp/recover. You can recover encrypted files/folders to their original location only.

   Example for Windows alternate location:

   - D:\cohesity_restore\1.txt
   - D:\cohesity_restore\bar

   User Account Requirements for VM Protection may need to be met to recover files to a Windows VM.

   If recovering to a standalone Hyper-V host or cluster, you must add the guest VM to the reverse lookup zone in the DNS server to complete the recovery successfully.
9. Optional. Edit the default settings of the following **Recovery options**:
   - **Overwrite Existing File/Folder**: By default, this option is enabled to overwrite the existing files and folders. Disable this option to create the files and folders in the specified location. Any duplicate files are skipped.

Example for a Windows alternate location with **Overwrite Existing File/Folder** enabled and the target already exists:

Files to be recovered: "C:\foo\1.txt", "C:\foo\test\1.txt", "C:\bar", "C:\foo\bar". Specified alternate location: "C:\restore". At the end of the copy, the target folder looks like this:

- C:\restore\1.txt
- C:\restore\cohesity<taskid>_0\1.txt
- C:\restore\bar
- C:\restore\cohesity<taskid>_1\bar

If **Overwrite Existing File/Folder** is enabled, recovering a file to source when the file is in Fuse may cause the open file to be overwritten. Whether overwriting occurs depends on the application using the file.

- **Preserve File/Folder Attributes**: By default, this option is enabled and the ACLs, permissions, and timestamps are preserved for all files and folders. If you disable this option, then ACLs and permissions are not preserved. If recovering both folders and files, then folders will receive the new timestamps, but files retain their original timestamps. If recovering only files, then files will receive the new timestamps.
- **Continue on Error**: Enable this option if you want to continue the recovery even if one of the objects encounters an error. By default, this option is disabled and the recovery operation will fail if one of the objects encounters an error.
- **Cluster Interface**: By default, the Auto Select option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the Interface Group drop-down.
- **Task Name**: Change the default name of the recovery task.

10. Click **Start Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Recover Files or Folders for Azure Native Snapshots to the Original Server

Prerequisites

- Firewall port 50051 must be open on the target VM. For more information, see Manage Firewall Ports
- The target VM must be reachable with private IP.
- The Azure agent must be installed on the source VM.

> **Note:** You can perform files and folder recovery to an Azure VM Linux instance only if the Azure VM Linux instance is of x86_64 architecture.

Recover Files and Folders to Original Server

Perform the following steps to recover files and folders to the original server:

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Click **Recover** at the top right of the page and then select **Files or Folders**.

   The Recover Files or Folders page appears.
3. Select any one of the following options to search for the file or folder:
   - **Files and Folders**: Allows you to search and recover files using file or folder names from any backup available on Cohesity.
   - **Browse or Specify Path for Search**: Allows you to search and recover files using the name of the server or Protection Group from any backup available on Cohesity.

If you select..	Then..
Files and Folders	a. Enter characters of the file name, path, or by specifying the wildcard character *. A list of items displays. You can optionally filter the search results by object type, source, object, Protection Group, Storage Domain, files only, or folders only. b. From the list of search results, select the required files or folders to recover. c. By default, the latest snapshot is selected for recovery. To recover from a different snapshot: i. From the selected list, mouse over the snapshot, and then click the **edit** icon. The Edit recovery point page appears. ii. By default, only the snapshots that are indexed are displayed. To display all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. iii. Select a date range and the snapshot point for recovery. By default, the snapshot is recovered from the local cluster. d. Go to step 4.

If you select..	Then..
Browse	1. Enter the full or partial server or Protection Group name. You can by specify the wildcard character *. You can also optionally filter the search results by object type, source, object, Protection Group, Storage Domain. 2. From the list of search results, select the object whose files or folders are to be recovered. 3. By default, the latest snapshot is selected for recovery. To recover from a different snapshot, click the snapshots drop-down in the top-left corner and select the snapshot you need. 4. **Browse on Indexed Data**: Toggle on this setting to browse the indexed data. It helps to speed up browsing of recovery data. By default, it only displays the files and folders that are indexed. Hidden files, folders, paths such as /usr, /var, /sys , /Windows, /ProgramData etc. are excluded from indexing. To display all the available files and folders, including hidden files and folders toggle off the **Browse on Indexed Data** setting. **Note:** • Changing the snapshot after selecting the items (files or folder) removes the selected items from the cart. • Enabling or disabling the **Browse on Indexed Data** option after selecting the items (files or folder) removes the selected items from the cart. • Deleted snapshots may be displayed as valid recovery points for a brief period until they are removed from the search index by a background process. 5. Browse to the file or folder that you want to recover by clicking a folder and subfolders. 6. Click **Save**. 7. After saving the selection, if you want to recover from a different snapshot or change the location from where the snapshot is recovered, perform the following steps: 1. From the selected list, mouse over the snapshot, and click the edit icon. The Edit recovery point page appears. 2. By default, only the snapshots that are indexed are displayed. To display

If you select..	Then..
	all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. 3. Select a date range and the snapshot point for recovery. By default, the snapshot is recovered from the local cluster. 8. Go to step 4.

The Cohesity cluster attempts to index all files and folders to a drive on both Windows and Linux systems. If the Cohesity cluster is unable to find mount point information about files or directories, it indexes and displays these files and directories in the `lvol_N` directory, where `N` is a unique number such as `1`.

On Windows systems, if the Cohesity cluster finds the mount point information about files and directories, it indexes and displays these files and directories with a drive letter such as `C:`.

On Linux systems, how files and directories are indexed and displayed is dependent on the conditions specified in the following table.

Server Type	Volume Type	

Linux Virtual Machine	Simple Volume	The Cohesity cluster detects mount points for entries in the `/etc/fstab` file with the following formats:
		`UUID=ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc /mnt ext4 auto 0`
		`UUID="ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc" /mnt ext4 auto 0`
		If the Cohesity cluster can detect a mount point, it indexes and displays files and directories in the volume with the mount point that was specified in the `/etc/fstab` file. For these example entries, files and directories are indexed with the `/mnt` mount path, such as `/mnt/example/test.txt`.
		If the Cohesity cluster cannot detect a mount point, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

Server Type	Volume Type	

Linux Virtual Machine	LVM Volume	The Cohesity cluster detects mount points for entries in the `/etc/fstab` file with the following formats:
		`UUID=ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc /mnt ext4 auto 0`
		`/dev/mapper/VG1-root /mnt ext4 defaults 1 1`
		`/dev/VG1/root /mnt ext4 defaults 1 1`
		If the Cohesity cluster can detect a mount point, it indexes and displays files and directories in the volume with the mount point specified in the `/etc/fstab` file. For these example entries, files and directories are indexed with the `/mnt` mount path, such as `/mnt/example/test.txt`.
		If the Cohesity cluster cannot detect a mount point, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

Linux Physical	LVM Volume	The Cohesity agent can only return mount data when the volume is mounted on the Linux physical Server. If the volume is mounted, the Cohesity cluster indexes and displays files and directories in the volume with the mount point such as `/mnt/example/test.txt`. If the volume is not mounted, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

4. Once you select the files and folder to recover, select one of the following options:
   - **Next: Recover Options**: If you select this option, then continue with the step 5 to configure the file recovery options.
   - **Download Files**: If you are recovering a single file, this option downloads the file to your browser's download folder. For all other selections, this creates a recovery task. When the task completes, from the Recoveries page, click the task name and then click **Download Files** to download the generated zip file.

     Character replacement explanation for : and \ in file and directory names in zip files

     If the original file or directory name contains a ':', it is replaced with '_COLON_' in the archive.
     Example:

- The original name is "a:b" then the archived name is "a_COLON_b"
- The original name is "a:b:c" then the archived name is "a_COLON_b_COLON_c"

If the original file or directory name contains a '\', it is replaced with '_BACK_SLASH_' in the archive.
Example:

- The original name is "x\y" then the archived name is "x_BACK_SLASH_y"
- The original name is "x\y\z" then the archived name is "x_BACK_SLASH_y_BACK_SLASH_z"

5. From the **Recover To**, select **Original Server** to recover the files or folders to a new server.
6. **Recover to Original Path**: To recover to a different location in the original server, disable the **Recover to Original Path** option, and then provide the location to which the files or folders are to be recovered in the **Recover To** field. By default, the files and folders will be recovered to the original location.
7. Optional. Edit the default settings of the following **Recovery options**:
   - **Overwrite Existing File/Folder**: By default, this option is enabled to overwrite the existing files and folders. Disable this option to create the files and folders in the specified location. Any duplicate files are skipped.

     Example for a Windows alternate location with **Overwrite Existing File/Folder** enabled and the target already exists:

     Files to be recovered: "C:\foo\1.txt", "C:\foo\test\1.txt", "C:\bar", "C:\foo\bar". Specified alternate location: "C:\restore". At the end of the copy, the target folder looks like this:

     - C:\restore\1.txt
     - C:\restore\cohesity<taskid>_0\1.txt
     - C:\restore\bar
     - C:\restore\cohesity<taskid>_1\bar

     If **Overwrite Existing File/Folder** is enabled, recovering a file to source when the file is in Fuse may cause the open file to be overwritten. Whether overwriting occurs depends on the application using the file.
   - **Preserve File/Folder Attributes**: By default, this option is enabled and the ACLs, permissions, and timestamps are preserved for all files and folders. If you disable this option, then ACLs and permissions are not preserved. If recovering both folders and files, then folders will receive the new timestamps, but files retain their original timestamps. If recovering only files, then files will receive the new timestamps.

- **Continue on Error**: Enable this option if you want to continue the recovery even if one of the objects encounters an error. By default, this option is disabled and the recovery operation will fail if one of the objects encounters an error.
- **Cluster Interface**: By default, the Auto Select option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the Interface Group drop-down.
- **Task Name**: Change the default name of the recovery task.

8. Click **Start Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Recover Azure VMs to a New Location

You can recover the VM files to an alternate datastore and create new instances of the VMs in a new location of a registered Azure source.

Before you can recover VMs to its new location, Snapshots of those volumes must exist on the Cohesity cluster. To create Snapshots, create and run a Protection Group.

To recover VMs to a new location:

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Click on **Recover** located at the top right of the page and then select **Virtual Machines > VMs**.

   The Virtual Machines page appears.
3. Search for Protected Object (VM) or Protection Group that contains the snapshots to recover from by entering characters of the VM name, Protection Group name, or by specifying the wildcard character *.

   A list of VMs displays.

   You can optionally filter the search results by Source, Protection Group, Storage Domain, or Date.
4. From the list of search results, select one or more VMs or Protection Groups that contain the snapshots to recover.

> **Note:**
> - If you have selected a Protection Group, then all the VMs backed up in the latest protection run of this Protection Group will be selected for recovery and the option to select those VMs individually will be greyed out in the search result list.
> - You can only select Protection Groups and VMs with snapshots stored in the same Storage Domain and belonging to the same source. Once you select a VM or Protection Group, the **Storage Domain** and **Source** filters will automatically get locked.

5. By default, the latest snapshot of the VMs is selected for recovery. To recover from a different snapshot, perform the following steps depending on the object selected:

> **Note:** In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

To choose a different snapshot for a..	Then..
Protection Group	1. From the selected lists, mouse over the snapshot, and then click the **edit** icon. 2. From the Protection Run drop-down menu, select the snapshot from which you want to recover the VMs. By default the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. 3. Click **Select Recovery Point** and then go to step 6.

To choose a different snapshot for a..	Then..
VM	From the selected lists, mouse over the snapshot, and then click the edit icon. The Edit recovery point for <VM_name> page appears. By default, the option to select the snapshot is displayed in **Timeline** mode. You can also choose to view the option in **List** mode by clicking the List tab in the top-right corner of the page. • To select a snapshot from the Timeline mode: a. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar. b. Select the snapshot to be recovered by clicking the corresponding blue dot. c. By default, the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. d. Click **Select Recovery Point** and then go to step 6. • To select a snapshot from the **List** mode: a. Select the List tab from the top-right corner of the Edit recovery point for <VM_name> page. By default, the page displays the snapshots available in the last one month. b. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range. c. Select the snapshots to be recovered. d. By default, the snapshot is recovered from the local Cohesity cluster. You can also select snapshots archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. e. Click **Select Recovery Point** and then go to step 6.

6. Click **Next: Recover Options**.

   From the **Recover To** options, select **New Location** and provide the following details to recover the VM to an alternate datastore and create new instances of the VMs in a new location of a registered Source.

   a. **Source:** Select a registered Source to recover the VMs to.
   b. **Resource Group, Storage Account:** Select the corresponding Resource Group and Storage Account to which the recovery has to be done. The storage account you select must be in the same region as the resource group. Any storage account not in the same region as the parent resource group will not be displayed as an option in the recovery workflow.
   c. **Storage Container:** Select the storage container in which page blobs will be created.
   d. **Compute:** Select the VM size type such as **Standard_D1** to use when recovering the VMs.
   e. **Availability Set:** Optionally, select the availability set to which the VM has to be recovered. For more information, see Azure Availability Sets.
   f. **Virtual Network:** Select the virtual network where the VM must be placed.
   g. **Subnets:** Subnets in the virtual network where VMs must be placed.

7. Optional. Edit the default settings of the following **Recovery Options**:

Recovery Options	Description
Rename	Add Prefix and/or Suffix strings to the names of the new VMs created by this task. For example, you could specify Prefix Test_ and Suffix _QA to the VM name WinOS and when the VM is recovered, the new VM that is created is called Test_WinOS_QA.

Recovery Options	Description

Azure SAS URL Type	For recovering Azure VMs, Cohesity uses the snapshots of Azure managed disks that are accessible through SAS URLs. Select one of the following endpoint options to access data from the SAS URL:
	• **Public Endpoint**: Select this option to access snapshots over a public network
	• **Private Endpoint**: Select this option to access snapshots using a private IP address from your virtual network. Provide the following details for configuring the private endpoint:
	  • **Region**: Select the region of the VM you have selected for recovery.
	  • **Virtual Network**: Select a virtual network in Azure. Ensure this virtual network is connected to the Cohesity cluster.
	  • **Subnet**: Select a subnet of the virtual network.
	Cohesity recommends using dedicated subnets for the Azure SAS URL endpoint.

Power State	To ensure that the restored Azure VMs are functioning properly, the VMs are powered on by default after the restoration process. However, you can enable the **Power Off** option if you prefer to keep the VMs powered off once Cohesity verifies their functionality. If you are recovering VMs from a Storage Domain with Cloud Tier enabled, Cohesity recommends keeping the VMs powered off.
Continue on Error	Enable **Continue recovery even if errors occur when recovering VMs** if you want the recovery task to continue even if errors occur when recovering the VMs. For example, if one of the VMs cannot be created, the Cohesity cluster will still attempt to create the other VMs. If this option is disabled, then the recovery task is discontinued if VM creation fails. However, if the VM creation succeeds, but VM storage migration fails, the task continues. By default this option is disabled.
Cluster Interface	By default, the **Auto Select** option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the **Interface Group** drop-down.
Task Name	Change the default name of the recovery task.

8. Click **Recover**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Recover Azure VMs to Original Location

Before you can recover VMs to its original location, snapshots of those volumes must exist on the Cohesity cluster. To create Snapshots, create and run a Protection Group.

To recover VMs to its original location:

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Click on **Recover** located at the top right of the page and then select **Virtual Machines > VMs**.

   The Virtual Machines page appears.
3. Search for a Protected Object (VM) or Protection Group that contains the snapshots to recover from by entering characters of the VM name, Protection Group name, or by specifying the wildcard character *.

   A list of VMs displays.

   You can optionally filter the search results by Source, Protection Group, Storage Domain, or Date.
4. From the list of search results, select one or more VMs or Protection Groups that contain the snapshots to recover.

   > **Note:**
   > - If you have selected a Protection Group, then all the VMs backed up in the latest protection run of this Protection Group will be selected for recovery and the option to select those VMs individually will be greyed out in the search result list.
   > - You can only select Protection Groups and VMs with snapshots stored in the same Storage Domain and belonging to the same source. Once you select a VM or Protection Group, the **Storage Domain** and **Source** filters will automatically get locked.
5. By default, the latest snapshot of the VMs is selected for recovery. To recover from a different snapshot, perform the following steps depending on the object selected:

   > **Note:** In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

To choose a different snapshot for a..	Then..
Protection Group	1. From the selected lists, mouse over the snapshot, and then click the **edit** icon. 2. From the Protection Run drop-down menu, select the snapshot from which you want to recover the VMs. By default the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. 3. Click **Select Recovery Point** and then go to step 6.

To choose a different snapshot for a..	Then..
VM	From the selected lists, mouse over the snapshot, and then click the edit icon. The Edit recovery point for <VM_name> page appears. By default, the option to select the snapshot is displayed in **Timeline** mode. You can also choose to view the option in **List** mode by clicking the List tab in the top-right corner of the page. • To select a snapshot from the Timeline mode: a. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar. b. Select the snapshot to be recovered by clicking the corresponding blue dot. c. By default, the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. d. Click **Select Recovery Point** and then go to step 6. • To select a snapshot from the **List** mode: a. Select the List tab from the top-right corner of the Edit recovery point for <VM_name> page. By default, the page displays the snapshots available in the last one month. b. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range. c. Select the snapshots to be recovered. d. By default, the snapshot is recovered from the local Cohesity cluster. You can also select snapshots archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. e. Click **Select Recovery Point** and then go to step 6.

6. Click **Next: Recover Options**.
7. From the **Recover To** options, select **Original Location** to recover the VM to the original location.
8. Optional. Edit the default settings of the following **Recovery Options**:

Recovery Options	Description
Rename	Add Prefix and/or Suffix strings to the names of the new VMs created by this task. For example you could specify Prefix `Test_ and Suffix _QA` to the VM name WinOS and when the VM is recovered, the new VM that is created is called `Test_WinOS_QA`.

Azure SAS URL Type	For recovering Azure VMs, Cohesity uses the snapshots of Azure managed disks that are accessible through SAS URLs. Select one of the following endpoint options to access data from the SAS URL:
	• **Public Endpoint:** Select this option to access snapshots over a public network.
	• **Private Endpoint**: Select this option to access snapshots using a private IP address from your virtual network. You can either enable the "**Use the same SAS URL details a Protection**" option or provide the following details for configuring the private endpoint:
	  • **Region**: Select the region of the VM you have selected for recovery.
	  • **Virtual Network**: Select a virtual network in Azure. Ensure this virtual network is connected to the Cohesity cluster.
	  • **Subnet**: Select a subnet of the virtual network.
	If you have selected VMs from multiple regions, then you must select at least one virtual network and subnet per region. Click the add icon to add regions and their virtual networks and subnets.
	Cohesity recommends using dedicated subnets for the Azure SAS URL endpoint.

Power State	To ensure that the restored Azure VMs are functioning properly, the VMs are powered on by default after the restoration process. However, you can enable the **Power Off** option if you prefer to keep the VMs powered off once Cohesity verifies their functionality. If you are recovering VMs from a Storage Domain with Cloud Tier enabled, Cohesity recommends keeping the VMs powered off.

Recovery Options	Description
Continue on Error	Enable **Continue recovery even if errors occur when recovering VMs** if you want the recovery task to continue even if errors occur when recovering the VMs. For example, if one of the VMs cannot be created, the Cohesity cluster will still attempt to create the other VMs. If this option is disabled, then the recovery task is discontinued if VM creation fails. However, if the VM creation succeeds, but VM storage migration fails, the task continues. By default this option is disabled.
Task Name	Change the default name of the recovery task.

9. Click **Recover**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Disaster Recovery of VMs Using Azure Cloud Edition

To provide disaster recovery failover and failback, Cohesity supports the Cloud Migration of VMs between hypervisors servers (VMware vCenter), Azure Cloud Services, and Cloud EditionCohesity clusters. For Hyper-V, Cohesity supports only failover to Azure.

Disaster recovery with Cloud Edition consists of the following two use cases:

Back Up VMs to On-Prem, Replicate and Failover to Azure Cloud

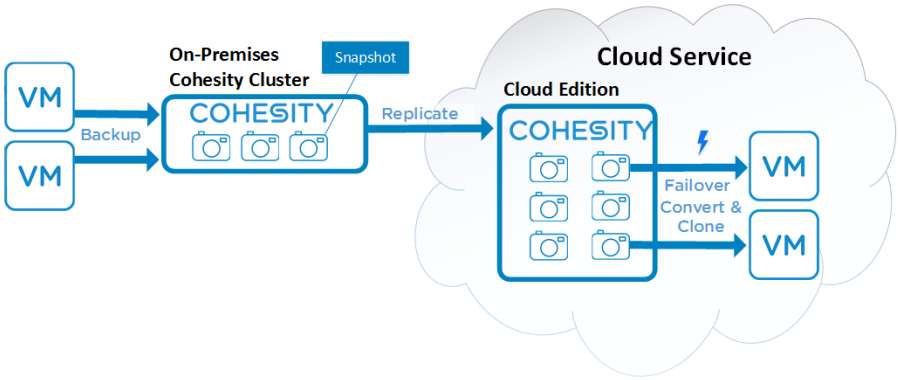
To provide disaster recovery failover and failback, Cohesity supports the Cloud Migration of VMs between hypervisors servers (VMware vCenter), Azure Cloud Services and Cloud EditionCohesity clusters. For Hyper-V, Cohesity supports only failover to Azure. Cohesity Cloud Edition supports the replication of VMs captured on an on-premises Cohesity cluster to Cloud Edition as shown by the example figure below. Starting from the left in the following figure, the use case shows how Protection Groups running on the on-premises Cohesity cluster captures Snapshots of VMs and stores these Snapshots on the on-premises Cluster. The Protection Policies associated with these Jobs, are configured to replicate (or copy) Snapshots from the on-premises Cohesity cluster to the Cloud EditionCohesity cluster.

From the Snapshots stored on the Cloud Edition, you can failover VMs. The failover process creates new VMs running in the Azure Cloud Service. As part of the Failover process, the VMs are converted and spun up in the Cloud Service.

Cohesity supports the failover of VMware VMs with UEFI boot mode enabled to Azure.

Failover to Azure supports the following UEFI boot mode enabled operating systems:

- Windows Server 2012, 2016, 2019



> **Important:** To support the failback (recovery) of these VMs back to the original Hypervisor server (such as VMware vCenter), Cohesity agents must be installed on the Windows VMs prior to backing up the snapshots on the on-premises Cohesity cluster. Failback is described in Back Up Azure Cloud VMs, Replicate to On-Prem and Failback to Hypervisor Server.

Verify the following requirements prior to backing up the VMs:

- If you are planning to perform failback (recovery) of the backed up VMs back to the Hypervisor server from the Cloud Service, then:
  - Before registering the VMs of the Hypervisor server with the on-premises Cohesity cluster, you must install Cohesity agent on the VMs if you are planning to back up the cloud VM back to the Cohesity cluster using the **Cohesity Protection Service** Protection Group type.
  - You do not need to install the Cohesity agent on the VMs if you are planning to backup the cloud VM back to the Cohesity cluster using native snapshots.

    > **Note:** You must install Cohesity agent on the Windows VMs before registering the VMs of the Hypervisor server with the on-premises Cohesity cluster. The Cohesity agent is required to bring all the disks on the VMs online.

- Failover and Failback of VMware VM to Azure supports the following operating systems:
  - Microsoft Windows Server 2012, Microsoft Windows Server 2016, and Microsoft Windows Server 2019, Microsoft Windows Server 2022
  - CentOS 6.0+ 64-bit, 7.0 - 7.9 64-bit, 8.0 64-bit
  - RHEL 6.7+ 64-bit, 7.0 - 7.9 64-bit, 8.0 - 8.2 64-bit

- VMware vSphere 5.5, 6.0, 6.5, and 6.7 is supported for cloning to Azure.
- AHV, RhV and AWS VMs are *not* supported for cloning to Azure.
- Cloning Snapshots to an Azure Cloud is supported for VMware and Hyper-V VMs with the following operating systems:
  - Linux CentOS 7 on LVM
    - You can clone as many disks as the selected VM supports. For example, if you select a Standard_DS1_v2 VM, four disks can be cloned.
    - When converting and cloning or copying Snapshots of a Linux VM with multiple disks, the disks must be mounted by UUID prior to being backed up by the Protection Group, as shown by the following example entry in a `/etc/fstab`:

      ```
      UUID=e12e623a-c6ee-4718-9b1a-802456e72258 /userdata ext4
      defaults,nofail 0 0
      ```

      For detailed instructions, see Edit /etc/fstab to use UUID.
  - Windows
    - You can clone as many disks as the selected VM supports. For example, if you select a Standard_DS1_v2 VM, four disks can be cloned.
    - For a Windows VM, if you want to access the newly created VM in the Cloud service using Remote Desktop, enable the Windows Remote Desktop on the VM prior to capturing the Snapshots of a Windows VM.
    - When backing up Windows VMs with multiple disks, before a Protection Group captures the Snapshot, the Cohesity agent and VMware tools must be installed on the VM and the VM must be running. The Cohesity agents installed must be of the same version as the Cohesity Cluster version. For more information, see Install and Manage the Agent on Windows Servers. In addition, port 50051 must be open in your Firewall. For more information, see Manage Firewall Ports.
    - Due to a Windows issue in builds 14393 and build 15063, a deployed Windows 10 or Windows 2016 VM may not be connected to the network. Resolve this by installing fix KB4073562 for build 14393 or KB4016240 for build 15063 or by updating Windows. For more information, see Cannot connect remotely to a Windows 10 or Windows Server 2016 VM in Azure because of netvsc.sys.
    - Make the disks online by default using the following SAN policy commands:
      - `diskpart`
      - `san policy=OnlineAll`

      For more information, see the SAN Policy documentation.

- Red Hat Enterprise Linux
  - You can clone as many disks as the selected VM supports. For example, if you select a Standard_DS1_v2 VM, four disks can be cloned.
  - For the list of supported RHEL versions, see Supported Software.
  - When converting and cloning or copying Snapshots of a Linux VM with multiple disks, the disks must be mounted by UUID prior to being backed up by the Protection Group, as shown by the following example entry in a `/etc/fstab`:

    ```
    UUID=e12e623a-c6ee-4718-9b1a-802456e72258 /userdata ext4
    defaults,nofail 0 0
    ```

    For detailed instructions, see Edit /etc/fstab to use UUID.
- The disk size of the VMware VMs must be a multiple of 1 GB.
- Cohesity does not support the CloudSpin of VMs whose OS Disk is formatted with XFS version 5 to Azure. This limitation applies to both Hyper-V and VMware VMs, regardless of their operating system type.
- Cohesity does not support CloudSpin of VMware VMs from VMware Cloud (VMC) to Azure.

Cloning Hyper-V VMs to Azure

- VMs that have one to five disks can be cloned. Each disk must be smaller than 2 TB.
- SUSE Linux VMs are *not* supported.
- All the Hyper-V versions supported by Cohesity for backup is supported for cloning to Azure. For the list of supported Hyper-V versions, see Supported Software.
- Generation 2 VMs are not supported by all VM sizes in Azure. For information on Generation 2 supported VM series, see Microsoft document.
- Cloning of Hyper-V VMs to Azure Stack Hub is not supported.

- For a Windows VM, if you want to access the newly created VM in the Cloud service using Remote Desktop, enable the Windows Remote Desktop on the VM prior to capturing the Snapshots of a Windows VM.

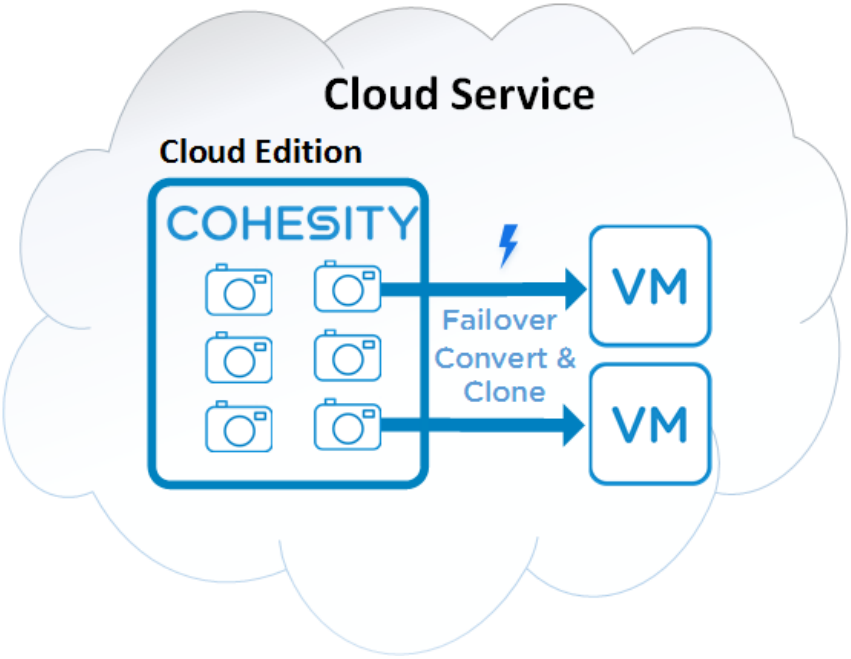
To back up VMs to an on-premises Cluster, replicate and failover to Cloud Edition:

1. Register the Hypervisor server with the on-premises Cohesity cluster
2. Set up replication between the on-premises Cohesity cluster and the Cloud Edition Cohesity cluster. For instructions, see Replication and Remote Access Setup.

3. On the on-premises Cohesity cluster, create a Policy that replicates to a Cloud Edition Cohesity cluster as shown in the top figure. For instructions, see Create or Edit a Standard Policy.
4. On the on-premises Cohesity cluster, create a Virtual Server Protection Group (such as `Win2k12`) that has **Cloud Migration** enabled. For detailed instructions, see Add or Edit a Protection Group for Virtual Servers. Associate the Policy created in the previous step with this Protection Group.

   When selecting Objects to be protected by a Protection Group, you can only select VMs with VMware tools installed, Remote Desktop enabled, and for Windows VM Cohesity agents also must be installed.

   When you create a Protection Group on the on-premises Cohesity cluster that replicates to a Cloud Edition Cohesity cluster, after the first Snapshot is replicated to the Cloud Edition Cluster, an Inactive copy of the Protection Group is created on the Cloud Edition Cluster that received the Snapshot. The new Inactive Protection Group on the Cloud Edition Cohesity cluster has the same name as the Protection Group on the on-premises Cohesity cluster, for example: `Win2k12`. The VM must be powered on and connected to the network when the Protection Group is running.
5. You can failover from the Snapshots that were replicated to the Cloud Edition Cluster. The failover process creates new VMs running in the Cloud Service (such as AWS or Azure). As part of the Failover process, the VMs are converted and spun up in the Cloud Service.



To failover from the Snapshots:

a. On the Cloud Edition Cohesity cluster that contains the replicated Snapshots, select **Data Protection > Protection** and browse for the Inactive Protection Group that was automatically created.

b. Click on the inactive Protection Group name.

c. Click the action icon (⋮) next to the Protection Group and select **Failover**.

d. From the **Failover to Source** drop-down, select the name of the registered Cloud Source where the VMs will be cloned to.

e. Click **Continue to Clone**.

f. Follow the instructions provided in Set Clone Options. You can also add custom tags to all the resources created during failover.

A clone task is created and the VM is created in the Azure Cloud Service and is powered up if that option was selected.

6. Follow the steps in the next part of the Disaster Recovery workflow which is documented in Back Up Azure Cloud VMs, Replicate to On-Prem and Failback to Hypervisor Server.

You can also use CloudSpin (test/dev clone) workflow to failover individual VMs within the Protection Group instead of failovering all VMs in the Protection Group. For more information, see Test & Dev Using CloudSpin.

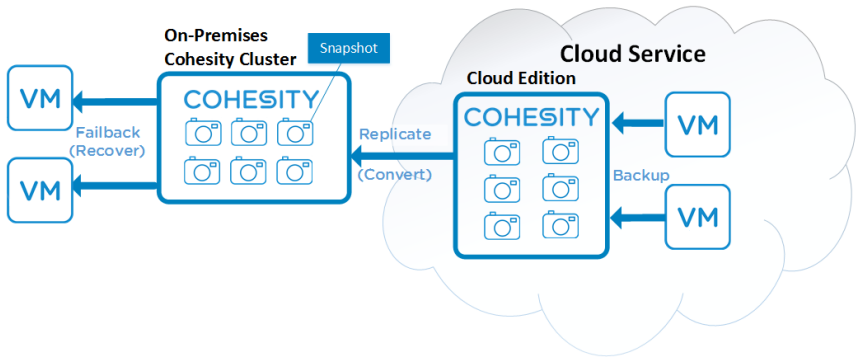
Back Up Azure Cloud VMs, Replicate to On-Prem and Failback to Hypervisor Server

To provide disaster recovery failover and failback, Cohesity supports the Cloud Migration of VMs between hypervisors servers (VMware vCenter), Azure Cloud Services and Cloud EditionCohesity clusters.

> **Note:** Failover of VMs born in the cloud to VMware vCenter is not supported.

This topic describes the second use case of disaster recovery using Cloud Edition—how to backup cloud VMs to the Cloud Edition cluster, replicate to the on-premise cluster, and then failback to the Hypervisor server.

For information on how the VMs are backed up in the Azure cloud service, see the first process of disaster recovery using Cloud Edition documented in Back Up VMs to On-Prem, Replicate and Failover to Azure Cloud.



As illustrated in the figure above, on the Cloud Edition running in the Cloud Service, a Protection Group using native snapshots or Cohesity Protection Service backs up the cloud VMs (as indicated by the backup arrow in the figure). The policy associated with the Protection Group specifies that these Snapshots are replicated to the on-premises Cohesity cluster (as indicated by the Replicate arrow). From those Snapshots stored on the on-premises Cohesity cluster, you can failback or recover the VMs back to their original location or a new location in your Hypervisor server such as a vCenter Server (as indicated by the Failback (Recover) arrow).

To back Up Cloud VMs to Cloud Edition, replicate to a on-premises Cohesity cluster and failback to a hypervisor server:

Verify the following requirements prior to failback:

- Th VMs that are backed up to the Cloud Service must have VMware Tools and Remote Desktop installed before the original Protection Group captures the Snapshots from the VMware vCenter Server as described in the Back Up VMs to On-Prem, Replicate and Failover to Azure Cloud.
- If you are backing up the Cloud VMs to the Cloud Edition Cluster using the Cohesity Protection Service Protection Group type, then the VMs that are backed up to the Cloud Service must also have Cohesity agent installed.

Steps:

1. If not already configured, set up replication between the Cloud Edition Cluster and the on-premises Cohesity cluster. For instructions, see Replication and Remote Access Setup.
2. On the Cloud Edition Cluster, create a Policy that replicates from the Cloud Edition Cluster to the on-premises Cohesity cluster as shown in the figure. For instructions, see Create or Edit a Standard Policy.
3. On the Cloud Edition Cluster, refresh the Object hierarchy for the Source of the VMs that will be backed up:
    a. Select **Data Protection > Sources**.
    b. Click the action icon (⋮) next to the Source and select **Refresh**.

4. On the Cloud Edition Cluster, create a Virtual Server Protection Group (such as `BackToPrem`) with Protection Group Type option as **Native Snapshots** or **Cohesity Protection Service**. Associate the Policy created in the previous step with this Protection Group. For detailed instructions, see Add or Edit a Protection Group for Virtual Servers. If **Cohesity Protection Service** is selected as the Protection Group type, then the VMs that are backed up to the Cloud Service (failovered VMs) must have Cohesity agent installed.

   When selecting Windows VM (Objects) to failover, you can only select Snapshots of VMs that have the Cohesity agent installed when they were created with the Back Up VMs to On-Prem, Replicate and Failover to Azure Cloud process. The VM should be powered on when the Protection Group is running.

   When you create a Protection Group on the Cloud Edition Cluster that replicates to an on-premises Cohesity cluster, after the first Snapshot is replicated to the on-premises Cluster, an Inactive copy of the Job is created on the on-premises Cluster that received the Snapshot. The new Inactive Job on the on-premisses Cohesity cluster has the same name as the Protection Group on the Cloud Edition Cluster, for example: `BackToPrem`.

5. You can failback (recover) the VMs to the original Hypervisor server or an alternate Hypervisor server:

   a. On the on-premises Cohesity cluster that contains the replicated Snapshots, select **Data Protection > Protection** and browse for the Inactive Job that was automatically created.

   
   b. Click on the inactive Job name.

   c. Browse for protection run that captured a Snapshot that you want to recover.

   d. Click the action icon (⋮) next to the Job and select **Recover VM**.

   e. Follow the instructions provided in Recover VMs.

   The VM is created in the Hypervisor server and is powered up if that option was selected. As part of the convert and clone process, the VMware Tools will be uninstalled. You must reinstall the VMware Tools.

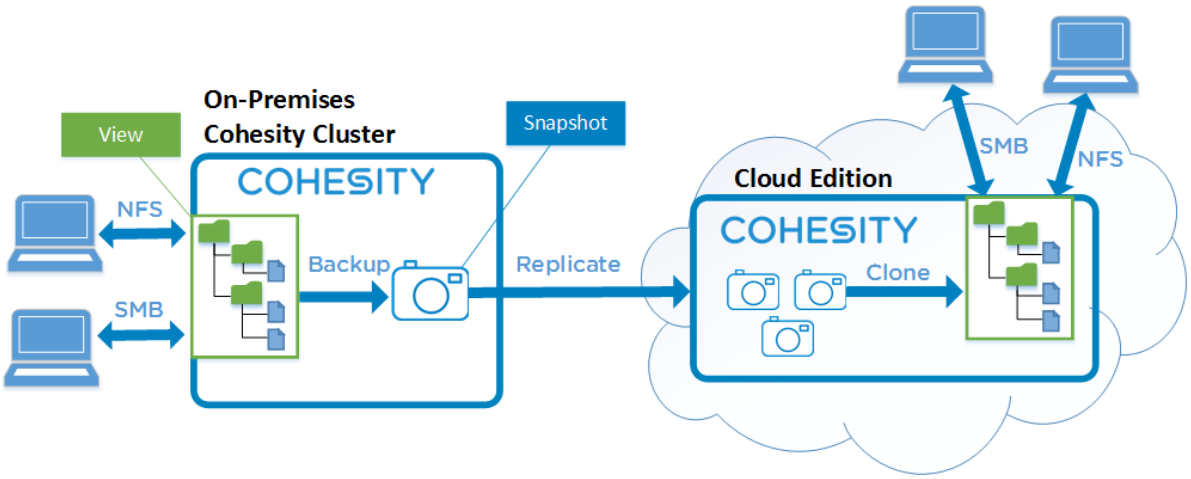
   > **Important:** Do not change the size of the partition or the disk of the recovered VM.

Disaster Recovery of Views in Azure Cloud Edition

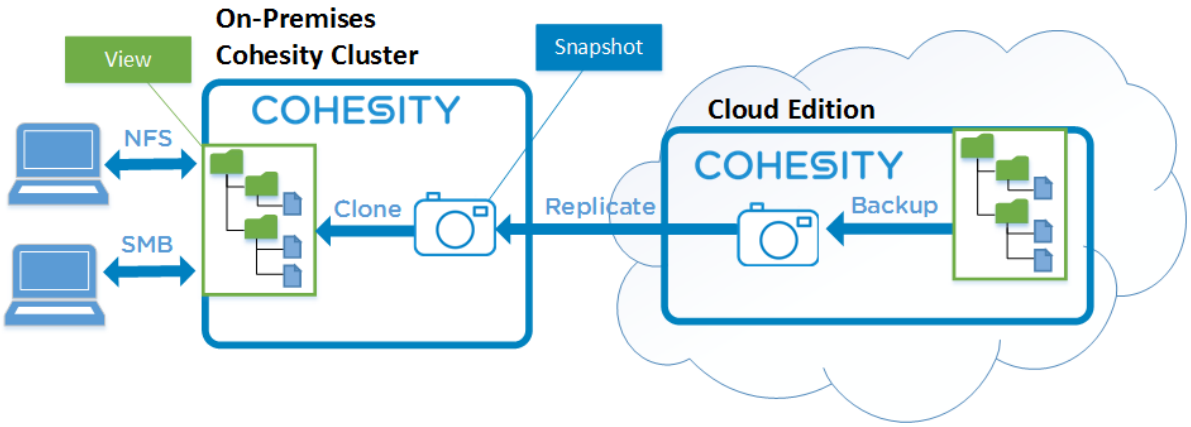
Cohesity Cloud Edition supports the disaster recovery of Views as shown by the following example figures.

Views can be used to store data such as files and directories. For example, other backup products can store data on a view that is hosted on the Cohesity cluster. To access a view from your system, you must mount the view.

On the left of the first figure, shows systems accessing a View hosted on an on-premises Cohesity cluster using the NFS or SMB protocols. A Protection Group running on the on-premises Cohesity cluster captures Snapshots of the View and stores these Snapshots on the Cluster. The Protection Policy associated with this Job, is configured to replicate (or copy) Snapshots from the on-premises Cohesity cluster to the Cohesity cluster Cloud Edition. From these Snapshots stored in the Cloud Edition, you can clone a new View that can be accessed by systems using the NFS or SMB protocols as shown on the right of the first figure.



You can backup Views hosted on the Cloud Edition as shown on the right of the following figure. A Protection Group captures a Snapshot of a View and stores the Snapshot on the Cohesity cluster Cloud Edition. The Protection Policy associated with this Job, is configured to replicate (or copy) Snapshots from the Cohesity cluster Cloud Edition to the on-premises Cohesity cluster. From these View Snapshots stored in the on-premises Cohesity cluster, you clone a View and make it available for mounting as shown on the left of the following figure.

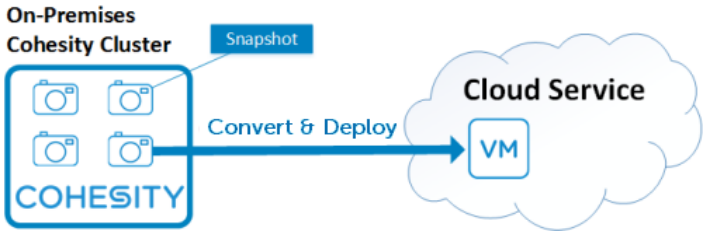


Clone Azure Virtual Machines

This chapter includes the following topics:

Clone VMs from On-Premises to Azure Cloud Service (On Demand CloudSpin)

Cohesity supports conversion of snapshots of VMs from an on-premises Cohesity cluster to the Azure Cloud service. After conversion, the VM runs in the Cloud service.



Prerequisites and Considerations

- For the list of VMs that supports CloudSpin to Azure, see Supported Software.
- Cohesity supports the CloudSpin of VMware VMs with UEFI boot mode enabled.
- Cohesity supports both on-demand and policy-based CloudSpin for snapshots stored on the Cohesity cluster (primary copy).
- Cohesity does not support on-demand and policy-based CloudSpin for archived or CloudRetrieved snapshots.
- Cohesity supports on-demand CloudSpin for snapshots that are replicated to another Cohesity cluster.
- Cloning VMware and Hyper-V VMs to Azure
  - Linux CentOS 7 on LVM
    - You can clone as many disks as the selected VM supports. For example, if you select a Standard_DS1_v2 VM, four disks can be cloned.
    - When converting and cloning or copying Snapshots of a Linux VM with multiple disks, the disks must be mounted by UUID prior to being backed up by the Protection Group, as shown by the following example entry in a `/etc/fstab`:

      ```
      UUID=e12e623a-c6ee-4718-9b1a-802456e72258 /userdata ext4
      defaults,nofail 0 0
      ```

      For detailed instructions, see Edit /etc/fstab to use UUID.
  - Windows
    - You can clone as many disks as the selected VM supports. For example, if you select a Standard_DS1_v2 VM, four disks can be cloned.

    - For a Windows VM, if you want to access the newly created VM in the Cloud service using Remote Desktop, enable the Windows Remote Desktop on the VM prior to capturing the Snapshots of a Windows VM.
    - When backing up Windows VMs with multiple disks, before a Protection Group captures the Snapshot, the Cohesity agent and VMware tools must be installed on the VM and the VM must be running. The Cohesity agents installed must be of the same version as the Cohesity Cluster version. For more information, see Install and Manage the Agent on Windows Servers. In addition, port 50051 must be open in your Firewall. For more information, see Manage Firewall Ports.
    - Due to a Windows issue in builds 14393 and build 15063, a deployed Windows 10 or Windows 2016 VM may not be connected to the network. Resolve this by installing fix KB4073562 for build 14393 or KB4016240 for build 15063 or by updating Windows. For more information, see Cannot connect remotely to a Windows 10 or Windows Server 2016 VM in Azure because of netvsc.sys.
    - Make the disks online by default using the following SAN policy commands:
        - `diskpart`
        - `san policy=OnlineAll`

      For more information, see the SAN Policy documentation.
- Red Hat Enterprise Linux
    - You can clone as many disks as the selected VM supports. For example, if you select a Standard_DS1_v2 VM, four disks can be cloned.
    - For the list of supported RHEL versions, see Supported Software.
    - When converting and cloning or copying Snapshots of a Linux VM with multiple disks, the disks must be mounted by UUID prior to being backed up by the Protection Group, as shown by the following example entry in a `/etc/fstab`:

      ```
      UUID=e12e623a-c6ee-4718-9b1a-802456e72258 /userdata ext4
      defaults,nofail 0 0
      ```

      For detailed instructions, see Edit /etc/fstab to use UUID.
- The disk size of the VMware VMs must be a multiple of 1 GB.
- Cohesity does not support the CloudSpin of VMs whose OS Disk is formatted with XFS version 5 to Azure. This limitation applies to both Hyper-V and VMware VMs, regardless of their operating system type.

    - Cohesity does not support CloudSpin of VMware VMs from VMware Cloud (VMC) to Azure.
- Cloning Hyper-V VMs to Azure
    - VMs that have one to five disks can be cloned. Each disk must be smaller than 2 TB.
    - SUSE Linux VMs are *not* supported.
    - All the Hyper-V versions supported by Cohesity for backup is supported for cloning to Azure. For the list of supported Hyper-V versions, see Supported Software.
    - Generation 2 VMs are not supported by all VM sizes in Azure. For information on Generation 2 supported VM series, see Microsoft document.
    - Cloning of Hyper-V VMs to Azure Stack Hub is not supported.

Convert and Deploy a VM from On-Premises to Azure

Verify that the above prerequisites are met prior to backing up the VMs.

1. Create a Protection Group to capture Snapshots of VMs. For more information, Add a Protection Group for Azure VM.
2. Register the Cloud service that the VMware VMs are cloned **to**. For detailed instructions, see either Register an Azure Cloud Source at Subscription Level.
3. Log in to the Cohesity Dashboard of the Cohesity cluster that contains the Snapshots to clone from. For example, log in to the on-premises Cohesity cluster.
4. To clone and convert the Virtual Server (VM), follow the instructions provided in Clone VMs and select an Azure Subscription Source.
5. After the Clone task completes, log in to the new VM in the Cloud service.

   For Azure:

    a. Log in to Microsoft Azure Portal.
    b. Search for the new Virtual Machine name.
    c. Click on the VM name.
    d. Under the **Subscription name**, copy the IP address of the new VM.
    e. Log in to the VM using the IP address. If Remote Desktop was installed in the VM that was cloned, you can log in using the Remote Desktop.
6. Multiple disks are automatically mounted on the Windows VM, if the following conditions are true before the Protection Group captures the Snapshot of a Windows VM:
    - A Cohesity agent is installed on the VM.
    - VMware tools are installed on the VM.
    - VM is running

If any of the conditions were not true when the Job captured the Snapshot, the `C:` drive is mounted but you must mount the other drives such as `D:` as described here:

a. If Remote Desktop is installed on the new cloned VM, log in to the new VM, start Remote Desktop Connection, enter the IP of the new cloned VM.
b. In the new VM, launch the Windows Disk Management.
c. Right click on a disk that is not mounted and select **Online**. Repeat for all other offline disks.

Tear Down a Launched VM from Cohesity Dashboard

1. In the Cohesity Dashboard, select **Test & Dev**.
2. Click the actions menu (⋮) next to the clone task you want to tear down and select **Tear Down**.

Clone VMs to Azure Cloud Using CloudSpin

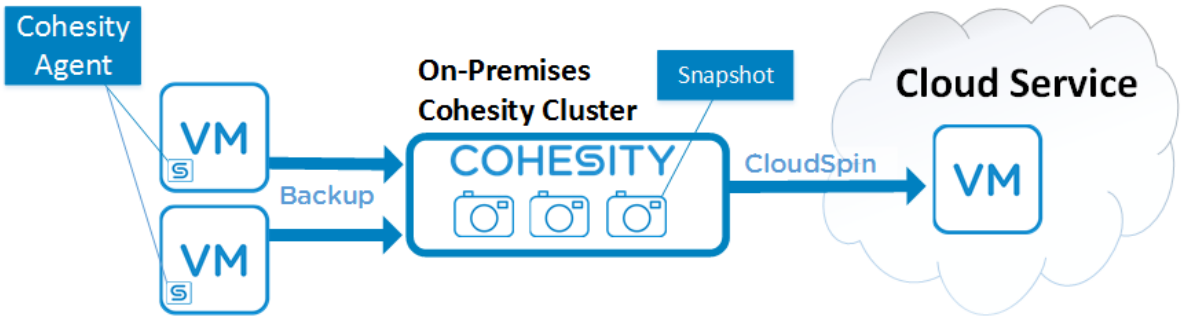
On a Cohesity cluster with a Protection Group that captures Snapshots of VMs with a CloudSpin schedule, the cluster clones VMs to Azure Cloud Service. You can then launch the VMs to a running state.

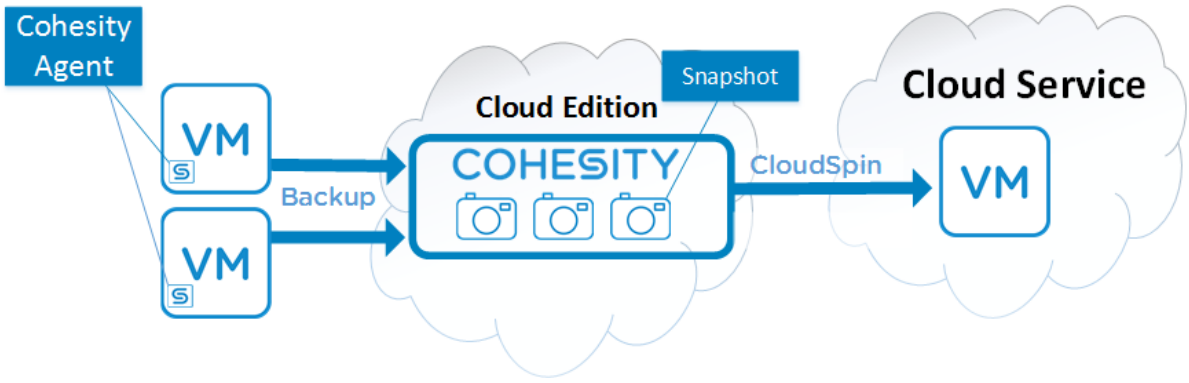
What happens during the CloudSpin process is dependent on the cloud service type:

- Cohesity supports CloudSpin of Hyper-V to Azure.
- Cohesity supports CloudSpin of VMware to Azure.
- During cloning to an Azure Cloud using Cloudspin, the Cohesity cluster converts the snapshot to VHD format and then copies the VHD image to a storage container in the Azure Cloud. Managed disks, including SSD and HDD, are also supported.
- For policy-based CloudSpin to Azure, the Storage Account must support page blobs.

For the list of VMs that supports CloudSpin to Azure, see Supported Software.

Cohesity supports CloudSpin on both the on-premises Cohesity cluster and Cloud Edition Cohesity clusters:





To use CloudSpin to clone Snapshots to Azure :

1. Verify the following requirements prior to backing up the VMs:
    - All the VMware vSphere versions supported by Cohesity for backup are supported for cloning to Azure. For the list of supported VMware vSphere versions, see Supported Software.
    - AHV, RhV and AWS VMs are *not* supported for cloning to Azure.
    - Cohesity does not support the CloudSpin of VMs whose OS Disk is formatted with XFS version 5 to Azure.
    - Cloning Snapshots to an Azure Cloud is supported for VMware and Hyper-V VMs with the following Operating Systems:
        - Linux CentOS 7 on LVM
            - You can clone as many disks as the selected VM supports. For example, if you select a Standard_DS1_v2 VM, four disks can be cloned.
            - When converting and cloning or copying Snapshots of a Linux VM with multiple disks, the disks must be mounted by UUID prior to being backed up by the Protection Group, as shown by the following example entry in a `/etc/fstab`:

              ```
              UUID=e12e623a-c6ee-4718-9b1a-802456e72258 /userdata ext4 defaults,nofail 0 0
              ```

              For detailed instructions, see Edit /etc/fstab to use UUID.
        - Windows
            - You can clone as many disks as the selected VM supports. For example, if you select a Standard_DS1_v2 VM, four disks can be cloned.
            - For a Windows VM, if you want to access the newly created VM in the Cloud service using Remote Desktop, enable the Windows

Remote Desktop on the VM prior to capturing the Snapshots of a Windows VM.

- When backing up Windows VMs with multiple disks, before a Protection Group captures the Snapshot, the Cohesity agent and VMware tools must be installed on the VM and the VM must be running. The Cohesity agents installed must be of the same version as the Cohesity Cluster version. For more information, see Install and Manage the Agent on Windows Servers. In addition, port 50051 must be open in your Firewall. For more information, see Manage Firewall Ports.
- Due to a Windows issue in builds 14393 and build 15063, a deployed Windows 10 or Windows 2016 VM may not be connected to the network. Resolve this by installing fix KB4073562 for build 14393 or KB4016240 for build 15063 or by updating Windows. For more information, see Cannot connect remotely to a Windows 10 or Windows Server 2016 VM in Azure because of netvsc.sys.
- Make the disks online by default using the following SAN policy commands:
  - `diskpart`
  - `san policy=OnlineAll`

  For more information, see the SAN Policy documentation.

- Red Hat Enterprise Linux
  - You can clone as many disks as the selected VM supports. For example, if you select a Standard_DS1_v2 VM, four disks can be cloned.
  - For the list of supported RHEL versions, see Supported Software.
  - When converting and cloning or copying Snapshots of a Linux VM with multiple disks, the disks must be mounted by UUID prior to being backed up by the Protection Group, as shown by the following example entry in a `/etc/fstab`:

    ```
    UUID=e12e623a-c6ee-4718-9b1a-802456e72258 /userdata ext4
    defaults,nofail 0 0
    ```

    For detailed instructions, see Edit /etc/fstab to use UUID.
- The disk size of the VMware VMs must be a multiple of 1 GB.
- Cohesity does not support the CloudSpin of VMs whose OS Disk is formatted with XFS version 5 to Azure. This limitation applies to both Hyper-V and VMware VMs, regardless of their operating system type.

    - Cohesity does not support CloudSpin of VMware VMs from VMware Cloud (VMC) to Azure.
  - Cloning Hyper-V VMs to Azure
    - VMs that have one to five disks can be cloned. Each disk must be smaller than 2 TB.
    - SUSE Linux VMs are *not* supported.
    - All the Hyper-V versions supported by Cohesity for backup is supported for cloning to Azure. For the list of supported Hyper-V versions, see Supported Software.
    - Generation 2 VMs are not supported by all VM sizes in Azure. For information on Generation 2 supported VM series, see Microsoft document.
    - Cloning of Hyper-V VMs to Azure Stack Hub is not supported.
2. Register a Cloud Source. Select **Data Protection > Sources** and from the **Register Source** drop-down, select **Azure Cloud**. A cloud source is a cloud service instance where the snapshots are converted and copied **to**. For details, see the appropriate Source topic:
   - Register an Azure Cloud Source at Subscription Level
3. For a Windows VM, if you want to access the newly created VM in the Cloud service using Remote Desktop, enable the Windows Remote Desktop on the VM prior to capturing the Snapshots of a Windows VM.
4. Create a Policy with a CloudSpin schedule that converts and copies Snapshots to the Cloud Source registered in the previous step. For detailed instructions, see Create or Edit a Standard Policy. Protection Groups that use this policy will automatically convert and copy Snapshots backed up by the Protection Group to a Cloud Source using the specified CloudSpin schedule.
5. Create a Protection Group that uses the Policy created in the previous step.

   After the Protection Group run and CloudSpin Copy Task are successfully completed, the VM can be launched.
6. Launch the VM created in the Cloud Service:

   Launch VM from the Cohesity Dashboard:

   a. Select **Data Protection > Protection**.
   b. Click the Job that backed up the VM to launch in the Cloud.
   c. Browse for a protection run that contains a Snapshot to convert to a VM. The protection run must have the Status of **Success** and the associated CloudSpin Copy task must be successful

.
   d. Click the date link of the protection run in the Start Time column to view the protection run details.

e. Click the VM **ClouldSpin Task** tab.

f. To launch, complete one of the following actions:

- Click the actions menu (⋮) and select **Launch Instance**. The following fields are displayed:
  - **Source**—Displays the registered source.
  - **Resource Group**—Displays the resource pool that stores the cloned VMs.
  - **Storage Account**—Displays the VM size used when creating the cloned VMs.
  - **Storage Container**—Displays the storage container used to store the cloned VMs.
  - **Compute**—Select the Microsoft Azure VM size type to use when creating the cloned VMs.
  - **Availability Set**—Optionally, select the availability set to which the VM has to be cloned. For more information, see Azure Availability Sets.
  - **Virtual Network**—Select the Microsoft Azure Virtual Network for the cloned VMs.
  - **Subnet**—Select the Microsoft Azure Virtual subnet for the cloned VMs.
  - **Use Azure Managed Disks**—To use Azure managed disks, enable the toggle and select the OS Disk Type and Data Disk Type.

    Click **Submit** to save the changes.
- Click **Launch All Instances**.

To tear down a launched VM, see Tear Down a Launched VM from Cohesity Dashboard.

Launch from Azure using PowerShell:

Follow these steps from the Create a Windows VM from a specialized disk using PowerShell topic in the Microsoft Azure Documentation:

a. Install the newest version of Powershell as described in Before you begin.

b. Follow the steps in Option 2: Upload a specialized VHD.

c. Follow the steps in Create the new VM.

To prevent a teardown of a cloned CloudSpin VM, see the How to prevent a tear down of a cloned CloudSpin VM KB article.

Tear Down a Launched VM from Cohesity Dashboard

- In the Cohesity Dashboard, select **Test & Dev**.
- For the clone task to tear down, click the actions menu (⋮) and select **Tear Down**.

Consideration

- Cohesity does not support CloudSpin of Active Directory VM directly to Azure. If you CloudSpin Active Directory VM directly to Azure, the VM does not boot and the **Choose an option Recovery** screen is displayed in **Boot Diagnostics**.

  Workaround: You need to first remove the Active Directory Domain Services in the on-premises VM, take a backup and CloudSpin it to Azure, and then add it to the Domain Controller on Azure. For more information, see Microsoft Documentation.
- Azure does not support booting UEFI VMs with unmanaged disks.
- The maximum data disk size supported for an Azure VM for CloudSpin is 8191 GiB.
- Cohesity does not support CloudSpin of VMware VMs from VMware Cloud (VMC) to Azure.
- Cohesity supports both on-demand and policy-based CloudSpin for snapshots stored on the Cohesity cluster (primary copy).
- Cohesity does not support on-demand and policy-based CloudSpin for archived or CloudRetrieved snapshots.
- Cohesity supports on-demand CloudSpin for snapshots that are replicated to another Cohesity cluster.

Edit /etc/fstab to use UUID

You must edit the `/etc/fstab` file and change the (non-LVM) entries to use UUIDs to identify the disk partitions. These changes must be made to the `/etc/fstab` file before the Protection Group (which captures the Snapshots to be cloned) is run.

For example, the following entry in the `/etc/fstab` table must be changed to use the UUID to identify the partition instead of the device file name of `/dev/sbd1`.

```
/dev/sdb1 /mnt/disk1    ext4    defaults        0 0
```

> **Note:**
> - Use labels or UUIDs instead of device names, as device names may change when other disks are added or removed.
> - Kernel name descriptors must not be used in configuration files as they are not persistent and may change during each boot. UUIDs or PARTUUIDs are preferred over labels.
> - Using only the device name in the absence of UUID or label might cause issues as these names are not unique. This can cause overwrites and eventual loss of an entire volume indexing itself.
> - Each volume must be uniquely identified by an identifier like UUID or label. **A missing unique identifier (UUID/label) can result in dummy volume names being used instead of actual volumes.**

You can determine the UUID by running the `blkid` command, for example:

```
# blkid /dev/sdb1
/dev/sdb1 UUID="12345cac-77bc-46b1-9f79-cb180e438c12" TYPE="ext4"
```

Edit the `/etc/fstab` as root and for this entry replace the device file name with the returned UUID, for example:

```
12345cac-77bc-46b1-9f79-cb180e438c12 /mnt/disk1 ext4    defaults        0 0
```

> **Note:** LVM volume entries should not be updated. LVM volumes start with the `/dev/mapper` prefix, for example: `/dev/mapper/centos-root` and `/dev/mapper/centos-swap`.

Repeat these steps for all entries in the `/etc/fstab` that are not LVM volume entries.

Replicate Azure Virtual Machines

This chapter includes the following topics:

Replicating VMs in Azure Cloud Edition

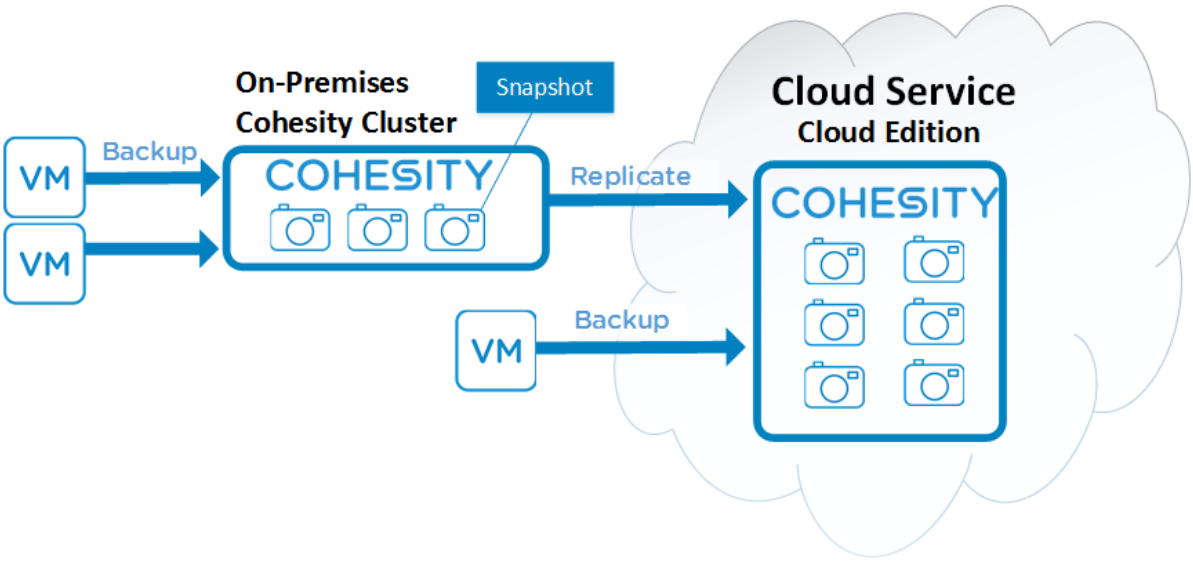
Cohesity Cloud Edition supports the replication of VMs captured on an on-premises Cohesity cluster to Cloud Edition as shown by the example figure below.

Starting from the left in the following figure, the use case shows how Protection Groups running on the on-premises Cohesity cluster captures Snapshots of VMs and stores these Snapshots on the on-premises Cluster. The Protection Policies associated with these Jobs,

are configured to replicate (or copy) Snapshots from the on-premises Cohesity cluster to the Cloud EditionCohesity cluster.

Starting from the left in the following figure, the bottom workflow shows how the Cloud Edition can directly backup a VM that is not in the Cloud. For example a VM in a vCenter server can be backed up directly to Cloud Edition running in a Azure Cloud service.

You can recover VMs from the Snapshots stored in the Cloud Edition running in the Azure Cloud service.



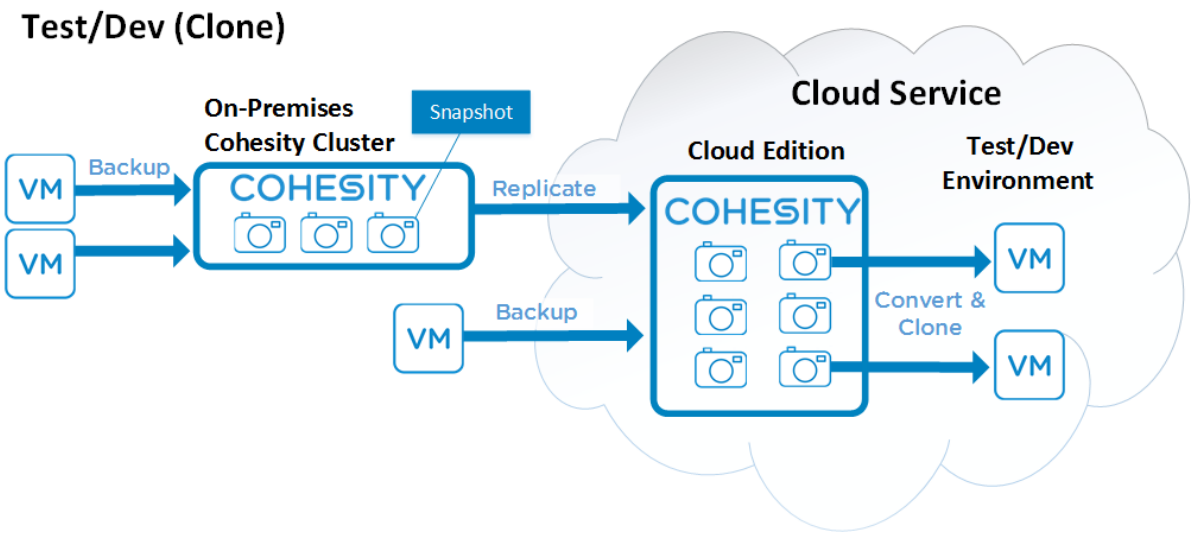
Replicate and Clone VMs in Azure Cloud Edition

CohesityCloud Edition supports Test/Dev (cloning) as shown by the following example figure.

Starting from the left in the following figure, the top workflow shows how Protection Groups running on the on-premises Cohesity cluster captures Snapshots of the VMs and stores these Snapshots on the on-premises Cluster. The Protection Policies associated with these Jobs, are configured to replicate (or copy) Snapshots from the on-premises Cohesity cluster to the Cohesity clusterCloud Edition.

Starting from the left in the following figure, the bottom workflow shows how the Cloud Edition can directly backup a VM that is not in the Cloud. For example a VM in a vCenter server can be backed up directly to Cloud Edition running in a Azure Cloud service.

From the Snapshots stored in the Cloud Edition on the Azure Cloud service, you can spin up test/dev environments using cloning.



To convert and clone VMs to a Cloud service:

1. Verify the following requirements prior to backing up the VMs:
   - For the list of VMs that supports CloudSpin to Azure, see Supported Software.
   - All the VMware vSphere versions supported by Cohesity for backup is supported for cloning to Azure. For the list of supported VMware vSphere versions, see Supported Software.
   - AHV, RhV and AWS VMs are *not* supported for cloning to Azure.

   Cloning Snapshots to an Azure Cloud is supported for VMware and Hyper-V VMs with the following operating systems:
   - Linux CentOS 7 on LVM
     - You can clone as many disks as the selected VM supports. For example, if you select a Standard_DS1_v2 VM, four disks can be cloned.
     - When converting and cloning or copying Snapshots of a Linux VM with multiple disks, the disks must be mounted by UUID prior to being backed up by the Protection Group, as shown by the following example entry in a `/etc/fstab`:

       ```
       UUID=e12e623a-c6ee-4718-9b1a-802456e72258 /userdata ext4
       defaults,nofail 0 0
       ```

       For detailed instructions, see Edit /etc/fstab to use UUID.
   - Windows
     - You can clone as many disks as the selected VM supports. For example, if you select a Standard_DS1_v2 VM, four disks can be cloned.

    - For a Windows VM, if you want to access the newly created VM in the Cloud service using Remote Desktop, enable the Windows Remote Desktop on the VM prior to capturing the Snapshots of a Windows VM.
    - When backing up Windows VMs with multiple disks, before a Protection Group captures the Snapshot, the Cohesity agent and VMware tools must be installed on the VM and the VM must be running. The Cohesity agents installed must be of the same version as the Cohesity Cluster version. For more information, see Install and Manage the Agent on Windows Servers. In addition, port 50051 must be open in your Firewall. For more information, see Manage Firewall Ports.
    - Due to a Windows issue in builds 14393 and build 15063, a deployed Windows 10 or Windows 2016 VM may not be connected to the network. Resolve this by installing fix KB4073562 for build 14393 or KB4016240 for build 15063 or by updating Windows. For more information, see Cannot connect remotely to a Windows 10 or Windows Server 2016 VM in Azure because of netvsc.sys.
    - Make the disks online by default using the following SAN policy commands:
        - `diskpart`
        - `san policy=OnlineAll`

      For more information, see the SAN Policy documentation.
- Red Hat Enterprise Linux
    - You can clone as many disks as the selected VM supports. For example, if you select a Standard_DS1_v2 VM, four disks can be cloned.
    - For the list of supported RHEL versions, see Supported Software.
    - When converting and cloning or copying Snapshots of a Linux VM with multiple disks, the disks must be mounted by UUID prior to being backed up by the Protection Group, as shown by the following example entry in a `/etc/fstab`:

      ```
      UUID=e12e623a-c6ee-4718-9b1a-802456e72258 /userdata ext4
      defaults,nofail 0 0
      ```

      For detailed instructions, see Edit /etc/fstab to use UUID.
- The disk size of the VMware VMs must be a multiple of 1 GB.
- Cohesity does not support the CloudSpin of VMs whose OS Disk is formatted with XFS version 5 to Azure. This limitation applies to both Hyper-V and VMware VMs, regardless of their operating system type.
- Cohesity does not support CloudSpin of VMware VMs from VMware Cloud (VMC) to Azure.

Cloning Hyper-V VMs to Azure

- VMs that have one to five disks can be cloned. Each disk must be smaller than 2 TB.
- SUSE Linux VMs are *not* supported.
- All the Hyper-V versions supported by Cohesity for backup is supported for cloning to Azure. For the list of supported Hyper-V versions, see Supported Software.
- Generation 2 VMs are not supported by all VM sizes in Azure. For information on Generation 2 supported VM series, see Microsoft document.
- Cloning of Hyper-V VMs to Azure Stack Hub is not supported.

2. Create a Protection Group to capture Snapshots of VMs. For more information, see Add a Protection Group for Azure VM.
3. Register the Cloud service that the VMware VMs are cloned **to**. For detailed instructions, see either Register an Azure Cloud Source at Subscription Level .
4. Log in to the Cohesity Dashboard of the Cohesity cluster that contains the Snapshots to clone from. That is, log in to the Cohesity cluster running in Azure.
5. Clone the VM in the Azure Cloud service. For detailed instructions, see Clone VMs.
6. After the Clone task completes, log in to the new VM in the Cloud service.

   For Azure:

   a. Log in to Microsoft Azure Portal.
   b. Search for the new Virtual Machine name.
   c. Click on the VM name.
   d. Under the **Subscription name**, copy the IP address of the new VM.
   e. Log in to the VM using the IP address. If Remote Desktop was installed in the VM that was cloned, you can log in using the Remote Desktop.
7. Multiple disks are automatically mounted on the Windows VM, if the following conditions are true before the Protection Group captures the Snapshot of a Windows VM:

   - A Cohesity agent is installed on the VM.
   - VMware tools are installed on the VM.
   - VM is running

   If any of the conditions were not true when the Job captured the Snapshot, the `C:` drive is mounted but you must mount the other drives such as `D:` as described here:

   a. If Remote Desktop is installed on the new cloned VM, log in to the new VM, start Remote Desktop Connection, enter the IP of the new cloned VM.
   b. In the new VM, launch the Windows Disk Management.

c. Right click on a disk that is not mounted and select **Online**. Repeat for all other offline disks.

Migrate Azure Virtual Machines

This chapter includes the following topics:

Migrate Cloud Edition Azure Nodes to Managed Disks

The nodes (VMs) in a Cloud Edition Azure cluster can use Azure-managed disks or unmanaged disks. Managed disks are described in Introduction to Azure Managed Disks.

Cohesity recommends that all nodes in a cluster use the same type of disk. You can migrate nodes from unmanaged disks to managed disks as described below.

Before Migrating the Nodes

Do the following before you migrate the nodes to use managed disks.

1. Take a snapshot of every node (VM) in the cluster as a backup precaution.
2. SSH into any node in the cluster.

   ```
   ssh cohesity@<ip_address>
   ```

3. Run the following commands and record the command output to verify disk utilization after the migration.

   ```
   df -h
   ```

   ```
   lsblk
   ```

Migrate the Nodes

To migrate the nodes to use managed disks, repeat the following steps for each node in the cluster.

1. Make sure there are no outstanding replication, archival or CloudSpin tasks active for the cluster.
2. In the Azure portal, click the Cloud Shell button shown below and activate the PowerShell environment.

   For more information, see Quickstart for PowerShell in Azure Cloud Shell.
3. In the PowerShell window, run the following commands to deallocate the node (VM).

   Replace *myResourceGroup* and *myVM* with the names of the resource group and VM instance name you want to deallocate.

   ```
   $rgName = "myResourceGroup"
   ```

```
$vmName = "myVM"
```

```
Stop-AzVM -ResourceGroupName $rgName -Name $vmName -Force
```

4. After the above commands run successfully, run the following command to initiate the migration.

```
ConvertTo-AzVMManagedDisk -ResourceGroupName $rgName -VMName $vmName
```

5. Repeat the previous steps for each node in the cluster.

Verify the Migration

1. SSH to any node in the cluster.
2. Run the following Cohesity CLI command to verify that all services are up and running.

```
iris_cli cluster status
```

3. Run the following commands and compare the results to the same command output that you recorded previously. The disk utilization should be the same as it was before the migration.

```
df -h
```

```
lsblk
```

Azure MySQL

Cohesity DataProtect provides a simple, fast, and cost-effective backup, recovery, and data management solution for Microsoft Azure MySQL databases.

Azure Database for MySQL is a fully managed relational database service offered by Microsoft Azure. It allows users to deploy, manage, and scale MySQL databases in the cloud without the need to manage the underlying infrastructure.

> **Important:** The backup and recovery of Azure MySQL is supported only on DataProtect for cloud in Azure (formerly known as Azure NGCE cluster). This is an Early Access feature. Contact your Cohesity account team to enable the feature.

This topic covers the following:

- Plan and Prepare for Azure MySQL Protection
- Register and Manage Azure MySQL Source
- Backup Azure MySQL Database
- Recover Azure MySQL Databases

Plan and Prepare for Azure MySQL Protection

Before you register an Azure MySQL source on Cohesity DataProtect, ensure the following requirements are met:

Required Permissions for Azure MySQL Protection

You must assign custom roles to the service account to enable Azure MySQL data protection. The following table lists the permissions and privileges that must be included in a custom role.

Permission	Description
Microsoft.DBforMySQL/flexibleServers/read	List and read the properties of the server.
Microsoft.DBforMySQL/flexibleServers/databases/read	List and read the properties of the database under a server.
Microsoft.DBforMySQL/flexibleServers/databases/write	Create or update the properties of the database.
Microsoft.DBforMySQL/flexibleServers/databases/delete	Delete the database.

Authentication for Azure MySQL Protection

You must authenticate the Cohesity cluster to discover the Azure MySQL databases using one of the following methods:

- **Username** and **password** of the Azure MySQL instance.
- **User Managed Identity**.

Configure Database User Associated with User Managed Identity

To configure a database user associated with User Managed Identity:

1. Get the client ID for managed identity using the following commands in Azure CLI:
   ```
   # az ad sp list --display-name <managed_identity_name> --query
   [*].appId
   --out tsv
   ```
2. Login to the MySQL server and create a user using the following commands:
   ```
   # SET aad_auth_validate_oids_in_tenant = OFF;
   # CREATE AADUSER '<db_user>' IDENTIFIED BY
   '<Generated_client_id>';
   # GRANT <Permissions> ON *.* TO '<db_user>'@'%'
   ```
3. Create a normal database user or one associated with the relevant User Managed Identity and grant the required permissions to that user using the following command:
   GRANT SELECT , INSERT , UPDATE, DELETE, CREATE, DROP , RELOAD,

```
PROCESS, REFERENCES, INDEX, ALTER, SHOW DATABASES, LOCK
TABLES, CREATE VIEW, SHOW VIEW, CREATE ROUTINE, ALTER ROUTINE,
SHOW_ROUTINE, EVENT , TRIGGER, SET_USER_ID ON *.* TO `<dbuser>`@'%'
WITH GRANT OPTION;
```

> **Note:** Replace *<dbuser>* in the above command with the actual name of the database user.

Firewall Ports for Azure MySQL Protection

Ensure connectivity from Cohesity DataProtect to the Azure MySQL server on port 3306.

Considerations for Azure MySQL Protection

- **Full backup support** - Only full backup is supported; incremental backup is not available for Azure MySQL.
- **Azure MySQL database size display** - The size of the database under Azure MySQL server will only be populated once the credentials are specified for the server entity. Otherwise, it will be reported as 0.
- **Attach metadata and credentials** - A database instance moved to a different resource group is considered a new entity. Hence, ensure that you attach the new metadata and credentials.
- **Azure MySQL version compatibility** - You can recover an Azure MySQL database to an alternate instance with an Azure MySQL version different than the backup instance, depending on the Azure MySQL version compatibility.
- **Database naming convention** -Backup and recovery of databases with names containing the characters **#** and **/** are not supported. Ensure the database names adhere to the naming conventions suggested by the cloud service.
- **Special character in password** - Server or database passwords do not support **;** (semicolon).
- **Database Level Protection** - Protection occurs at the database level and not server level; backup and recovery are performed for the databases on the server. Cohesity does not change or create an Azure MySQL server in the workflows. Hence, the properties of the server like tags are not recovered.

Register and Manage Azure MySQL Source

You must register Azure as a data source in Cohesity DataProtect to protect your Azure MySQL databases. After registering Azure MySQL as a source, you can:

- Update the Azure MySQL source configuration.
- Refresh the Azure MySQL source details.
- Unregister the Azure MySQL source from the Cohesity DataProtect.

Register Azure MySQL as a Source

Before registering Azure MySQL as a source, ensure to check the requirements and considerations.

To register Azure MySQL as a source:

1. In **DataProtect**, navigate to **Data Protection > Sources > Register**, and then select **Cloud Platforms > Azure**.

   The **Register Azure Source** window is displayed.

2. In the **Source Details** page,
   1. In the **Domain Name** field, provide the unique tenant ID assigned by Azure. For information on getting the tenant ID, see Get tenant ID.
   2. In the **Azure Workloads** section, under **Database**, select **MySQL**.
   3. Click **Continue**.
3. In the **Azure Apps** page,
   1. In the **Azure App ID** field, enter the application ID assigned by Azure during the service principal creation process.
   2. In the **App Secret Key** field, enter the application secret key for setting up authentication for the service principal.

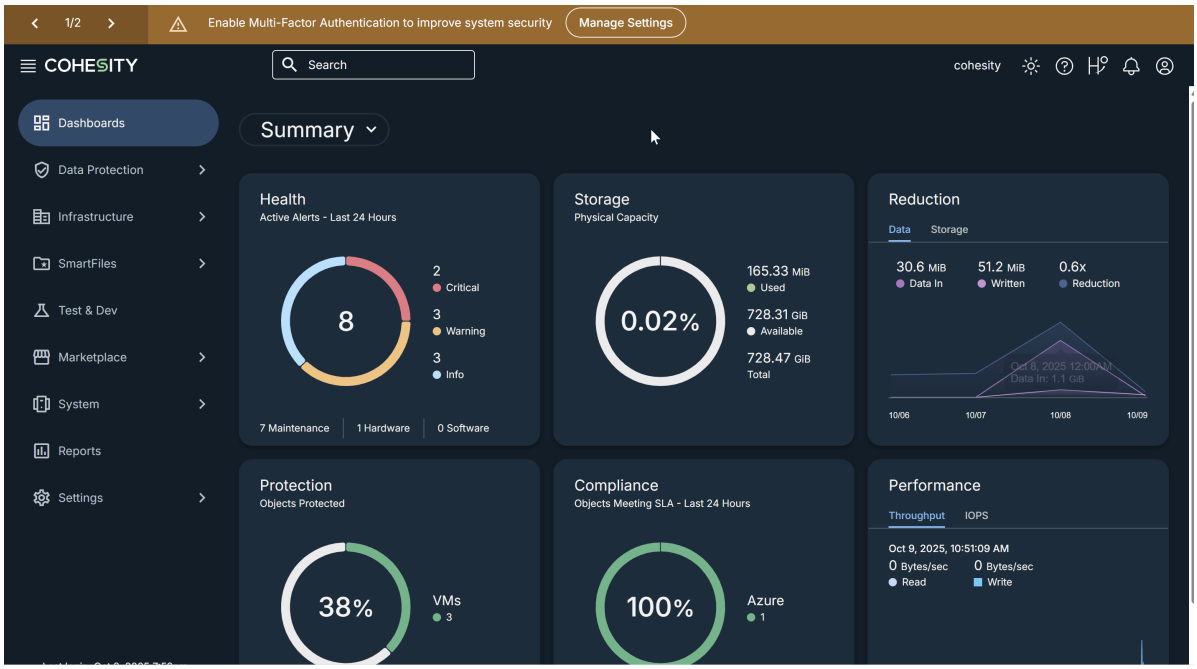
      > **Note:** Manual creation of Azure App requires significantly more effort and time. It involves several steps within Microsoft Azure for configuration.

   3. Click **Continue**.
4. In the **Subscriptions** page,
   1. In the **Subscription ID** field, enter the subscription IDs of the subscriptions where the database you want to protect belongs to.

      You can add multiple subscription IDs by clicking the **+** icon.

      > **Note:** The subscriptions must be manually added and will not be automatically discovered.

   2. Click **Register**.



The source will be registered and displayed under the **Azure** section in the **Data Protection > Sources** page. You can click on the source to view the entity tree of the Azure MySQL Servers and databases.

Update Azure MySQL Source Configuration

You can update the registered Azure MySQL source to add or remove the Azure services, and subscriptions protected by the Cohesity DataProtect from your Azure MySQL source.

To edit an Azure MySQL source:

1. In **DataProtect**, navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure MySQL sources and select **Edit**.
3. In the **Edit Azure Source** form, select or unselect the Azure services you need and click **Continue** to update Azure Application ID, Azure secret key, or add or remove subscriptions.
4. Once you edit the Azure MySQL Source, click **Update**.

Refresh Azure MySQL Source

You can refresh the Azure MySQL source configuration and fetch the latest changes on your Azure environment.

To refresh the Azure MySQL source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure MySQL source and select **Refresh**.

Unregister Azure MySQL Source

If you plan to stop backing up your Azure MySQL, you can unregister the Azure MySQL source from Cohesity DataProtect.

> **Note:** Before you unregister an Azure MySQL source from Cohesity DataProtect, you must unprotect all the protected objects in that Azure MySQL source.

To unregister the Azure MySQL source:

1. In **DataProtect**, navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure MySQL source and select **Unregister**.
3. In the **Unregister Source** dialog, click **Unregister**.

Backup Azure MySQL Database

After registering your Azure MySQL source in Cohesity DataProtect, Cohesity uses the cloud credentials provided to authenticate with Azure.

Once authenticated, Cohesity automatically discovers all the subscriptions that the service account can access, as well as all supported workloads such as Azure MySQL databases within those subscriptions. The discovered workloads appear under **Data Protection > Sources**. You can select the **MySQL** tab to view all the databases discovered.

Hierarchy View displays the entity hierarchy of the Azure MySQL objects, allowing you to navigate from the resource group-level down to individual databases.

Azure MySQL Entity Hierarchy

The Azure MySQL entity hierarchy follows this structure:

Structure	Description
Subscription	Logical container for managing billing, resources, and permissions for services.
Resource Group	Logical container for organizing and managing related Azure resources, such as virtual machines, storage accounts, and web apps.
Database Server	Fully managed MySQL database instance hosted within the Azure cloud.
Database	Fully managed relational database service in Microsoft Azure.

Backup Scope by Azure MySQL Hierarchy

Cohesity cluster allows you to backup Azure MySQL databases at different levels of the hierarchy.

You can choose to back up:

- **Subscription** – Protect all Azure MySQL databases within the subscription.
- **Resource Group** – Protect all Azure MySQL databases within the resource group.
- **Database Server** – Protect all Azure MySQL databases within the database server.
- **Database** – Protect individual Azure MySQL database.

Supported Backup Types

Cohesity supports only full backups for Azure MySQL. Incremental backups are not supported.

Protect Azure MySQL

Azure MySQL databases are protected using a Protection Group and a Protection Policy.

A Protection Group enables you to select and group the objects that you want to backup. It uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured and replicated.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select which standard or custom policy to use when creating a Protection Group. For more information, see Manage Protection Policy.

Prerequisites to Protect Azure MySQL

Set Azure MySQL Server Credentials

For Backup, the database credentials are used to authenticate and connect to the MySQL server. Once the connection is established, the relevant database can be dumped and protected.

For Azure MySQL, you can set credentials at the Azure MySQL Server level. This information is used to connect to the database during backup and recovery. You can also add credentials at any higher level in the hierarchy, such as the subscription. Credentials added at a higher level automatically apply to all objects beneath it.

The Cohesity cluster searches for credentials in a bottom-up manner, starting from the specific entity (for example, a server) and moving up the hierarchy until valid credentials are found. When multiple credentials exist, the credentials closest to the MySQL server take precedence.

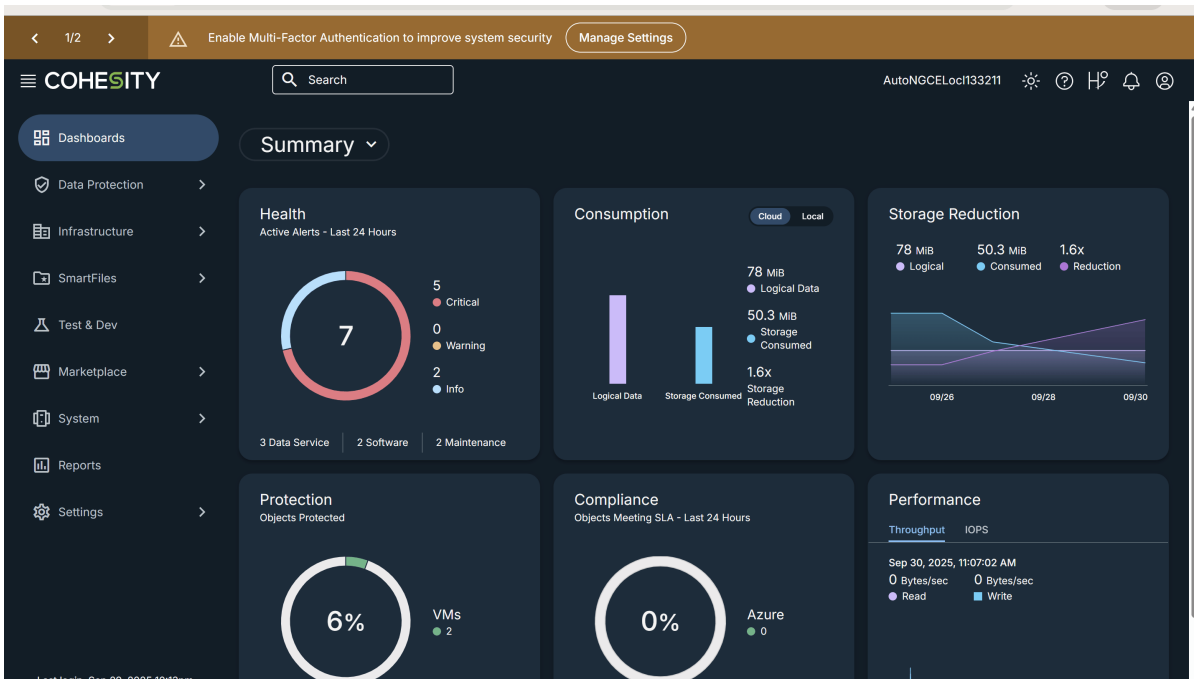
For example:

- If **region-1** has a set of credentials and **server-1** under that region has its own, the Cohesity cluster uses the credentials on **server-1** to authenticate to **server-1**.
- Another server, **server-2**, under the same region, the Cohesity cluster uses the region-level credentials for authentication because that is the closest level where credentials are specified.

To set the database credentials:

1. In **DataProtect**, navigate to **Data Protection > Sources**, find the registered Azure source, and click on it.
2. Click on the **MySQL** tab.
3. Select the checkbox next to the required Azure MySQL Server.
4. Click the **Database Credentials** button.
5. You can select one of the following options:
    1. **Username and Password** - Provide the database admin username and password. These credentials are required for leaf-level databases. The account must have access to all databases within the MySQL server.
    2. **User Managed Identity (UMI)** - Uses authentication automatically managed by Azure. For more information, see Configure Database User Associated with User Managed Identity.

        > **Note:**
        > - User Managed Identity must be attached to the Azure VM on which Cohesity DataProtect is deployed.
        > - UMI authentication method does not work across tenants.
        > - Authentication fails if the database credentials provided are incorrect. Ensure that the username/password/UMI ClientID is correct, and/or the UMI associated database user is properly configured.
6. Click **Save**.



Protect Azure MySQL Databases

To protect your Azure MySQL Server databases:

1. In **DataProtect** navigate to **Data Protection > Sources**.
2. Find the registered Azure MySQL source and click on it.
3. Click on the **MySQL** tab.
4. Use the checkboxes to select the objects for protection. You can select the tenants , subscriptions , resource groups , databases server , or databases under them. For more information, see Azure MySQL Entity Hierarchy.
   You can also use the **List View** to select the instances for protection from a flat, searchable list or **Tags View** to select the instances based on tags.
   - To protect all objects in the source, click the checkbox next to **Object**.
   - To protect all the child objects under the Azure MySQL Server, click the checkbox next to the Azure MySQL Server and click the **Select All Child Objects** option.
   - To auto-protect the Azure MySQL Server, click the checkbox next to the Azure MySQL Server object and select the **Auto-Protect This Azure MySQL Server** option.

> **Note:** Object-level exclusion is not supported during Azure MySQL protection.

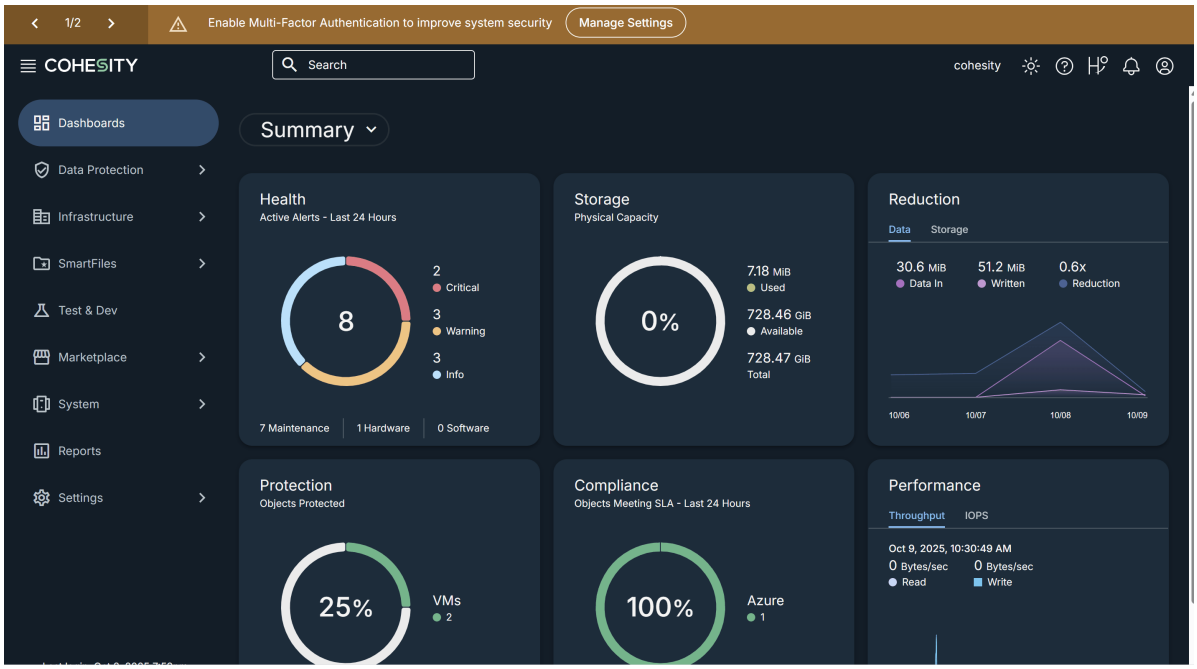
5. Click **Protect**.
6. Choose a policy to specify backup frequency and retention. If you do not have a policy, you can easily create one.

> **Note:** Periodic full is not recommended for Azure MySQL since all incremental backups are converted to full backups. If periodic full is part of the policy, two full backups will run sequentially when new databases are onboarded.

7. Optionally, to configure any of the advanced settings, select **More Options**.
8. Click **Protect**.

   You can monitor the status of the backup on the **Activity** page. Also, the **Activity** tab of a specific Azure MySQL shows the history of all protection runs, including the one in progress.

   Cohesity DataProtect starts backing up the databases you selected.



Advanced Settings

Section	Setting	Description
Settings	**Start Time**	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
	SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

Section	Setting	Description
Additional Settings	**Pause Future Runs**	Toggle on this option to stop protection runs from executing. Once you enable this option, no protection runs will be scheduled.
	End Date	If you need to end protection on a specific date, enable this option to select the date.
	QoS Policy	Select an appropriate quality of service (QoS) policy. Cohesity recommends specifying Backup HDD, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Object. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Object. Only specify this policy if you need fast ingest speed for a small number of Objects. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the current running task.
	Alerts	Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when an Object completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Object fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the takes longer than the time specified in the SLA field. Emails are sent when warning alerts are created.

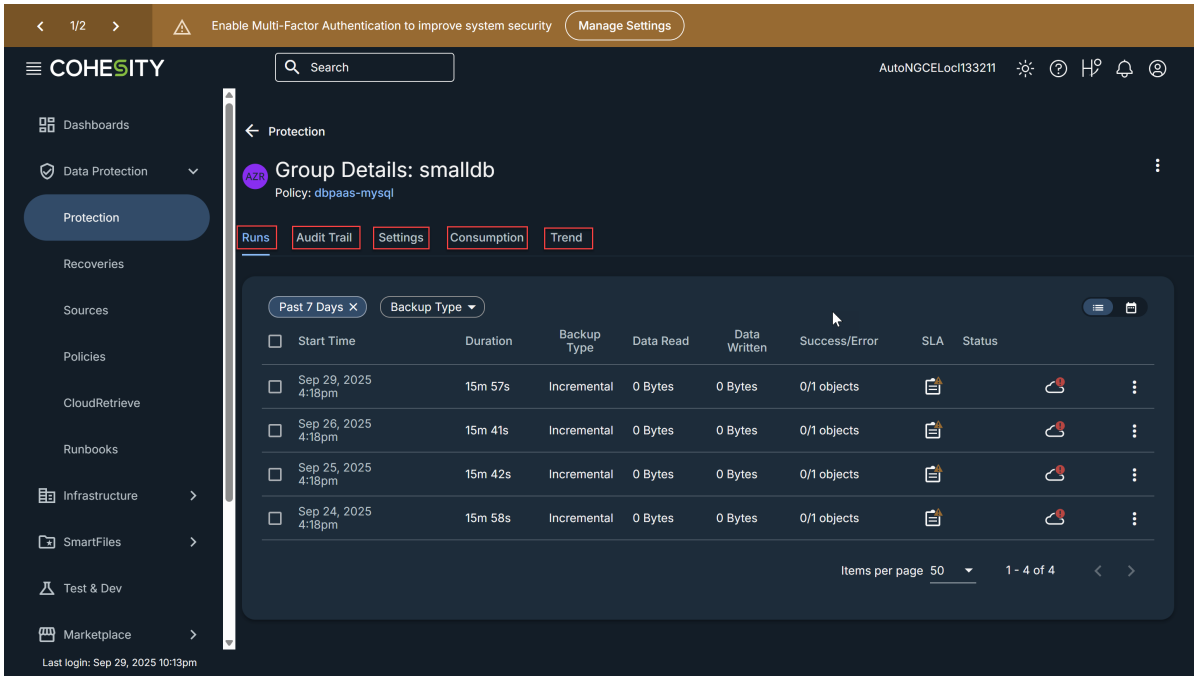
Section	Setting	Description
	Priority	Select a priority for the Object Protection Group Execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the runs: • High-priority protection runs • Medium-priority protection runs • Low-priority protection runs
	Description	Enter a brief description of the object.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.



Manage Azure MySQL Backup Configuration

In the Cohesity Platform, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Objects to the Protection Group

You can add new objects to the existing Protection Group for backup. The newly added object is backed up from the next protection run, and it will be a full backup for the newly added object.

To add objects to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for Azure MySQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ in the **Objects** section.
5. In the **Objects** section, Click the plus icon (**+**) to enter multiple objects that you plan to back up. click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for Azure MySQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to

execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for Azure MySQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a protection run:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for Azure MySQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Delete Protection Group Only
    - Delete Protection Group and Snapshots

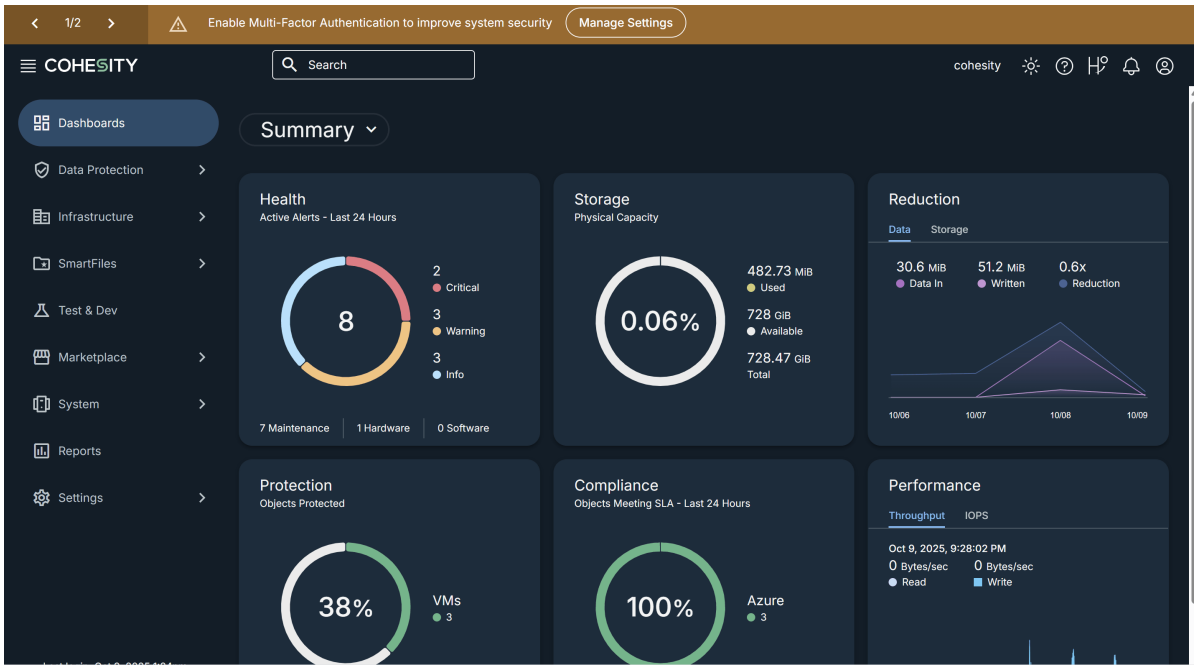
Recover Azure MySQL Databases

After you protect your Azure MySQL databases, you can recover them from Cohesity DataProtect to their original or a new location.

To recover protected Azure MySQL databases:

1. In **DataProtect**, navigate to **Data Protection > Sources**.
2. Click the required Azure MySQL source and click the **MySQL** tab.
3. Select the **Protection Status** as **Protected**.
4. Use the filters, search box, and views to locate and select the required databases.
5. Click **Recover** at the top to open the **New Recovery** form with the **Latest** snapshot (protection run).

    If you need to recover from an earlier snapshot, click the **Edit** icon to open the **Recovery Point** page.
    Click **List** to view the available recovery points by timestamp and click **Select Recovery Point**.
6. Under **Recover To**, select either of the following:
    1. **Original PaaS Instance** - To recover the Azure MySQL database to the Azure MySQL Server instance or Managed Instance from which the database was backed up.
    2. **Alternate PaaS Instance**. Select a target Azure MySQL Server instance or Managed Instance to which the Azure MySQL database will be recovered.
7. Select your **Recovery Options**:
    1. **Rename**. Add a Prefix and/or Suffix to the full name of the recovered Azure MySQL database.
    2. **Task Name**. Change the default name of the recovery task.
8. Click **Recover**.



You can monitor the status of the recovery on the **Activity** page.

Cohesity DataProtect starts recovering the selected Azure MySQL databases.

Azure Cosmos DB - Cassandra

Cohesity provides a simple, fast, and cost-effective backup, recovery, and data management solution for Azure Cosmos DB - Cassandra keyspaces.

Azure Cosmos DB - Cassandra is a fully managed NoSQL database service that enables you to run Cassandra workloads in the cloud with minimal changes to your application code.

> **Important:** The backup and recovery of Azure Cosmos DB - Cassandra is supported only on DataProtect for cloud in Azure (formerly known as Azure NGCE cluster). This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

Plan and Prepare for Azure Cosmos DB – Cassandra Protection

You must ensure the following requirements are met before you register an Azure Cosmos DB - Cassandra source on the Cohesity cluster.

Required Permissions for Azure Cosmos DB – Cassandra Protection

You must assign custom roles to the service account to enable Azure Cosmos DB – Cassandra protection.

The following table lists the permissions and privileges that must be included in a custom role.

Permission	Description
Microsoft.Resources/subscriptions/resourceGroups/read	Gets or lists resource groups.
Microsoft.DocumentDB/databaseAccounts/read	Gets or lists Cosmos DB Accounts.
Microsoft.DocumentDB/databaseAccounts/cassandraKeyspaces/throughputSettings/read	Reads Cassandra keyspace throughput.
Microsoft.DocumentDB/databaseAccounts/cassandraKeyspaces/tables/throughputSettings/read	Reads Cassandra table throughput.
Microsoft.DocumentDB/databaseAccounts/cassandraKeyspaces/views/throughputSettings/read	Reads Cassandra Materialized View throughput.
Microsoft.DocumentDB/databaseAccounts/cassandraKeyspaces/read	Gets or lists Cassandra Keyspaces.

Permission	Description
Microsoft.Insights/Metrics/Read	Retrieves operational metrics from Azure Monitor for Cosmos DB Cassandra table/keyspace. This permission enables the backup/recovery process to query Azure Monitor metrics for Request Unit (RU) consumption during data ingestion. The agent uses these metrics to dynamically calculate the optimal backup/recovery speed that maximizes throughput while staying within provisioned RU limits, preventing throttling errors and minimizing retime.

Required Roles for Azure Cosmos DB – Cassandra Protection

To create custom roles using the Azure Portal, use the following format:

```
{
"properties": {
"roleName": "AzureCosmosDBCassandraBackupRecovery",
"description": "Permission for Azure Cosmos DB Cassandra Keyspaces Backup
and Recovery",
"assignableScopes": [
"/subscriptions/subscriptionID"
],
"permissions": [
```

```
{
"actions": [
"Microsoft.Resources/subscriptions/resourceGroups/read",
"Microsoft.DocumentDB/databaseAccounts /read",
"Microsoft.DocumentDB/databaseAccounts /cas-
sandraKeyspaces/throughputSettings/read",
"Microsoft.Docu-
mentDB/databaseAccounts/cassandraKeyspaces/tables/throughputSettings/read"
"Microsoft.Docu-
mentDB/databaseAccounts/cassandraKeyspaces/views/throughputSettings/read",
“Microsoft.DocumentDB/databaseAccounts/cassandraKeyspaces/read”,

For information on creating a custom role, see Create or update Azure custom roles using the Azure portal.

Firewall Ports for Azure Cosmos DB – Cassandra Protection

Azure Cosmos DB offers two modes of connection - gateway mode and direct mode.

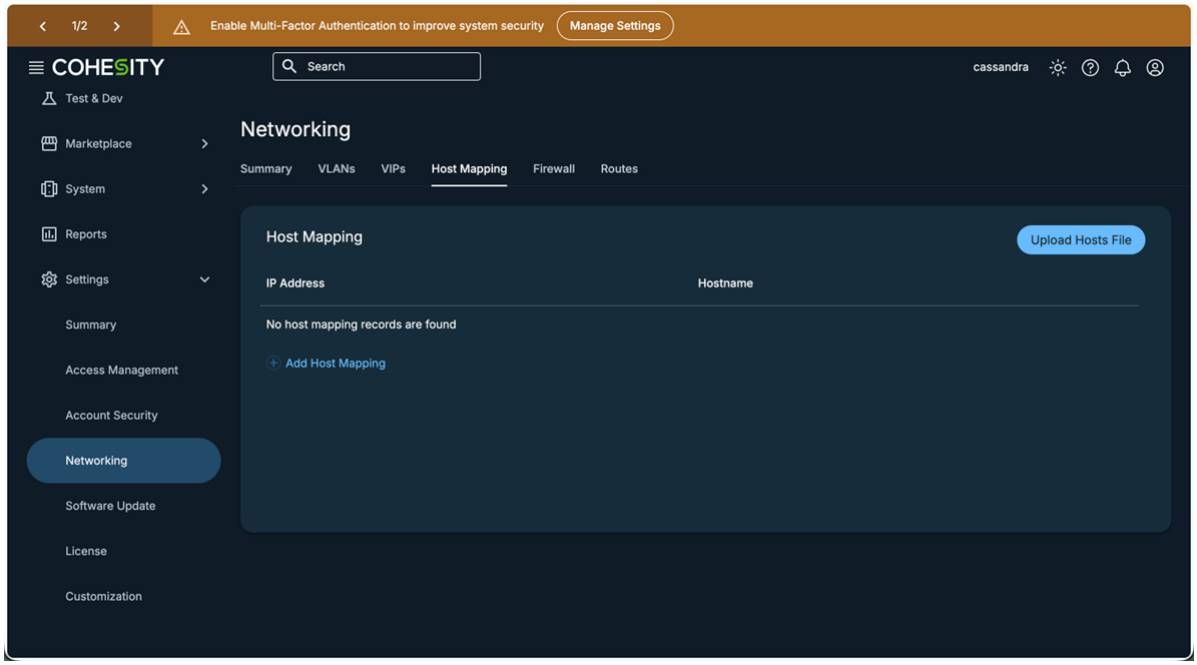
Connection Mode	Supported Protocol	API/Service Port
Gateway	HTTPS	Cassandra - 10350
Direct	TCP (Encrypted via TLS)	When using public/service endpoints: ports in the 10000 through 20000 range. When using private endpoints: ports in the 0 through 65535 range.

You can connect to the Azure Cosmos DB - Cassandra account from the Cohesity host using the following methods under **Settings > Networking** in the Microsoft Azure portal:

- Public Access
  - All networks.
  - Selected networks (with Cohesity host CIDR range in the Firewall allowed host - moderate security).
- Private Access

To use this method, you must create a Private EndPoint. For more information, see Create a private endpoint by using the Azure portal. Once the EndPoint is created,

1. Login to the Cohesity cluster.
2. Navigate to **Settings > Networking > Host Mapping**.
3. Add the Cassandra Private Endpoint IP host mapping.



Authentication for Azure Cosmos DB - Cassandra Keyspace Protection

You must authenticate Cohesity to discover the Azure Cosmos DB - Cassandra keyspaces using the **Username** and **Password** of the Azure Cosmos DB - Cassandra Account.

Considerations for Azure Cosmos DB - Cassandra Keyspace Protection

Review and understand the following limitations and considerations before you protect Azure Cosmos DB - Cassandra Keyspace:

- **Full back up support** - Only full backup is supported; incremental backup is not available for Azure Cosmos DB - Cassandra protection.
- **Attach metadata and credentials** - When you recover a keyspace to a different account, ensure that you attach the metadata and credentials to the destination account.
- **Rename keyspace during recovery** - Keyspace names can have up to 48 alpha-numeric characters and can contain underscores; only letters and numbers are supported as the first character.
- **Keyspace-Level Protection** - Protection occurs at the keyspace level and not account level; backup and recovery are performed for the keyspaces on the account.

Cohesity does not change or create an Azure Cosmos DB-Cassandra account in the workflows. Hence, the properties of the account like tags are not recovered.

- **Ingest rate during recovery** - Ingest rate during recovery can be changed to a value between 0.1 and 1.0. The default value is 0.4, which is 40% of the maximum theoretical ingest rate capacity. This helps in resolving rate limit errors during recovery.
- **Serverless vs provisioned throughput** - Keyspace belonging to an account with Serverless mode cannot be recovered to the one with provisioned throughput capacity mode and vice versa.
- **SSR (Server Side Retry)** - During backup and recovery, SSR must be enabled on the source and destination Cassandra account. This is mandatory for the backup and recovery to be successful.
- **TTL (Time-to-live) on recovered tables** - When recovering Azure Cosmos DB-Cassandra tables, the default_time_to_live (TTL) setting is preserved from the source table and applied to the recovered table. As a result, any newly inserted rows in the recovered table will automatically expire after a duration of Row creation time + default_time_to_live (in seconds).

  This ensures consistency with the TTL-based data expiration behavior of the original table.

  > **Note:** Row-level TTL settings are not retained during backup. When data is recovered, the TTL for those rows is set to the table's default_time_to_live value.

- **Index Name on Recovery** - Index names are not retained during the backup and recovery of Azure Cosmos DB-Cassandra tables. While index names are accepted syntactically by the service, they are not functionally relevant in Azure Cosmos DB-Cassandra. To ensure consistency and compatibility, index names are regenerated during the recovery process.
- **Materialized views support** - If the source table includes materialized views, during recovery the destination account must have Materialized Views settings enabled. This is mandatory for successful recovery of materialized views. As per Azure, materialized views are not recommended for production workloads. For more information, see Materialized Views in Azure Cosmos DB for Apache Cassandra.
- **Replication regions** - To get optimum performance during recovery, it is recommended to disable multi-region replication. After recovery, you can re-enable multi-region replication.
- **Version Downgrade not supported**: Recovering a backup taken from a higher database version to a lower version is not supported.

Register and Manage Azure Source

You must register Azure as a source on the Cohesity cluster to protect your Azure Cosmos DB - Cassandra keyspaces.

After registering Azure as a source, you can:

- Update the Azure source configuration.
- Refresh the Azure source details.
- Unregister the Azure source from Cohesity cluster.

Register Azure as a Source

Before registering Azure as a source, ensure to check the requirements and considerations.

To register Azure as a source:

1. Navigate to **Data Protection > Sources > Register**, and then select **Cloud Platforms > Azure**.

   The **Register Azure Source** window is displayed.
2. In the **Source Details** page,
   1. In the **Domain Name** field, provide the unique tenant ID assigned by Azure. For information on getting the tenant ID, see Get tenant ID.
   2. In the **Azure Workloads** section, under **Database**, select **Cosmos DB - Cassandra**.
   3. Click **Continue**.
3. In the **Azure Apps** page,
   1. In the **Application ID** field, enter the application ID assigned by Azure during the service principal creation process.
   2. In the **Application Secret Key** field, enter the application secret key for setting up authentication for the service principal.

      > **Note:** Manual creation of Azure App requires significantly more effort and time. It involves several steps within Microsoft Azure for configuration.

   3. Click **Continue**.
4. In the **Subscriptions** page,
   1. In the **Subscription ID** field, enter the subscription IDs of the subscriptions where the keyspace you want to protect belongs to.

      You can add multiple subscription IDs by clicking the **+** icon.

> **Note:** The subscriptions must be manually added and will not be automatically discovered.

2. Click **Register**.

The source will be registered and displayed under the **Azure** section in the **Data Protection > Sources** page. You can click on the source and navigate to the **Cosmos DB - Cassandra** tab to view the entity tree of the keyspaces.

Update Azure Source Configuration

You can update the registered Azure source to add or remove the Azure services, and subscriptions protected by Cohesity from your Azure source.

To edit an Azure source:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure sources and select **Edit**.
3. In the **Edit Azure Source** page,
   a. Select or unselect the Azure services you need and click **Continue**.
   b. Update Azure Application ID, Azure secret keyand click **Continue**.
   c. Add or remove subscriptions and click **Update**.

> **Note:**
> - The listed subscriptions are added only after an administrator has manually linked them to Microsoft Azure.
> - Before you remove a subscription from the Azure source, you must unprotect all the protected objects in the subscription.

Refresh Azure Source

You can refresh the Azure source configuration and fetch the latest changes on your Azure environment.

To refresh the Azure source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure source and select **Refresh**.

Unregister Azure Source

If you plan to stop backing up your Azure keyspaces, you can unregister the Azure source from the Cohesity cluster.

> **Note:** Before you unregister an Azure source from the Cohesity cluster, you must unprotect all the protected objects in that Azure source.

To unregister the Azure source:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure source and select **Unregister**.
3. In the **Unregister Source** dialog, click **Unregister**.

> **Note:** The source and all the keyspaces in the source will be unregistered. Use the checkbox to unregister specific keyspaces.

Backup Azure Cosmos DB - Cassandra Keyspace

After registering your Azure source in the Cohesity cluster, Cohesity uses the cloud credentials provided to authenticate with Azure.

Once authenticated, Cohesity automatically discovers all the subscriptions that the service account can access, as well as all supported workloads such as Azure Cosmos DB - Cassandra keyspaces within those subscriptions. The discovered workloads appear under **Data Protection > Sources**. You can select the **Cosmos DB - Cassandra** tab to view all the keyspaces discovered.

Hierarchy View displays the entity hierarchy of the Azure Cosmos DB - Cassandra objects, allowing you to navigate from the resource group-level down to individual keyspaces.

Azure Cosmos DB - Cassandra Entity Hierarchy

The Azure Cosmos DB - Cassandra entity hierarchy follows this structure:

Structure	Description
Tenant	Dedicated instance of the identity service.
Subscription	Logical container for managing billing, resources, and permissions for services.
Resource Group	Logical container for organizing and managing related Azure resources, such as virtual machines, storage accounts, and web apps.

Structure	Description
Cosmos DB Cassandra Account	Fully managed NoSQL database service hosted within the Azure cloud.
Keyspace	The top-level container for your data which holds tables. It is analogous to a database in RDBMS.

Backup Scope by Azure Cosmos DB - Cassandra Hierarchy

Cohesity allows you to backup Azure Cosmos DB - Cassandra keyspaces at different levels of the hierarchy.

You can choose to back up:

- **Tenant** – Protect all Azure Cosmos DB - Cassandra keyspaces within the tenant.
- **Subscription** – Protect all Azure Cosmos DB - Cassandra keyspaces within the subscription.
- **Resource Group** – Protect all Azure Cosmos DB - Cassandra keyspaces within the resource group.
- **Cosmos DB Cassandra Account** – Protect all Azure Cosmos DB - Cassandra keyspaces within the Cosmos DB Account.
- **Keyspace** – Protect individual Azure Cosmos DB - Cassandra keyspace.

Supported Backup Types

Cohesity supports full backups for Azure Cosmos DB - Cassandra. Incremental backups are not supported.

Protect Azure Cosmos DB - Cassandra Keyspaces

Azure Cosmos DB - Cassandra keyspaces are protected using a Protection Group and a Protection Policy.

A Protection Group enables you to select and group the objects that you want to backup. It uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured and replicated.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select which standard or custom policy to use when creating a Protection Group. For more information, see Manage Protection Policy.

Prerequisites to Protect Azure Cosmos DB - Cassandra

Set Azure Cosmos DB - Cassandra Database Credentials

For Backup, the account credentials are used to authenticate and connect to the Cosmos DB - Cassandra Account. Once the connection is established, the relevant keyspace can be dumped and protected.

For Azure Cosmos DB - Cassandra, you can set credentials at the resource group, subscription, and tenant level. This information is used to connect to the keyspace during backup and recovery.

To set the keyspace credentials:

1. Navigate to **Data Protection > Sources**, find the registered Azure source, and click on it.
2. Click on the **Cosmos DB - Cassandra** tab.
3. Select the checkbox next to the required Azure Cosmos DB - Cassandra Account.
4. Click the **Database Credentials** button.
5. Provide the **Username and Password** of the keyspace admin. These credentials are required for leaf-level keyspaces.
6. Click **Save**.

Protect Azure Cosmos DB - Cassandra Keyspaces

To protect your Azure Cosmos DB - Cassandra Account keyspaces:

1. Navigate to **Data Protection > Protection > Protect**, and then select **Azure > Cosmos DB - Cassandra**.
2. In the **New Protection** page, click **Add Objects** and select your registered source.

   Use the checkboxes to select the objects for protection. You can select the tenants, subscriptions, resource groups, Cosmos DB Cassandra accounts, or keyspaces under them. For more information, see Azure Cosmos DB - Cassandra Entity Hierarchy.

   You can also use **List View** to select the instances for protection from a flat, searchable list.

   You can auto-protect all the objects under a resource group, subscription, or tenant using the AutoProtect icon.

   To exclude an auto-protected object, click on the AutoProtect icon next to the object.
3. Click **Continue**.

4. Click **Protection Group** and provide a name for your protection group.
5. Click **Policy** and choose a policy to specify backup frequency and retention. If you do not have a policy, you can easily create one.
6. Optionally, to configure any of the settings or additional settings, select **More Options**.
7. Click **Protect**.

You can monitor the status of the backup on the **Activity** page. Also, the **Activity** tab of a specific Azure Cosmos DB - Cassandra shows the history of all protection runs, including the one in progress.

Cohesity starts backing up the keyspaces you selected.

Settings

Setting	Description
Storage Domain	Select the appropriate Storage Domain. For more information, see Manage Storage Domains.
Start Time	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

Additional Settings

Pause Future Runs	Toggle on this option to stop protection runs from executing. Once you enable this option, no protection runs will be scheduled.
End Date	If you need to end protection on a specific date, enable this option to select the date.

QoS Policy	Select an appropriate quality of service (QoS) policy. Cohesity recommends specifying Backup HDD, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Object. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Object. Only specify this policy if you need fast ingest speed for a small number of Objects. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the current running task.
Alerts	Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when an Object completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Object fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the takes longer than the time specified in the SLA field. Emails are sent when warning alerts are created.
Priority	Select a priority for the Object Protection Group Execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the runs: • High-priority protection runs • Medium-priority protection runs • Low-priority protection runs
Description	Enter a brief description of the object.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.

Manage Azure Cosmos DB - Cassandra Backup Configuration

Backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Objects to the Protection Group

You can add new objects to the existing Protection Group for backup. The newly added object is backed up from the next protection run, and it will be a full backup for the newly added object.

To add objects to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for Azure Cosmos DB - Cassandra.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ⋮ in the **Objects** section.
5. In the **Objects** section, Click the plus icon (**+**) to enter multiple objects that you plan to back up. click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for Azure Cosmos DB - Cassandra.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for Azure Cosmos DB - Cassandra.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a protection run:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for Azure Cosmos DB - Cassandra.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Delete Protection Group Only
    - Delete Protection Group and Snapshots

Recover Azure Cosmos DB - Cassandra Keyspaces

After you protect your Azure Cosmos DB - Cassandra Keyspaces, you can recover them from Cohesity to their original or a new location.

To recover protected Azure Cosmos DB - Cassandra keyspaces:

1. Navigate to **Data Protection > Recoveries > Recover**, and then select **Azure > Cosmos DB - Cassandra**.
2. In the **New Recovery** page, use the filter, search box, and views to locate and select the required keyspaces.

    The latest snapshot will be displayed (protection run).

    If you need to recover an earlier snapshot, click the **Edit** icon to open the **Recovery Point** page.

    Click **List** to view the available recovery points by timestamp and click **Select Recovery Point**.
3. Click **Next: Recover Options**.
4. Under **Recover To**, select either of the following:
    - **Original Location** - To recover the Azure Cosmos DB - Cassandra keyspace to the Azure Cosmos DB - Cassandra instance or Managed Instance from which the keyspace was backed up.

        Recovering to the original location will replace any existing database with the same name in the selected instance. Type **YES** to confirm.
    - **New Location** - Select a target Azure Cosmos DB - Cassandra instance or Managed Instance to which the Azure Cosmos DB - Cassandra keyspace will be recovered. Toggle on **Overwrite existing database(s)** to allow Cohesity to overwrite the existing databases in the target location. Type **YES** to confirm.
5. Select your **Recovery Options**:
    - **Rename**. Add a Prefix and/or Suffix to the full name of the recovered Azure Cosmos DB - Cassandra keyspace.

- **Task Name**. Change the default name of the recovery task.
- **Ingest Rate Cap**. Limit the data ingestion rate to 40% of theoretical maximum to avoid exceeding the provisioned throughput (RU/s) of the Azure Cosmos DB - Cassandra workload. Recommended for preventing rate limit errors.
  Ingest rates can be between 0.1 and 1.0. The default value is 0.4, which is 40% of the maximum theoretical ingest rate capacity.

6. Click **Recover**.

You can monitor the status of the recovery on the **Activity** page.

Cohesity starts recovering the selected Azure Cosmos DB - Cassandra keyspaces.

Azure Cosmos DB - MongoDB

Cohesity provides a simple, fast, and cost-effective backup, recovery, and data management solution for Azure Cosmos DB - MongoDB databases.

Azure Cosmos DB offers an API for MongoDB, which allows you to use Azure Cosmos DB like a native MongoDB database. This compatibility allows the use of existing MongoDB applications, tooling, drivers, and SDKs.

> **Important:** The backup and recovery of Azure Cosmos DB - MongoDB is supported only on DataProtect for cloud in Azure (formerly known as Azure NGCE cluster). This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

Plan and Prepare for Azure Cosmos DB - MongoDB Protection

You must ensure the following requirements are met before you register an Azure Cosmos DB - MongoDB source on Cohesity.

Required Permissions for Azure Cosmos DB - MongoDB Protection

You must assign custom roles to the service account to enable Azure Azure Cosmos DB - MongoDB data protection. The following table lists the permissions and privileges that must be included in a custom role.

Permission	Description
Microsoft.DocumentDB/databaseAccounts/read	Read a database account.

Permission	Description
Microsoft.DocumentDB/databaseAccounts/mongodbDatabases/read	Read a MongoDB database or list all the MongoDB databases.
Microsoft.DocumentDB/databaseAccounts/mongodbDatabases/write	Create a MongoDB database.
Microsoft.DocumentDB/databaseAccounts/mongodbDatabases/collections /read	Read a MongoDB collection or list all the MongoDB collections.
Microsoft.DocumentDB/databaseAccounts/mongodbDatabases/collections /write	Create or update a MongoDB collection.
Microsoft.DocumentDB/databaseAccounts/mongodbDatabases/delete	Delete MongoDB database.
Microsoft.DocumentDB/databaseAccounts/mongodbDatabases/collections/throughputSettings/read	Read a MongoDB collection throughput.
Microsoft.DocumentDB/databaseAccounts/mongodbDatabases/collections/throughputSettings/write	Update MongoDB collection throughput.

Authentication for Azure Cosmos DB - MongoDB Database Protection

You must authenticate the Cohesity cluster to discover the Azure Cosmos DB - MongoDB databases using the **Username** and **Password** of the Azure Cosmos DB - MongoDB database.

Considerations for Azure Cosmos DB - MongoDB Database Protection

Review and understand the following limitations and considerations before you protect Azure Cosmos DB - MongoDB Database:

- **Account with vCore/DocumentDB cluster** - Discovery, protection, and recovery are not supported if the account is configured using the vCore/DocumentDB cluster.
- **Account with customized key** - Backup and recovery are not supported if the account is configured with a customized key.
- **MongoDB 3.2** - Azure Cosmos DB for MongoDB version 3.2 is not supported.
- **Naming rules** - The following are the rules for naming the databases:
  - The length of the database names must be between 3 and 63 characters.
  - Database names support all characters except #, /, ?,&, <, >, =, }, $, {,], [,", ', ., \ .
- **Version Downgrade not supported**: Recovering a backup taken from a higher database version to a lower version is not supported.

Register and Manage Azure Source

You must register Azure as a source on the Cohesity cluster to protect your Azure Cosmos DB - MongoDB databases.

After registering Azure as a source, you can:

- Update the Azure source configuration.
- Refresh the Azure source details.
- Unregister the Azure source from Cohesity cluster.

Register Azure as a Source

Before registering Azure as a source, ensure to check the requirements and considerations.

To register Azure as a source:

1. Navigate to **Data Protection > Sources > Register**, and then select **Cloud Platforms > Azure**.

   The **Register Azure Source** window is displayed.
2. In the **Source Details** page,
   1. In the **Domain Name** field, provide the unique tenant ID assigned by Azure. For information on getting the tenant ID, see Get tenant ID.
   2. In the **Azure Workloads** section, under **Database**, select **Cosmos DB - MongoDB** .
   3. Click **Continue**.
3. In the **Azure Apps** page,

1. In the **Application ID** field, enter the application ID assigned by Azure during the service principal creation process.
2. In the **Application Secret Key** field, enter the application secret key for setting up authentication for the service principal.

   > **Note:** Manual creation of Azure App requires significantly more effort and time. It involves several steps within Microsoft Azure for configuration.

3. Click **Continue**.

4. In the **Subscriptions** page,
   1. In the **Subscription ID** field, enter the subscription IDs of the subscriptions where the database you want to protect belongs to.

      You can add multiple subscription IDs by clicking the **+** icon.

      > **Note:** The subscriptions must be manually added and will not be automatically discovered.

   2. Click **Register**.

   The source will be registered and displayed under the **Azure** section in the **Data Protection > Sources** page. You can click on the source and navigate to the **Cosmos DB - MongoDB** tab to view the entity tree of the databases.

Update Azure Source Configuration

You can update the registered Azure source to add or remove the Azure services, and subscriptions protected by Cohesity from your Azure source.

To edit an Azure source:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure sources and select **Edit**.
3. In the **Edit Azure Source** page,
   a. Select or unselect the Azure services you need and click **Continue**.
   b. Update Azure Application ID, Azure secret keyand click **Continue**.
   c. Add or remove subscriptions and click **Update**.

> **Note:**
> - The listed subscriptions are added only after an administrator has manually linked them to Microsoft Azure.
> - Before you remove a subscription from the Azure source, you must unprotect all the protected objects in the subscription.

Refresh Azure Source

You can refresh the Azure source configuration and fetch the latest changes on your Azure environment.

To refresh the Azure source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure source and select **Refresh**.

Unregister Azure Source

If you plan to stop backing up your Azure databases, you can unregister the Azure source from the Cohesity cluster.

> **Note:** Before you unregister an Azure source from the Cohesity cluster, you must unprotect all the protected objects in that Azure source.

To unregister the Azure source:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure source and select **Unregister**.
3. In the **Unregister Source** dialog, click **Unregister**.

> **Note:** The source and all the databases in the source will be unregistered. Use the checkbox to unregister specific databases.

Backup Azure Cosmos DB - MongoDB Database

After registering your Azure source in the Cohesity cluster, Cohesity uses the cloud credentials provided to authenticate with Azure.

Once authenticated, Cohesity automatically discovers all the subscriptions that the service account can access, as well as all supported workloads such as Azure Cosmos DB - MongoDB databases within those subscriptions. The discovered workloads appear under **Data Protection > Sources**. You can select the **Cosmos DB - MongoDB** tab to view all the databases discovered.

Hierarchy View displays the entity hierarchy of the Azure Cosmos DB - MongoDB objects, allowing you to navigate from the resource group-level down to individual databases.

Azure Cosmos DB - MongoDB Entity Hierarchy

The Azure Cosmos DB - MongoDB entity hierarchy follows this structure:

Structure	Description
Tenant	Dedicated instance of the identity service.
Subscription	Logical container for managing billing, resources, and permissions for services.
Resource Group	Logical container for organizing and managing related Azure resources, such as virtual machines, storage accounts, and web apps.
Cosmos DB MongoDB Account	Fully managed Cosmos DB - MongoDB database service hosted within the Azure cloud.
Database	Fully managed NoSQL database in Microsoft Azure. The size of the databases is displayed only after valid credentials are set at the database account level and the source is refreshed.

Backup Scope by Azure Cosmos DB - MongoDB Hierarchy

Cohesity cluster allows you to backup Azure Cosmos DB - MongoDB databases at different levels of the hierarchy.

You can choose to back up:

- **Tenant** – Protect all Azure Cosmos DB - MongoDB databases within the tenant.
- **Subscription** – Protect all Azure Cosmos DB - MongoDB databases within the subscription.
- **Resource Group** – Protect all Azure Cosmos DB - MongoDB databases within the resource group.
- **Cosmos DB MongoDB Account** – Protect all Azure Cosmos DB - MongoDB databases within the account.
- **Database** – Protect individual Azure Cosmos DB - MongoDB database.

Supported Backup Types

Cohesity supports full backups for Azure Cosmos DB - MongoDB. Incremental backups are not supported.

Protect Azure Cosmos DB - MongoDB Databases

Azure Cosmos DB - MongoDB databases are protected using a Protection Group and a Protection Policy.

A Protection Group enables you to select and group the objects that you want to backup. It uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured and replicated.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select which standard or custom policy to use when creating a Protection Group. For more information, see Manage Protection Policy.

Prerequisites to Protect Azure Cosmos DB - MongoDB

Set Azure Cosmos DB - MongoDB Database Credentials

For Backup, the database credentials are used to authenticate and connect to the Cosmos DB - MongoDB account. Once the connection is established, the relevant database can be dumped and protected.

For Azure Cosmos DB - MongoDB, you can set credentials at the Azure Cosmos DB - MongoDB account level. This information is used to connect to the database during backup and recovery.

To set the database credentials:

1. Navigate to **Data Protection > Sources**, find the registered Azure source, and click on it.
2. Click on the **Cosmos DB - MongoDB** tab.
3. Select the checkbox next to the required Azure Cosmos DB - MongoDB account.
4. Click the **Database Credentials** button.
5. Under **Username and Password**, provide the Cosmos DB account credentials. These credentials are required for leaf-level databases. The account must have access to all databases within the Cosmos DB - MongoDB account.
6. Click **Save**.

Enable Server Side Retry (SSR)

You must enable Server Side Retry (SSR) to automate operation retries. This is required for handling rate limiting errors and addressing failure when the rate limit is reached.

Perform the following to enable SSR:

1. Sign in to the Azure portal.
2. Navigate to your Azure Cosmos DB - MongoDB account.
3. Go to the **Features** pane under the **Settings** section.
4. Select **Server Side Retry**.
5. Click **Enable** to enable this feature for all collections in your account.

For more information, see Prevent rate-limiting errors for Azure Cosmos DB for MongoDB operations.

Protect Azure Cosmos DB - MongoDB Databases

To protect your Azure Cosmos DB - MongoDB databases:

1. Navigate to **Data Protection > Protection > Protect**, and then select **Azure > Cosmos DB - MongoDB**.
2. In the **New Protection** page, click **Add Objects** and select your registered source.
3. Use the checkboxes to select the objects for protection. You can select the tenants, subscriptions, resource groups, Cosmos DB MongoDB accounts, or databases under them. For more information, see Azure Cosmos DB - MongoDB Entity Hierarchy.

   You can also use **List View** to select the database entities for protection from a flat, searchable list.

   You can auto-protect all the objects under a resource group, subscription, or tenant using the AutoProtect icon .

   To exclude an auto-protected object, click on the AutoProtect icon next to the object.
4. Click **Continue**.
5. Click **Protection Group** and provide a name for your protection group.
6. Click **Policy** and choose a policy to specify backup frequency and retention. If you do not have a policy, you can easily create one.
7. Optionally, to configure any of the settings or additional settings, select More Options.
8. Click **Protect**.

You can monitor the status of the backup on the **Activity** page. Also, the **Activity** tab of a specific Azure Cosmos DB - MongoDB shows the history of all protection runs, including the one in progress.

Cohesity starts backing up the databases you selected.

Settings

Setting	Description
Storage Domain	Select the appropriate Storage Domain. For more information, see Manage Storage Domains.
Start Time	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

Additional Settings

Pause Future Runs	Toggle on this option to stop protection runs from executing. Once you enable this option, no protection runs will be scheduled.
End Date	If you need to end protection on a specific date, enable this option to select the date.
QoS Policy	Select an appropriate quality of service (QoS) policy. Cohesity recommends specifying Backup HDD, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Object. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Object. Only specify this policy if you need fast ingest speed for a small number of Objects. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the current running task.

Alerts	Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when an Object completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Object fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the takes longer than the time specified in the SLA field. Emails are sent when warning alerts are created.
Priority	Select a priority for the Object ProtectionGroupxecution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the runs: • High-priority protection runs • Medium-priority protection runs • Low-priority protection runs
Description	Enter a brief description of the object.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.

Manage Azure Cosmos DB - MongoDB Backup Configuration

Backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Objects to the Protection Group

You can add new objects to the existing Protection Group for backup. The newly added object is backed up from the next protection run, and it will be a full backup for the newly added object.

To add objects to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for Azure Cosmos DB - MongoDB.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ in the **Objects** section.
5. In the **Objects** section, Click the plus icon (**+**) to enter multiple objects that you plan to back up. click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for Azure Cosmos DB - MongoDB.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for Azure Cosmos DB - MongoDB.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a protection run:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for Azure Cosmos DB - MongoDB.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.

4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Delete Protection Group Only
    - Delete Protection Group and Snapshots

Recover Azure Cosmos DB - MongoDB Databases

After you protect your Azure Cosmos DB - MongoDB databases, you can recover them from Cohesity to their original or a new location.

Prerequisites to Recover Azure Cosmos DB - MongoDB

Enable Server Side Retry (SSR)

You must enable Server Side Retry (SSR) to automate operation retries. This is required for handling rate limiting errors and addressing failure when the rate limit is reached.

Perform the following to enable SSR:

1. Sign in to the Azure portal.
2. Navigate to the target Azure Cosmos DB - MongoDB account.
3. Go to the **Features** pane under the **Settings** section.
4. Select **Server Side Retry**.
5. Click **Enable** to enable this feature for all collections in your account.

For more information, see Prevent rate-limiting errors for Azure Cosmos DB for MongoDB operations.

Recover Azure Cosmos DB - MongoDB Databases

To recover protected Azure Cosmos DB - MongoDB databases:

1. Navigate to **Data Protection > Recoveries > Recover**, and then select **Azure > Cosmos DB - MongoDB**.
2. In the **New Recovery** page, use the filter, search box, and views to locate and select the required databases.

   The latest snapshot will be displayed (protection run).

   If you need to recover an earlier snapshot, click the **Edit** icon to open the **Recovery Point** page.
3. Click **List** to view the available recovery points by timestamp and click **Select Recovery Point**.
4. Click **Next: Recover Options**.
5. Under **Recover To**, select either of the following:

- **Original Location** - To recover the Azure Cosmos DB - MongoDB database to the same Azure Cosmos DB - MongoDB account from which the database was backed up.

  If overwrite is enabled, recovering to the original location will replace any existing database with the same name in the selected account. Type **YES** to confirm.

- **New Location** - Select a target Azure Cosmos DB - MongoDB account to which the Azure Cosmos DB - MongoDB database will be recovered. Toggle on **Overwrite existing database(s)** to allow Cohesity to overwrite the existing databases in the target location. Type **YES** to confirm.

6. Select your **Recovery Options**:
   - **Rename**. Add a Prefix and/or Suffix to the full name of the recovered Azure Cosmos DB - MongoDB database.
   - **Task Name**. Change the default name of the recovery task.
7. Click **Recover**.

You can monitor the status of the recovery on the **Activity** page.

Cohesity starts recovering the selected Azure Cosmos DB - MongoDB databases.

Azure Cosmos DB - NoSQL

Cohesity provides a simple, fast, and cost-effective backup, recovery, and data management solution for Azure Cosmos DB - NoSQL databases.

Azure Cosmos DB - NoSQL is a fully managed, serverless, and globally distributed NoSQL database service offered by Microsoft Azure. It is designed for modern application development, including AI applications and agents, providing high performance, availability, and scalability for handling massive volumes of NoSQL and vector data.

> **Important:** The backup and recovery of Azure Cosmos DB - NoSQL is supported only on DataProtect for cloud in Azure (formerly known as Azure NGCE cluster). This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

Plan and Prepare for Azure Cosmos DB – NoSQL Protection

You must ensure the following requirements are met before you register an Azure Cosmos DB - NoSQL source on Cohesity:

Required Permissions for Azure Cosmos DB – NoSQL Protection

You must assign custom roles to the service account to enable Azure Cosmos DB – NoSQL protection.

The following table lists the permissions and privileges that must be included in a custom role.

Permission	Description
Microsoft.DocumentDB/databaseAccounts/read	Read Cosmos DB account properties and metadata
Microsoft.DocumentDB/databaseAccounts/sqlDatabases/read	Read SQL database properties and metadata
Microsoft.DocumentDB/databaseAccounts/sqlDatabases/write	Create or update SQL databases
Microsoft.DocumentDB/databaseAccounts/sqlDatabases/containers/read	Read container properties and metadata
Microsoft.DocumentDB/databaseAccounts/sqlDatabases/containers/write	Create or update containers
Microsoft.DocumentDB/databaseAccounts/sqlDatabases/containers/throughputSettings/read	Read container throughput settings (RU/s)
Microsoft.DocumentDB/databaseAccounts/sqlDatabases/containers/throughputSettings/write	Update container throughput settings (RU/s)
Microsoft.DocumentDB/databaseAccounts/sqlDatabases/containers/storedProcedures/read	Read stored procedures
Microsoft.DocumentDB/databaseAccounts/sqlDatabases/containers/storedProcedures/write	Create or update stored procedures

Permission	Description
Microsoft.DocumentDB/databaseAccounts/sqlDatabases/containers/triggers/read	Read triggers
Microsoft.DocumentDB/databaseAccounts/sqlDatabases/containers/triggers/write	Create or update triggers
Microsoft.DocumentDB/databaseAccounts/sqlDatabases/containers/userDefinedFunctions/read	Read user-defined functions
Microsoft.DocumentDB/databaseAccounts/sqlDatabases/containers/userDefinedFunctions/write	Create or update user-defined functions
Microsoft.DocumentDB/databaseAccounts/sqlDatabases/throughputSettings/read	Read database throughput settings (RU/s)
Microsoft.DocumentDB/databaseAccounts/sqlDatabases/throughputSettings/write	Update database throughput settings (RU/s)

Required Roles for Azure Cosmos DB – NoSQL Protection

To create custom roles using the Azure Portal, use the following format:

```
{
"RoleName": "CosmosDB-Backup-Restore-Role",
"Type": "CustomRole",
"AssignableScopes": ["/subscriptions/subscriptionID"],
"Permissions": [{
"DataActions": [
"Microsoft.DocumentDB/databaseAccounts/readMetadata",
"Microsoft.DocumentDB/databaseAccounts/sqlDatabases/read",
"Microsoft.DocumentDB/databaseAccounts/sqlDatabases/write",
"Microsoft.DocumentDB/databaseAccounts/sqlDatabases/containers/read",
"Microsoft.DocumentDB/databaseAccounts/sqlDatabases/containers/write",
"Microsoft.DocumentDB/databaseAccounts/sqlDatabases/containers/items/read",
"Microsoft.Docu-
mentDB/databaseAccounts/sqlDatabases/containers/items/create",
"Microsoft.Docu-
mentDB/databaseAccounts/sqlDatabases/containers/items/upsert",
"Microsoft.Docu-
mentDB/databaseAccounts/sqlDatabases/containers/executeQuery",
```

```
"Microsoft.Docu-
mentDB/databaseAccounts/sqlDatabases/containers/readChangeFeed"
]
}]
}
```

Firewall Ports for Azure Cosmos DB – NoSQL Protection

Azure Cosmos DB offers two modes of connection - gateway mode and direct mode.

Connection Mode	Supported Protocol	API/Service Port
Gateway	HTTPS	SQL (443), MongoDB (10255), Table (443), Cassandra (10350), Graph (443)
Direct	TCP (Encrypted via TLS)	When using public/service endpoints: ports in the 10000 through 20000 range. When using private endpoints: ports in the 0 through 65535 range.

For more information, see Azure Cosmos DB SQL SDK connectivity modes.

Authentication for Azure Cosmos DB - NoSQL Database Protection

You must authenticate the Cohesity cluster to discover the Azure Cosmos DB - NoSQL databases using the **Username** and **Password** of the Azure Cosmos DB - NoSQL database.

Considerations

Review and understand the following limitations and considerations before you protect Azure Cosmos DB - NoSQL Database:

- **Full backup support** - Only full backup is supported; incremental backup is not available for Azure Cosmos DB - NoSQL protection.
- **Attach metadata and credentials** - When you recover a database to a different account, ensure that you attach the metadata and credentials to the destination account.
- **Rename database during recovery** - Database names can have up to 48 alpha-numeric characters and can contain underscores; only letters and numbers are supported as the first character.
- **Database-Level Protection** - Protection occurs at the database level and not account level; backup and recovery are performed for the databases on the account. Cohesity does not change or create an Azure Cosmos DB-NoSQL account in the workflows. Hence, the properties of the account like tags are not recovered.

- **Serverless vs provisioned throughput** - Database belonging to an account with Serverless mode cannot be recovered to the one with provisioned throughput capacity mode and vice versa.
- **Partition key configuration** - During recovery, the partition key configuration of the source container must match the destination. The partition key cannot be changed during recovery operations.
- **Indexing policy preservation** - The indexing policy from the source container is preserved and applied to the recovered container. Custom indexing policies are maintained during recovery.
- **Unique key constraints** - Unique key constraints defined on the source container are preserved during recovery. Ensure the destination account supports the same unique key configurations.
- **TTL (Time-to-live) on recovered containers** - When recovering Azure Cosmos DB-NoSQL containers, the default TTL setting is preserved from the source container and applied to the recovered container. As a result, any newly inserted items in the recovered container will automatically expire after a duration of Item creation time + default TTL (in seconds).

  This ensures consistency with the TTL-based data expiration behavior of the original container.

  > **Note:** Item-level TTL settings are not retained during backup. When data is recovered, the TTL for those items is set to the container's default TTL value.

- **Stored procedures, triggers, and UDFs** - Stored procedures, triggers, and user-defined functions (UDFs) defined on the source container are backed up and recovered to the destination container. Ensure the destination account has the necessary permissions to execute these server-side logic components.
- **Change feed configuration** - Change feed settings are not preserved during recovery. After recovery, you may need to reconfigure the change feed processors and their lease containers.
- **Analytical store** - If the source container has an analytical store enabled, the destination container must also support analytical store. This feature must be enabled at the account level before recovery.
- **Replication regions** - To get optimum performance during recovery, it is recommended to disable multi-region replication. After recovery, you can re-enable multi-region replication.
- **Custom role permissions** - For backup and recovery using custom roles, ensure the service principal has the following minimum data plane permissions:

  - **Backup**: readMetadata, sqlDatabases/read, containers/read, items/read, executeQuery, readChangeFeed.
  - **Recovery**: readMetadata, sqlDatabases/read, sqlDatabases/write, containers/read, containers/write, items/create, items/upsert.
- **Rate limiting and throttling** - During backup and recovery, monitor the HTTP 429 (Too Many Requests) responses. Adjust the ingest rate or increase provisioned throughput temporarily to avoid throttling.
- **Container throughput** - Ensure the destination container has sufficient provisioned throughput (RU/s) to handle recovery. Insufficient throughput will result in throttling and extended recovery times.
- **Hierarchical partition keys** - If the source container uses hierarchical partition keys (multi-level partitioning), the destination account must support this feature. Hierarchical partition keys are preserved during recovery.
- **Version Downgrade not supported**: Recovering a backup taken from a higher database version to a lower version is not supported.

Register and Manage Azure Source

You must register Azure as a source on the Cohesity cluster to protect your Azure Cosmos DB - NoSQL databases.

After registering Azure as a source, you can:

- Update the Azure source configuration.
- Refresh the Azure source details.
- Unregister the Azure source from Cohesity cluster.

Register Azure as a Source

Before registering Azure as a source, ensure to check the requirements and considerations.

To register Azure as a source:

1. Navigate to **Data Protection > Sources > Register**, and then select **Cloud Platforms > Azure**.

   The **Register Azure Source** window is displayed.
2. In the **Source Details** page,
   1. In the **Domain Name** field, provide the unique tenant ID assigned by Azure. For information on getting the tenant ID, see Get tenant ID.
   2. In the **Azure Workloads** section, under **Database**, select **Cosmos DB - NoSQL**.
   3. Click **Continue**.
3. In the **Azure Apps** page,

1. In the **Application ID** field, enter the application ID assigned by Azure during the service principal creation process.
2. In the **Application Secret Key** field, enter the application secret key for setting up authentication for the service principal.

   > **Note:** Manual creation of Azure App requires significantly more effort and time. It involves several steps within Microsoft Azure for configuration.

3. Click **Continue**.

4. In the **Subscriptions** page,
   1. In the **Subscription ID** field, enter the subscription IDs of the subscriptions where the database you want to protect belongs to.

      You can add multiple subscription IDs by clicking the **+** icon.

      > **Note:** The subscriptions must be manually added and will not be automatically discovered.

   2. Click **Register**.

   The source will be registered and displayed under the **Azure** section in the **Data Protection > Sources** page. You can click on the source and navigate to the **Cosmos DB - NoSQL** tab to view the entity tree of the databases.

Update Azure Source Configuration

You can update the registered Azure source to add or remove the Azure services, and subscriptions protected by Cohesity from your Azure source.

To edit an Azure source:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure sources and select **Edit**.
3. In the **Edit Azure Source** page,
   a. Select or unselect the Azure services you need and click **Continue**.
   b. Update Azure Application ID, Azure secret keyand click **Continue**.
   c. Add or remove subscriptions and click **Update**.

> **Note:**
> - The listed subscriptions are added only after an administrator has manually linked them to Microsoft Azure.
> - Before you remove a subscription from the Azure source, you must unprotect all the protected objects in the subscription.

Refresh Azure Source

You can refresh the Azure source configuration and fetch the latest changes on your Azure environment.

To refresh the Azure source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure source and select **Refresh**.

Unregister Azure Source

If you plan to stop backing up your Azure databases, you can unregister the Azure source from the Cohesity cluster.

> **Note:** Before you unregister an Azure source from the Cohesity cluster, you must unprotect all the protected objects in that Azure source.

To unregister the Azure source:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure source and select **Unregister**.
3. In the **Unregister Source** dialog, click **Unregister**.

> **Note:** The source and all the databases in the source will be unregistered. Use the checkbox to unregister specific databases.

Backup Azure Cosmos DB - NoSQL Database

After registering your Azure Cosmos DB - NoSQL source in Cohesity, Cohesity uses the cloud credentials provided to authenticate with Azure.

Once authenticated, Cohesity automatically discovers all the subscriptions that the service account can access, as well as all supported workloads such as Azure Cosmos DB - NoSQL databases within those subscriptions. The discovered workloads appear under **Data Protection > Sources**. You can select the **Cosmos DB - NoSQL** tab to view all the databases discovered.

Hierarchy View displays the entity hierarchy of the Azure Cosmos DB - NoSQL objects, allowing you to navigate from the resource group-level down to individual databases.

Azure Cosmos DB - NoSQL Entity Hierarchy

The Azure Cosmos DB - NoSQL entity hierarchy follows this structure:

Structure	Description
Tenant	Dedicated instance of the identity service.
Subscription	Logical container for managing billing, resources, and permissions for services.
Resource Group	Logical container for organizing and managing related Azure resources, such as virtual machines, storage accounts, and web apps.
Cosmos DB NoSQL Account	Fully managed Cosmos DB - NoSQL database service hosted within the Azure cloud.
Database	Fully managed NoSQL database in Microsoft Azure.

Backup Scope by Azure Cosmos DB - NoSQL Hierarchy

Cohesity cluster allows you to backup Azure Cosmos DB - NoSQL databases at different levels of the hierarchy.

You can choose to back up:

- **Tenant** – Protect all Azure Cosmos DB - NoSQL databases within the tenant.
- **Subscription** – Protect all Azure Cosmos DB - NoSQL databases within the subscription.
- **Resource Group** – Protect all Azure Cosmos DB - NoSQL databases within the resource group.
- **Cosmos DB - NoSQL Account** – Protect all Azure Cosmos DB - NoSQL databases within the Cosmos DB – NoSQL account.
- **Database** – Protect individual Azure Cosmos DB - NoSQL database.

Supported Backup Types

Cohesity supports only full backups for Azure Cosmos DB - NoSQL. Incremental backups are not supported.

Protect Azure Cosmos DB - NoSQL Databases

Azure Cosmos DB - NoSQL databases are protected using a Protection Group and a Protection Policy.

A Protection Group enables you to select and group the objects that you want to backup. It uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured and replicated.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select which standard or custom policy to use when creating a Protection Group. For more information, see Manage Protection Policy.

Prerequisites to Protect Azure Cosmos DB – NoSQL

Set Azure Cosmos DB - NoSQL Database Credentials

For Backup, the database credentials are used to authenticate and connect to the Cosmos DB - NoSQL account. Once the connection is established, the relevant database can be dumped and protected.

For Azure Cosmos DB - NoSQL, you can set credentials at the Azure Cosmos DB - NoSQL account level. This information is used to connect to the database during backup and recovery.

To set the database credentials:

1. Navigate to **Data Protection > Sources**, find the registered Azure source, and click on it.
2. Click on the **Cosmos DB - NoSQL** tab.
3. Select the checkbox next to the required Azure Cosmos DB - NoSQL account.
4. Click the **Database Credentials** button.

   > **Note:** Always add credentials to the Cosmos DB - NoSQL account. Do not add credentials to individual databases.

5. Under **Username and Password**, provide the account admin username and password. These credentials are the same for all leaf-level databases. The account must have access to all databases within the Cosmos DB - NoSQL account.
6. Click **Save**.

Protect Azure Cosmos DB - NoSQL Databases

To protect your Azure Cosmos DB - NoSQL databases:

1. Navigate to **Data Protection > Protection > Protect**, and then select **Azure > Cosmos DB - NoSQL**.
2. In the **New Protection** page, click **Add Objects** and select your registered source.
3. Use the checkboxes to select the objects for protection. You can select the tenants, subscriptions, resource groups, Cosmos DB - NoSQL account, or databases under them. For more information, see Azure Cosmos DB - NoSQL Entity Hierarchy.

   You can also use **List View** to select the instances for protection from a flat, searchable list.

   You can auto-protect all the objects under a resource group, subscription, or tenant using the AutoProtect icon .

   To exclude an auto-protected object, click on the AutoProtect icon next to the object.
4. Click **Continue**.
5. Click **Protection Group** and provide a name for your protection group.
6. Click **Policy** and choose a policy to specify backup frequency and retention. If you do not have a policy, you can easily create one.
7. Optionally, to configure any of the settings or additional settings, select More Options.
8. Click **Protect**.

You can monitor the status of the backup on the **Activity** page. Also, the **Activity** tab of a specific Azure Cosmos DB - NoSQL shows the history of all protection runs, including the one in progress.

Cohesity starts backing up the databases you selected.

Settings

Setting	Description
Storage Domain	Select the appropriate Storage Domain. For more information, see Manage Storage Domains.

Setting	Description
Start Time	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

Additional Settings

Pause Future Runs	Toggle on this option to stop protection runs from executing. Once you enable this option, no protection runs will be scheduled.
End Date	If you need to end protection on a specific date, enable this option to select the date.
QoS Policy	Select an appropriate quality of service (QoS) policy. Cohesity recommends specifying Backup HDD, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Object. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Object. Only specify this policy if you need fast ingest speed for a small number of Objects. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the current running task.
Alerts	Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when an Object completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Object fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the takes longer than the time specified in the SLA field. Emails are sent when warning alerts are created.

Priority	Select a priority for the Object ProtectionGroupxecution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the runs: • High-priority protection runs • Medium-priority protection runs • Low-priority protection runs
Description	Enter a brief description of the object.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.

Manage Azure Cosmos DB - NoSQL Backup Configuration

Backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Objects to the Protection Group

You can add new objects to the existing Protection Group for backup. The newly added object is backed up from the next protection run, and it will be a full backup for the newly added object.

To add objects to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for Azure Cosmos DB - NoSQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ⋮ in the **Objects** section.
5. In the **Objects** section, Click the plus icon (**+**) to enter multiple objects that you plan to back up. click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for Azure Cosmos DB - NoSQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for Azure Cosmos DB - NoSQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a protection run:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for Azure Cosmos DB - NoSQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Delete Protection Group Only
    - Delete Protection Group and Snapshots

Recover Azure Cosmos DB - NoSQL Databases

After you protect your Azure Cosmos DB - NoSQL databases, you can recover them from Cohesity to their original or a new location.

To recover protected Azure Cosmos DB - NoSQL databases:

1. Navigate to **Data Protection > Recoveries > Recover**, and then select **Azure > Cosmos DB - NoSQL**.

2. In the **New Recovery** page, use the filter, search box, and views to locate and select the required databases.

   The latest snapshot will be displayed (protection run).

   If you need to recover an earlier snapshot, click the **Edit** icon to open the **Recovery Point** page.
3. Click **List** to view the available recovery points by timestamp and click **Select Recovery Point**.
4. Click **Next: Recover Options**.
5. Under **Recover To**, select either of the following:
   - **Original Location** - To recover the Azure Cosmos DB - NoSQL database to the Azure Cosmos DB - NoSQL account from which the database was backed up.

     Recovering to the original location will replace any existing database with the same name in the selected instance. Type **YES** to confirm.
   - **New Location** - Select a target Azure Cosmos DB - NoSQL account to which the Azure Cosmos DB - NoSQL database will be recovered. Toggle on **Overwrite existing database(s)** to allow Cohesity to overwrite the existing databases in the target location. Type **YES** to confirm.
6. Select your **Recovery Options**:
   - **Rename**. Add a Prefix and/or Suffix to the full name of the recovered Azure Cosmos DB - NoSQL database.
   - **Task Name**. Change the default name of the recovery task.
7. Click **Recover**.

You can monitor the status of the recovery on the **Activity** page.

Cohesity starts recovering the selected Azure Cosmos DB - NoSQL databases.

Azure Cosmos DB - Table

Cohesity provides a simple, fast, and cost-effective backup, recovery, and data management solution for Azure Cosmos DB - Table.

Azure Cosmos DB -Table is a fully managed NoSQL database service that provides a highly scalable and globally distributed store for key-value and tabular data, using the familiar Azure Table storage APIs. It is ideal for applications that require fast, high-performance storage for structured, non-relational data, like device registries, user profiles, or configuration data.

> **Important:** The backup and recovery of Azure Cosmos DB - Table is supported only on DataProtect for cloud in Azure (formerly known as Azure NGCE cluster). This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

Plan and Prepare for Azure Cosmos DB - Table Protection

You must ensure the following requirements are met before you register an Azure Cosmos DB - Table source on Cohesity:

Required Permissions for Azure Cosmos DB - Table Protection

Action Permissions

Permission	Description
Microsoft.Resources/subscriptions/resourceGroups/read	Read resource group properties and metadata.
Microsoft.DocumentDB/databaseAccounts/read	Read a Cosmos DB account's properties and configuration.
Microsoft.DocumentDB/databaseAccounts/tables/write	Create or update a Table resource in the Cosmos DB account.
Microsoft.DocumentDB/databaseAccounts/tables/read	List or read Table resources in the Cosmos DB account.
Microsoft.DocumentDB/databaseAccounts/tables/delete	Delete tables in a Cosmos DB account.

DataAction Permissions

You must create a custom role and assign the permissions using Azure CLI, since providing data plane access to a Cosmos DB account is not supported through the Azure portal UI.

Permission	Description
Microsoft.DocumentDB/databaseAccounts/readMetadata	Read account-level metadata needed for data-plane operations (e.g., databases/tables definitions).

Permission	Description
Microsoft.DocumentDB/databaseAccounts/sqlDatabases/containers/readChangeFeed	Read a container/table's change feed to track item/entity changes.
Microsoft.DocumentDB/databaseAccounts/sqlDatabases/containers/items/create	Create items/entities in a container/table.
Microsoft.DocumentDB/databaseAccounts/sqlDatabases/containers/items/read	Read items/entities in a container/table.
Microsoft.DocumentDB/databaseAccounts/sqlDatabases/containers/items/upsert	Create or replace items/entities in a container/table.

Add Data Plane Access to Service Principal for Azure CosmosDB - Table Account

Assigning the Cosmos DB Built-in Data Contributor role to a Service Principal enables you to perform data operations like read/write on a CosmosDB Table API account.

Prerequisites

Ensure that the following is available:

1. **User with the Global Administrator role**. This allows the user to assign roles to other users or identities.
2. **Service Principal Object ID**. This refers to the Application ID on the Azure portal. Ensure to use a Service Principal with the Contributor role for the CosmosDB account.
3. **CosmosDB account name**.
4. **Subscription ID**.
5. **Resource group name**. The name of the resource group in which the CosmosDB account is present.

Assign Built-in Data Contributor Role for Data Plane Access

Use the Azure CLI to run the following commands to assign the Cosmos DB Built-in Data Contributor role to the Service Principal. This grants data plane permissions for read/write operations on Azure Cosmos DB - Table.

```
az cosmosdb table role assignment create \
--account-name <cosmosdb-account-name> \
--resource-group <resource-group-name> \
--scope "/" \
--principal-id <service-principal-object-id> \
--role-definition-id "00000000-0000-0000-0000-000000000002"
```

```
az cosmosdb table role assignment create \
--account-name "<cosmosdb-account-name>" \
--resource-group " <resource-group-name> " \
--principal-id " <service-principal-object-id> " \
--role-definition-id "/subscriptions/<subscription-id>/re-
sourceGroups/<resource-group-name>/-
providers/Microsoft.DocumentDB/databaseAccounts/<cosmosdb-account-
name>/tableRoleDefinitions/00000000-0000-0000-0000-000000000002" \
--scope "/subscriptions/<subscription-id>/resourceGroups/<resource-group-
name>/providers/Microsoft.DocumentDB/databaseAccounts/<cosmosdb-account-
name>" \
--role-assignment-id "$(uuidgen)"
```

where,

- **<cosmosdb-account-name>**: The name of the Azure Cosmos DB-Table account.
- **<resource-group-name>**: The name of the resource group in which the Cosmos DB Table account is present.
- **<service-principal-object-id>**: the object ID of the Service Principle. This is available in the Service Principal page in the Azure portal.
- **<role-definition-id>**: The ID of the role definition to assign.
- **<subscription-id>**: The ID of the subscription in which the resource group is present.
- **<scope>**: The data plane resource path at which this role assignment is being granted. This can be fully qualified or start with the database name. For example, /dbs/mydb/colls/mycontainer.
- **<role-assignment-id>**: A unique identifier for the role assignment. If not provided, a GUID will be generated.

For more information, see Grant data plane role-based access.

Considerations for Azure Cosmos DB - Table Protection

- **Recovery Failure from Replicated Cluster** - Recovery from a replicated cluster of Azure Cosmos DB-Table may fail with the following error: “kStale: File previously opened with higher session ID: <xxx_yyy>”.
- **Recovery Validation UI Warning** - During recovery validation, the following warning may be displayed in the UI: “Metadata view RecordIO client not available”. This warning does not impact the actual recovery process.
- **Version Downgrade not supported**: Recovering a backup taken from a higher database version to a lower version is not supported.

Register and Manage Azure Source

You must register Azure as a source on the Cohesity cluster to protect your Azure Cosmos DB - Table databases.

After registering Azure as a source, you can:

- Update the Azure source configuration.
- Refresh the Azure source details.
- Unregister the Azure source from Cohesity cluster.

Register Azure as a Source

Before registering Azure as a source, ensure to check the requirements and considerations.

To register Azure as a source:

1. Navigate to **Data Protection > Sources > Register**, and then select **Cloud Platforms > Azure**.

   The **Register Azure Source** window is displayed.
2. In the **Source Details** page,
   1. In the **Domain Name** field, provide the unique tenant ID assigned by Azure. For information on getting the tenant ID, see Get tenant ID.
   2. In the **Azure Workloads** section, under **Database**, select **Cosmos DB - Table**.
   3. Click **Continue**.
3. In the **Azure Apps** page,
   1. In the **Application ID** field, enter the application ID assigned by Azure during the service principal creation process.
   2. In the **Application Secret Key** field, enter the application secret key for setting up authentication for the service principal.

      > **Note:** Manual creation of Azure App requires significantly more effort and time. It involves several steps within Microsoft Azure for configuration.

   3. Click **Continue**.
4. In the **Subscriptions** page,
   1. In the **Subscription ID** field, enter the subscription IDs of the subscriptions where the database you want to protect belongs to.

      You can add multiple subscription IDs by clicking the **+** icon.

> **Note:** The subscriptions must be manually added and will not be automatically discovered.

2. Click **Register**.

The source will be registered and displayed under the **Azure** section in the **Data Protection > Sources** page. You can click on the source and navigate to the **Cosmos DB - Table** tab to view the entity tree of the databases.

Update Azure Source Configuration

You can update the registered Azure source to add or remove the Azure services, and subscriptions protected by Cohesity from your Azure source.

To edit an Azure source:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure sources and select **Edit**.
3. In the **Edit Azure Source** page,
   a. Select or unselect the Azure services you need and click **Continue**.
   b. Update Azure Application ID, Azure secret keyand click **Continue**.
   c. Add or remove subscriptions and click **Update**.

> **Note:**
> - The listed subscriptions are added only after an administrator has manually linked them to Microsoft Azure.
> - Before you remove a subscription from the Azure source, you must unprotect all the protected objects in the subscription.

Refresh Azure Source

You can refresh the Azure source configuration and fetch the latest changes on your Azure environment.

To refresh the Azure source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure source and select **Refresh**.

Unregister Azure Source

If you plan to stop backing up your Azure databases, you can unregister the Azure source from the Cohesity cluster.

> **Note:** Before you unregister an Azure source from the Cohesity cluster, you must unprotect all the protected objects in that Azure source.

To unregister the Azure source:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure source and select **Unregister**.
3. In the **Unregister Source** dialog, click **Unregister**.

> **Note:** The source and all the databases in the source will be unregistered. Use the checkbox to unregister specific databases.

Backup Azure Cosmos DB - Table

After registering your Azure Cosmos DB - Table source, Cohesity discovers all the subscriptions that the service account can access, as well as all supported workloads such as Azure Cosmos DB - Table tables within those subscriptions. The discovered workloads appear under **Data Protection > Sources**. You can select the **Cosmos DB - Table** tab to view all the tables discovered.

Hierarchy View displays the entity hierarchy of the Azure Cosmos DB - Table objects, allowing you to navigate from the resource group-level down to individual tables.

Azure Cosmos DB - Table Entity Hierarchy

The Azure Cosmos DB - Table entity hierarchy follows this structure:

Structure	Description
Tenant	Dedicated instance of the identity service.
Subscription	Logical container for managing billing, resources, and permissions for services.
Resource Group	Logical container for organizing and managing related Azure resources, such as virtual machines, storage accounts, and web apps.

Structure	Description
Cosmos DB Table Account	Fully managed Cosmos DB - Table database service hosted within the Azure cloud.
Table	Fully managed Table tables in Microsoft Azure.

Backup Scope by Azure Cosmos DB - Table Hierarchy

Cohesity cluster allows you to backup Azure Cosmos DB - Table at different levels of the hierarchy.

You can choose to back up:

- **Tenant** – Protect all Azure Cosmos DB - Table tables within the tenant.
- **Subscription** – Protect all Azure Cosmos DB - Table tables within the subscription.
- **Resource Group** – Protect all Azure Cosmos DB - Table tables within the resource group.
- **Cosmos DB Table Account** – Protect all Azure Cosmos DB - Table tables within the Cosmos DB Account.
- **Tables** – Protect individual Azure Cosmos DB - Table tables.

Supported Backup Types

Cohesity supports full backups for Azure Cosmos DB - Table. Incremental backups are not supported.

Protect Azure Cosmos DB - Table

Azure Cosmos DB - Table tables are protected using a Protection Group and a Protection Policy.

A Protection Group enables you to select and group the objects that you want to backup. It uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured and replicated.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select which standard or custom policy to use when creating a Protection Group. For more information, see Manage Protection Policy.

Protect Azure Cosmos DB - Table

To protect your Azure Cosmos DB - Table tables:

1. Navigate to **Data Protection > Protection**, click **Protect**, and then select **Azure > Cosmos DB - Table**.
2. In the **New Protection** page, click **Add Objects** and select your registered source.
3. Use the checkboxes to select the objects for protection. You can select the tenants, subscriptions, resource groups, Cosmos DB – Table account, or tables under them. For more information, see Azure Cosmos DB - Table Entity Hierarchy.

   You can also use **List View** to select the instances for protection from a flat, searchable list.

   You can auto-protect all the objects under a resource group, subscription, or tenant using the AutoProtect icon.

   To exclude an auto-protected object, click on the AutoProtect icon next to the object.
4. Click **Continue**.
5. Click **Protection Group** and provide a name for your protection group.
6. Click **Policy** and choose a policy to specify backup frequency and retention. If you do not have a policy, you can easily create one.
7. Optionally, to configure any of the settings or additional settings, select More Options.
8. Click **Protect**.

You can monitor the status of the backup on the **Activity** page. Also, the **Activity** tab of a specific Azure Cosmos DB - Table shows the history of all protection runs, including the one in progress.

Cohesity starts backing up the tables you selected.

Settings

Setting	Description
Storage Domain	Select the appropriate Storage Domain. For more information, see Manage Storage Domains.
Start Time	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.

Setting	Description
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

Additional Settings

Pause Future Runs	Toggle on this option to stop protection runs from executing. Once you enable this option, no protection runs will be scheduled.
End Date	If you need to end protection on a specific date, enable this option to select the date.
QoS Policy	Select an appropriate quality of service (QoS) policy. Cohesity recommends specifying Backup HDD, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Object. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Object. Only specify this policy if you need fast ingest speed for a small number of Objects. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the current running task.
Alerts	Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when an Object completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Object fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the takes longer than the time specified in the SLA field. Emails are sent when warning alerts are created.

Priority	Select a priority for the Object ProtectionGroupxecution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the runs: • High-priority protection runs • Medium-priority protection runs • Low-priority protection runs
Description	Enter a brief description of the object.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.

Manage Azure Cosmos DB - Table Backup Configuration

Backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Objects to the Protection Group

You can add new objects to the existing Protection Group for backup. The newly added object is backed up from the next protection run, and it will be a full backup for the newly added object.

To add objects to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for Azure Cosmos DB - Table.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ⋮ in the **Objects** section.
5. In the **Objects** section, Click the plus icon (**+**) to enter multiple objects that you plan to back up. click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for Azure Cosmos DB - Table.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for Azure Cosmos DB - Table.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a protection run:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for Azure Cosmos DB - Table.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Delete Protection Group Only
    - Delete Protection Group and Snapshots

Recover Azure Cosmos DB - Table

After you protect your Azure Cosmos DB - Table, you can recover them from Cohesity to their original or a new location.

To recover protected Azure Cosmos DB - Table tables:

1. Navigate to **Data Protection > Recoveries > Recover**, and then select **Azure > Cosmos DB - Table**.

2. In the **New Recovery** page, use the filters, search box, and views to locate and select the required tables.

   The latest snapshot will be displayed (protection run).

   If you need to recover an earlier snapshot, click the **Edit** icon to open the **Recovery Point** page.

   Click **List** to view the available recovery points by timestamp and click **Select Recovery Point**.
3. Click **Next: Recover Options**.
4. Under **Recover To**, select either of the following:
   - **Original Location** - To recover the Azure Cosmos DB - Table tables to the Azure Cosmos DB - Table instance or Managed Instance from which the table was backed up.

     Recovering to the original location will replace any existing table with the same name in the selected instance. Type YES to confirm.
   - **New Location** - Select a target Azure Cosmos DB - Table instance or Managed Instance to which the Azure Cosmos DB - Table will be recovered. Toggle on **Overwrite existing database(s)** to allow Cohesity to overwrite the existing databases in the target location. Type **YES** to confirm.
5. Select your **Recovery Options**:
   - **Rename**. Add a Prefix and/or Suffix to the full name of the recovered Azure Cosmos DB - Table table.
   - **Task Name**. Change the default name of the recovery task.
6. Click **Recover**.

You can monitor the status of the recovery on the **Activity** page.

Cohesity starts recovering the selected Azure Cosmos DB - Table tables.

Azure SQL Database

Cohesity provides a simple, fast, and cost-effective backup, recovery, and data management solution for Azure SQL databases.

Azure SQL database is a fully managed, intelligent, relational database-as-a-service (DBaaS) offered by Microsoft Azure. It provides a cloud-based SQL Server database engine, optimized for modern cloud applications and websites.

> **Important:** The backup and recovery of Azure SQL is supported only on DataProtect for cloud in Azure (formerly known as Azure NGCE cluster). This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

Plan and Prepare for Azure SQL Protection

You must ensure the following requirements are met before you register an Azure SQL source on Cohesity:

Required Permissions for Azure SQL Protection

The following permissions are required for the custom role used by Managed identity:

Permission	Description
Microsoft.Authorization/*/read	List the permission associated with resource for given credentials
Microsoft.Subscription/*/read	Get resource group and location information
Microsoft.Resources/*/read	Get SQL database and corresponding provider protected recovery (PIT,LTR)
Microsoft.ManagedIdentity/userAssignedIdentities/read	Get the list of UMI in the given subscription
Microsoft.Sql/servers/read	Get the list the SQL server
Microsoft.Sql/servers/databases/read	Get the list of Databases in the SQL server
Microsoft.Sql/servers/databases/write	Create temporary database from PIT in the SQL server
Microsoft.Sql/servers/databases/delete	Delete temporary database from SQL server

Authentication for Azure SQL Database Protection

You must authenticate to Azure SQL database from the Cohesity cluster using one of the following methods:

- Username and Password
- User Managed Identity (UMI)
- System Managed Identity (SMI)

Username and Password

This method uses the credentials of the admin user for the SQL server. This is the user account configured during server creation.

For backup, you can create a custom user. Connect to the SQL server using SQL management studio or SQLCMD and run the following commands:

1. To create login user on the server:

```
#CREATE LOGIN [newlogin] WITH PASSWORD = 'somepassword;
```

2. To create same user under database which should be backed up by user **newlogin**:

```
User <database>;
#CREATE USER [newlogin] FOR LOGIN [newlogin];
ALTER ROLE db_owner ADD MEMBER [newlogin];
```

3. Run the following command on the master system database:

```
CREATE USER [newlogin] FOR LOGIN [newlogin];
```

For recovery, the default admin credentials created during server creation are required if the custom user credentials were set for authentication before backup. During recovery, you must change the credentials back to the default admin credentials.

User Managed Identity (UMI)

This method uses a user-assigned managed identity to authenticate to the Azure SQL database.

Perform the following to use the UMI authentication:

1. Create a user-assigned managed identity. For more information, see Manage user-assigned managed identities using the Azure portal.
2. Assign the **Managed Identity Operator** role to the UMI identity. For more information, see User-assigned managed identity.
3. Set the UMI as the identity for all the cluster nodes. Ensure that the UMI is from the same subscription as the one in which the SQL database exists. For more information, see Assign a user-assigned managed identity to an existing VM.
4. Assign this User Managed Identity as Entra ID Admin on the server. For more information, see Set Microsoft Entra admin.
5. Assign the required user managed identity to Azure SQL instance/server under the Identity section - User assigned managed identity on the Azure Portal.

System Managed Identity (SMI)

This method uses a unique identity that is automatically created by Azure when you enable SMI on the node. This identity belongs only to the specific node and is deleted if the node is deleted.

Each node in the cluster includes its own SMI (multiple distinct identities). Since the Azure SQL database allows only one Microsoft Entra admin per node, having multiple nodes, each with a different SMI may cause issues.

To mitigate this issue, you can perform the following:

1. Create a Microsoft Entra group.
2. Add all the nodes' SMI identities as group members.
3. Assign this group as Microsoft Entra Admin.

This ensures that all the nodes can be authenticated using their respective SMIs through the group.

> **Note:** SMIs are not created separately as a resource. You must enable it on the cluster nodes from the Azure portal.

Perform the following to use the SMI authentication:

1. Enable system-assigned managed identity on all the nodes of the cluster. For more information, see Enable system-assigned managed identity on an existing VM.
2. Create a Microsoft Entra basic group and add SMI's of all the nodes created in previous step as members. The SMI name is the same as the VM (node) name, which can be easily searched for while finding members to include in the group. For more information, see Create a basic group and add members.
3. Assign this Microsoft Entra basic group as Entra ID Admin on the server. For more information, see Set Microsoft Entra admin.

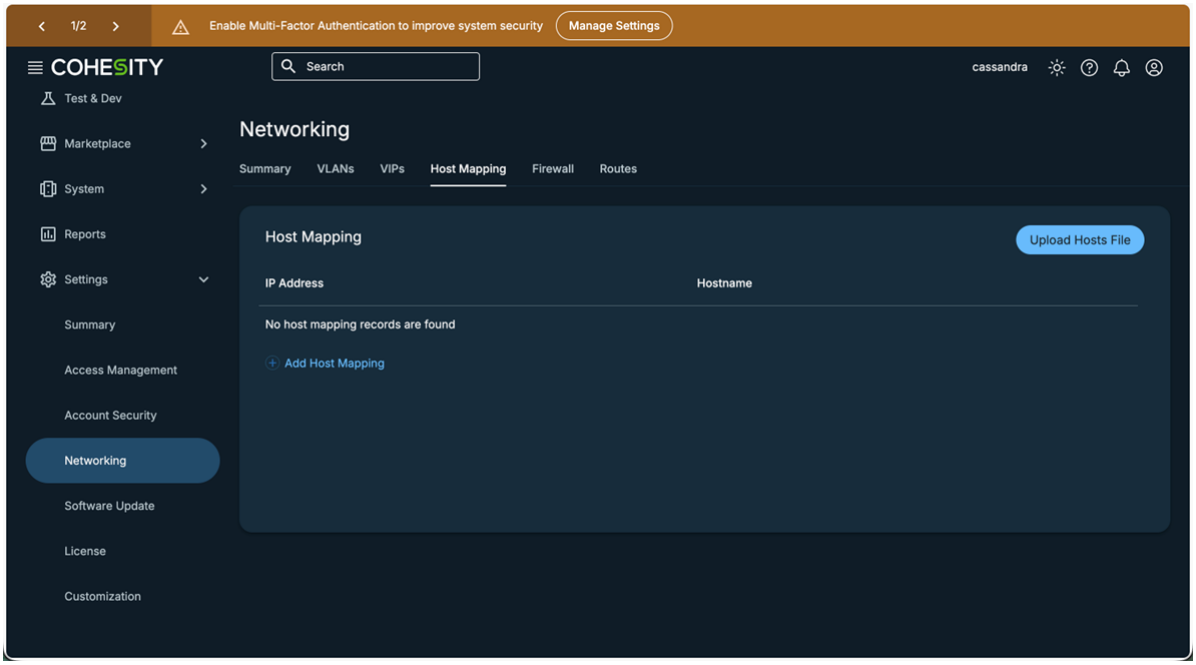
Firewall Ports for Azure SQL Database Protection

Ensure connectivity from Cohesity DataProtect to the Azure SQL database on port 1433.

You can connect to the Azure SQL databases from the Cohesity host using the following methods under **Settings > Networking** in the Microsoft Azure portal:

- Public Access
  - All networks.
  - Selected networks (with Cohesity host CIDR range in the Firewall allowed host - moderate security).
- Private Access
  - To use this method, you must create a Private EndPoint. For more information, see Create a private endpoint by using the Azure portal.
  - Once the EndPoint is created, login to the Cohesity cluster.
  - Navigate to **Settings > Networking > Host Mapping**.

- Add the SQL Private Endpoint IP host mapping.



Considerations for Azure SQL Protection

Review and understand the following limitations and considerations before you protect Azure SQL database:

- **Database-level configurations** - Configuring credentials at database level is not supported.
- **Column-level encryption** - Database protection does not support column-level encryption.
- **Database Tables** - Backup and recovery of the following tables in the databases are not supported:
  - GRAPH_TABLE,
  - TEMPORAL_TABLE,
  - LEDGER_TABLE,
  - MEMORY_OPTIMIZED_TABLE
- **Backup failure with invalid object name error**: Subsequent full/incremental backups of an Azure SQL Server backup may fail with the following error: "Invalid object name 'cdc.<schema_name>_<table_name>_CT'"

  This issue occurs while executing the backup query script with a transfer object in the query (to transfer table from one schema to another).

This may cause a mismatch between the user tables and their associated CDC tables. The mismatch typically arises after the schema changes or when database objects are moved between schemas after CDC is enabled.

Workaround:

Perform the following:

1. Disable CDC on the database before running the backup.
2. Login to the SQL database using the following command:

   ```
   sqlcmd -S hostname -U user -d database_name
   ```

3. Run the following command on the SQL database:

   ```
   # EXEC sys.sp_cdc_disable_db
   ```

4. Perform a full backup. The CDC will be automatically enabled during the next backup.

- **Incremental backup fall back to full backup**: Incremental backups fall back to full backup in the following cases:
  - Schema changes are detected during backup.
  - The state file from an earlier backup is not available.
  - CDC is enabled/disabled on the database/tables.
  - Previous full backup does not exist.
- **Insufficient tempDB storage** - If a backup fails due to insufficient tempDB storage on the SQL server, perform the following:
  1. Login to the Azure portal.
  2. Navigate to **Protection Group > Additional Setting > CDC processing location > SQLDB server or Client**.
  3. Select the **Client-Side** processing for CDC processing.
- **VNet settings for Azure SQL** - An Azure VM used as a DataProtect node must be present in the same VNet as that of the Azure-managed instance. Alternatively, if the DataProtect node and SQL-managed instance are in different VNet, then both the VNets must peer to access the database instance.
- **Backup failure due to Readlock** - Backup fails when Readlock is placed on the database or resource group.
- For Azure databases, if a backup is generated by the native backup database workflow, using TDE enabled by Customer-managed Keys or TDE disabled, these types of tables are supported.
- **Database diagrams** - Database diagrams are not recovered.

- **Mandatory client certificate** - Backup and recovery are not supported for the databases that mandatorily require client certificates for connection to DataProtect.
- **Default ports** - Only default ports are supported.
- **Database names with special characters** - Backup and recovery of databases with names containing the characters '#' and '/' are not supported. Also, the database name should adhere to the naming conventions suggested by the cloud vendors.
- **Passwords with special characters** – Semicolon (;) is not supported in server or database passwords.
- **Subscriptions of different tenants** - Azure Managed Identity is not supported across subscriptions of different tenants.
- **Version Downgrade not supported**: Recovering a backup taken from a higher database version to a lower version is not supported.

Register and Manage Azure Source

You must register Azure as a source on the Cohesity cluster to protect your Azure SQL databases.

After registering Azure as a source, you can:

- Update the Azure source configuration.
- Refresh the Azure source details.
- Unregister the Azure source from Cohesity cluster.

Register Azure as a Source

Before registering Azure as a source, ensure to check the requirements and considerations.

To register Azure as a source:

1. Navigate to **Data Protection > Sources > Register**, and then select **Cloud Platforms > Azure**.

   The **Register Azure Source** window is displayed.
2. In the **Source Details** page,
   1. In the **Domain Name** field, provide the unique tenant ID assigned by Azure. For information on getting the tenant ID, see Get tenant ID.
   2. In the **Azure Workloads** section, under **Database**, select **SQL**.
   3. Click **Continue**.
3. In the **Azure Apps** page,
   1. In the **Application ID** field, enter the application ID assigned by Azure during the service principal creation process.

2. In the **Application Secret Key** field, enter the application secret key for setting up authentication for the service principal.

   > **Note:** Manual creation of Azure App requires significantly more effort and time. It involves several steps within Microsoft Azure for configuration.

3. Click **Continue**.

4. In the **Subscriptions** page,

   1. In the **Subscription ID** field, enter the subscription IDs of the subscriptions where the database you want to protect belongs to.

      You can add multiple subscription IDs by clicking the **+** icon.

      > **Note:**
      > - Subscriptions must be manually added and will not be automatically discovered.
      > - Subscriptions must be linked to existing service principal credentials/ AppIDs that have already been added.
      > - Multiple AppID/service principal credentials are not supported.

   2. Click **Register**.

   The source will be registered and displayed under the **Azure** section in the **Data Protection > Sources** page. You can click on the source and navigate to the **SQL** tab to view the entity tree of the databases.

Update Azure Source Configuration

You can update the registered Azure source to add or remove the Azure services, and subscriptions protected by Cohesity from your Azure source.

To edit an Azure source:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure sources and select **Edit**.
3. In the **Edit Azure Source** page,
   a. Select or unselect the Azure services you need and click **Continue**.
   b. Update Azure Application ID, Azure secret keyand click **Continue**.
   c. Add or remove subscriptions and click **Update**.

> **Note:**
> - The listed subscriptions are added only after an administrator has manually linked them to Microsoft Azure.
> - Before you remove a subscription from the Azure source, you must unprotect all the protected objects in the subscription.

Refresh Azure Source

You can refresh the Azure source configuration and fetch the latest changes on your Azure environment.

To refresh the Azure source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure source and select **Refresh**.

Unregister Azure Source

If you plan to stop backing up your Azure databases, you can unregister the Azure source from the Cohesity cluster.

> **Note:** Before you unregister an Azure source from the Cohesity cluster, you must unprotect all the protected objects in that Azure source.

To unregister the Azure source:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure source and select **Unregister**.
3. In the **Unregister Source** dialog, click **Unregister**.

> **Note:** The source and all the databases in the source will be unregistered. Use the checkbox to unregister specific databases.

Backup Azure SQL Database

After registering your Azure source in the Cohesity cluster, Cohesity uses the cloud credentials provided to authenticate with Azure.

Once authenticated, Cohesity automatically discovers all the subscriptions that the service account can access, as well as all supported workloads such as Azure SQL databases within those subscriptions. The discovered workloads appear under **Data Protection > Sources**. You can select the **SQL** tab to view all the databases discovered.

Hierarchy View displays the entity hierarchy of the Azure SQL objects, allowing you to navigate from the resource group-level down to individual databases.

Azure SQL Database Entity Hierarchy

The Azure SQL entity hierarchy follows this structure:

Structure	Description
Tenant	Dedicated instance of the identity service.
Subscription	Logical container for managing billing, resources, and permissions for services.
Resource Group	Logical container for organizing and managing related Azure resources, such as virtual machines, storage accounts, and web apps.
Azure SQL Server	Fully managed SQL database instance hosted within the Azure cloud.
Database	Fully managed relational database service in Microsoft Azure.

Backup Scope by Azure SQL Hierarchy

Cohesity cluster allows you to backup Azure SQL databases at different levels of the hierarchy.

You can choose to back up:

- **Tenant** – Protect all Azure SQL databases within the tenant.
- **Subscription** – Protect all Azure SQL databases within the subscription.
- **Resource Group** – Protect all Azure SQL databases within the resource group.
- **Azure SQL Server** – Protect all Azure SQL databases within the database server.
- **Database** – Protect individual Azure SQL database.

Supported Backup Types

Cohesity supports full backups and Change Data Capture (CDC)-based incremental backups for Azure SQL.

Protect Azure SQL Databases

Azure SQL databases are protected using a Protection Group and a Protection Policy.

A Protection Group enables you to select and group the objects that you want to backup. It uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured and replicated.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select which standard or custom policy to use when creating a Protection Group. For more information, see Manage Protection Policy.

Prerequisites to Protect Azure SQL

Set Azure SQL Database Credentials

Before backing up the Azure SQL databases that are discovered in Cohesity DataProtect, you must configure credentials for the databases. These credentials enable secure authentication and connectivity between Cohesity and the Azure SQL databases.

Consider the following:

- You must use the credentials that you have already configured for the Managed Instances in your Azure environment. Once these credentials are validated and the connection is established, Cohesity can access the databases within the instance to perform operations such as dumping, protecting, and recovering.
- You can set credentials for the SQL database at the following levels in the entity hierarchy: Tenant, Subscription, Resource group, Azure SQL server. You cannot set credentials for individual databases.
- The credentials you set are applied to all child objects within the selected object.
- It is recommended to apply credentials at the Azure SQL server level. If you apply credentials at a higher level in the entity hierarchy (Resource group, Subscription, or Tenant), they will be applied to all child-level databases. If the credentials do not match any of the databases at the child-level, the backup of the databases may fail.

To set the database credentials:

1. Navigate to **Data Protection > Sources**, find the registered Azure source, and click on it.
2. Click on the **SQL** tab.
3. Select the checkbox next to the required Azure SQL Server.
4. Click the **Database Credentials** button and select one of the following:
    - **Username and Password** - Provide the database admin username and password. These credentials are required for leaf-level databases. The account must have access to all databases within the SQL server. For more information,

see Username and Password.

- **User Managed Identity** - Provide the Managed Identity Client ID. This uses authentication managed by Azure. For more information, see User Managed Identity.
  User Managed Identity must be attached to the Azure VM on which Cohesity DataProtect is deployed and does not work across tenants.
- **System Managed Identity** - Select the option.
  System Managed Identity must be enabled on the Azure VM on which Cohesity DataProtect is deployed and does not work across tenants. For more information, see System Managed Identity.

5. Click **Save**.

Protect Azure SQL Databases

To protect your Azure SQL databases:

1. Navigate to **Data Protection > Protection > Protect**, and then select **Azure > SQL**.
2. In the **New Protection** page, click **Add Objects** and select your registered source.
3. Use the checkboxes to select the objects for protection. You can select the tenants, subscriptions, resource groups, SQL servers, or databases under them. For more information, see Azure SQL Entity Hierarchy.

   You can also use List View to select the instances for protection from a flat, searchable list.

   You can auto-protect all the objects under a resource group, subscription, or tenant using the AutoProtect icon .

   To exclude an auto-protected object, click on the AutoProtect icon next to the object.
4. Click **Continue**.
5. Click **Protection Group** and provide a name for your protection group.
6. Click **Policy** and choose a policy to specify backup frequency and retention. If you do not have a policy, you can easily create one.
7. Optionally, to configure any of the settings or additional settings, select More Options.
8. Click **Protect**.

You can monitor the status of the backup on the **Activity** page. Also, the **Activity** tab of a specific Azure SQL shows the history of all protection runs, including the one in progress.

Cohesity starts backing up the databases you selected.

Settings

Setting	Description
Storage Domain	Select the appropriate Storage Domain. For more information, see Manage Storage Domains.
Start Time	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

Additional Settings

Pause Future Runs	Toggle on this option to stop protection runs from executing. Once you enable this option, no protection runs will be scheduled.
End Date	If you need to end protection on a specific date, enable this option to select the date.
QoS Policy	Select an appropriate quality of service (QoS) policy. Cohesity recommends specifying Backup HDD, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Object. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Object. Only specify this policy if you need fast ingest speed for a small number of Objects. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the current running task.

Alerts	Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when an Object completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Object fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the takes longer than the time specified in the SLA field. Emails are sent when warning alerts are created.
Priority	Select a priority for the Object Protection Grou execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the runs: • High-priority protection runs • Medium-priority protection runs • Low-priority protection runs
Description	Enter a brief description of the object.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.

Manage Azure SQL Backup Configuration

Backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Objects to the Protection Group

You can add new objects to the existing Protection Group for backup. The newly added object is backed up from the next protection run, and it will be a full backup for the newly added object.

To add objects to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for Azure SQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ in the **Objects** section.
5. In the **Objects** section, Click the plus icon (**+**) to enter multiple objects that you plan to back up. click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for Azure SQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for Azure SQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a protection run:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for Azure SQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Delete Protection Group Only
    - Delete Protection Group and Snapshots

Recover Azure SQL Databases

After you protect your Azure SQL databases, you can recover them from Cohesity to their original or a new location.

To recover protected Azure SQL databases:

1. Navigate to **Data Protection > Recoveries > Recover**, and then select **Azure > SQL**.
2. In the **New Recovery** page, use the filter, search box, and views to locate and select the required databases.

   The latest snapshot will be displayed (protection run).

   If you need to recover an earlier snapshot, click the **Edit** icon to open the **Recovery Point** page.

   Click **List** to view the available recovery points by timestamp and click **Select Recovery Point**.
3. Click **Next: Recover Options**.
4. Under **Recover To**, select either of the following:
   - **Original Location** - To recover the Azure SQL database to the Azure SQL instance or Managed Instance from which the database was backed up.

     Recovering to the original location will replace any existing database with the same name in the selected instance. Type **YES** to confirm.
   - **New Location** - Select the source and a target Azure SQL instance or Managed Instance to which the Azure SQL database will be recovered. Toggle on **Overwrite existing database(s)** to allow Cohesity to overwrite the existing databases in the target location. Type **YES** to confirm.
5. Select your **Recovery Options**:
   - **Rename**. Add a Prefix and/or Suffix to the full name of the recovered Azure SQL database.
   - **Task Name**. Change the default name of the recovery task.
6. Click **Recover**.

You can monitor the status of the recovery on the **Activity** page.

Cohesity starts recovering the selected Azure SQL databases.

Azure SQL Managed Instance

Cohesity provides a simple, fast, and cost-effective backup, recovery, and data management solution for Microsoft Azure SQL Managed Instance.

Azure Database for Azure SQL Managed Instance is a fully managed relational database service offered by Microsoft Azure. It enables users to deploy, manage, and scale Azure SQL Managed Instance in the cloud without the need to manage the underlying infrastructure.

> **Important:** The backup and recovery of Azure SQL Managed Instance is supported only on DataProtect for cloud in Azure (formerly known as Azure NGCE cluster).
> This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

This topic covers the following:

Plan and Prepare for Azure SQL Managed Instance Protection

Protecting Azure SQL Managed Instance involves a few key steps: registering the Azure SQL Managed Instance that is to be protected with Cohesity cluster, configuring authentication, and performing backups. Once the backup is completed, you can restore the data to the original location or an alternate destination as needed.

Required Permissions for Azure SQL Managed Instance Protection

The following set of permissions are required to discover the SQL Managed Instance to the Cohesity cluster.

Permissions	Description
Microsoft.Authorization/*/read Microsoft.Subscription/*/read Microsoft.AzureActiveDirectory/directories/read	To list the permissions associated with a resource for a given credential.
Microsoft.Resources/*/read	To get resource group and location information.
Microsoft.Sql/*/read	To get SQL Managed Instance.
Microsoft.ManagedIdentity/userAssignedIdentities/read	To get the list of user-assigned managed identities (UMI) in the given subscription.
Microsoft.Sql/managedInstances/databases/write	To create a new database during recovery.
Microsoft.Sql/managedInstances/databases/delete	To delete a database during an overwrite recovery.

Authentication for Azure SQL Managed Instance Protection

You must authenticate to Azure SQL Managed instance with Cohesity cluster for cloud in Azure to perform backup and restore. You can use one of the methods such as Username and Password, User Managed Identity, or System Managed Identity.

- Username and Password:

  With this method, you need to provide the credentials of the admin user of the SQL Managed Instance. This is the user account configured in your Azure environment during SQL Managed Instance creation. If needed, instead of using the admin user credentials, you can create a custom user and use it for authentication during backups. However, for restoring that backup, the admin user credentials are required. So, if you have used custom user credentials for backup authentication, you must change them back to the admin user credentials at the time of restore.
  You can use the following commands to create a custom user on the server/Managed Instance:

  - To create a custom user on the server/Managed Instance:
    ```
    #CREATE LOGIN [newlogin] WITH PASSWORD = 'somepassword;
    ```
  - To create same user under database which should be backed up by the custom user you have created:
    ```
    #CREATE USER [newlogin] FOR LOGIN [newlogin];

    #ALTER ROLE db_owner ADD MEMBER [newlogin];
    ```
  - Run the following command on the master system database:
    ```
    #CREATE USER [newlogin] FOR LOGIN [newlogin];
    ```

- User Managed Identity (UMI):

  It uses a user assigned managed identity to authenticate to the Azure SQL Managed Instance. For this authentication, you must assign the Managed Identity Operator role to the UMI identity. Also, this UMI needs to be from the same subscription as the one in which the SQL Managed instance exists.

  A single identity is shared by all nodes in the cluster. This identity should be assigned as the Microsoft Entra admin of the SQL Managed instance. Ensure all cluster nodes have this UMI set as their identity. To use the UMI method for authentication, you must perform the following activities as prerequisite:

  - Create a user-assigned managed identity that would be used for authentication.
    Manage user-assigned managed identities
  - Assign the Managed Identity Operator role to the UMI identity.
    Assign Azure roles to a managed identity
  - Set the UMI as identity of the cluster nodes.
    Assign a user-assigned managed identity
  - Assign this User Managed identity as Entra ID Admin on the server.
    Set Microsoft Entra admin
  - Assign the UMI to Azure SQL Managed Instance/server under the Identity section > User assigned managed identity on the Azure Portal.

- System Managed Identity (SMI):

It uses a unique identity that is automatically created by Azure when you enable SMI on the node. This identity belongs only to that node and is deleted if the node is deleted. Each node in your cluster will have its own SMI, meaning multiple distinct identities. However, Azure SQL Managed Instance allows only one Microsoft Entra admin per node. This creates a challenge when you have multiple nodes, each with a different SMI. To mitigate this issue, you can do the following:

- Create a Microsoft Entra group.
- Add all the nodes' SMI identities as group members.
- Assign this group as Microsoft Entra Admin.

This way, all nodes can authenticate using their respective SMIs through the group. SMI is not created separately as a resource here. You need to enable it on the cluster nodes from the Azure portal.
To use the SMI method for authentication, you must perform the following activities as prerequisite:

- Enable system-assigned managed identity on all the nodes of the cluster. Enable system-assigned managed identity
- Create a Microsoft Entra basic group and add SMI's of all the nodes created in previous step as members. SMI name is the same as the VM (node) name which can be easily searched for while finding member to include in the group. Create a basic group and add members
- Assign this Microsoft Entra basic group as Entra ID Admin on the server. Set Microsoft Entra admin

Firewall Ports for Azure SQL Managed Instance Protection

Ensure connectivity from Cohesity cluster to the Azure SQL Managed Instance server on port 1433.

Considerations for Azure SQL Managed Instance Protection

You must review the following considerations before you proceed for registration, backup, or recovery:

- Only full backup is supported; incremental backup is not available for Azure SQL Managed Instance Protection.
- Database protection does not support column-level encryption.
- Backup and recovery are not supported for the following:
  - GRAPH_TABLE,
  - TEMPORAL_TABLE,
  - LEDGER_TABLE,
  - MEMORY_OPTIMIZED_TABLE

- Incremental backups fall back to full backups in the following cases:
  - Schema changes are detected during backup.
  - The full backup state file from an earlier backup is not available.
  - CDC (Change Data Capture) is enabled or disabled on the database/tables.
  - A previous full backup does not exist.
- If a backup fails due to insufficient tempDB storage on the SQL Managed Instance, you need to select the Client-side processing for CDC. Go to **Protection Group** > **Additional Settings** > **CDC processing location** > select **Client**.
- Restoring a backup taken from a higher database version to a lower version is not supported.
- If public access to the SQL Managed Instance is not available and a private endpoint is used for connectivity, add the private endpoint mapping in Cohesity Host Mapping, so name resolution works over the private network. Go to **Settings** > **Networking** > **Host Mapping** and add the required endpoints.
- An Azure VM, which is used as a Cohesity cluster node, should be in the same Vnet as that of the Azure-managed instance. Alternatively, if the Cohesity cluster node and SQL-managed instance are in different Vnet, then both the Vnets must peer to access the database instance.
- Backup fails when Readlock is placed on the database or resource group.
- Database diagrams are not restored.
- Backup and restore are not supported for the databases, which makes it mandatory to use client certificates for their connection to Cohesity cluster.
- Only default ports are supported.
- Database names containing the characters '#' and '/' are not supported for backup and restore operations. Also, the database name should adhere to the naming conventions suggested by the cloud vendors.
- ";" is not supported in server or database passwords.
- Restore across subscriptions of different tenantsis not supported.
- Backup failure with invalid object name error: Subsequent full/incremental backups of an Azure SQL Managed Instance backup may fail with the following error, "Invalid object name 'cdc.<schema_name>_<table_name>_CT'".
  - This issue occurs while executing the backup query script with a transfer object in the query (to transfer table from one schema to another).
  - This may cause a mismatch between the user tables and their associated CDC tables. The mismatch typically arises after the schema changes or when database objects are moved between schemas after CDC is enabled. Workaround:

- Disable CDC on the database before running the backup.
- Run the following command: # EXEC sys.sp_cdc_disable_db
- Perform a full backup. The CDC will be automatically enabled during the next backup.

Register and Manage Azure Source

At the time of registration, you can select the databases you want to protect, such as SQL MI, MySQL, Tables, and so on. After registering, you can refresh the registered Azure source to get updates from the source Azure tenant, such as additions or deletions of any objects like databases. You can also update the configuration, including the subscription, the Application ID, and the Application Secret used for registration. Additionally, you can select or deselect any database types you have selected for protection. If required, you can also unregister the entire Azure tenant that you registered with Cohesity cluster.
Before registration, you must review the requirements and considerations in the Plan and Prepare for Azure SQL Managed Instance Protection topic.

After registration, you can:

- Update the Azure source configuration.
- Refresh the Azure source details.
- Unregister the Azure source from the Cohesity DataProtect.

Register Azure as a Source

Before registration, you must review the requirements and considerations in the Plan and Prepare for Azure SQL Managed Instance Protection topic.

To register your Azure tenant as a source with Cohesity cluster:

1. Navigate to **Data Protection > Sources**.
2. Click **Register** > **Cloud Platforms** > **Azure**.
   The **Register Azure Source** window is displayed.
3. In the **Source Details** page,
   1. In the **Domain Name** field, provide the unique tenant ID assigned by Azure. For information on getting the tenant ID, see Get tenant ID.
   2. In the **Azure Workloads** section, under **Database**, select **SQL MI**.
   3. Click **Continue**.
4. In the **Azure Apps** page,
   1. In the **Azure App ID** field, enter the application ID assigned by Azure during the service principal creation process.
   2. In the **App Secret Key** field, enter the application secret key for setting up authentication for the service principal.

> **Note:** Manual creation of Azure App requires significantly more effort and time. It involves several steps within Microsoft Azure for configuration.

3. Click **Continue**.

5. In the **Subscriptions** page,
    1. In the **Subscription ID** field, enter the subscription IDs of the subscriptions where the database you want to protect belongs to.

       You can add multiple subscription IDs by clicking the **+** icon.

       > **Note:** The subscriptions must be manually added and will not be automatically discovered.

    2. Click **Register**.

    The source is registered. You can view it under **Data Protection** > **Sources**. The source appears in the **Azure** section. Click the registered Azure source, then go to the **SQL Managed Instance** tab to view the entity hierarchy of Azure SQL Managed Instance.

Update Azure Source Configuration

To edit an Azure source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure sources and select **Edit**.
3. In the **Edit Azure Source** page,
    1. Select or clear the checkboxes of the Azure databases as required, and then click **Continue**.
    2. Update Azure Application ID and Azure Application Secret Key as required, and then click **Continue**.
    3. Remove the existing subscription or add more subscriptions as required.

       > **Note:** Before you remove a subscription from the registered Azure source, you must unprotect all the protected objects in that subscription.

    4. Click **Update**.

Refresh Azure Source Configuration

To refresh the Azure source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure source and select **Refresh**.

Unregister Azure Source

If you plan to stop backing up your registered Azure tenant, you can unregister it from Cohesity cluster.

> **Note:** Before you unregister the registered Azure source from Cohesity clustert, you must unprotect all the protected objects under that source.

To unregister the Azure source:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure source and select **Unregister**.
3. In the **Unregister Source** dialog, click **Unregister**.

Backup Azure SQL Managed Instance

After registration of your Azure tenant as a source, Cohesity uses the cloud credentials to authenticate with Azure.

After authentication, Cohesity cluster auto-discovers all the subscriptions (that the service account can access) and supported workloads such as Azure SQL Managed Instance, MySQL, and so on within those subscriptions.

The discovered workloads appear under **Data Protection** > **Sources**, under the **Azure** section. Click your Azure instance and then click **SQL Managed Instance** tab to view all the discovered objects.

Hierarchy View displays the entity hierarchy of the Azure SQL Managed Instance, allowing you to navigate from the tenant-level down to individual databases.

Azure SQL Managed Instance Entity Hierarchy

The Azure SQL Managed Instance entity hierarchy follows this structure:

Structure	Description
Tenant	Dedicated instance of the identity service.

Structure	Description
Subscription	Logical container for managing billing, resources, and permissions for services.
Resource Group	Logical container for organizing and managing related Azure resources, such as virtual machines, storage accounts, and web apps.
Managed Instance	Fully SQL Managed Instance hosted within the Azure cloud.
Database	Fully managed relational database service in Microsoft Azure.

Backup Scope by Azure SQL Managed Instances Hierarchy

Cohesity cluster allows you to backup Azure SQL Managed Instance database(s) at different levels of hierarchy.

You can choose any of the following objects to back up:

- **Tenant** – Protect all Azure SQL Managed Instance databases within the tenant.
- **Subscription** – Protect all Azure SQL Managed Instance databases within the subscription.
- **Resource Group** – Protect all Azure SQL Managed Instance databases within the resource group.
- **Database Server** – Protect all Azure SQL Managed Instance databases within the database server.
- **Database** – Protect individual databases.

Supported Backup Types

Full and incremental backups of Azure SQL Managed Instance are supported.

Protect Azure SQL Managed Instance

To back up a registered Azure SQL Managed Instance, you must:

1. Decide whether to use an existing Protection policy or create a new one with the required parameters.
2. Decide which objects to include in the Protection Group.
3. Set credentials for authentication.

A Protection Group enables you to select and group the objects that you want to backup. It uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured and replicated.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select which standard or custom policy to use when creating a Protection Group. For more information, see Manage Protection Policy.

Prerequisites to Protect Azure SQL Managed Instance

Configure Authentication for Azure SQL Managed Instance

Before performing a backup of Azure SQL Managed Instances that are discovered in Cohesity cluster, you must configure credentials for these Managed Instances. These credentials are essential because they enable secure authentication and connectivity between Cohesity and your Azure SQL Managed Instance. Without valid credentials, the backup process cannot access your Managed Instance or its databases.

You need to enter the credentials that you have already configured for the Managed Instances in your Azure environment. Once these credentials are validated and the connection is established, Cohesity can access the databases within the instance to perform operations such as dumping, protecting and restoring in case required.

Consider the following points:

1. You can set credentials for the SQL Managed Instance at any object in the entity hierarchy.
    1. Tenant
    2. Subscription
    3. Resource group
    4. Instance level
2. The credentials you set are applied to all child objects within the selected object.
3. You cannot set credentials for individual databases.
4. It is recommended to apply credentials at the Managed Instance level. As if you apply credentials at a higher level in the entity hierarchy (Resource group, Subscription, or Tenant), they will be applied to all child-level Managed Instances. If the credentials do not match any of the Managed Instances at the child-level, the backup of the databases within those Managed Instances will fail.
5. Three authentication methods are supported:
    1. Username and Password
    2. User Managed Identity
    3. System Managed Identity

To set the credentials for Azure SQL Managed Instance:

1. Navigate to **Data Protection > Sources**, find the registered Azure source, and click on it.
2. Click on the **SQL Managed Instance** tab.
3. Click the Hierarchy view icon (if you are in a different view) to display the hierarchy. This view makes it easier to view the entity hierarchy and select the required object.
4. Select the checkbox next to object to which you want to set credentials and click **Select All Child Objects**.
5. Click **Database Credentials**.
6. You can select one of the following options:
    1. **Username and Password** - Enter the SQL Managed Instance admin username and password. The account must have access to all databases within the Azure SQL Managed Instance. Or enter the credentials of the custom user created for backup.
    2. **User Managed Identity (UMI)** - Uses authentication automatically managed by Azure.

        > **Note:**
        > - User Managed Identity must be attached to the Azure VM on which Cohesity cluster is deployed.
        > - User Managed Identity authentication method does not work across tenants.
        > - Authentication fails if the database credentials provided are incorrect. Ensure that the username/password/UMI ClientID is correct, and/or the User Managed Identity associated database user is properly configured.

    3. **System Managed Identity**: Select the option.

        > **Note:**
        > - System Managed Identity must be attached to the Azure VM on which Cohesity cluster is deployed.
        > - System Managed Identity authentication method does not work across tenants.

7. Click **Save**.

Protect Azure SQL Managed Instance

Before you proceed to protect an Azure SQL Managed Instance, make sure that the authentication is configured.

> **Note:** An object cannot be included in two different protection groups for protection.

1. Navigate to **Data Protection > Protection**.
2. Click **Protect** > **Azure** > **SQL Managed Instance**.
3. On the **New Protection** page,
    1. Click **Add Objects**. From the **Registered Source** field, select the Azure instance you have registered.
    2. Do any of the following:
        1. To apply auto-protection,
            1. To apply auto-protection for the objects (Tenants, Subscriptions, Resource Groups, Managed Instances, and Databases), click the auto-protection icon next to it.
            2. All child objects under the selected object will be auto protected.
            3. Note: Auto-protection is not supported for individual database-level. To apply auto-protection for databases, you must select a parent object in the hierarchy.
            4. To exclude any object from auto-protection, click the auto-protection icon next to that object.
        2. To apply manual protection,
            1. To apply manual protection, click the checkboxes of the objects (Tenant, Subscription, Resource Group, Managed Instance, and Database) you want to protect.
            2. The child objects under the selected object will be selected.
            3. You can select or deselect checkboxes of the objects as required.
    3. click **Continue**.
4. On the **New Protection** page,
    1. Enter a name for your Protection Group.
    2. Click **Policy** and select the policy to specify backup frequency and retention. If you do not have a policy, you can create one.
5. Optionally, to configure any of the advanced settings, select **More Options**.
6. Click **Protect**.

Advanced Settings

Section	Setting	Description
Settings	**Storage Domain**	Select the appropriate Storage Domain. For more information, see Manage Storage Domains.
	Start Time	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
	SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

Section	Setting	Description
Additional Settings	**Pause Future Runs**	Toggle on this option to stop protection runs from executing. Once you enable this option, no protection runs will be scheduled.
	End Date	If you need to end protection on a specific date, enable this option to select the date.
	QoS Policy	Select an appropriate quality of service (QoS) policy. Cohesity recommends specifying Backup HDD, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Object. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Object. Only specify this policy if you need fast ingest speed for a small number of Objects. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the current running task.
	Alerts	Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when an Object completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Object fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the takes longer than the time specified in the SLA field. Emails are sent when warning alerts are created.

Section	Setting	Description
	Priority	Select a priority for the Object Protection Group Execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the runs: • High-priority protection runs • Medium-priority protection runs • Low-priority protection runs
	Description	Enter a brief description of the object.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.

Manage Azure SQL Managed Instance Backup Configuration

In the Cohesity cluster, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Objects to the Protection Group

You can add new objects to the existing Protection Group for backup. The newly added object is backed up from the next protection run, and it will be a full backup for the newly added object.

To add objects to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ in the **Objects** section.

5. In the **Objects** section, Click the plus icon (**+**) to enter multiple objects that you plan to back up. click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a protection run:

1. Navigate to **Data Protection** > **Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all associated local and archived snapshots. Replicated snapshots must be deleted from the remote cluster. Cloudspin artifacts generated by the Protection Group must be manually deleted from the respective cloud portals. Snapshots under DataLock cannot be deleted.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Keep the **Delete Snapshots** toggle disabled to delete the Protection Group only.
    - Enable the **Delete Snapshots** toggle to delete the Protection Group and all associated snapshots.
5. Type **YES** to confirm that you want to delete the Protection Group.
6. Click **Delete Group**.

Recover Azure SQL Managed Instance Databases

After you protect your Azure SQL Managed Instance, you can recover them from Cohesity cluster to their original location or a new location.

> **Note:**
> - If you plan to overwrite an existing database, Cohesity recommends backing up the database first.
> - To restore to a new location, the destination instance credential validation must be done, and the host mapping of the destination instance must be added in **Settings**> **Networking**> **Host Mapping**.

To recover protected Azure SQL Managed Instance databases:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** > **Azure** > **SQL Managed Instance**.
3. On the **New Recovery** page,
    1. Use the filters and search box to locate the required databases. Wildcards are supported.
    2. Select the required database that is to be recovered.
    3. Click **Next: Recovery Option**.
    4. In the **Recover To** section, do one of the following:
        1. To restore to the original location:
            1. Select the **Original Location** option to recover the database to its original location. Consider the following points:
                1. The existing database at that location with the same name will always be overwritten.
                2. You must type **Yes** to confirm and proceed.
                3. To avoid overwriting the database with the same name, enter a new name in the **Rename** field below. The database will be recovered with the new name you have provided.
        2. To restore to a new location:
            1. Select the **New Location** option to recover the database to an alternative SQL Managed Instance.
            2. Select the registered Azure tenant from the **Source** drop-down and select the Managed Instance to which you want to recover the

database.

3. To overwrite an existing database, toggle on the **Overwrite existing database(s)** option and type **Yes** to confirm.
4. If you want to recover the database with a different name, enter the new name in the **Rename** field below.
5. If you enter a new name, the database will be restored at the selected location with the new assigned name.
6. If you do not enter a new name, the existing database with the same name will be overwritten.

4. Select your **Recovery Options**:
    1. **Rename**. If you have renamed the database, it will be recovered with the new name at either the original or the new location, based on the option you have selected.
    2. **Task Name**. Change the default name of the recovery task.
5. Click **Recover**.

Azure Table Storage

Cohesity provides a simple, fast, and cost-effective backup, recovery, and data management solution for Microsoft Azure Table Storage. Table Storage is a fully managed relational database service offered by Microsoft Azure. It enables users to deploy, manage, and scale Azure Table Storage in the cloud without the need to manage the underlying infrastructure.

> **Important:** The backup and recovery of Azure Table Storage is supported only on DataProtect for cloud in Azure (formerly known as Azure NGCE cluster).
> This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

This topic covers the following:

Plan and Prepare for Azure Table Storage Protection

Protecting Azure Table Storage involves a few key steps: registering the Azure Table Storage Account that is to be protected with Cohesity cluster and performing backups. Once the backup is completed, you can restore the Tables to the original location or an alternate destination as needed.

Required Permissions for Azure Table Storage Protection

The following set of permissions are required to discover the Azure Table Storage Accounts to Cohesity cluster.

Permissions	Description
Microsoft.Storage/storageAccounts/tableServices/tables/read	Read/list tables and get table properties in a storage account.
Microsoft.Storage/storageAccounts/tableServices/tables/write	Create or update tables in a storage account.
Microsoft.Storage/storageAccounts/tableServices/tables/delete	Delete tables in a storage account.
Microsoft.Resources/subscriptions/resourceGroups/read	Read/list resource groups and view their properties.
Microsoft.Storage/storageAccounts/read	Read/list storage accounts and view their properties.
Microsoft.Storage/storageAccounts/tableServices/tables/entities/read	Read/query table entities (retrieve entities from tables).
Microsoft.Storage/storageAccounts/tableServices/tables/entities/write	Insert, update, merge, or upsert table entities.

Considerations for Azure Table Storage Protection

You must review the following considerations before you proceed for registration, backup, or recovery:

- Restoring a backup taken from a higher database version to a lower version is not supported.

Register and Manage Azure Source

At the time of registration, you can select the databases you want to protect, such as SQL Manaed Instance, MySQL, Tables, and so on. After registering, you can refresh the registered Azure source to get updates from the source Azure tenant, such as additions or deletions of any objects like databases. You can also update the configuration, including the subscription, the Application ID, and the Application Secret used for registration. Additionally, you can select or deselect any database types you have selected for protection. If required, you can also unregister the entire Azure tenant that you registered with Cohesity cluster.
Before registration, you must review the requirements and considerations in the Plan and Prepare for Azure Table Storage Protection topic.

After registration, you can:

- Update the Azure source configuration.
- Refresh the Azure source details.
- Unregister the Azure source from the Cohesity DataProtect.

Register Azure as a Source

Before registration, you must review the requirements and considerations in the Plan and Prepare for Azure Table Storage Protection topic.

To register your Azure tenant as a source with Cohesity cluster:

1. Navigate to **Data Protection > Sources**.
2. Click **Register** > **Cloud Platforms** > **Azure**.
   The **Register Azure Source** window is displayed.
3. In the **Source Details** page,
   1. In the **Domain Name** field, provide the unique tenant ID assigned by Azure. For information on getting the tenant ID, see Get tenant ID.
   2. In the **Azure Workloads** section, under **Database**, select **Table Storage**.
   3. Click **Continue**.
4. In the **Azure Apps** page,
   1. In the **Azure App ID** field, enter the application ID assigned by Azure during the service principal creation process.
   2. In the **App Secret Key** field, enter the application secret key for setting up authentication for the service principal.

      > **Note:** Manual creation of Azure App requires significantly more effort and time. It involves several steps within Microsoft Azure for configuration.

   3. Click **Continue**.
5. In the **Subscriptions** page,
   1. In the **Subscription ID** field, enter the subscription IDs of the subscriptions where the database you want to protect belongs to.

      You can add multiple subscription IDs by clicking the **+** icon.

      > **Note:** The subscriptions must be manually added and will not be automatically discovered.

   2. Click **Register**.

The source is registered. You can view it under **Data Protection** > **Sources**. The source appears in the **Azure** section. Click the registered Azure source, then go to the **Table Storage** tab to view the entity hierarchy of Azure Table Storage.

Update Azure Source Configuration

To edit an Azure source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure sources and select **Edit**.
3. In the **Edit Azure Source** page,
    1. Select or clear the checkboxes of the Azure databases as required, and then click **Continue**.
    2. Update Azure Application ID and Azure Application Secret Key as required, and then click **Continue**.
    3. Remove the existing subscription or add more subscriptions as required.

        > **Note:** Before you remove a subscription from the registered Azure source, you must unprotect all the protected objects in that subscription.

    4. Click **Update**.

Refresh Azure Source Configuration

To refresh the Azure source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure source and select **Refresh**.

Unregister Azure Source

If you plan to stop backing up your registered Azure tenant, you can unregister it from Cohesity cluster.

> **Note:** Before you unregister the registered Azure source from Cohesity cluster, you must unprotect all the protected objects under that source.

To unregister the Azure source:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure source and select **Unregister**.

3. In the **Unregister Source** dialog, click **Unregister**.

Backup Table Storage

After registration of your Azure tenant as a source, Cohesity uses the cloud credentials to authenticate with Azure.

After authentication, Cohesity cluster auto-discovers all the subscriptions (that the service account can access) and supported workloads such as Table Storage, MySQL, and so on within those subscriptions.

The discovered workloads appear under **Data Protection** > **Sources**, under the **Azure** section. Click your Azure instance and then click **Table Storage** tab to view all the discovered objects.

Hierarchy View displays the entity hierarchy of the Table Storage, allowing you to navigate from the tenant-level down to individual databases.

Azure Table Storage Entity Hierarchy

The Azure Table Storage entity hierarchy follows this structure:

Structure	Description
Tenant	Dedicated instance of the identity service.
Subscription	Logical container for managing billing, resources, and permissions for services.
Resource Group	Logical container for organizing and managing related Azure resources, such as virtual machines, storage accounts, and web apps.
Storage Accounts	Fully managed Table Storage account hosted within the Azure cloud.
Storage Account Tables	Fully managed relational database service in Microsoft Azure.

Backup Scope by Table Storage Hierarchy

Cohesity cluster allows you to backup Table Storage database(s) at different levels of hierarchy.

You can choose any of the following objects to back up:

- **Tenant** – Protect all Azure Table Storages within the tenant.
- **Subscription** – Protect all Table Storages within the subscription.

- **Resource Group** – Protect all Azure Table Storages within the resource group.
- **Storage Account** – Protect all Table Storage Tables within the database storage accounts.
- **Database** – Protect individual Tables.

Supported Backup Types

Only full backups are supported. Incremental backups are not supported.

Protect Azure Table Storage

To back up a registered Azure Table Storage, you must:

1. Decide whether to use an existing Protection policy or create a new one with the required parameters.
2. Decide which objects to include in the Protection Group.

A Protection Group enables you to select and group the objects that you want to backup. It uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured and replicated.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select which standard or custom policy to use when creating a Protection Group. For more information, see Manage Protection Policy.

Protect Azure Table Storage

Before you proceed to protect an Azure Table Storage, make sure that the authentication is configured.

> **Note:** An object cannot be included in two different protection groups for protection.

1. Navigate to **Data Protection > Protection**.
2. Click **Protect** > **Azure** > **Table Storage**.
3. On the **New Protection** page,
    1. Click **Add Objects**. From the **Registered Source** field, select the Azure instance you have registered.
    2. Do any of the following:
        1. To apply auto-protection,
            1. To apply auto-protection for the objects (Tenants, Subscriptions, Resource Groups, Managed Instances, and Databases), click the auto-protection icon next to it.

2. All child objects under the selected object will be auto protected.
3. Note: Auto-protection is not supported for individual database-level. To apply auto-protection for databases, you must select a parent object in the hierarchy.
4. To exclude any object from auto-protection, click the auto-protection icon next to that object.

2. To apply manual protection,
    1. To apply manual protection, click the checkboxes of the objects (Tenant, Subscription, Resource Group, Managed Instance, and Database) you want to protect.
    2. The child objects under the selected object will be selected.
    3. You can select or deselect checkboxes of the objects as required.
3. click **Continue**.

4. On the **New Protection** page,
    1. Enter a name for your Protection Group.
    2. Click **Policy** and select the policy to specify backup frequency and retention. If you do not have a policy, you can create one.
5. Optionally, to configure any of the advanced settings, select **More Options**.
6. Click **Protect**.

Advanced Settings

Section	Setting	Description
Settings	**Storage Domain**	Select the appropriate Storage Domain. For more information, see Manage Storage Domains.
	Start Time	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
	SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

Section	Setting	Description
Additional Settings	**Pause Future Runs**	Toggle on this option to stop protection runs from executing. Once you enable this option, no protection runs will be scheduled.
	End Date	If you need to end protection on a specific date, enable this option to select the date.
	QoS Policy	Select an appropriate quality of service (QoS) policy. Cohesity recommends specifying Backup HDD, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Object. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Object. Only specify this policy if you need fast ingest speed for a small number of Objects. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the current running task.
	Alerts	Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when an Object completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Object fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the takes longer than the time specified in the SLA field. Emails are sent when warning alerts are created.

Section	Setting	Description
	Priority	Select a priority for the Object Protection Group Execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the runs: • High-priority protection runs • Medium-priority protection runs • Low-priority protection runs
	Description	Enter a brief description of the object.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.

Manage Table Storage Backup Configuration

In the Cohesity cluster, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Objects to the Protection Group

You can add new objects to the existing Protection Group for backup. The newly added object is backed up from the next protection run, and it will be a full backup for the newly added object.

To add objects to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ in the **Objects** section.

5. In the **Objects** section, Click the plus icon (**+**) to enter multiple objects that you plan to back up. click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a protection run:

1. Navigate to **Data Protection** > **Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all associated local and archived snapshots. Replicated snapshots must be deleted from the remote cluster. Cloudspin artifacts generated by the Protection Group must be manually deleted from the respective cloud portals. Snapshots under DataLock cannot be deleted.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Keep the **Delete Snapshots** toggle disabled to delete the Protection Group only.
    - Enable the **Delete Snapshots** toggle to delete the Protection Group and all associated snapshots.
5. Type **YES** to confirm that you want to delete the Protection Group.
6. Click **Delete Group**.

Recover Azure Table Storage

After you protect your Azure Table Storage, you can recover them from Cohesity cluster to their original location or a new location.

> **Note:** If you plan to overwrite an existing database, Cohesity recommends backing up the database first.

To recover protected Azure Table Storage databases:

1. Navigate to **Data Protection** > **Recoveries**.

   Select the required database that is to be recovered.
2. Click **Recover** > **Azure** > **Table Storage**.
3. On the **New Recovery** page,
    1. Use the filters and search box to locate the required databases. Wildcards are supported.
    2. Select the required database that is to be recovered.
    3. Click **Next: Recovery Option**.
    4. In the **Recover To** section, do one of the following:
        1. To restore to the original location:
            1. Select the **Original Location** option to recover the database to its original location. Consider the following points:
                1. The existing database at that location with the same name will always be overwritten.
                2. You must type **Yes** to confirm and proceed.
                3. To avoid overwriting the database with the same name, enter a new name in the **Rename** field below. The database will then be recovered with the new name you have provided.
        2. To restore to a new location:
            1. Select the **New Location** option to recover the database to an alternative Table Storage Account.
            2. Select the registered Azure tenant from the **Source** drop-down and then select the **Storage Account** to which you want to recover the Storage Account Tables.
            3. To overwrite an existing Storage Account Tables, toggle on the **Overwrite existing database(s)** option and type **Yes** to confirm.

4. If you want to recover the database with a different name, enter the new name in the **Rename** field below.
5. If you enter a new name, the database will be restored at the selected location with the new assiged name.
6. If you do not enter a new name, the existing database with the same name will be overwritten.

4. Select your **Recovery Options**:
    1. **Rename**. If you have renamed the database, it will be recovered with the new name at either the original or the new location, based on the option you have selected.
    2. **Task Name**. Change the default name of the recovery task.
5. Click **Recover**.

Azure PostgreSQL

Cohesity provides a simple, fast, and cost-effective backup, recovery, and data management solution for Microsoft Azure PostgreSQL databases.

Azure Database for Azure PostgreSQL is a fully managed relational database service offered by Microsoft Azure. It enables users to deploy, manage, and scale Azure PostgreSQL databases in the cloud without the need to manage the underlying infrastructure.

> **Important:** The backup and recovery of Azure PostgreSQL is supported only on DataProtect for cloud in Azure (formerly known as Azure NGCE cluster).
> This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

This topic covers the following:

Plan and Prepare for Azure PostgreSQL Protection

Protecting Azure PostgreSQL involves a few key steps: registering the Azure PostgreSQL instance to be protected, configuring authentication, and performing backups. Once the backup is completed, you can restore the data to the original location or an alternate destination as needed.

Required Permissions for Azure PostgreSQL Protection

The following set of permissions are required to discover PostgreSQL to Cohesity cluster.

Permissions	Description
Microsoft.Authorization/*/read Microsoft.Subscription/*/read	To list the permission associated with the resource for the given credential.
Microsoft.Resources/*/read	To get resource group and location information.
Microsoft.DBforAzurePostgreSQL/servers/databases/write	To create a database in Azure PostgreSQL server.
Microsoft.DBforAzurePostgreSQL/servers/databases/delete	To delete a database in Azure PostgreSQL server.
Microsoft.DBforAzurePostgreSQL/flexibleServers/read	To list and get details of Azure PostgreSQL Flexible server.
Microsoft.DBforAzurePostgreSQL/flexibleServers/databases/read	To list and get details of databases in Azure PostgreSQL Flexible server.
Microsoft.DBforAzurePostgreSQL/flexibleServers/databases/write	To create a database in Azure PostgreSQL Flexible server.

Authentication for Azure PostgreSQL Protection

You must authenticate to Azure PostgreSQL with Cohesity cluster to perform backup and restore operations. You can use the credentials of the admin user. This is the user account configured in your Azure environment during PostgreSQL creation.

If needed, instead of using the admin user credentials, you can create a custom user and use it for authentication during backups. However, for restoring that backup, the admin user credentials are required. So, if you have used custom user credentials for backup authentication, you must change them back to the admin user credentials at the time of restore.

You can use the following commands to create a custom user on the server/Managed Instance:

- To create custom user:

  ```
  #CREATE USER <dbuser> WITH PASSWORD '<password>' CREATEDB;
  ```

- To grant the required role to the user:

  ```
  #GRANT azure_pg_admin TO <dbuser>;
  ```

Firewall Ports for Azure PostgreSQL Protection

Ensure connectivity from Cohesity cluster to the Azure PostgreSQL server on port 5432.

Considerations for Azure PostgreSQL Protection

You must review the following considerations before you proceed for registration, backup, or recovery:

- Cohesity cluster does not restore accounts and their grants to the destination server.
- Restoring a backup taken from a higher PostgreSQL database version to a lower version is not supported.
- Restoring security privileges is not supported.
- Use the --no-owner and --no-privileges options during restore.
  After restore, metadata captured at the time of backup is shown as the owner/ACL in the progress log restore activity on the web UI.
- Restore does not fail if the owner or role does not exist on the destination.
- Modify database ownership after restore.
- Azure PostgreSQL database restore from a single server to a flexible server or vice versa is not supported.
- Unsupported characters in database names during restore: `, @, \, [,], !, #, %, ^, ., ,, &, *, (,), <, >, ?, /, |, }, {, ~, :, ', ", ;, +, =, -
- Uppercase names are not supported for new accounts added after PostgreSQL server creation.
- If full backups fail due to temporary objects, delete the temporary objects manually and run the backup again.

Register and Manage Azure Source

At the time of registration, you can select the databases you want to protect, such as SQL MI, MySQL, Tables, and so on. After registering, you can refresh the registered Azure source to get updates from the source Azure tenant, such as additions or deletions of any objects like databases. You can also update the configuration, including the subscription, the Application ID, and the Application Secret used for registration. Additionally, you can select or deselect any database types you have selected for protection. If required, you can also unregister the entire Azure tenant that you registered with Cohesity cluster.
Before registration, you must review the requirements and considerations in the Plan and Prepare for PostgreSQL Protection topic.

After registration, you can:

- Update the Azure source configuration.
- Refresh the Azure source details.
- Unregister the Azure source from the Cohesity DataProtect.

Register Azure as a Source

Before registration, you must review the requirements and considerations in the Plan and Prepare for PostgreSQL Protection topic.

To register your Azure tenant as a source with Cohesity cluster:

1. Navigate to **Data Protection > Sources**.
2. Click **Register** > **Cloud Platforms** > **Azure**.
   The **Register Azure Source** window is displayed.
3. In the **Source Details** page,
   1. In the **Domain Name** field, provide the unique tenant ID assigned by Azure. For information on getting the tenant ID, see Get tenant ID.
   2. In the **Azure Workloads** section, under **Database**, select **PostgreSQL**.
   3. Click **Continue**.
4. In the **Azure Apps** page,
   1. In the **Azure App ID** field, enter the application ID assigned by Azure during the service principal creation process.
   2. In the **App Secret Key** field, enter the application secret key for setting up authentication for the service principal.

      > **Note:** Manual creation of Azure App requires significantly more effort and time. It involves several steps within Microsoft Azure for configuration.

   3. Click **Continue**.
5. In the **Subscriptions** page,
   1. In the **Subscription ID** field, enter the subscription IDs of the subscriptions where the database you want to protect belongs to.

      You can add multiple subscription IDs by clicking the **+** icon.

      > **Note:** The subscriptions must be manually added and will not be automatically discovered.

   2. Click **Register**.

   The source is registered. You can view it under **Data Protection** > **Sources**. The source appears in the **Azure** section. Click the registered Azure source, then go to the **PostgreSQL** tab to view the entity hierarchy of Azure PostgreSQL.

Update Azure Source Configuration

To edit an Azure source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure sources and select **Edit**.
3. In the **Edit Azure Source** page,
    1. Select or clear the checkboxes of the Azure databases as required, and then click **Continue**.
    2. Update Azure Application ID and Azure Application Secret Key as required, and then click **Continue**.
    3. Remove the existing subscription or add more subscriptions as required.

        > **Note:** Before you remove a subscription from the registered Azure source, you must unprotect all the protected objects in that subscription.

    4. Click **Update**.

Refresh Azure Source Configuration

To refresh the Azure source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure source and select **Refresh**.

Unregister Azure Source

If you plan to stop backing up your registered Azure tenant, you can unregister it from Cohesity cluster.

> **Note:** Before you unregister the registered Azure source from Cohesity cluster, you must unprotect all the protected objects under that source.

To unregister the Azure source:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure source and select **Unregister**.
3. In the **Unregister Source** dialog, click **Unregister**.

Backup Azure PostgreSQL

After registration of your Azure tenant as a source, Cohesity uses the cloud credentials to authenticate with Azure.

After authentication, Cohesity cluster auto-discovers all the subscriptions (that the service account can access) and supported workloads such as PostgreSQL, Azure SQL Managed Instance, MySQL, and so on within those subscriptions.

The discovered workloads appear under **Data Protection** > **Sources**, under the **Azure** section. Click your Azure instance and then click **PostgreSQL** tab to view all the discovered objects.

Hierarchy View displays the entity hierarchy of the Azure PostgreSQL, allowing you to navigate from the tenant-level down to individual databases.

Azure PostgreSQL Entity Hierarchy

The Azure PostgreSQL entity hierarchy follows this structure:

Structure	Description
Tenant	Dedicated instance of the identity service.
Subscription	Logical container for managing billing, resources, and permissions for services.
Resource Group	Logical container for organizing and managing related Azure resources, such as virtual machines, storage accounts, and web apps.
Database Servers	Fully managed Azure PostgreSQL server instance hosted within the Azure cloud.
Database	Fully managed relational database service in Microsoft Azure.

Backup Scope by Azure PostgreSQL Hierarchy

Cohesity cluster allows you to backup Azure PostgreSQL database(s) at different levels of hierarchy.

You can choose any of the following objects to back up:

- **Tenant** – Protect all Azure PostgreSQL databases within the tenant.
- **Subscription** – Protect all Azure PostgreSQL databases within the subscription.
- **Resource Group** – Protect all Azure PostgreSQL databases within the resource group.
- **Database Server** – Protect all Azure PostgreSQL databases within the database server.
- **Database** – Protect individual databases.

Supported Backup Types

Only full backups are supported. Incremental backups are not supported.

Protect Azure PostgreSQL

To back up a registered Azure PostgreSQL, you must:

1. Decide whether to use an existing Protection policy or create a new one with the required parameters.
2. Decide which objects to include in the Protection Group.
3. Set credentials for authentication.

A Protection Group enables you to select and group the objects that you want to backup. It uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured and replicated.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select which standard or custom policy to use when creating a Protection Group. For more information, see Manage Protection Policy.

Prerequisites to Protect Azure PostgreSQL

Configure Authentication for Azure PostgreSQL

Before performing a backup of Azure PostgreSQLs that are discovered in Cohesity cluster, you must configure credentials for these Managed Instances. These credentials are essential because they enable secure authentication and connectivity between Cohesity and your Azure PostgreSQL. Without valid credentials, the backup process cannot access your Managed Instance or its databases.

You need to enter the credentials that you have already configured for the Managed Instances in your Azure environment. Once these credentials are validated and the connection is established, Cohesity can access the databases within the instance to perform operations such as dumping, protecting and restoring in case required.

Consider the following points:

1. You can set credentials for the PostgreSQL at any object in the entity hierarchy.
    1. Tenant
    2. Subscription
    3. Resource group
    4. Instance level
2. The credentials you set are applied to all child objects within the selected object.
3. You cannot set credentials for individual databases.

4. It is recommended to apply credentials at the Managed Instance level. As if you apply credentials at a higher level in the entity hierarchy (Resource group, Subscription, or Tenant), they will be applied to all child-level Managed Instances. If the credentials do not match any of the Managed Instances at the child-level, the backup of the databases within those Managed Instances will fail.

To set the credentials for Azure PostgreSQL:

1. Navigate to **Data Protection > Sources**, find the registered Azure source, and click on it.
2. Click on the **PostgreSQL** tab.
3. Click the Hierarchy view icon (if you are in a different view) to display the hierarchy. This view makes it easier to view the entity hierarchy and select the required object.
4. Select the checkbox next to object to which you want to set credentials and click **Select All Child Objects**.
5. Click **Database Credentials**.
6. You can select one of the following options:
    1. **Username and Password** - Enter the PostgreSQL admin username and password. The account must have access to all databases within the Azure PostgreSQL. Or enter the credentials of the custom user created for backup.
7. Click **Save**.

Protect Azure PostgreSQL

Before you proceed to protect an Azure PostgreSQL, make sure that the authentication is configured.

> **Note:** An object cannot be included in two different protection groups for protection.

1. Navigate to **Data Protection > Protection**.
2. Click **Protect** > **Azure** > **PostgreSQL**.
3. On the **New Protection** page,
    1. Click **Add Objects**. From the **Registered Source** field, select the Azure instance you have registered.
    2. Do any of the following:

1. To apply auto-protection,
    1. To apply auto-protection for the objects (Tenants, Subscriptions, Resource Groups, Servers, and Databases), click the auto-protection icon next to it.
    2. All child objects under the selected object will be auto protected.
    3. Note: Auto-protection is not supported for individual database-level. To apply auto-protection for databases, you must select a parent object in the hierarchy.
    4. To exclude any object from auto-protection, click the auto-protection icon next to that object.
2. To apply manual protection,
    1. To apply manual protection, click the checkboxes of the objects (Tenant, Subscription, Resource Group, Servers, and Database) you want to protect.
    2. The child objects under the selected object will be selected.
    3. You can select or deselect checkboxes of the objects as required.
3. click **Continue**.

4. On the **New Protection** page,
    1. Enter a name for your Protection Group.
    2. Click **Policy** and select the policy to specify backup frequency and retention. If you do not have a policy, you can create one.
5. Optionally, to configure any of the advanced settings, select **More Options**.
6. Click **Protect**.

Advanced Settings

Section	Setting	Description
Settings	**Storage Domain**	Select the appropriate Storage Domain. For more information, see Manage Storage Domains.
	Start Time	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
	SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

Section	Setting	Description
Additional Settings	**Pause Future Runs**	Toggle on this option to stop protection runs from executing. Once you enable this option, no protection runs will be scheduled.
	End Date	If you need to end protection on a specific date, enable this option to select the date.
	QoS Policy	Select an appropriate quality of service (QoS) policy. Cohesity recommends specifying Backup HDD, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Object. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Object. Only specify this policy if you need fast ingest speed for a small number of Objects. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the current running task.
	Alerts	Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when an Object completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Object fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the takes longer than the time specified in the SLA field. Emails are sent when warning alerts are created.

Section	Setting	Description
	Priority	Select a priority for the Object Protection Group Execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the runs: • High-priority protection runs • Medium-priority protection runs • Low-priority protection runs
	Description	Enter a brief description of the object.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.

Manage PostgreSQL Backup Configuration

In the Cohesity cluster, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Objects to the Protection Group

You can add new objects to the existing Protection Group for backup. The newly added object is backed up from the next protection run, and it will be a full backup for the newly added object.

To add objects to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ in the **Objects** section.

5. In the **Objects** section, Click the plus icon (**+**) to enter multiple objects that you plan to back up. click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a protection run:

1. Navigate to **Data Protection** > **Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all associated local and archived snapshots. Replicated snapshots must be deleted from the remote cluster. Cloudspin artifacts generated by the Protection Group must be manually deleted from the respective cloud portals. Snapshots under DataLock cannot be deleted.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Keep the **Delete Snapshots** toggle disabled to delete the Protection Group only.
    - Enable the **Delete Snapshots** toggle to delete the Protection Group and all associated snapshots.
5. Type **YES** to confirm that you want to delete the Protection Group.
6. Click **Delete Group**.

Recover Azure PostgreSQL Databases

After you protect your Azure PostgreSQL, you can recover them from Cohesity cluster to their original location or a new location.

> **Note:**
> - If you plan to overwrite an existing database, Cohesity recommends backing up the database first.
> - To restore to a new location, the destination instance credential validation must be done, and the host mapping of the destination instance must be added in **Settings**>**Networking**> **Host Mapping**.

To recover protected Azure PostgreSQL databases:

1. Navigate to **Data Protection** > **Recoveries**.

   Select the required database that is to be recovered.
2. Click **Recover** > **Azure** > **PostgreSQL**.
3. On the **New Recovery** page,
    1. Use the filters and search box to locate the required databases. Wildcards are supported.
    2. Select the required database that is to be recovered.
    3. Click **Next: Recovery Option**.
    4. In the **Recover To** section, do one of the following:
        1. To restore to the original location:
            1. Select the **Original Location** option to recover the database to its original location. Consider the following points:
                1. The existing database at that location with the same name will always be overwritten.
                2. You must type **Yes** to confirm and proceed.
                3. To avoid overwriting the database with the same name, enter a new name in the **Rename** field below. The database will be recovered with the new name you have provided.
        2. To restore to a new location:
            1. Select the **New Location** option to recover the database to an alternative PostgreSQL.

2. Select the registered Azure tenant from the **Source** drop-down and then select the PostgreSQL server to which you want to recover the database.
3. To overwrite an existing database, toggle on the **Overwrite existing database(s)** option and type **Yes** to confirm.
4. If you want to recover the database with a different name, enter a new name in the **Rename** field below.
5. If you enter a new name, the database will be restored at the selected location with the new name assigned.
6. If you do not enter a new name, the existing database with the same name will be overwritten.

4. Select your **Recovery Options**:
    1. **Rename**. If you have renamed the database, it will be recovered with the new name at either the original or the new location, based on the option you have selected.
    2. **Task Name**. Change the default name of the recovery task.
5. Click **Recover**.

Azure Blob Storage and Azure Data Lake Storage

Azure Blob Storage and Azure Data Lake Storage are types of storage accounts in Microsoft Azure, designed for storing unstructured data. Within these storage accounts, you can create containers (for Blob Storage) or file systems (for Data Lake Storage) to organize and manage your data. Azure Data Lake Storage (ADLS) offers a hierarchical namespace, enabling efficient file system operations and enhanced file-level security, while Azure Blob Storage utilizes a flat namespace for simpler object storage. Cohesity seamlessly integrates with Azure, providing a straightforward, fast, and cost-effective solution for backup, recovery, and data management across both Azure Blob Storage and Azure Data Lake Storage accounts.

Plan and Prepare for Azure Blob and Data Lake Storage Protection

To protect Azure Blob Storage and Azure Data Lake Storage with Cohesity, you must register your Azure as a source in the Cohesity cluster and perform backup and recovery operations.

Ensure you meet the pre-requisites and understand the considerations before registering Azure as a source.

Prerequisites for Registering Azure Source

Before registering Azure with the Cohesity cluster, you must perform the following steps:

1. Register an application with Microsoft Entra ID and create a service principal. For information, see the Azure documentation.
2. Create an application secret key for setting up authentication for the service principal. For information, see the Azure documentation.
3. Create a custom role at subscription level with the required permissions for backup and recovery.
4. For information about creating a custom role, see the Azure documentation.
5. Assign the custom role to the Microsoft Entra ID application created in step 1.

The Entra ID and application secret key are required when you register the Azure source with the Cohesity cluster.

Permissions Required for Azure Storage Protection

The following table lists the permissions and privileges that must be included in a custom role.

Permission Type	Premission

Actions	`Microsoft.Storage/storageAccounts/read`
	`Microsoft.Storage/storageAccounts/listkeys/action`
	`Microsoft.Storage/storageAccounts/regeneratekey/action`

DataActions	`Microsoft.Storage/storageAccounts/blobServices/containers/blobs/*`
	`Microsoft.Storage/storageAccounts/read`
	`Microsoft.Storage/storageAccounts/blobServices/read`

Considerations for Azure Storage Protection

Review and understand the following considerations before you protect Azure Blob Storage and Data Lake Storage:

- The Microsoft Entra ID you create must have access to the Storage Container you want to protect.
- Protection of Page blobs and blobs in the archive tier are not supported.
- Both full and incremental backups are supported.

Register and Manage Azure Source

To protect your Azure Blob Storage and ADLS, you need to register Azure as a source on the Cohesity cluster. After registering Azure as a source, you can:

- Update the Azure source configuration.
- Refresh the Azure source details.

- Unregister the Azure source.

Register Azure as a Source

Before registering Azure as a source, ensure to check the requirements and considerations.

To register Azure as a source:

1. Navigate to **Data Protection > Sources > Register**, and then select **Cloud Platforms > Azure**.

   The **Register Azure Source** window is displayed.

2. In the **Source Details** page,
   1. In the **Domain Name** field, provide the unique tenant ID assigned by Azure. For information on getting the tenant ID, see Get tenant ID.
   2. In the **Azure Workloads** section, under **Storage**, select **Blob and Data Lake Storage**.
   3. Click **Continue**.
3. In the **Azure Apps** page,
   1. In the **Application ID** field, enter the Entra ID assigned by Azure during the service principal creation process.
   2. In the **Application Secret Key** field, enter the application secret key for setting up authentication for the service principal.

      > **Note:** Manual creation of Azure App requires significantly more effort and time. It involves several steps within Microsoft Azure for configuration.

   3. Click **Continue**.
4. In the **Subscriptions** page,
   1. In the **Subscription ID** field, enter the subscription IDs of the subscriptions where the Storage Containers you want to protect belongs to.

      You can add multiple subscription IDs by clicking the **+** icon.

      > **Note:** The subscriptions must be manually added and will not be automatically discovered.

   2. Click **Register**.

   The source will be registered and displayed under the Azure section in the **Data Protection** > **Sources** page. You can click on the source and navigate to the **Blob and Data Lake Storage** tab to view the entity tree of the Storage Containers.

Update Azure Source Configuration

You can update the registered Azure source to add or remove the Azure services, and subscriptions protected by Cohesity from your Azure source.

To edit an Azure source:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure sources and select **Edit**.
3. In the **Edit Azure Source** page,
    a. Select or unselect the Azure services you need and click **Continue**.
    b. Update Azure Entra ID, Azure secret key and click **Continue**.
    c. Add or remove subscriptions and click **Update**.

> **Note:**
> - The listed subscriptions are added only after an administrator has manually linked them to Microsoft Azure.
> - Before you remove a subscription from the Azure source, you must unprotect all the protected objects in the subscription.

Refresh Azure Source

You can refresh the Azure source configuration and fetch the latest changes on your Azure environment.

To refresh the Azure source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure source and select **Refresh**.

Unregister Azure Source

If you plan to stop backing up your Azure Storage Containers, you can unregister the Azure source from the Cohesity cluster.

> **Note:** Before you unregister an Azure source from the Cohesity cluster, you must unprotect all the protected Storage Containers in that Azure source.

To unregister the Azure source:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Azure source and select **Unregister**.

3. In the **Unregister Source** dialog, click **Unregister**.

> **Note:** The source and all the resources in the source will be unregistered.

Backup Azure Blob and Data Lake Storage

After registering your Azure source, Cohesity uses the cloud credentials provided to authenticate with Azure.

Once authenticated, Cohesity automatically discovers all the subscriptions that the service account can access, as well as all supported workloads such as Azure Blob and Data Lake Storage within those subscriptions. The discovered workloads appear under **Data Protection** > **Sources**. You can select the **Blob and Data Lake Storage** tab to view all the Storage Containers discovered.

The Hierarchy view displays the entity hierarchy of Azure, allowing you to navigate from the tenant-level down to individual Storage Container.

Azure Storage Container Entity Hierarchy

The **Blob and DataLake Storage** entity hierarchy in the Cohesity cluster follows this structure:

Structure	Description
Tenant	The top-level Azure Active Directory boundary that contains subscriptions.
Subscription	Logical container for managing billing, resources, and permissions for services.
Resource Group	Logical container for organizing and managing related Azure resources, such as virtual machines, storage accounts, and storage services.
Storage Account	The Azure Blob Storage or Azure Data Lake Storage having storage container to protect.
Storage Container	The namespace within Azure Blob Storage or Data Lake Storage. Containers store data objects such as blobs.

Backup Scope by Azure Storage Hierarchy

The Cohesity cluster allows you to backup Azure Storage Container at different levels of the hierarchy.

You can choose to back up any of these levels in hierarchy:

- **Tenant level**– Protect all Azure Storage Accounts (Blob/ADLS) across all levels.
- **Subscription level** – Protect all Azure Blob or Data Lake Storage Accounts within the Subscription.
- **Resource Group level**– Protect all Azure Blob Storage or ADLS Storage Accounts within the subscription.
- **Storage Account level**– Protect all containers within a selected Azure Blob or ADLS Storage Account.
- **Storage Container** – Protect individual containers within an Azure Blob or ADLS Storage Account.

Supported Backup Types

Cohesity supports both full and incremental backups for Azure Blob and Data Lake Storage.

Protect Azure Blob or Data Lake Storage Containers

In Cohesity, the containers of Azure Blob and Data Lake Storage Accounts are protected using a Protection Group and a Protection Policy. The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select standard or custom policy to use when creating a Protection Group. For more information, see Manage Policies.

To protect a Storage Container:

1. Navigate to **Data Protection** > **Protection**.
2. Click **Protect** on the top-right of the page and then select **Azure** > **Blob and Data Lake Storage**.
3. In the **New Protection** page, click **Add Objects** and select your registered source or click **Register Source** to add a new one.
4. Select the Storage Container using one of the following views or option:
    - **List View**: Use this option to select the Storage Container for protection from a flat, searchable list.
    - **Hierarchy View**: Use this option to select Storage Container for protection at various hierarchy levels.

      Optionally,

        - You can click the auto-protect icon at the tenant level, subscription level, and Storage account level to automatically protect newly added Storage Container.

- You can exclude the Storage Container from auto-protection within an tenant, Subscription, resource group, or Storage Account by clicking the auto-protect icon ( ) next to the Storage Container. The Storage Container excluded from auto-protection are displayed with the exclude ( ) icon.

- **Tags**: Use this option to select the Storage Container for protection based on tags. Select the checkbox of a tag, and then select **Select All Child Objects** to include all containers with that tag for protection.

  Optionally:

  - You can configure auto-protection based on a tag. You can select the tag checkbox and then choose **Auto Protect This Tag** to automatically protect all newly added Storage Containers with this tag.
  - You can exclude the Storage Containers from auto-protection within a tag by clicking the auto-protect icon ( ) next to the Storage Container. The Storage Containers excluded from auto-protection are displayed with the exclude ( ) icon.
  - You can exclude Storage Containers with a specific tag from auto-protection by clicking the exclude icon (⊘). The tag excluded from auto-protection are displayed with the exclude icon.

5. Click **Continue**.
6. Provide a name for the **Protection Group**. The name can contain alphanumeric characters, underscores, dashes, and periods.
7. From the **Policy** drop-down, create or select and existing policy.
8. Select **More Options** to change or configure any of the advanced settings.
9. Click **Protect**.

Advanced Settings

Section	Setting	Description
Settings	**Start Time**	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
	SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

Section	Setting	Description
Additional Settings	**Pause Future Runs**	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
	End Date	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
	QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. • **Backup Auto**: This policy achieves similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. The data is written to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. For best performance, we recommend the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
	Alerts	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.

Section	Setting	Description
	Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: • High-priority protection runs • Medium-priority protection runs • Low-priority protection runs
	Description	**Optional**. Enter a brief description about the Protection Group.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.

Manage Storage Container Backup Configuration

In the Cohesity, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Object(s) to the Protection Group

Depending on the Protection Type you chose while creating the Protection Group, you can add new Storage Containers to the existing Protection Group for backup. The newly added object is backed up from the next protection run, and it will be a full backup for the newly added object.

To add object(s) to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had created for Storage Container.

3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click in the **Objects** section.
5. In the **Objects** section, click the plus icon (**+**) to enter multiple objects that you plan to back up. Click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Storage Container.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Storage Container.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a recovery run:

1. Navigate to **Data Protection** > **Protection**.
2. Click the action menu (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the product UI.

To delete the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Storage Container.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - **Delete Protection Group Only**
    - **Delete Protection Group and Snapshots**

Recover Azure Blob or Data Lake Storage Account Containers

You can restore the Storage Containers of Azure Blob or Data Lake Storage Account either to its original location or to a different location.

> **Note:** We recommend that you review the Plan and Prepare for Azure Blob and Data Lake Storage Protection.

To recover a Storage Container:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **Azure** > **Blob and DataLake Storage**.
3. Search for the Storage Container by entering characters of the Storage Container name, or by specifying the wildcard character *.
4. From the list of search results, select the Storage Container to recover. By default, the latest snapshot of the Storage Container is selected for recovery. To recover from a different snapshot, perform the following steps depending on the object selected:

   From the selected lists, mouse over the snapshot, and then click the edit icon. The **Edit recovery point for *<container_name>*** page appears. By default, the option to select the snapshot is displayed in the **List** mode. You can also choose to view the option in the **Timeline** mode by clicking the **Timeline** tab in the top-right corner of the page.

   - To select a snapshot from the **List** mode:
     a. Select the **List** tab from the top-right corner of the **Edit recovery point for *<container_name>*** page. By default, the page displays the snapshots available in the last one month. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.
     b. Select the snapshots to be recovered.
     c. By default, the snapshot is recovered from the local Cohesity cluster.
     d. Click **Select Recovery Point** and then go to step 5.
   - To select a snapshot from the **Timeline** mode:
     a. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar.
     b. Select the snapshot to be recovered by clicking the corresponding blue dot.
     c. By default, the snapshot is recovered from the local Cohesity cluster.
     d. Click **Select Recovery Point** and then go to step 5.
5. Click **Next: Recover Options**.

6. In the **Recover To** section, select any one of the following options based on where you want to restore the container and then provide the required information:
   - **Original Location**: Restore into the original container.
     a. Enable **Overwrite existing container(s)** to recover the Storage Container by overwriting the original container. Type **Yes** to confirm.

        If the source and target objects are identical, then the target container will not be updated even if the **Overwrite existing container(s)** option is enabled.

     b. Optionally, in the **Prefix or file path (optional)** field, add a prefix or file path to the files of the containers that are recovered.
   - **New Location**: Restore into another container within the same or a different Azure source.
     a. From the **Source** drop-down, select a registered Azure source and from the **Container** drop-down, select the target Storage Container to which you want to restore the object from the source containers.

        If the source and target objects are identical, then the target container will not be updated even if the **Overwrite existing container(s)** option is enabled.

     b. To overwrite any existing Storage Container with the same name, enable **Overwrite existing container(s)** and type **Yes** to confirm.

        If the source and target objects are identical, then the target container will not be updated even if the **Overwrite existing container(s)** option is enabled.

     c. Optionally, in the **Prefix or file path (optional)** field, add a prefix or file path to the files of the containers that are recovered.

   > **Note:** Restoring to a new location also replaces any existing Storage Container with the same name in the selected instance.

7. In the **Recovery Options** section, configure the following options:
   a. **Granular recovery**: To perform granular recovery the Storage Container, toggle on **Enable to recover specific prefixes or file paths** and provide the prefix of the files to be recovered.

      For example, **Finance/statement/document**.

      You can click the add icon to provide multiple prefixes.

      The maximum number of prefixes that you can provide per recovery task is 100.

b. **Continue on Error**: Enable this option if you want to continue the recovery even if one of the files in the container encounters an error. By default, this option is disabled and the recovery operation will fail if one of the files encounters an error.

c. **Task Name**: Update the default name of the recovery task.

8. Click **Recover**.

GCP

Cohesity natively integrates with Google Cloud to provide a simple, fast, and cost-effective solution for backup, recovery, and data management of Google Cloud Services, such as virtual machines, databases and so on.

This chapter includes the following topics:

GCP Virtual Machines

Cohesity natively integrates with Google Cloud to provide a simple, fast, and cost-effective solution for backup, recovery, and data management of Google Cloud Services, such as virtual machines.

This chapter includes the following topics:

Plan and Prepare for GCP Protection

Review the following prerequisites and considerations of GCP.

Prerequisites

- To add a new node to a Cohesity cluster, both the node and Cohesity cluster must have Cohesity 6.0 or later installed. For more information, see Manage Nodes.
- Make sure `google.apis.com` is reachable through firewall port 443 when registering the GCP Source.
- You must allowlist the following source FQDNs for registering and backing up the GCP source:
  - https://accounts.google.com/
  - https://www.googleapis.com/
  - https://storage.googleapis.com
  - https://vpcaccess.googleapis.com/
  - https://cloudfunctions.googleapis.com/
  - https://cloudresourcemanager.googleapis.com/

Considerations

Review the following considerations of GCP native snapshotting:

- App consistent backup is not supported.
- Recovering files/folders to source is not supported. File download is supported.
- Cloning is not supported.
- For incremental snapshots, native backup uses source side dedup and not Google API as Google does not have any APIs for incremental backup. Hence full and incremental backups after the first run takes about the same time to complete.
- For backup and recovery of GCP VMs, the service account, the VPC and Subnet where the fleet instances are launched should be on the same project.
- You can perform files and folder recovery to an GCP VM Linux instance only if the GCP VM Linux instance is of x86_64 architecture.
- File-level recovery is not supported for GCP VMs with XFSv5 file system.
- You cannot exclude disk at the object-level for auto-protected VMs. To exclude disk for auto-protect VMs, you must use the **Volume Exclusion Settings** option in the Additional Settings.
- When browsing files or folders for recovery, Cohesity does not display files or folders with an absolute path length exceeding approximately 3,500 characters. To recover these files or folders, select the parent directory.

GCP Permissions

The following tables list the GCP permissions required for cloud services.

GCP Native Backup and Recovery

Following are the permission required for GCP native backup and recovery:

```
compute.addresses.createInternal
compute.addresses.deleteInternal
compute.disks.create
compute.disks.createSnapshot
compute.disks.delete
compute.disks.get
compute.disks.list
compute.disks.setLabels
compute.disks.use
compute.images.useReadOnly
compute.instances.attachDisk
compute.instances.create
compute.instances.delete
compute.instances.detachDisk
```

```
compute.instances.get
compute.instances.list
compute.instances.setDeletionProtection
compute.instances.setLabels
compute.instances.setMetadata
compute.instances.setTags
compute.instances.setServiceAccount
compute.instances.stop
compute.instances.update
compute.networks.get
compute.networks.list
compute.projects.get
compute.regions.list
compute.snapshots.create
compute.snapshots.delete
compute.snapshots.get
compute.snapshots.setLabels
compute.snapshots.useReadOnly
compute.subnetworks.list
compute.subnetworks.use
compute.subnetworks.useExternalIp
compute.zones.list
compute.zoneOperations.get
iam.serviceAccounts.actAs
resourcemanager.projects.get
vpcaccess.connectors.list
vpcaccess.locations.list
```

Cloud Archival

Action	Permissions
Cloud Archive	`storage.buckets.get` `storage.objects.create`
Cloud Recovery	`storage.buckets.get` `storage.objects.create`

Cloud Edition

Action	Permissions

Shared VPC

During source registration, if you are registering a shared VPC, enter the VPC and the subnet name associated with the VPC in the following format:

`<host-project-id>/<vpc-name>` where `<host-project-id>` is the host project in Shared VPC.

`<host-project-id>/<subnet-name>` where `<host-project-id>` is the host project in Shared VPC.

The registered service account must have the Compute Network User IAM role in the host project. For more information, see Register or Edit a GCP Source.

Create an IAM Custom Role for GCP

You need to create IAM custom roles when registering GCP as a source on the Cohesity cluster.

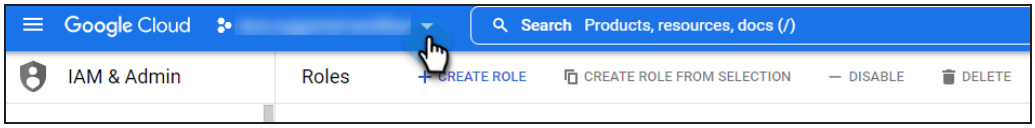
Prerequisites

Before you begin creating IAM custom roles, ensure the following prerequisites are met:

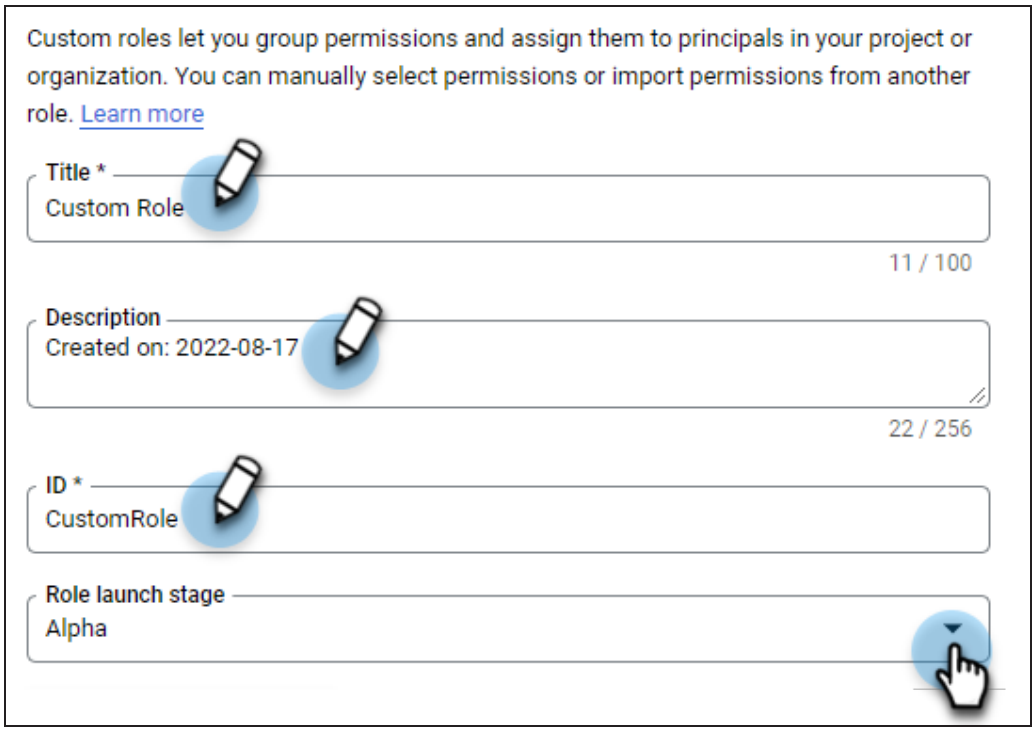
- Enable IAM API. For more information, see Add Project IDs to Allowlist.
- Create service accounts. For more information, see Creating and managing service accounts.

Perform the following steps to create an IAM custom role:

1. In the Google Cloud Platform Console, navigate to **IAM & Admin**.
2. From the drop-down located at the top of the page, select the project in which you want to create the custom role.

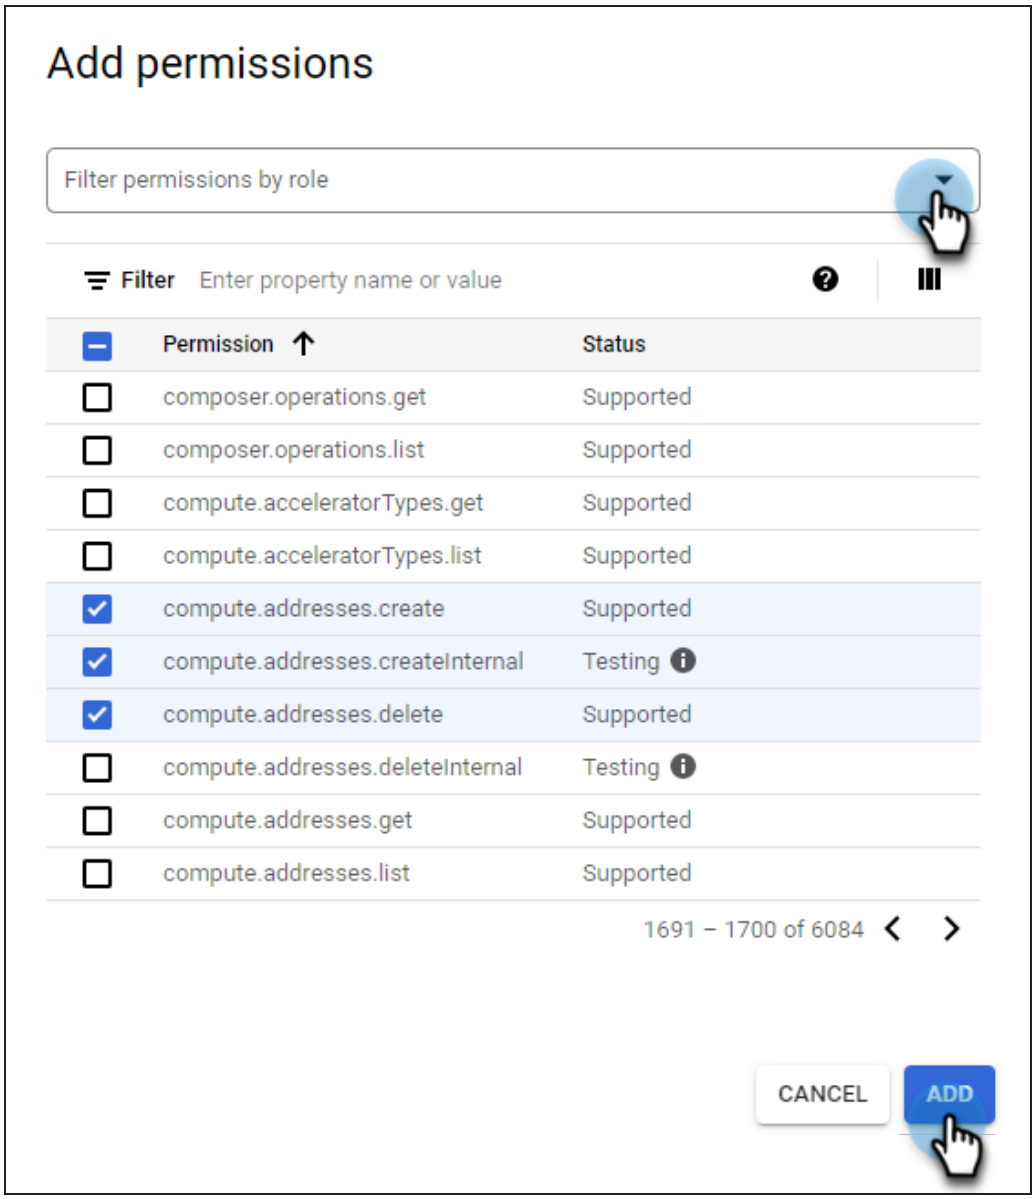


3. Click **Create Role**.
4. In the **Title** field, enter a title for the role.
5. In the **Description** field, enter a brief description.
6. In the **ID** field, enter the ID.
7. From the **Role launch stage** drop-down, select the role launch stage for the role.



8. Click **Add Permissions**. The **Add Permissions** page is displayed.

9. Select the permission you want to include in the role from the list or filter the permissions by role. For GCP permissions required for cloud services, see GCP Permissions.
10. Click **Add** to add the permissions to the role.



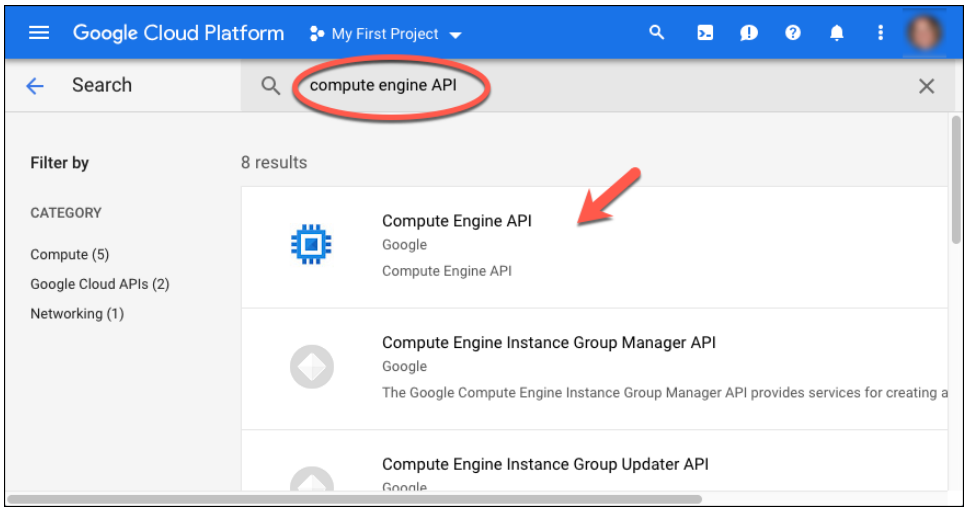
Enable GCP APIs

The following GCP APIs must be enabled for GCP native backup support:

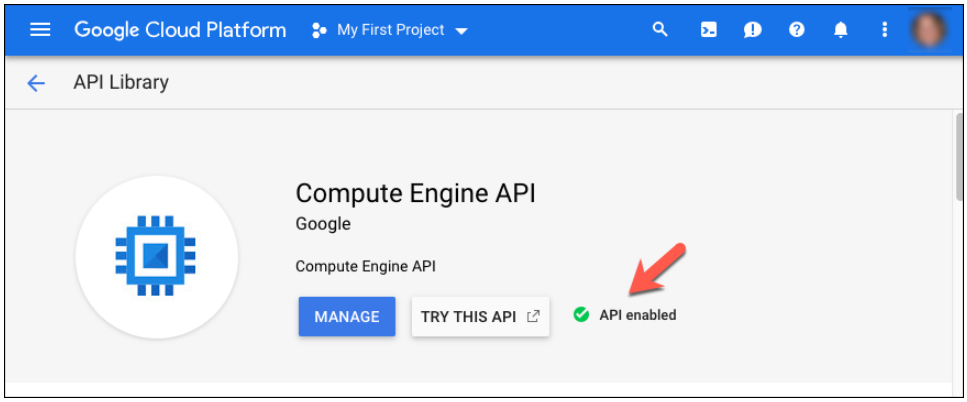
- Compute Engine API
- Cloud Resource Manager API

To enable the APIs:

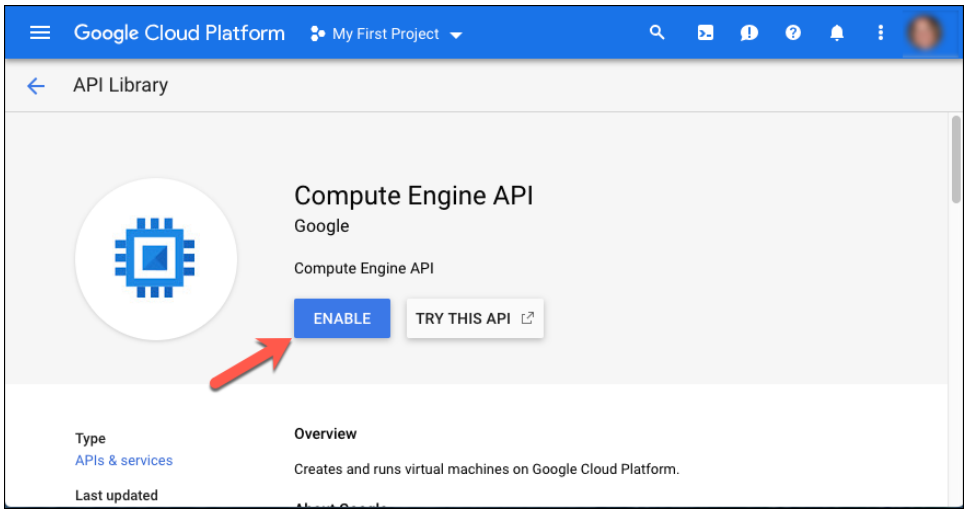
1. In the Google Cloud Platform Console, in the project you are using for GCP, go to **APIs & Services > Library**.
2. Search for one of the APIs listed above and then click the API tile as shown below.



3. If the tile indicates **API enabled**, perform the previous step for the next API.



If the tile displays the **Enable** button, click it and respond to any billing prompts as needed.



4. Repeat the steps above for the other APIs.

Add Project IDs to Allowlist

Add the following project IDs to the allowlist on the GCP Organization Policies page if the GCP organization has a policy that restricts the use of images belonging to external projects. You must add the project IDs to the allowlist for creating Cohesity cluster and backup and recovery of native VMs.

Project IDs	Description
cloud-edition-exports	Required for creating Cohesity cluster.
cohesity-public	Required for backup and recovery of native VMs.

Register or Edit a GCP Source

Before you can register the GCP source:

- Prerequisites
- Add Project IDs to Allowlist
- Review and understand the Plan and Prepare for GCP Protection.

After creating the IAM user and enabling the APIs, you can register the source:

1. In the Cohesity Dashboard, select **Data Protection > Sources**.
2. Select **Register > Virtual Machines**.
3. From the **Select Hypervisor Source Type** drop-down, select **Cloud > GCP: IAM User**.

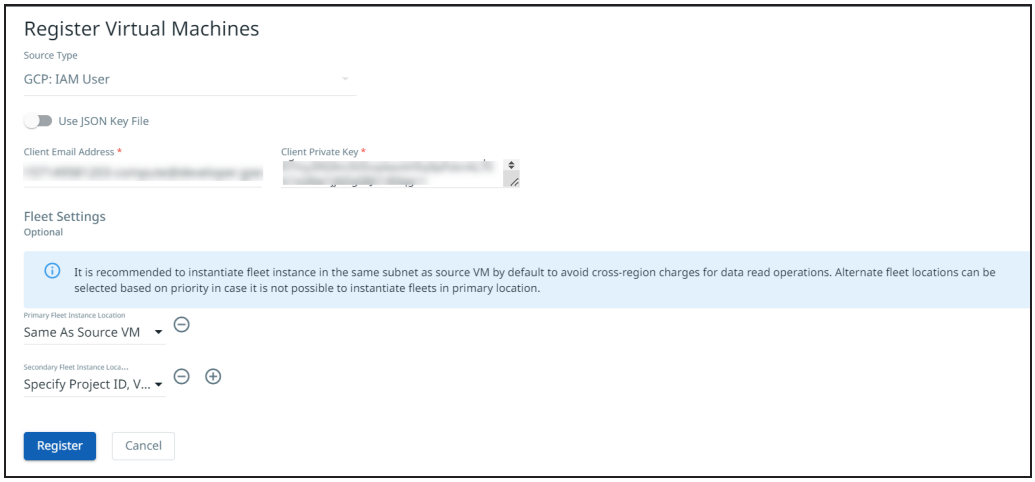
4. Either enable the **Use JSON Key File** option and upload the **Service Account JSON Key File** or disable the **Use JSON Key File** option and provide the following details:

Field Name	Description
Client Email Address	The client email address for the GCP service account associated with the project. You can find the client email address on the IAM page in the Google Cloud Platform Console. The service account must be assigned the Editor role in GCP. Example: `servaccnt@project-name.iam.gserviceaccount.com` **Tip:** The portion of the email address to the left of the at symbol @ will be used as the Source name. For the example above, the Source name will be `servaccnt`. **Note:** A single service account can be used to protect multiple GCP projects. When a service account is registered on the Cohesity cluster as a source, all GCP projects in which the service account has Editor access are made available for protection.
Client Private Key	The private key for the service account. The key could have been downloaded as a JSON file and retained when the service account was created, or the key could have been generated and downloaded after the account was created. Paste the entire private key into this field, from `-----BEGIN PRIVATE KEY-----` to `-----END PRIVATE KEY-----`.

Field Name	Description
Fleet Settings	Specify the VPC and subnet in which the GCP fleet instance should be launched. You can specify the fleet instance location twice as primary and secondary so that if the fleet instance location specified in the primary is unavailable, the location specified in the secondary will be considered. Following are the fleet instance location you can choose: **Same as Source VM**: (Default behavior) The fleet instance will be launched in the same VPC and subnet of the VMs that are to be protected. **Note:** It is recommended to launch the fleet instance in the same VPC and subnet as source VMs to avoid cross-region charges for data read operations. • **Specify ProjectID, VPC, and Subnets**: The fleet instance will be launched in one of the specified subnets, depending on the IP availability in the subnet. If the GCP source is not registered with the Cohesity cluster, the cluster cannot detect the Project and the associated VPC and subnets. To configure the source for launching the fleet instance, you must first register the source and then update the registered source to specify the Project IDs, VPCs, and subnets. For more information, see Configure Project IDs, VPCs and Subnet for Fleet Instance. **Note:** If you have not selected the **Fleet Settings** option, then the GC fleet instance is launched in the same VPC and subnet of the VMs that are to be protected.

5. Click **Register**.

   The following figure is the screenshot of the GCP registeration page:



Customer-Managed Key Restoration

Cohesity now supports backing up encrypted GCP VMs. The source VM encrypted using Customer-Managed Key encryption can now be recovered back to the same location. The recovered VM is encrypted with the same key as the original source VM.

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

Configure Project IDs, VPCs and Subnet for Fleet Instance

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

To configure a new VPC and subnet for the GCP fleet instance:

1. In the Cohesity Dashboard, select **Data Protection** > **Sources**.
2. Navigate the hierarchy to the registered GCP source for which you want to configure a new VPC and subnet for the fleet instance.
3. Click the actions menu next to the GCP source and select **Edit**.

   The Edit Source page appears.
4. From the **Primary Fleet Instance Location** drop-down list, select **Specify ProjectID, VPC, and Subnet** and provide the following information:
   1. **Project ID**: Select the Google Cloud Platform (GCP) project which will be used by the Cohesity cluster to launch the temporary proxy VM (fleet instance) used for backup and recovery operations.

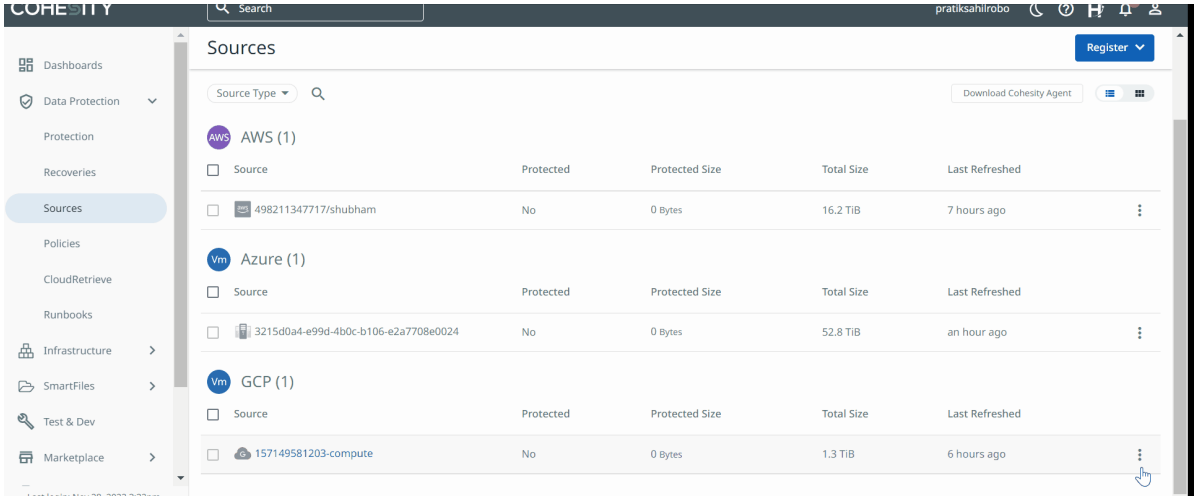
      Example: `my-company-project`
   2. **VPC**: Select the Virtual Private Cloud network name associated with the project. The Cohesity cluster will use this VPC to launch the temporary proxy VM used during backup and recovery operations.
   3. **Subnet**: A subnet name associated with the VPC. The Cohesity cluster will use this subnet to launch the temporary proxy VM used during backup and recovery operations. The subnet belongs to a specific region.

      Example: `mycompany-google-subnet-us-west1`
5. (*Optional*) Click the add icon to specify multiple numbers of fleet instance locations. The maximum number of fleet instance locations you can specify is 20. If the subnet you specified in the first entry is unavailable or the IP in the subnet is exhausted, then based on the order you specified the instance location, the fleet instance will be launched in the next subnet and so on, until Cohesity finds a subnet that is available. If none of the subnets are available, then the fleet instance will either be launched in the secondary location (if present) or the backup and recovery of GCP VMs will fail.

6. Click **Save**.

   The GCP fleet instance will be launched in the specified subnet when you backup the VMs of the GCP cloud service to the Cohesity cluster.

   The following animated image shows how to configure Project ID, VPC, and subnet to launch the fleet instance:



Unregister GCP Source

If you plan to stop taking backup of the GCP VMs, you can unregister the GCP source from the Cohesity cluster. Before you unregister, you must delete all the Protection Groups associated with the GCP source.

To unregister a GCP source on the Cohesity cluster:

1. In the Cohesity Dashboard, select **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the GCP source and select **Unregister**.
3. Click **Unregister**.

> **Note:** When you unregister a source, all the objects in the source will be unprotected. Any new protection after the re-registration of the source will trigger a full backup and not an incremental backup.

Protect GCP VMs

In Cohesity, GCP VMs with their shielded VM properties are protected using a Protection Group and a Protection Policy. A Protection Group uses the schedules and settings defined in the policy to determine when and how backups are captured, archived, or replicated.

A Protection Policy is a reusable set of settings that define how and when objects are protected and replicated. You can select which standard or custom policy to use when creating a Protection Group. For more information, see Create or Edit a Standard Policy.

> **Note:** Backup and recovery of GCP VMs requires a proxy VM (fleet instance) to be launched on the cloud source. For enhanced security, after creating the proxy VM on the cloud source, Cohesity automatically deploys an X.509 certificate. Contact Cohesity Support if you want to launch the proxy VM with its Shielded VM properties enabled.

To protect GCP VMs:

1. Navigate to **Data Protection** > **Protection**.
2. Click **Protect** on the top-right of the page and then select **Virtual Machines**.
3. Click **Add Objects** and from the **Registered Source** drop-down list, select the GCP source you want to back up.

   You can also register a new source with the Cohesity cluster so you can protect it.
4. From the objects list, select the VMs you want to protect.

   Optionally, you can:

   - Click the auto protect ( ) icon to enable **Auto Protect** at various hierarchy levels (Source, Project, Region, Availability Zone). The auto-protect option enables you to automatically protect the new VMs that are added.
   - Click the **Tags** icon on the right and select a tag to:
     - Auto Protect ( ) the VMs having this tag.
     - Exclude ( ) the auto protection of VMs having this tag.

       If a VM has multiple tags with Auto Protect and Exclude applied, exclusion takes precedence. These excluded VMs are also excluded even if a parent object is auto protected.

     The **Tags** button will not be displayed if the Cohesity cluster detects that no sources have tags assigned to them.
   - Exclude any disks of the VM from protection. To exclude the disks:
     a. Click the edit icon displayed next to the VM of which you want to exclude the disk.
     b. Unselect the disks which you want to exclude from protection.

> **Note:**
> - You cannot exclude the root disk from protection.
> - You cannot exclude disk at the object-level for auto-protected VMs. To exclude disk for auto-protect VMs, you must use the **Volume Exclusion Settings** option in the Additional Settings.

5. Click **Continue**.
6. In the **Protection Group** field, enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.
7. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, see Create or Edit a Standard Policy.
8. If you want to change or configure any of the additional setings, then select **More Options** and perform the below steps or else, click **Protect**.
9. Optionally, from the **Policy** drop-down list, you can change the policy you selected earlier or create a new Protection Policy. For more information, see Create or Edit a Standard Policy.
10. In the **Storage Domain** field, select the appropriate storage domain.
11. In the **Start Time** field, the default time zone is the browser's time zone. You can change the time zone of the job by selecting a different time zone.
12. In the **SLA** field, select how long the administrator expects a Protection Group run to take.
    1. **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).
    2. **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run.
13. If you need to change any of the advanced settings on the Protection Group page, click the down arrow icon next to **Additional Settings** and click **Edit** on the right. For more information, see Additional Settings.
14. Click **Protect**.

    The protection of GCP VMs is now active and running.

Additional Settings

Additional Settings	Description
Pause Future Runs	Toggle on this option to stop protection runs of the Protection Group from executing. Once you enable this option, no protection runs will be scheduled for this Protection Group.
End Time	Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts prior to this date runs until completion even if it completes after this date.
QoS Policy	Select an appropriate quality of service (QoS) policy. **Note:** Cohesity recommends specifying **Backup HDD**, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy.
Indexing	This option is toggled on by default to index the data of the Protection Group. Indexing improves files and folders search. Cohesity performs incremental indexing where only the data that has changed since the previous snapshot is scanned and indexed.

Additional Settings	Description
Exclusions	Enable **Exclude Disks** to specify the disks to exclude for all VMs in this Protection Group. You can use the following parameters to form a boolean expression for excluding disks: • **Type**: The type of persistent disk - Standard, Balanced, SSD, Extreme. • **Name**: Name of the disk. • **Label**: Label name tagged with the disk. For example, if you have provided the following boolean expression for exclusion: (`'Type' = Balanced AND 'Name'=gcp AND 'label' = region-us-east) OR ('label'=region-us-west)`. Then the Cohesity cluster will exclude the disks of the VMs that are of type, `Balanced persistent disks` with "`gcp`" as the disk name, and with label name as "`region-us-east`" or disks with "`region-us-west`" as the label name. > **Note:** Exclusion of disks enabled at the object level will take precedence over the exclusion configured here. Enable **Exclude VMs with no disk** to exclude the VM with no disk from protection. Cancel Run at Quite Start Time	*Available only if the selected policy has at least one quiet time period.* Toggle it on to specify that all currently executing protection runs should abort if a quiet time period specified for the Protection Group starts. If the option is toggled off, then after a protection run starts, it continues to execute even when a quiet time period specified for this Protection Group starts. However, a new protection run will not start during a quiet time period.

Additional Settings	Description
Alerts	Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts.
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs
Email Recipients	You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection run.
Description	Enter a brief description about the Protection Group.

Manage GCP Recovery

This chapter includes the following topics:

Recover GCP VMs

You can recover GCP VMs from a snapshot created by a Protection Group.

1. In the cluster UI, select **Data Protection > Recoveries**.
2. Click **Recover** > **Virtual Machines** > **VMs** located at the top right of the page.
3. Search for a protected object (VM) or Protection Group that contains the snapshots to recover from. Enter characters of the VM name or Protection Group name and a list of items displays. You can optionally specify the wildcard character *. You can also optionally narrow the search results by specifying filter criteria, for example, you can filter the search results by a specific Protection Group. Click the **Add Filters** icon, specify the filter and click **Add**.
4. Select a Protection Group or a VM.

> **Note:**
> - If you have selected a Protection Group, then all the VMs backed up in the latest protection run of this Protection Group will be selected for recovery and the option to select those VMs individually will be greyed out in the search result list.
> - You can only select Protection Groups and VMs with snapshots stored in the same Storage Domain and belonging to the same source. Once you select a VM or Protection Group, the Storage Domain and Source filters will automatically get locked.

5. By default, the latest snapshot of the VMs is selected for recovery. To recover from a different snapshot, perform the following steps depending on the object selected:

> **Note:** In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

To choose a different snapshot for a...	Then...
Protection Group	1. From the selected lists, mouse over the snapshot, and then click the **edit** icon. 2. From the **Protection** Run drop-down menu, select the snapshot from which you want to recover the GCP VM. By default the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. 3. Click **Select Recovery Point** and then go to step 6.

To choose a different snapshot for a...	Then...
VM	From the selected lists, mouse over the snapshot, and then click the edit icon. The Edit recovery point for <VM_name> page appears. By default, the option to select the snapshot is displayed in **Timeline** mode. You can also choose to view the option in **List** mode by clicking the List tab in the top-right corner of the page. • To select a snapshot from the Timeline mode: a. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar. b. Select the snapshot to be recovered by clicking the corresponding blue dot. c. By default, the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. d. Click **Select Recovery Point** and then go to step 6. • To select a snapshot from the **List** mode: a. Select the **List** tab from the top-right corner of the Edit recovery point for <VM_name> page. By default, the page displays the snapshots available in the last one month. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range. b. Select the snapshots to be recovered. c. By default, the snapshot is recovered from the local Cohesity cluster. You can also select snapshots archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. d. Click **Select Recovery Point** and then go to step 6.

6. Click **Next: Recover Options**.

   From the **Recover To** options, select one of the following:

   - **Original Location**: Select this option to recover the VM their original location
   - **New Location**: Select this option to recover the VM to an alternate project, region and availability zone. Provide the following information:
     - **Source**: Select a registered Source to recover the VMs to.
     - **Project**: Select a Google Cloud Platform (GCP) project to recover the VMs to.
     - **Region**: Select a region in the project to recover the VMs to.
     - **Availability Zone**: Select an availability zone in GCP to recover the VMs.
     - **VPC**: Select a Virtual Private Cloud (VPC) to store the recovered VMs.
7. Under **Recovery Options**, edit the default settings. Click the **edit** icon to edit the settings:
   a. **Rename**: Add a Prefix and/or Suffix to the recovered GCP VMs.
   b. **Power State**: To ensure that the restored GCP VMs are functioning properly, the VMs are powered on by default after the restoration process. However, you can enable the **Power Off** option if you prefer to keep the VMs powered off once Cohesity verifies their functionality. If you are recovering VMs from a Storage Domain with Cloud Tier enabled, Cohesity recommends keeping the VMs powered off.
   c. **Continue on Error**: Enable this option if you want to continue the recovery even if one of the objects encounters an error. By default, this option is disabled and the recovery operation will fail if one of the objects encounters an error.
   d. **Task Name**: Change the default name of the recovery task.
8. Click **Recover**.

Cohesity begins to restore the selected GCP VMs.

Recover Files or Folders for GCP to the New Server

Prerequisites

- You must install the Cohesity agent on the target VM.
- Firewall port 50051 must be open on the target VM. It is required for transferring the files from the Cohesity cluster to the target VM. For more information, see Manage Firewall Ports.
- The target VM must be reachable with private IP.

> **Note:** You can perform files and folder recovery to an GCP VM Linux instance only if the GCP VM Linux instance is of x86_64 architecture.

Recover Files and Folders to New Server

Perform the following steps to recover files and folders to the new server:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** at the top right of the page and then select **Files or Folders**.

   The Recover Files or Folders page appears.
3. Select any one of the following options to search for the file or folder:
   - **Files and Folders**: Allows you to search and recover files using file or folder names from any backup available on Cohesity.
   - **Browse or Specify Path for Search**: Allows you to search and recover files using the name of the server or Protection Group from any backup available on Cohesity.

If you select..	Then..
Files and Folders	a. Enter characters of the file name, path, or by specifying the wildcard character *. A list of items displays. You can optionally filter the search results by object type, source, object, Protection Group, Storage Domain, files only, or folders only. b. From the list of search results, select the required files or folders to recover. c. By default, the latest snapshot is selected for recovery. To recover from a different snapshot: i. From the selected list, mouse over the snapshot, and then click the **edit** icon. The Edit recovery point page appears. ii. By default, only the snapshots that are indexed are displayed. To display all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. iii. Select a date range and the snapshot point for recovery. By default, the snapshot is recovered from the local cluster. d. Go to step 4.

If you select..	Then..
Browse	1. Enter the full or partial server or Protection Group name. You can by specify the wildcard character *. You can also optionally filter the search results by object type, source, object, Protection Group, Storage Domain. 2. From the list of search results, select the object whose files or folders are to be recovered. 3. By default, the latest snapshot is selected for recovery. To recover from a different snapshot, click the snapshots drop-down in the top-left corner and select the snapshot you need. 4. **Browse on Indexed Data**: Toggle on this setting to browse the indexed data. It helps to speed up browsing of recovery data. By default, it only displays the files and folders that are indexed. Hidden files, folders, paths such as /usr, /var, /sys , /Windows, /ProgramData etc. are excluded from indexing. To display all the available files and folders, including hidden files and folders toggle off the **Browse on Indexed Data** setting. **Note:** • Changing the snapshot after selecting the items (files or folder) removes the selected items from the cart. • Enabling or disabling the **Browse on Indexed Data** option after selecting the items (files or folder) removes the selected items from the cart. • Deleted snapshots may be displayed as valid recovery points for a brief period until they are removed from the search index by a background process. 5. Browse to the file or folder that you want to recover by clicking a folder and subfolders. 6. Click **Save**. 7. After saving the selection, if you want to recover from a different snapshot or change the location from where the snapshot is recovered, perform the following steps: 1. From the selected list, mouse over the snapshot, and click the edit icon. The Edit recovery point page appears. 2. By default, only the snapshots that are indexed are displayed. To display

If you select..	Then..
	all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. 3. Select a date range and the snapshot point for recovery. By default, the snapshot is recovered from the local cluster. 8. Go to step 4.

The Cohesity cluster attempts to index all files and folders to a drive on both Windows and Linux systems. If the Cohesity cluster is unable to find mount point information about files or directories, it indexes and displays these files and directories in the `lvol_N` directory, where `N` is a unique number such as `1`.

On Windows systems, if the Cohesity cluster finds the mount point information about files and directories, it indexes and displays these files and directories with a drive letter such as `C:`.

On Linux systems, how files and directories are indexed and displayed is dependent on the conditions specified in the following table.

Server Type	Volume Type	

Linux Virtual Machine	Simple Volume	The Cohesity cluster detects mount points for entries in the `/etc/fstab` file with the following formats:
		`UUID=ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc /mnt ext4 auto 0`
		`UUID="ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc" /mnt ext4 auto 0`
		If the Cohesity cluster can detect a mount point, it indexes and displays files and directories in the volume with the mount point that was specified in the `/etc/fstab` file. For these example entries, files and directories are indexed with the `/mnt` mount path, such as `/mnt/example/test.txt`.
		If the Cohesity cluster cannot detect a mount point, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

Server Type	Volume Type	

Linux Virtual Machine	LVM Volume	The Cohesity cluster detects mount points for entries in the `/etc/fstab` file with the following formats:
		`UUID=ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc /mnt ext4 auto 0`
		`/dev/mapper/VG1-root /mnt ext4 defaults 1 1`
		`/dev/VG1/root /mnt ext4 defaults 1 1`
		If the Cohesity cluster can detect a mount point, it indexes and displays files and directories in the volume with the mount point specified in the `/etc/fstab` file. For these example entries, files and directories are indexed with the `/mnt` mount path, such as `/mnt/example/test.txt`.
		If the Cohesity cluster cannot detect a mount point, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

4. Once you select the files and folder to recover, select one of the following options:
   - **Next: Recover Options**: If you select this option, then continue with the step 5 to configure the file recovery options.
   - **Download Files**: If you are recovering a single file, this option downloads the file to your browser's download folder. For all other selections, this creates a recovery task. When the task completes, from the Recoveries page, click the task name and then click **Download Files** to download the generated zip file.

     Character replacement explanation for : and \ in file and directory names in zip files

     If the original file or directory name contains a ':' , it is replaced with '_COLON_' in the archive.
     Example:
     - The original name is "a:b" then the archived name is "a_COLON_b"
     - The original name is "a:b:c" then the archived name is "a_COLON_b_COLON_c"

     If the original file or directory name contains a '\', it is replaced with '_BACK_SLASH_' in the archive.
     Example:

- The original name is "x\y" then the archived name is "x_BACK_SLASH_y"
- The original name is "x\y\z" then the archived name is "x_BACK_SLASH_y_BACK_SLASH_z"

5. From the **Recover To**, select **New Server** to recover the files or folders to a new server.
6. **Source**: From the **Source** drop-down menu, select a registered server to which you want to recover the files and folders. You can also register a new source by clicking **Register Source**.
7. **Target**: From the Target (for VM and physical server) or Volume (for NAS) drop-down menu, select a VM or volume to which the files and files are to be recovered.

   > **Note:** For recovering files and folders of a VMware VM, ensure that VMware Tools are installed and running on the target VM. The target list displayed includes only VMs with VMware Tools installed and running.

8. **Recover to**: In the **Recover to** field, change the default location to which the files or folders are recovered. By default, the files and folders are recovered to the /**tmp**/ directory for VMs.

   For NAS, an example path on an alternate location could be /tmp/recover. You can recover encrypted files/folders to their original location only.

   Example for Windows alternate location:

   - D:\cohesity_restore\1.txt
   - D:\cohesity_restore\bar

   User Account Requirements for VM Protection may need to be met to recover files to a Windows VM.

   If recovering to a standalone Hyper-V host or cluster, you must add the guest VM to the reverse lookup zone in the DNS server to complete the recovery successfully.
9. Optional. Edit the default settings of the following **Recovery options**:
   - **Overwrite Existing File/Folder**: By default, this option is enabled to overwrite the existing files and folders. Disable this option to create the files and folders in the specified location. Any duplicate files are skipped.

     Example for a Windows alternate location with **Overwrite Existing File/Folder** enabled and the target already exists:

     Files to be recovered: "C:\foo\1.txt", "C:\foo\test\1.txt", "C:\bar", "C:\foo\bar". Specified alternate location: "C:\restore". At the end of the copy, the target folder looks like this:

- C:\restore\1.txt
- C:\restore\cohesity<taskid>_0\1.txt
- C:\restore\bar
- C:\restore\cohesity<taskid>_1\bar

If **Overwrite Existing File/Folder** is enabled, recovering a file to source when the file is in Fuse may cause the open file to be overwritten. Whether overwriting occurs depends on the application using the file.

- **Preserve File/Folder Attributes**: By default, this option is enabled and the ACLs, permissions, and timestamps are preserved for all files and folders. If you disable this option, then ACLs and permissions are not preserved. If recovering both folders and files, then folders will receive the new timestamps, but files retain their original timestamps. If recovering only files, then files will receive the new timestamps.
- **Continue on Error**: Enable this option if you want to continue the recovery even if one of the objects encounters an error. By default, this option is disabled and the recovery operation will fail if one of the objects encounters an error.
- **Cluster Interface**: By default, the Auto Select option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the Interface Group drop-down.
- **Task Name**: Change the default name of the recovery task.

10. Click **Start Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

BigQuery

Cohesity natively integrates with Google Cloud to provide a simple, fast, and cost-effective solution for backup, recovery, and data management of Google Cloud databases, including BigQuery.

This chapter includes the following topics:

Plan and Prepare for BigQuery Data Protection

To protect BigQuery datasets with the Cohesity cluster, you must register your Google Cloud environment as a source in the Cohesity cluster and perform backup and recovery operations. The following table lists the requirements are grouped into those needed only for source registration and those needed for both backup and restore.

Requirement	When Needed	Details
Service Account	Source registration	Create a dedicated service account in Google Cloud for Cohesity. Assign the required permissions to the service account for BigQuery protection.
Service Account Key	Source registration	Generate a JSON key for the service account to allow authentication from outside Google Cloud.
Project ID	Source registration	The Google Cloud Project ID of the project associated with the service account.
Virtual Private Cloud (VPC)	Source registration	The name of the Virtual Private Cloud network to connect the Cohesity cluster with Google Cloud.
Subnet	Source registration	The name of the subnet within the VPC for network connectivity.
Network Connectivity	Source registration, backup/restore	Ensure the Cohesity cluster can reach `google.apis.com` over firewall port **443**.
Allowlisted Domains	Source registration, backup/restore	Allowlist the following FQDNs for source registration and data protection operations: • `https://accounts.google.com/` • `https://www.googleapis.com/` • `https://storage.googleapis.com` • `https://vpcaccess.googleapis.com/` • `https://cloudfunctions.googleapis.com/` • `https://cloudresourcemanager.googleapis.com/`
Staging Bucket for Backup and Restore	Backup/Restore	You must have a staging bucket in Google Cloud Storage to enable backup and restore operations for BigQuery datasets. • **Auto Create**: Cohesity can automatically create a staging bucket when you configure backup and recovery for BigQuery datasets. • **Manual Create**: You can manually create one or more staging buckets in Google Cloud Storage. Use different staging buckets for protecting different datasets or for recovery operations. Each bucket can be in the same or a different region as the dataset. > **Note:** Using a bucket in a different region than the dataset may incur additional Google Cloud Storage costs.

Required Permissions for BigQuery Data Protection

The following table lists the permissions and privileges that must be included in a custom role. Assign this role to the service account to enable BigQuery data protection.

Type	Permission	Purpose
Google Cloud Storage	`storage.buckets.get`	Retrieve the metadata of a specific Cloud Storage bucket
	`storage.buckets.getIamPolicy`	Read the Identity and Access Management (IAM) policy of a specific Cloud Storage bucket.
	`storage.buckets.setIamPolicy`	Ability to read the Identity and Access Management (IAM) policy (ACLs) for a specific Cloud Storage bucket.
	`storage.objects.create`	Create new objects (files) within a specified Cloud Storage bucket
	`storage.objects.delete`	Ability to delete objects (files) from a Cloud Storage bucket.
	`storage.objects.get`	Ability to read the data and metadata of an object stored in a Cloud Storage bucket.
	`storage.objects.list`	List the objects (files) within a specified Cloud Storage bucket.

Type	Permission	Purpose
BigQuery	`bigquery.config.get`	View project-level BigQuery configuration settings.

Type	Permission	Purpose
	`bigquery.datasets.create`	Create new datasets within a project.

Type	Permission	Purpose
	`bigquery.datasets.delete`	Delete existing datasets.

Type	Permission	Purpose
	bigquery.datasets.get	Retrieve metadata for a specific dataset.
	bigquery.jobs.create	Submit new query or load jobs.
	bigquery.jobs.get	View metadata and status of a specific job.
	bigquery.jobs.list	List jobs submitted by the current user.
	bigquery.jobs.listAll	List all jobs in the project, including those submitted by other users.
	bigquery.jobs.update	Update job metadata (for example, labels).
	bigquery.routines.get	Retrieve metadata for a specific routine (for example, UDF or stored procedure).
	bigquery.routines.list	List routines in a dataset.
	bigquery.tables.create	Create new tables in a dataset.
	bigquery.tables.createSnapshot	Create a snapshot of an existing table for backup or archival.
	bigquery.tables.delete	Delete tables from a dataset.
	bigquery.tables.deleteSnapshot	Delete a snapshot table.
	bigquery.tables.export	Export table data to external storage (for example, Cloud Storage).
	bigquery.tables.get	Retrieve metadata for a specific table.
	bigquery.tables.getData	Read data from a table (used in queries or API calls).
	bigquery.tables.list	List all tables in a dataset.
	bigquery.tables.update	Update table metadata (for example, schema, description, labels).
	bigquery.tables.updateData	Modify table data (for example, insert, update, delete rows).

Create an IAM Custom Role in GCP

To enable BigQuery data protection, you must create an IAM custom role in Google Cloud and assign it to the service account used by the Cohesity cluster.

For detailed instructions, refer to the following topics in the Google Cloud documentation:

- Create a custom IAM role
- Assign a role to a service account

> **Note:** Before you begin creating IAM custom role, ensure that you have created a dedicated service account in Google Cloud for the Cohesity cluster.

Create Staging Bucket on Google Cloud Storage

To enable BigQuery data protection with the Cohesity cluster, you need a staging bucket in Google Cloud Storage. The staging bucket is used to temporarily store exported BigQuery datasets during backup and recovery operations.

You can choose one of the following options when setting up the staging bucket:

- **Auto Create**: Cohesity can automatically create a staging bucket for you as part of the backup configuration workflow in the Cohesity cluster.
- **Create Manually**: Manually create and specify an existing Google Cloud Storage bucket to be used for staging.

> **Note:** Create one or more staging buckets in Google Cloud Storage. You can use different staging buckets for protecting different datasets or for recovery operations. Each bucket can be in the same or a different region as the dataset. Note that using a different region may incur additional Google Cloud Storage costs.

Manually Create a Staging Bucket

To manually create a staging bucket:

1. In the **Google Cloud** console, go to the Cloud Storage **Buckets** page.
2. Click **Create**.
3. On the **Create a bucket** page, provide the following information. After completing each section, click **Continue** to proceed:
    1. **Get started**: Enter a unique name for the staging bucket. Follow naming guidelines to ensure compatibility.

2. **Choose where to store your data**: Select either **Region** or **Multi-region** as the location type.
3. **Choose how to store your data**: Select **Set a default class**, then choose **Standard** as the default storage class.
4. **Choose how to control access to objects**:
    - Enable **Enforce public access prevention**.
    - Select **Uniform as the access control model**.
5. **Choose how to protect object data**:
    - Under **Data protection**, enable **Soft delete policy (For data recovery)** and select **Use default retention duration**.
    - Under **Data encryption**, select **Google-managed encryption key** as the encryption method.
6. Click **Create**.

Considerations for BigQuery Data Protection

Review and understand the following limitations and known issues before you protect BigQuery datasets:

- **User permissions are not restored** — Google Cloud project users and their permissions are excluded from restores. The restored dataset owner will be the GCP service principal configured in the Cohesity cluster when you registered the Google Cloud as a source.
- **Daily export limit** — Google Cloud imposes a maximum data export limit of 50 TB per project, per day.
- **Tags are not restored** — Dataset and table tags are not included in backups or restores.
- **Unsupported data types** — A record with the data type: DATETIME in the tables is not supported for backup.
- **Linked datasets** — Datasets linked from other projects are not discovered, backed up, or restored.
- **External datasets** — Datasets that reference external data sources outside BigQuery (for example, data in Cloud Storage or Spanner) are not discovered, backed up, or restored.
- **Schema requirements** — Tables without a defined schema or without any columns cannot be backed up.
- **Access controls not supported** — Tables that use column-level access control or row-level security cannot be backed up.
- **Backup type limitation** — Only full backups are supported; incremental backups are not available for BigQuery datasets.

Register and Manage Google Cloud Source

To protect your BigQuery datasets, you need to register your Google Cloud environment as a source on the Cohesity cluster. After registering your Google Cloud environment as a source, you can:

- Update the Google Cloud source configuration.
- Refresh the source details.
- Unregister the Google Cloud source from the Cohesity cluster.

Register Google Cloud as a Source

Before registering Google Cloud as a source, make sure you have completed all prerequisite tasks and reviewed the considerations.

To register Google Cloud source:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Register** at the top-right of the page and then select **Cloud Platforms** > **Google Cloud Platform**.
3. In the **Register GCP Source** dialog box, perform the following:
    1. Configure the following:

Field	Description
GCP Project ID	The Google Cloud Project ID of the project associated with the service account.
Virtual Private Cloud (VPC)	The name of the VPC network that connects the Cohesity cluster to Google Cloud.
Subnet	The subnet within the VPC for network connectivity.

    2. Under the **Authentication Method** section, choose any one of the following:
        - **Upload JSON Key File** - Upload the service account JSON key file. You can either drag and drop the file or click to upload the JSON file.
        - **Enter Email and Private Key** - Manually enter the service account email address and private key associated with the service account.
    3. Click **Register**.

The Cohesity cluster authenticates with Google Cloud using the provided service account credentials (JSON key or email and private key). Once authenticated, it automatically discovers all projects that the service account can access, as well as all supported workloads such as BigQuery datasets within those projects.

The discovered workloads appear under **Data Protection** > **Sources**, and when you open the registered Google Cloud source, each workload type is displayed on its own tab.

Update the Google Cloud Source Configuration

After registering Google Cloud as a source in the Cohesity cluster, you may have updated your environment in one or more of the following ways:

- Changed the project associated with the service account
- Updated VPC or subnet details
- Generated a new JSON key file for the service account

You can update the Google Cloud registration details provided during the source registration with the latest Google Cloud configuration details.

To edit the Google Cloud source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Google Cloud source and select **Edit**.
3. In the **Edit GCP Source** page, update the required configurations.
4. Click **Update**.

Refresh Google Cloud Source

You can refresh the Google Cloud source configuration and fetch the latest changes on your Google Cloud environment.

To refresh the Google Cloud source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Google Cloud source and select **Refresh**.

Unregister Google Cloud Source

If you plan to stop taking the backup of your Google Cloud source, you can unregister the Google Cloud source from the Cohesity Cluster.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the Google Cloud source.

To unregister the Google Cloud source:

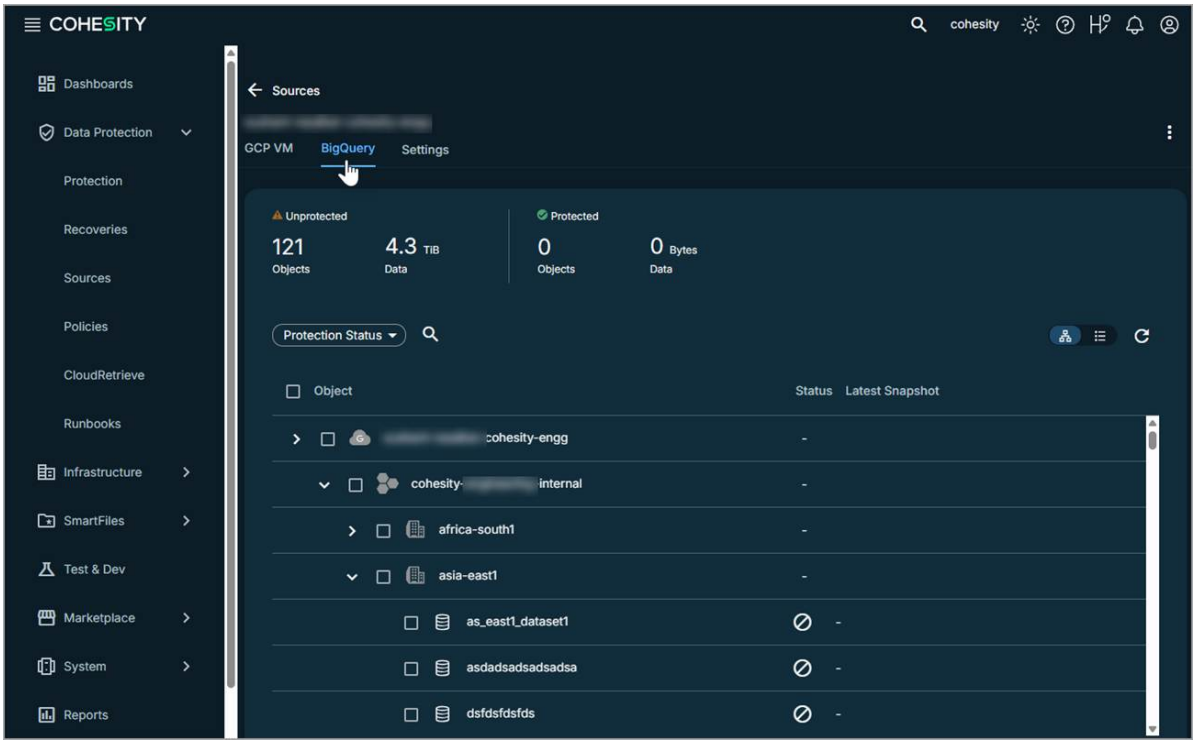
1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Google Cloud source and select **Unregister**.

Backup BigQuery Datasets

After registering your Google Cloud source in the Cohesity cluster, it uses the provided service account credentials (JSON key or email and private key) to authenticate with Google Cloud.

Once authenticated, it automatically discovers all projects that the service account can access, as well as all supported workloads such as BigQuery datasets within those projects. The discovered workloads appear under **Data Protection** > **Sources**. When you open the registered Google Cloud source, each workload type is displayed on its own tab. Select the **BigQuery** tab to view all the discovered datasets.

The **BigQuery** tab displays the entity hierarchy for the BigQuery environment, allowing you to navigate from the project level down to individual datasets.

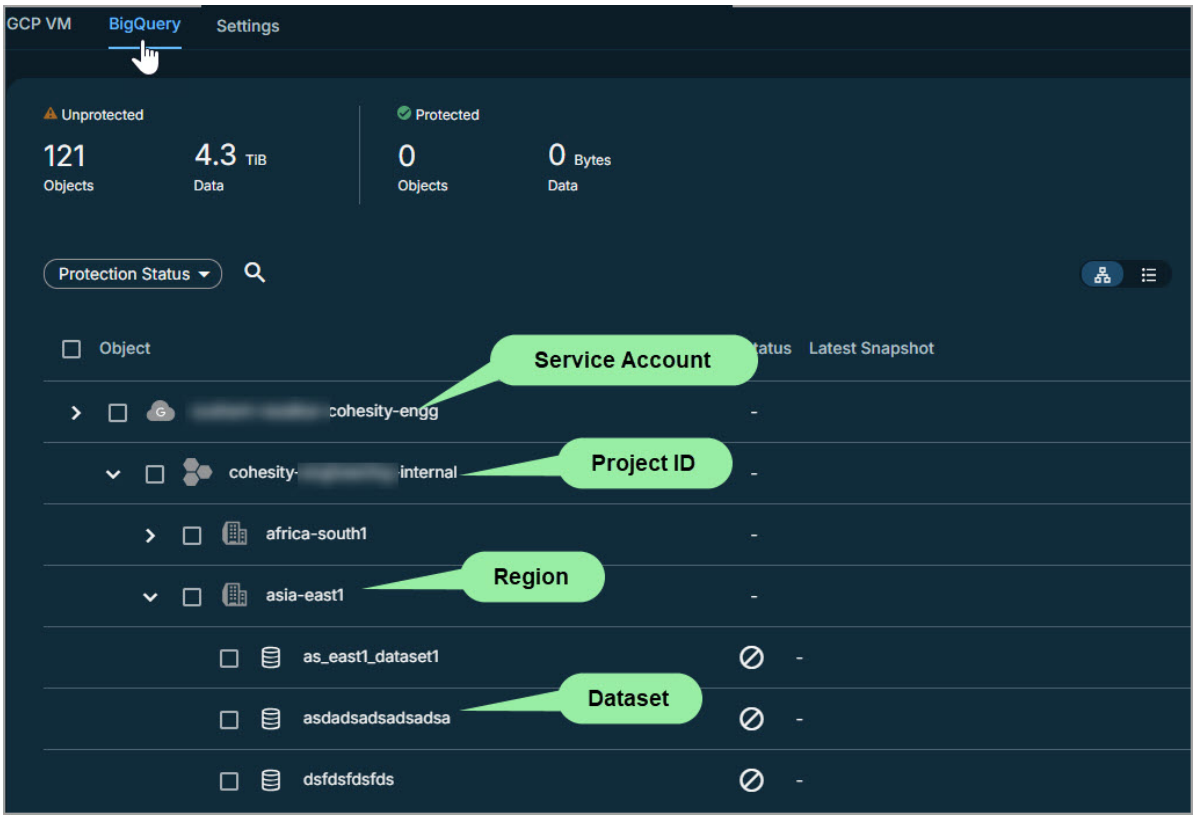


BigQuery Entity Hierarchy

The BigQuery entity hierarchy in the Cohesity cluster follows this structure:

Structure	Description
Service Account	The dedicated service account in Google Cloud assigned to Cohesity cluster for BigQuery protection.

Structure	Description
Project ID	The Google Cloud Project ID of the project (s) accessible with the service account.
Region	The Google Cloud region where the datasets reside.
Dataset	The dataset that can be selected for backup and recovery.



Backup Scope by BigQuery Hierarchy

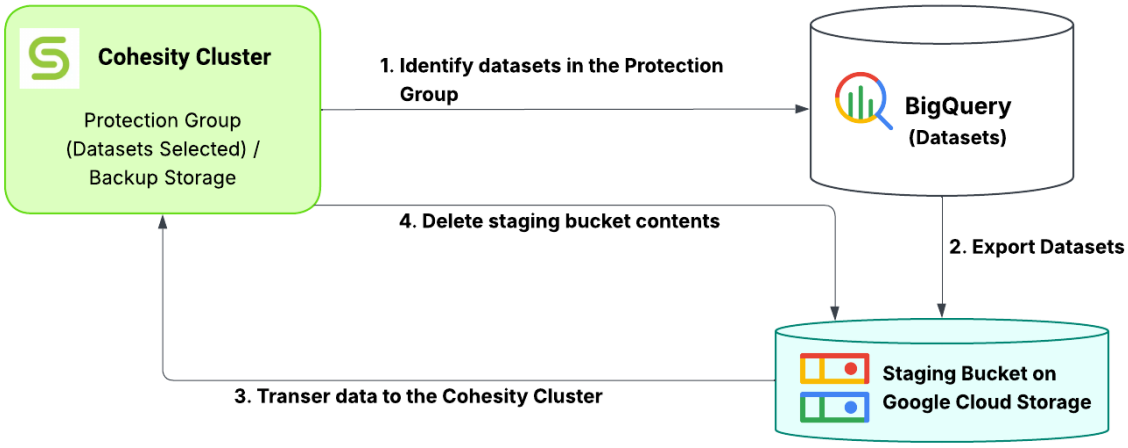
Cohesity cluster allows you to back up BigQuery datasets at different levels of the hierarchy. You can choose to back up:

- **Individual dataset** – Back up a single dataset.
- **Multiple datasets within a region** – Back up selected datasets from the same region.
- **Region level** – Back up all datasets within a specific region.

- **Multiple datasets across regions** – Back up selected datasets from different regions.
- **Project level** – Back up all datasets in all regions within the specified Project ID.

BigQuery Backup Process

When you run a protection job in the Cohesity cluster to back up BigQuery datasets, the datasets specified in the Protection Group are first exported from BigQuery to a staging bucket in Google Cloud Storage. The Cohesity cluster then copies the data from the staging bucket to the cluster. After the backup completes successfully, the contents of the staging bucket are deleted to free up storage.



Supported Backup Types

Cohesity supports only full backups for BigQuery datasets. Incremental backups are not supported.

Protect BigQuery

In the Cohesity cluster, Google Cloud BigQuery datasets are protected using a Protection Group and a Protection Policy. The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select standard or custom policy to use when creating a Protection Group. For more information, see Manage Protection Policy.

> **Note:** Cohesity supports only full backups for BigQuery datasets. Incremental backups are not supported.

Prerequisites

Before you protect BigQuery datasets, ensure that a staging bucket is available in Google Cloud Storage. You can either use an existing bucket or allow Cohesity to automatically create one during the backup configuration.

- If you choose to **Auto Create** the staging bucket: Cohesity automatically creates a staging bucket in the same region as your dataset(s) when you start a backup operation.
- If you choose to **specify an existing bucket**: You can specify an existing bucket located in the same region as the datasets being protected. Using a bucket in a different region is supported but may incur additional Google Cloud Storage charges.

> **Note:** After each protection job run, Cohesity deletes only the temporary data stored in the staging bucket during backup operations. The staging bucket itself is retained and reused for future backup operations to minimize storage costs and avoid cross-region charges.

Protect BigQuery Datasets

To protect BigQuery datasets:

1. Navigate to **Data Protection** > **Protection**. Click **Protect** on the top-right of the page and then select **Google Cloud** > **BigQuery**.
2. From the **Source** drop-down list, select a registered Google Cloud source, or click **Register Source** to add a new one.
3. In the **Objects** section, choose datasets using one of the following views:
   - **Hierarchy View (default)**: Browse objects by backup scope. You can enable **Auto Protect** at the source, project, or region level.
   - **List View**: Select datasets from a flat, searchable list.
4. In the **Protection Name** field, enter a name from the Protection Group.
5. In the **Staging Bucket** section, choose one of the following options:
   - **Auto Create**: Cohesity automatically creates a temporary staging bucket in the same region as your dataset(s). The bucket follows the naming format `cohe-<project-id >-<region-name>`.

     Where:
     - `project-id` is the Google Cloud project ID.
     - `region-name` is the Google Cloud region where the datasets reside.

- **Specify Bucket to Use**: Enter the name of an existing staging bucket in Google Cloud Storage (GCS) that you created for backups.

After each protection job run, Cohesity deletes only the temporary data stored in the staging bucket during backup operations. The staging bucket itself is retained and reused for future backup operations to minimize storage costs and avoid cross-region charges.

6. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, see Manage Protection Policy.
7. In the **Settings** section, configure the following:

Settings	Description
Storage Domain	Select the appropriate Storage Domain. For more information, see Manage Storage Domains.
Start Time	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. > **Note:** This option is not applicable for BigQuery data protection. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

8. In the **Additional Settings** section, configure the following:

Additional Settings	Description
Pause Future Runs	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
End Date	Optional. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup Target HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup Target SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Alerts	Optional. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.

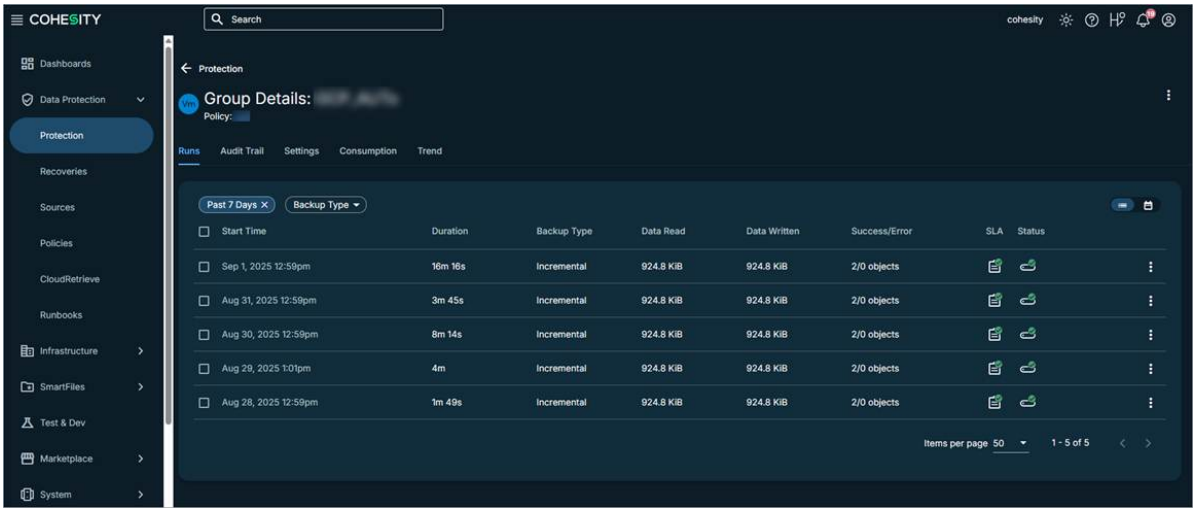
Additional Settings	Description
Priority	Select a priority for the Protection Group execution. The Cohesity cluster supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs
Description	Optional. Enter a brief description about the Protection Group.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.



Manage BigQuery Backup Configuration

In the Cohesity cluster, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Object(s) to the Protection Group

You can add new object(s) to the existing Protection Group for backup. The newly added object is backed up from the next protection run.

To add object(s) to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for BigQuery.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ in the **Objects** section.
5. In the **Objects** section, Click the plus icon (**+**) to enter multiple objects that you plan to back up. click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for BigQuery.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for BigQuery.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a protection run:

1. Navigate to **Data Protection** > **Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all associated local and archived snapshots. Replicated snapshots must be deleted from the remote cluster. Snapshots under DataLock cannot be deleted.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for BigQuery.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
   - Keep the **Delete Snapshots** toggle disabled to delete the Protection Group only.
   - Enable the **Delete Snapshots** toggle to delete the Protection Group and all associated snapshots.
5. Type **YES** to confirm that you want to delete the Protection Group.
6. Click **Delete Group**.

Recover BigQuery Datasets

You can restore BigQuery datasets either to their original GCP source or to a different GCP source and region.

Prerequisites

Before you restore BigQuery datasets, ensure that a staging bucket is available in Google Cloud Storage. You can either use an existing bucket or allow Cohesity to automatically create one during the restore process.

- If you choose to **Auto Create** the staging bucket: Cohesity automatically creates a staging bucket in the same region as your dataset(s) when you start the recovery.
- If you choose to **specify an existing bucket**: You can specify an existing bucket located in the same region as the recovery target. Using a bucket in a different region is supported but may incur additional Google Cloud Storage charges.

> **Note:** After each recovery job run, Cohesity deletes only the temporary data stored in the staging bucket. The staging bucket itself is retained and reused for future recovery operations to minimize storage costs and avoid cross-region charges.

Recover BigQuery Datasets

To recover BigQuery datasets:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **Google Cloud** > **BigQuery**.
3. Search for the dataset by entering characters of the dataset name, or by specifying the wildcard character *.
4. From the list of search results, select the database to recover.
    - By default, the latest snapshot of the database is selected for recovery.
    - To recover from a different snapshot, hover over the snapshot and click the Edit icon. The **Edit Recovery Point for <database_name>** page appears.
    - By default, snapshots are displayed in **List** mode. You can switch to **Timeline** mode by clicking the **Timeline** tab in the top-right corner of the page.

      To select a snapshot from the **List** mode:

        a. On the **List** tab, snapshots available in the past month are displayed by default.
        b. To view snapshots from a different range, select a date range from the **Date** drop-down list.
        c. Select the snapshot(s) to recover.
        d. By default, the snapshot is recovered from the local Cohesity cluster.
        e. Click **Select Recovery Point** and then go to step 5.

      To select a snapshot from the **Timeline** mode:

        a. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar.
        b. Select the snapshot to be recovered by clicking the corresponding blue dot.
        c. By default, the snapshot is recovered from the local Cohesity cluster.
        d. Click **Select Recovery Point** and then go to step 5.
5. Click **Next: Recover Options**.
6. In the **Recover To** section, select any one of the following options based on your requirements:

Option	Description
Original Location	Restore the dataset to the same project from which it was backed up. > **Note:** Restoring to the original location replaces any existing dataset with the same name.
New Location	Restore the dataset to an alternate location in a different GCP source. Select a registered GCP source, project, and region. To overwrite an existing dataset with the same name, enable **Overwrite existing dataset(s)** and type **YES**. > **Note:** Restoring to a new location also replaces any existing dataset with the same name in the selected region.

7. In **Restore Staging Bucket** section, choose one of the following options:
   - **Auto Create**: Cohesity automatically creates a temporary staging bucket in the same region as your dataset(s) for the recovery operation. The bucket follows the naming format: `cohe-<project-id>-<region-name>`.

     Where:
     - `project-id` is the Google Cloud project ID.
     - `region-name` is the Google Cloud region where the datasets reside.
   - **Specify Bucket to Use**: Enter the name of an existing staging bucket in Google Cloud Storage (GCS) that you created for recovery.

   Cohesity deletes only the temporary data stored in the staging bucket during each recovery operation. The bucket itself is retained and reused for future recovery operations to minimize storage costs and avoid cross-region charges.
8. In the **Recovery Options** section, configure the following options:

Options	Description
Rename	Enter a new name for the dataset if you want to rename it after recovery.
Task Name	Update the default name of the recovery task.

9. Click **Recover**.

Spanner

Cohesity Platform natively integrates with Google Cloud to provide a simple, fast, and cost-effective solution for backup, recovery, and data management of Google Cloud databases, including Spanner.

> **Important:** The backup and recovery of Google Cloud Spanner is supported only on DataProtect for cloud in GCP (formerly known as GCP NGCE cluster). This is a Controlled Availability feature, contact your Cohesity account team to enable the feature.

This chapter includes the following topics:

Plan and Prepare for Spanner Data Protection

To protect Spanner databases with Cohesity, you must register your Google Cloud environment as a source in the Cohesity cluster and perform backup and recovery operations. The following table lists the requirements and are grouped into those needed only for source registration and those needed for both backup and restore.

Requirement	When Needed	Details
Service Account	Source registration	Create a dedicated service account in Google Cloud for Cohesity. Assign the required roles to the service account for Spanner protection.
Service Account Key	Source registration	Generate a JSON key for the service account to allow authentication from outside Google Cloud.
Project ID	Source registration	The Google Cloud Project ID of the project associated with the service account.
Virtual Private Cloud (VPC)	Source registration	The name of the Virtual Private Cloud network to connect the Cohesity cluster with Google Cloud.
Subnet	Source registration	The name of the subnet within the VPC for network connectivity.
Network Connectivity	Source registration, backup/restore	Ensure that the Cohesity cluster can reach `google.apis.com` over firewall port **443**.

Requirement	When Needed	Details
Allowlisted Domains	Source registration, backup/restore	Allowlist the following FQDNs for source registration and data protection operations: • `https://accounts.google.com/` • `https://www.googleapis.com/` • `https://storage.googleapis.com` • `https://vpcaccess.googleapis.com/` • `https://cloudfunctions.googleapis.com/` • `https://cloudresourcemanager.googleapis.com/` • `https://spanner.googleapis.com` • `https://dataflow.googleapis.com` • `https://oauth2.googleapis.com`
Staging Bucket for Backup and Restore	Backup/Restore	You must have a staging bucket in Google Cloud Storage to enable backup and restore operations for Spanner databases. • **Auto Create**: Cohesity can automatically create a staging bucket when you configure protection for a Spanner database. • **Manual Create**: You can manually create one or more staging buckets in Google Cloud Storage. Use different staging buckets for protecting different databases or for recovery operations. Each bucket can be in the same or a different region as the database. > **Note:** Using a bucket in a different region than the database may incur additional Google Cloud Storage costs.

Required Roles for Spanner Data Protection

The following table lists the roles that must be assigned to the service account to enable Spanner data protection.

Role Name	Purpose/Scope
Cloud Spanner Admin	Manage Spanner resources

Role Name	Purpose/Scope
Dataflow Admin	Manage Dataflow jobs for export/import
Storage Admin	Access and manage GCP buckets
Log Viewer	View logs for troubleshooting
DataBoost Role	Use DataBoost for performance
Cloud Spanner Reader	Read database data
Cloud Spanner Database Admin	Administer database operations

> **Note:**
> - Assign these roles to the service account at the appropriate scope (project, database, or database) to ensure successful backup and restore operations.
> - For DataBoost-enabled exports, the additional DataBoost role is required.

Create Staging Bucket on Google Cloud Storage

To enable Spanner data protection with the Cohesity cluster, you need a staging bucket in Google Cloud Storage. The staging bucket is used to temporarily store exported Spanner data during backup and recovery operations.

You can choose one of the following options when setting up the staging bucket:

- **Auto Create**: Cohesity can automatically create a staging bucket for you as part of the backup configuration workflow in the Cohesity cluster.
- **Create Manually**: Manually create and specify an existing Google Cloud Storage bucket to be used for staging.

> **Note:**
> - You can create one or more staging buckets in Google Cloud Storage. Different staging buckets can be used for protecting different databases or for recovery operations.
> - A staging bucket can be in the same or a different region as the database. However, using a bucket in a different region may incur additional Google Cloud Storage costs.
> - By default, backup and restore operations fail if the staging bucket is not created in the default leader region of the database configuration. Contact Cohesity Support if you want to enable cross-region transfers.

Manually Create a Staging Bucket

To manually create a staging bucket:

1. In the **Google Cloud** console, go to the Cloud Storage **Buckets** page.
2. Click **Create**.
3. On the **Create a bucket** page, provide the following information. After completing each section, click **Continue** to proceed:
    1. **Get started**: Enter a unique name for the staging bucket. Follow naming guidelines to ensure compatibility.
    2. **Choose where to store your data**: Select **Region** as the location type.

        > **Note:** Do not select Multi-region. Multi-regional buckets are not supported for Spanner backup or recovery operations. If you need to use an existing multi-regional bucket, contact Cohesity Support for guidance.

    3. **Choose how to store your data**: Select **Set a default class**, then choose **Standard** as the default storage class.
    4. **Choose how to control access to objects**:
        - Enable **Enforce public access prevention**.
        - Select **Uniform as the access control model**.
    5. **Choose how to protect object data**:
        - Under **Data protection**, enable **Soft delete policy (For data recovery)** and select **Use default retention duration**.

> **Note:** To avoid unnecessary storage charges, disable the Soft delete policy on staging buckets used for backup and restore operations. Cohesity automatically deletes all staged data after each operation. If soft delete is enabled, this temporary data will be retained for the full soft-delete retention period resulting in additional costs.

- Under **Data encryption**, select **Google-managed encryption key** as the encryption method.

6. Click **Create**.

Considerations for Spanner Data Protection

Review and understand the following limitations and known issues before you protect Spanner databases with Cohesity .

- **Full Backups Only**: Only full backups are supported. Incremental backups and point-in-time recovery (PITR) are not supported.
- **Database-Level Operations**: Backups and recovery operations are performed at the database level. Table-level operations are not supported.
- **Data Format**: Backup data is exported in Avro format. Some Spanner-specific data types or extensions may require adjustments before being restored or imported into other SQL databases.
- **Edition Compatibility**: Backups and restores are supported across all Spanner editions (Standard, Enterprise, and Enterprise+). Cross-edition recovery is allowed but may be limited to features or datatypes common to both editions. For best results, restore to the same edition whenever possible.
- **Database-Level Recovery**: Recovery of complete Spanner instances is not supported. You can restore only individual databases.
- **Overwrite Behavior**: Restoring over an existing database with same name in an instance requires deletion of existing conflicting database. If drop protection is enabled , deletion will fail, and manual intervention is required.
- **Performance Optimization**: Improve backup performance by increasing the number of Dataflow workers and enabling Boost. For large databases, horizontal scaling (adding more workers) is typically more effective than vertical scaling.

Register and Manage Google Cloud Source

To protect your Spanner databases, you need to register your Google Cloud environment as a source on the Cohesity cluster. After registering your Google Cloud environment as a source, you can:

- Update the Google Cloud source configuration.
- Refresh the source details.
- Unregister the Google Cloud source from the Cohesity cluster.

Register Google Cloud as a Source

Before registering Google Cloud as a source, make sure you have completed all prerequisite tasks and reviewed the considerations.

To register Google Cloud source:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Register** at the top-right of the page and then select **Cloud Platforms** > **Google Cloud Platform**.
3. In the **Register GCP Source** dialog box, perform the following:
    1. Configure the following:

Field	Description
GCP Project ID	The Google Cloud Project ID of the project associated with the service account.
Virtual Private Cloud (VPC)	The name of the VPC network that connects the Cohesity cluster to Google Cloud.
Subnet	The subnet within the VPC for network connectivity.

    2. Under the **Authentication Method** section, choose any one of the following:
        - **Upload JSON Key File** - Upload the service account JSON key file. You can either drag and drop the file or click to upload the JSON file.
        - **Enter Email and Private Key** - Manually enter the service account email address and private key associated with the service account.
    3. Click **Register**.

The Cohesity cluster authenticates with Google Cloud using the provided service account credentials (JSON key or email and private key). Once authenticated, it automatically discovers all projects that the service account can access, as well as all supported workloads such as Spanner databases within those projects.

The discovered workloads appear under **Data Protection** > **Sources**, and when you open the registered Google Cloud source, each workload type is displayed on its own tab.

Update the Google Cloud Source Configuration

After registering Google Cloud as a source in the Cohesity cluster, you may have updated your environment in one or more of the following ways:

- Changed the project associated with the service account
- Updated VPC or subnet details
- Generated a new JSON key file for the service account

You can update the Google Cloud registration details provided during the source registration with the latest Google Cloud configuration details.

To edit the Google Cloud source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Google Cloud source and select **Edit**.
3. In the **Edit GCP Source** page, update the required configurations.
4. Click **Update**.

Refresh Google Cloud Source

You can refresh the Google Cloud source configuration and fetch the latest changes on your Google Cloud environment.

To refresh the Google Cloud source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Google Cloud source and select **Refresh**.

Unregister Google Cloud Source

If you plan to stop taking the backup of your Google Cloud source, you can unregister the Google Cloud source from the Cohesity cluster.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the Google Cloud source.

To unregister the Google Cloud source:

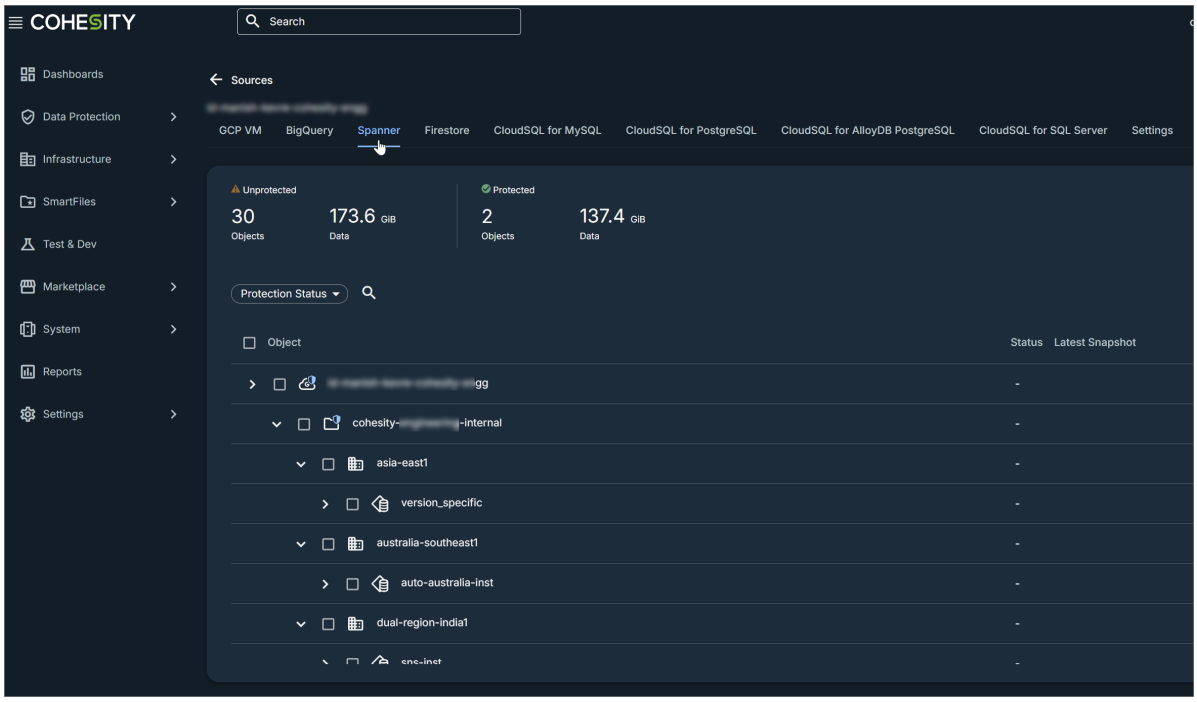
1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Google Cloud source and select **Unregister**.

Backup Spanner Databases

After registering your Google Cloud source in the Cohesity cluster, it uses the provided service account credentials (JSON key or email and private key) to authenticate with Google Cloud.

Once authenticated, it automatically discovers all projects that the service account can access, as well as all supported workloads such as Spanner databases within those projects. The discovered workloads appear under **Data Protection** > **Sources**. When you open the registered Google Cloud source, each workload type is displayed on its own tab. Select the **Spanner** tab to view all the discovered databases.

The **Spanner** tab displays the entity hierarchy for the Spanner environment, allowing you to navigate from the project level down to individual databases.

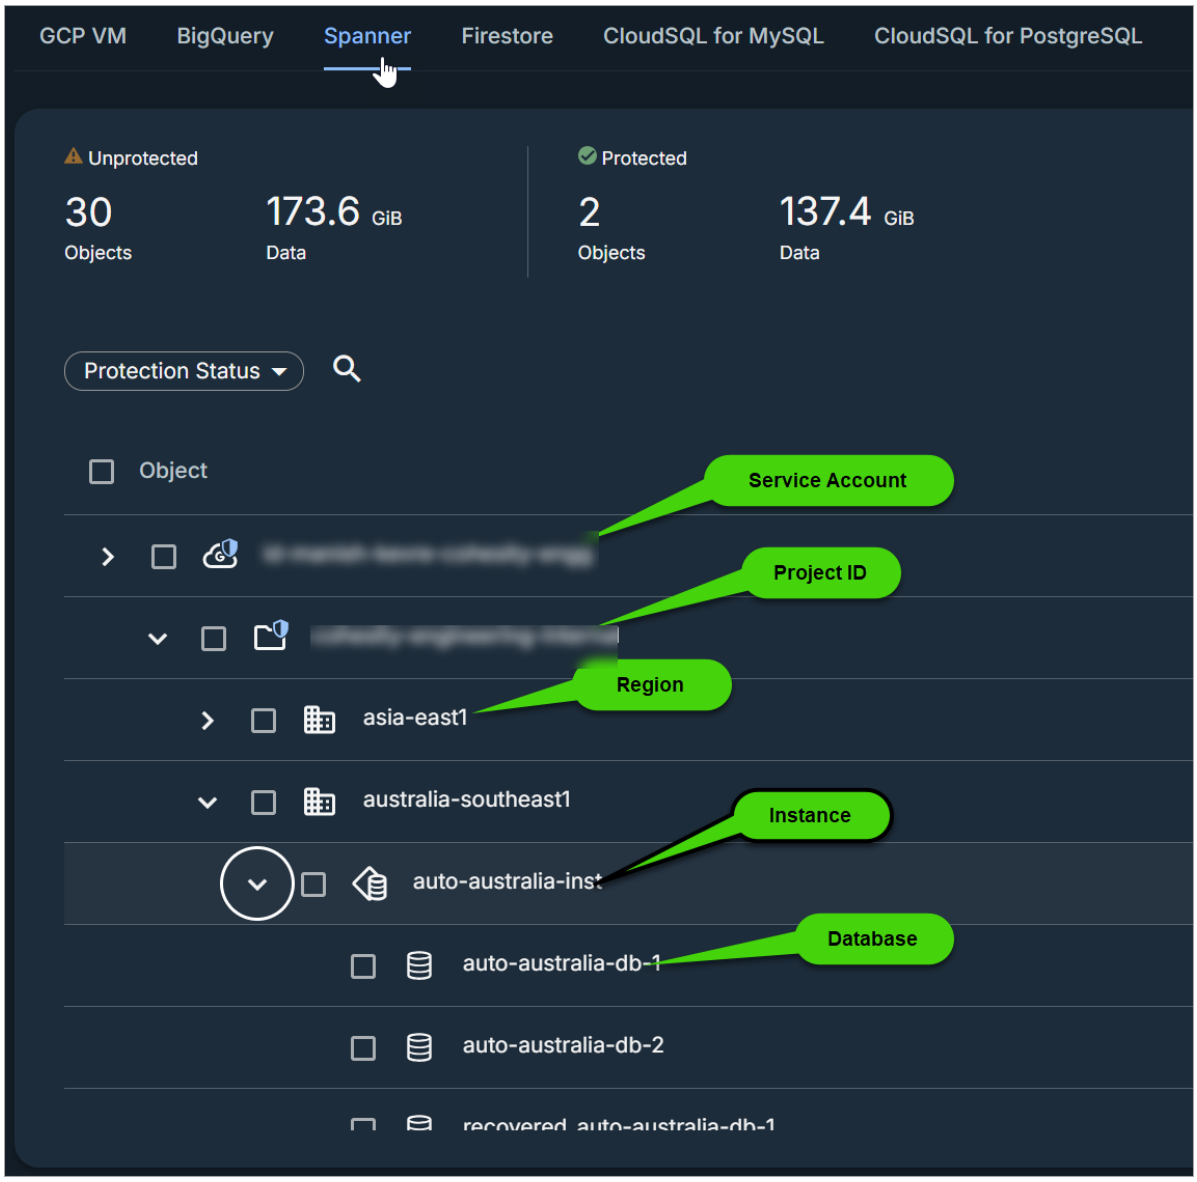


Spanner Entity Hierarchy

The following hierarchy describes how Spanner entities are organized and displayed in the Cohesity cluster:

Structure	Description
Service Account	The Google Cloud service account configured for Cohesity to perform Spanner backup and recovery operations.
Project ID	The Google Cloud Project ID that the service account has permissions to access.

Structure	Description
Region	The Google Cloud region or multi-region configuration where the Spanner instance is hosted.
Instance	The Spanner instance available for backup and recovery.
Dataset	The individual Spanner database that can be backed up or restored. Cohesity supports both Spanner-supported dialects: Google Standard SQL and PostgreSQL.



Backup Scope by Spanner Hierarchy

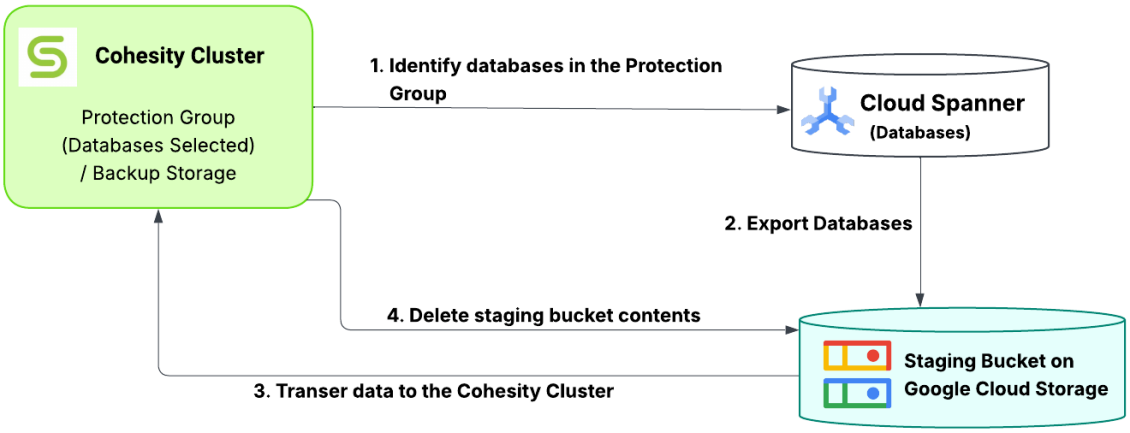
The Cohesity cluster allows you to back up Spanner databases at different levels within the hierarchy. You can choose to back up:

- **Individual Database**: Back up a single selected database.
- **Multiple Databases within an Instance**: Back up selected databases within the same Spanner instance.
- **Multiple databases across instances**: Back up selected databases from different instances, as long as all instances are located in the same region or in the **default leader region**.
- **Instance Level**: Back up all databases within the selected Spanner instance.

Spanner Backup Process

When you run a protection job in the Cohesity cluster, one or more selected Spanner databases are exported to a Google Cloud Storage staging bucket. The staging bucket temporarily stores the exported data before it is ingested into the Cohesity cluster. The Cohesity cluster verifies that the selected bucket meets configuration requirements and ensures that the backup runs efficiently.

During the process, the Spanner databases are securely exported to the staging bucket as full backups. After the export completes, the Cohesity cluster automatically copies the data from the staging bucket to the cluster for retention. Once ingestion is successful, the Cohesity cluster applies the defined retention policies. The contents of the staging bucket are then automatically deleted to free up storage and reduce costs.



Supported Backup Types

Cohesity supports only full backups for Spanner databases. Incremental backups are not supported.

Protect Spanner

In the Cohesity cluster, Spanner database are protected using a Protection Group and a Protection Policy. The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select standard or custom policy to use when creating a Protection Group. For more information, see Manage Protection Policy.

> **Note:** Cohesity supports only full backups for Spanner databases. Incremental backups are not supported.

Prerequisites

Before you protect Spanner databases, ensure that a staging bucket exists in Google Cloud Storage (GCS) for storing exported data during backups. You can:

- **Auto Create**: Allow Cohesity to automatically create a temporary staging bucket during protection configuration.
  - The staging bucket is created in the same region as the database(s).
  - For multi-region deployments, the bucket is created in the **default leader region**.
- **Manually Create**: Create one or more staging buckets in GCS. You can use different buckets for protecting different databases or for recovery operations.

> **Note:**
> - Staging buckets created in a different region than the Spanner database will cause backup and restore operations to fail by default.
> - Cohesity supports using a staging bucket only in the default leader region of the database.
> - If you need to use a staging bucket in a different region, contact ontact Cohesity Support to enable cross-region transfers.
>
> For more information, refer to Dual-region configurations or Multi-region configurations sections on Google Cloud Spanner documentation.

Protect Spanner Databases

To protect Spanner databases:

1. Navigate to **Data Protection** > **Protection**. Click **Protect** on the top-right of the page and then select **Google Cloud** > **Spanner**.
2. From the **Source** drop-down list, select a registered Google Cloud source, or click **Register Source** to add a new one.
3. In the **Objects** section, choose databases using one of the following views:
   - **Hierarchy View (default)**: Browse objects by backup scope. You can enable **Auto Protect** at the source, project , region, and instance level.
   - **List View**: Select databases from a flat, searchable list.
4. In the **Protection Name** field, enter a name from the Protection Group.
5. In the **Staging Bucket** section, choose one of the following options:

- **Auto Create**: Cohesity automatically creates a temporary staging bucket in the same region as your database(s). For multi-region deployments, the bucket is created in the default leader region. The bucket follows the naming format `cohe-<project-id >-<region-name>`.

  Where:

  - `project-id` is the Google Cloud project ID.
  - `region-name` is the Google Cloud region where the database **default leader region** resides.
- **Specify Bucket to Use**: Enter the name of an existing staging bucket in Google Cloud Storage (GCS) that you created for backups.

6. In the Network Configurations section, provide the following Google Cloud VPC details:
   - **VPC Network**: Enter the name of the Google Cloud VPC network to be used for backup operations. Ensure that the network has connectivity to both the Spanner instance and the Google Cloud Storage staging bucket. You can also specify default if the default VPC is configured in your project.
   - **VPC Subnet**: Specify the subnet within the selected VPC network that must be used for all backup activities. Subnets in Google Cloud are region-specific, so ensure that the subnet you select corresponds to the region of your Spanner instance. If your project uses default networking, you can also specify default as the subnet.
7. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, see Manage Protection Policy.
8. In the **Settings** section, configure the following:

Settings	Description
Storage Domain	Select the appropriate Storage Domain. For more information, see Manage Storage Domains.
Start Time	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.

Settings	Description
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. > **Note:** This option is not applicable for Spanner data protection. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

9. In the **Additional Settings** section, configure the following:

Additional Settings	Description
Max Dataflow Workers	Specify the maximum number of Dataflow workers that can be created during backup operations. This value sets the upper limit for autoscaling. Dataflow increases the number of workers based on workload, but it will not create more workers than the limit you set. A higher limit can improve performance but may increase cost and requires sufficient GCP quotas. **Default**: 10 **Recommendations**: • Keep 10 for most environments. • Increase for large databases or tighter backup windows. • Decrease if you need to limit resource usage or have quota constraints.
Data Boost	Enabled by default, Data Boost is a fully managed, serverless service provided by Google cloud that provides independent compute resources. For more information, see Data Boost on Google Cloud Documentation.
Pause Future Runs	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.

Additional Settings	Description
End Date	Optional. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup Target HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup Target SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Alerts	Optional. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.

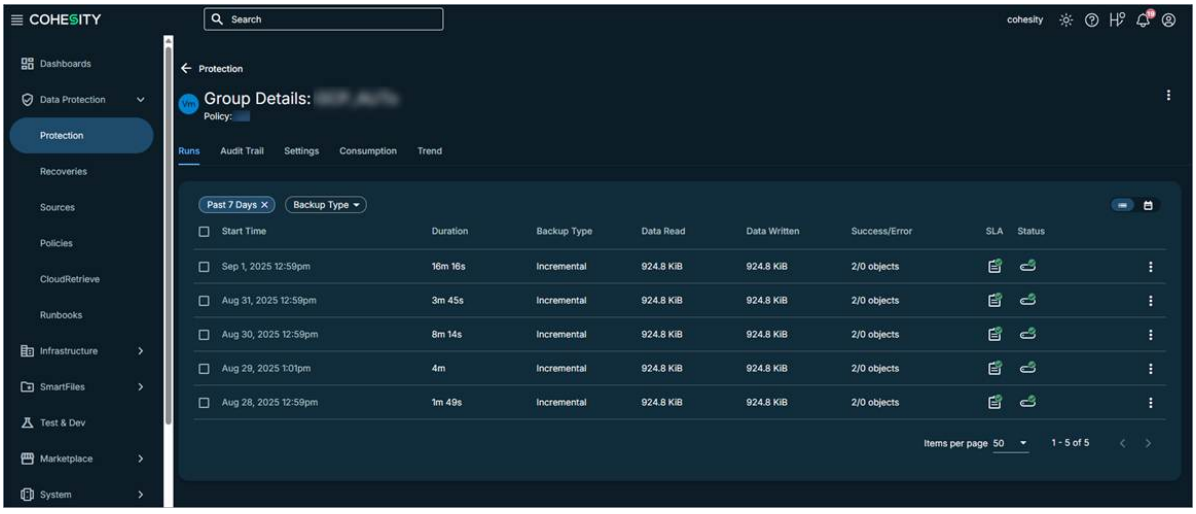
Additional Settings	Description
Priority	Select a priority for the Protection Group execution. The Cohesity cluster supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs
Description	Optional. Enter a brief description about the Protection Group.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.



Manage Spanner Backup Configuration

In the Cohesity cluster, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Object(s) to the Protection Group

You can add new object(s) to the existing Protection Group for backup. The newly added object is backed up from the next protection run.

To add object(s) to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Spanner .
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ in the **Objects** section.
5. In the **Objects** section, Click the plus icon (**+**) to enter multiple objects that you plan to back up. click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Spanner .
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Spanner .
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a protection run:

1. Navigate to **Data Protection** > **Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all associated local and archived snapshots. Replicated snapshots must be deleted from the remote cluster. Snapshots under DataLock cannot be deleted.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Spanner .
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
   - Keep the **Delete Snapshots** toggle disabled to delete the Protection Group only.
   - Enable the **Delete Snapshots** toggle to delete the Protection Group and all associated snapshots.
5. Type **YES** to confirm that you want to delete the Protection Group.
6. Click **Delete Group**.

Recover Spanner Databases

You can recover Spanner databases either to their original Google Cloud source or to a different source, instance and region.

Spanner Recovery Process

When a recovery job runs on the Cohesity cluster, the selected Spanner database backups are exported to a Google Cloud Storage staging bucket. The Cohesity cluster then recreates the database in the target environment and transfers the exported data to it.

After the data transfer and database creation are complete, the Cohesity cluster triggers a Spanner import job. Google Cloud Spanner automatically ingests the database data from the staging bucket into the Spanner deployment.

Once the import is successful, the staged backup data is automatically deleted from the bucket to free up storage and minimize costs.

> **Note:**
> Under normal conditions, staged backup data in the staging bucket is automatically cleaned up after the import completes. However, in certain failure scenarios, the cleanup may not occur. In such cases, you should manually verify and delete any remaining staged data.
>
> Cleanup may fail in scenarios such as:
>
> - **Import job submission failure during recovery**. Staged data may remain if the import job could not be triggered.
> - **Duplicate subtask–related errors during backup or restore**. These errors may interrupt cleanup, leaving temporary data in the staging bucket.

Prerequisites

Before you recover Spanner databases, ensure that a staging bucket is available in Google Cloud Storage. You can either use an existing bucket or allow Cohesity to automatically create one during the restore process.

- If you choose to **Auto Create** the staging bucket: Cohesity automatically creates a staging bucket in the same region as your database(s) when you start the recovery. For multi-region deployments, the bucket is created in the **default leader region**.
- If you choose to **specify an existing bucket**: You can specify an existing bucket located in the same region as the recovery target. Using a staging bucket in a different region than the target instance's default leader region is not supported by default. Contact Cohesity Support if cross-region usage is required.

> **Note:** After each recovery job run, Cohesity deletes only the temporary data stored in the staging bucket. The staging bucket itself is retained and reused for future recovery operations to minimize storage costs and avoid cross-region charges .

Recover Spanner Databases

To recover Spanner databases:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **Google Cloud** > **Spanner**.
3. Search for the database by entering characters of the database name, or by specifying the wildcard character *.
4. From the list of search results, select the database to recover.

- By default, the latest snapshot of the database is selected for recovery.
- To recover from a different snapshot, hover over the snapshot and click the Edit icon. The **Edit Recovery Point for <database_name>** page appears.
- By default, snapshots are displayed in **List** mode. You can switch to **Timeline** mode by clicking the **Timeline** tab in the top-right corner of the page.

  To select a snapshot from the **List** mode:

  a. On the **List** tab, snapshots available in the past month are displayed by default.

  b. To view snapshots from a different range, select a date range from the **Date** drop-down list.

  c. Select the snapshot(s) to recover.

  d. By default, the snapshot is recovered from the local Cohesity cluster.

  e. Click **Select Recovery Point** and then go to step 5.

  To select a snapshot from the **Timeline** mode:

  a. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar.

  b. Select the snapshot to be recovered by clicking the corresponding blue dot.

  c. By default, the snapshot is recovered from the local Cohesity cluster.

  d. Click **Select Recovery Point** and then go to step 5.

5. Click **Next: Recover Options**.
6. In the **Recover To** section, select any one of the following options based on your requirements:

Option	Description
Original Location	Restore the database to the same project from which it was backed up. **Note:** • Restoring to the original location replaces any existing database with the same name. • If you need to restore to the same instance without removing the existing database, use the **Rename** option in the Recovery Options section to specify a new database name.
New Location	Restore the database to an alternate location in a different GCP source. Select a registered GCP source and Spanner instance. To overwrite an existing database with the same name, enable **Overwrite existing database(s)** and type **YES**. **Note:** Restoring to a new location also replaces any existing database with the same name in the selected region.

7. In **Restore Staging Bucket** section, choose one of the following options:
   - **Auto Create**: Cohesity automatically creates a temporary staging bucket in the same region as your database(s) for the recovery operation. For multi-region deployments, the bucket is created in the **default leader region**. The bucket follows the naming format: `cohe-<project-id>-<region-name>`.

     Where:
     - `project-id` is the Google Cloud project ID.
     - `region-name` is the Google Cloud region where the databases reside.
   - **Specify Bucket to Use**: Enter the name of an existing staging bucket in Google Cloud Storage (GCS) that you created for recovery.

   Cohesity deletes only the temporary data stored in the staging bucket during each recovery operation. The bucket itself is retained and reused for future recovery operations to minimize storage costs and avoid cross-region charges.
8. In the **Network Configurations** section, provide the following Google Cloud VPC details:
   - **VPC Network**: Enter the name of the Google Cloud VPC network to be used for the restore operation. Ensure that the network has connectivity to both the target Spanner instance and the Google Cloud Storage staging bucket.

- **VPC Subnet**: Specify the subnet associated with the region of the target Spanner instance configuration within the selected VPC network. This subnet will be used for the current restore operation.

9. In the **Recovery Options** section, configure the following options:

Options	Description
Rename	Enter a new name for the database if you want to recover it to the same instance without deleting an existing database with the same name.
Max Dataflow Workers	Specify the maximum number of Dataflow workers to use for recovery operations. More workers improve performance but may increase costs and require sufficient GCP quotas. **Default**: 10 **Recommendations**: • Keep 10 for most environments. • Increase for large databases or tighter backup windows. • Decrease if you need to limit resource usage or have quota constraints.
Task Name	Update the default name of the recovery task.

10. Click **Recover**.

Firestore

Cohesity natively integrates with Google Cloud to provide a simple, fast, and cost-effective solution for backup, recovery, and data management of Google Cloud databases, including Firestore.

> **Important:** The backup and recovery of Google Cloud Firestore is supported only on DataProtect for cloud in GCP (formerly known as GCP NGCE cluster). This is a Controlled Availability feature, contact your Cohesity account team to enable the feature.

This chapter includes the following topics:

Plan and Prepare for Firestore Data Protection

To protect Firestore databases with the Cohesity cluster, you must register your Google Cloud environment as a source in the Cohesity cluster and perform backup and recovery operations. The following table lists the requirements are grouped into those needed only for source registration and those needed for both backup and restore.

Requirement	When Needed	Details
Service Account	Source registration	Create a dedicated service account in Google Cloud for Cohesity. Assign the required roles to the service account for Firestore protection.
Service Account Key	Source registration	Generate a JSON key for the service account to allow authentication from outside Google Cloud.
Project ID	Source registration	The Google Cloud Project ID of the project associated with the service account.
Virtual Private Cloud (VPC)	Source registration	The name of the Virtual Private Cloud network to connect the Cohesity cluster with Google Cloud.
Subnet	Source registration	The name of the subnet within the VPC for network connectivity.
Network Connectivity	Source registration, backup/restore	Ensure the Cohesity cluster can reach `google.apis.com` over firewall port **443**.
Allowlisted Domains	Source registration, backup/restore	Allowlist the following FQDNs for source registration and data protection operations: • `https://accounts.google.com/` • `https://www.googleapis.com/` • `https://storage.googleapis.com` • `https://vpcaccess.googleapis.com/` • `https://cloudfunctions.googleapis.com/` • `https://cloudresourcemanager.googleapis.com/`
Staging Bucket for Backup and Restore	Backup/Restore	You must have a staging bucket in Google Cloud Storage to enable backup and restore operations for Firestore databases. • **Auto Create**: Cohesity can automatically create a staging bucket when you configure backup and recovery for Firestore databases. • **Manual Create**: You can manually create one or more staging buckets in Google Cloud Storage. Use different staging buckets for protecting different databases or for recovery operations. Each bucket can be in the same or a different region as the database. **Note:** Using a bucket in a different region than the database may incur additional Google Cloud Storage costs.

Required Roles for Firestore Data Protection

The following table lists the roles that must be assigned to the service account to enable Firestore data protection.

Role Name	Purpose/Scope
Storage Admin	Access and manage GCS buckets.
Firebase Admin	List, Create, Delete, Export and Import Firestore database.

Create Staging Bucket on Google Cloud Storage

To enable Firestore data protection with the Cohesity cluster, you need a staging bucket in Google Cloud Storage. The staging bucket is used to temporarily store exported Firestore databases during backup and recovery operations.

You can choose one of the following options when setting up the staging bucket:

- **Auto Create**: Cohesity can automatically create a staging bucket for you as part of the backup configuration workflow in the Cohesity cluster.
- **Create Manually**: Manually create and specify an existing Google Cloud Storage bucket to be used for staging.

> **Note:** Create one or more staging buckets in Google Cloud Storage. You can use different staging buckets for protecting different databases or for recovery operations. Each bucket can be in the same or a different region as the database. Note that using a different region may incur additional Google Cloud Storage costs.

Manually Create a Staging Bucket

To manually create a staging bucket:

1. In the **Google Cloud** console, go to the Cloud Storage **Buckets** page.
2. Click **Create**.
3. On the **Create a bucket** page, provide the following information. After completing each section, click **Continue** to proceed:

1. **Get started**: Enter a unique name for the staging bucket. Follow naming guidelines to ensure compatibility.
2. **Choose where to store your data**: Select either **Region** or **Multi-region** as the location type.
3. **Choose how to store your data**: Select **Set a default class**, then choose **Standard** as the default storage class.
4. **Choose how to control access to objects**:
   - Enable **Enforce public access prevention**.
   - Select **Uniform as the access control model**.
5. **Choose how to protect object data**:
   - Under **Data protection**, enable **Soft delete policy (For data recovery)** and select **Use default retention duration**.
   - Under **Data encryption**, select **Google-managed encryption key** as the encryption method.
6. Click **Create**.

Considerations for Firestore Data Protection

Review and understand the following limitations and known issues before you protect Google Cloud Firestore databases.

- **Database-Level Protection Only**: Backups and restores are performed at the database level. Individual collections cannot be selected for backup or restore.
- **Full Backups Only**: Incremental and log-based backups are not supported. Each backup creates a full copy of the database.
- **No Snapshot Isolation**: Backup consistency is based on the snapshot time. Updates made during export may not be included.
- **Point-in-Time Recovery (PITR)**: PITR is optional and available for up to seven days. It incurs additional Google Cloud costs.
- **Quota Limits**: Firestore allows a maximum of 20 export/import requests per minute and up to 50 concurrent operations per project. Exceeding limits can result in failures.
- **Manual Service Account Configuration**: Service accounts must be registered and assigned required IAM roles for Firestore and Cloud Storage operations.
- **No Transaction or Log Backups**: Firestore does not support log-based backups.
- **Overwrite Behavior**: Restoring a database with the overwrite option deletes all collections before import. If the restore fails, data loss can occur.
- **No Maintenance Mode**: Firestore does not support disabling access during recovery. Pause application writes manually to maintain consistency.

Register and Manage Google Cloud Source

To protect your Firestore Databases, you need to register your Google Cloud environment as a source on the Cohesity cluster. After registering your Google Cloud environment as a source, you can:

- Update the Google Cloud source configuration.
- Refresh the source details.
- Unregister the Google Cloud source from the Cohesity cluster.

Register Google Cloud as a Source

Before registering Google Cloud as a source, make sure you have completed all prerequisite tasks and reviewed the considerations.

To register Google Cloud source:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Register** at the top-right of the page and then select **Cloud Platforms** > **Google Cloud Platform**.
3. In the **Register GCP Source** dialog box, perform the following:
    1. Configure the following:

Field	Description
GCP Project ID	The Google Cloud Project ID of the project associated with the service account.
Virtual Private Cloud (VPC)	The name of the VPC network that connects the Cohesity cluster to Google Cloud.
Subnet	The subnet within the VPC for network connectivity.

    2. Under the **Authentication Method** section, choose any one of the following:
        - **Upload JSON Key File** - Upload the service account JSON key file. You can either drag and drop the file or click to upload the JSON file.
        - **Enter Email and Private Key** - Manually enter the service account email address and private key associated with the service account.
    3. Click **Register**.

The Cohesity cluster authenticates with Google Cloud using the provided service account credentials (JSON key or email and private key). Once authenticated, it automatically discovers all projects that the service account can access, as well as all supported workloads such as Firestore Databases within those projects.

The discovered workloads appear under **Data Protection** > **Sources**, and when you open the registered Google Cloud source, each workload type is displayed on its own tab.

Update the Google Cloud Source Configuration

After registering Google Cloud as a source in the Cohesity cluster, you may have updated your environment in one or more of the following ways:

- Changed the project associated with the service account
- Updated VPC or subnet details
- Generated a new JSON key file for the service account

You can update the Google Cloud registration details provided during the source registration with the latest Google Cloud configuration details.

To edit the Google Cloud source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Google Cloud source and select **Edit**.
3. In the **Edit GCP Source** page, update the required configurations.
4. Click **Update**.

Refresh Google Cloud Source

You can refresh the Google Cloud source configuration and fetch the latest changes on your Google Cloud environment.

To refresh the Google Cloud source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Google Cloud source and select **Refresh**.

Unregister Google Cloud Source

If you plan to stop taking the backup of your Google Cloud source, you can unregister the Google Cloud source from the Cohesity Cluster.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the Google Cloud source.

To unregister the Google Cloud source:

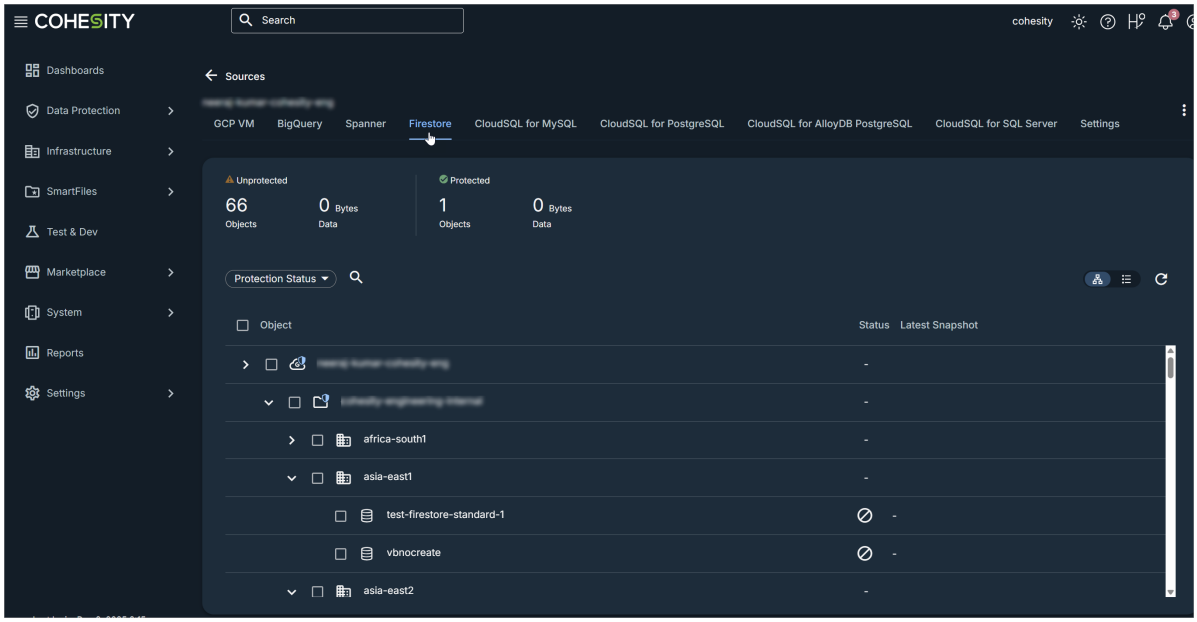
1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Google Cloud source and select **Unregister**.

Backup Firestore Databases

After registering your Google Cloud source in the Cohesity cluster, it uses the provided service account credentials (JSON key or email and private key) to authenticate with Google Cloud.

Once authenticated, it automatically discovers all projects that the service account can access, as well as all supported workloads such as Firestore databases within those projects. The discovered workloads appear under **Data Protection** > **Sources**. When you open the registered Google Cloud source, each workload type is displayed on its own tab. Select the **Firestore** tab to view all the discovered databases.

The **Firestore** tab displays the entity hierarchy for the Firestore environment, allowing you to navigate from the project level down to individual databases.

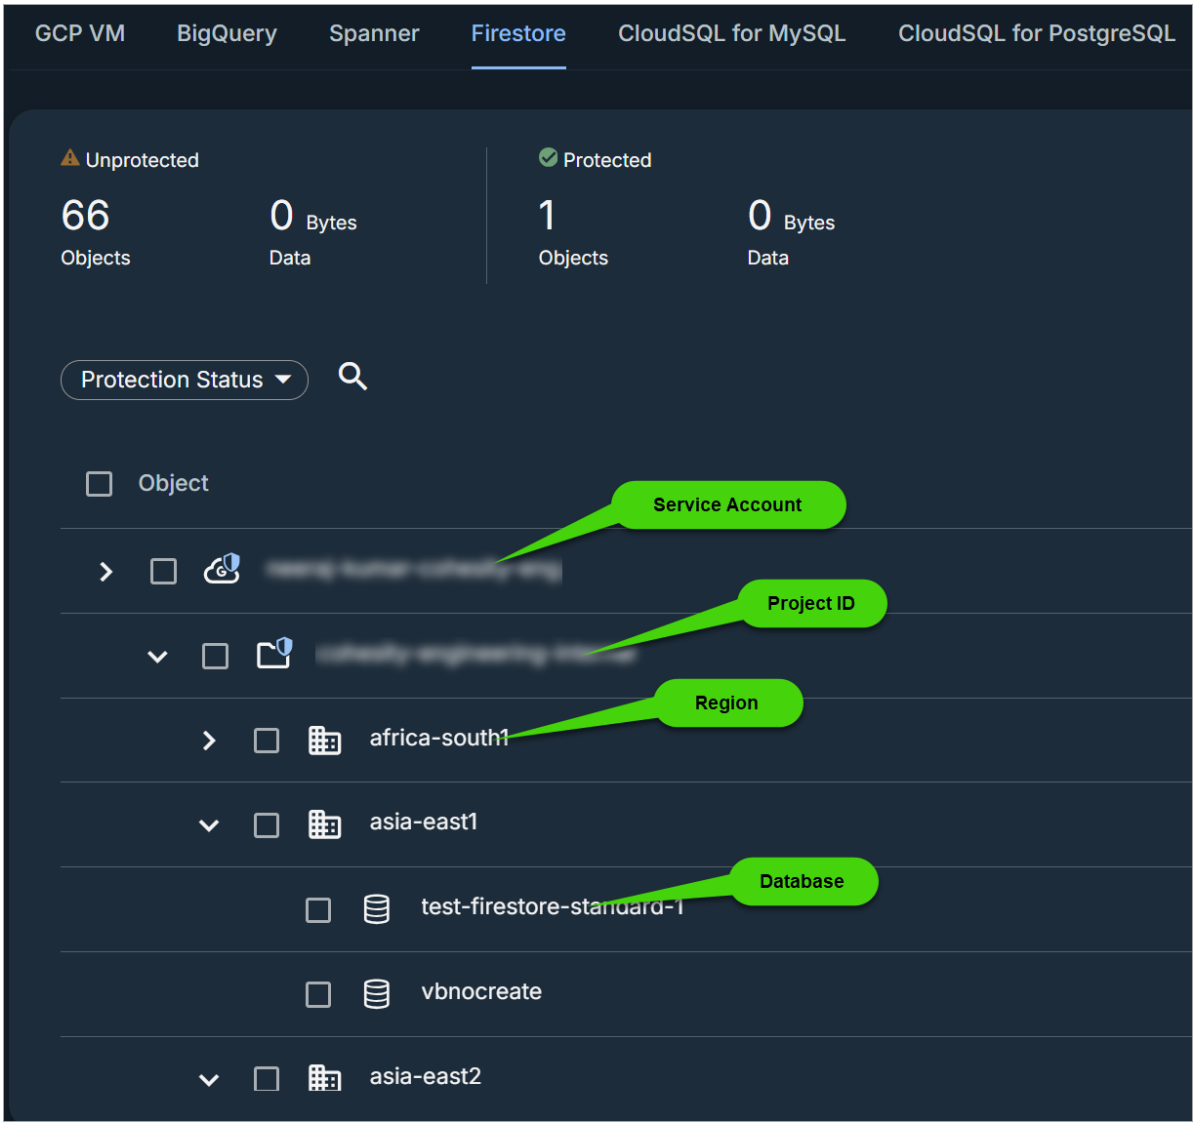


Firestore Entity Hierarchy

The Firestore entity hierarchy in the Cohesity cluster follows this structure:

Structure	Description
Service Account	The dedicated service account in Google Cloud assigned to Cohesity cluster for Firestore protection.
Project ID	The Google Cloud Project ID of the project (s) accessible with the service account.

Structure	Description
Region	The Google Cloud region where the databases reside.
Database	The database that can be selected for backup and recovery.



Backup Scope by Firestore Hierarchy

Cohesity cluster allows you to back up Firestore databases at different levels of the hierarchy. You can choose to back up:

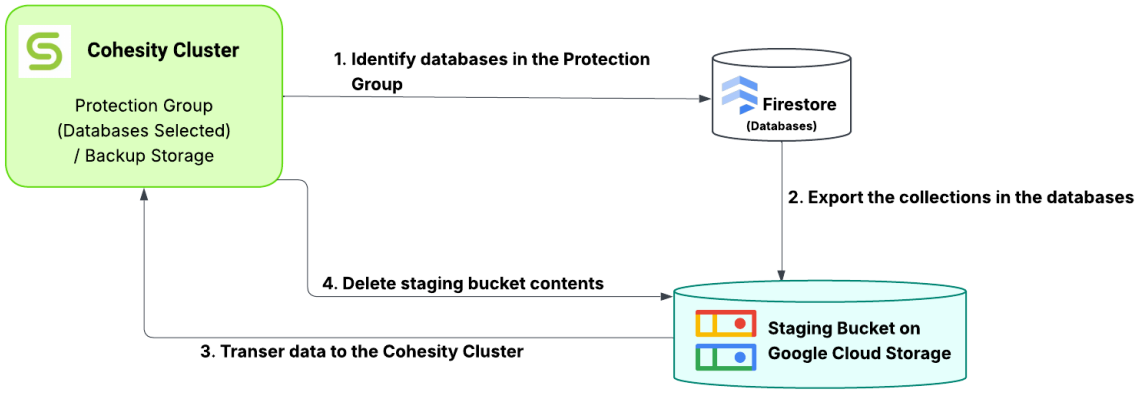
- **Individual database** – Back up a single database.
- **Multiple databases within a region** – Back up selected databases from the same region.
- **Region level** – Back up all databases within a specific region.
- **Multiple databases across regions** – Back up selected databases from different regions.
- **Project level** – Back up all databases in all regions within the specified Project ID.

Firestore Backup Process

When you run a protection job in the Cohesity cluster, the selected Firestore database(s) and their collections are exported to a Google Cloud Storage (GCS) staging bucket. The staging bucket temporarily stores the exported data before it is ingested into the Cohesity cluster.

After the export completes, the Cohesity cluster copies the data from the staging bucket into the cluster for retention and applies the defined retention policies.

Once ingestion is complete, Cohesity automatically deletes only the temporary data from the staging bucket to free up storage and reduce Google Cloud Storage costs.



Supported Backup Types

Cohesity supports only full backups for Firestore databases. Incremental backups are not supported.

Protect Firestore

In the Cohesity cluster, Google Cloud Firestore databases are protected using a Protection Group and a Protection Policy. The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select standard or custom policy to use when creating a Protection Group. For more information, see Manage Protection Policy.

> **Note:** Cohesity supports only full backups for Firestore databases. Incremental backups are not supported.

Prerequisites

Before you protect Firestore databases, ensure that a staging bucket is available in Google Cloud Storage. You can either use an existing bucket or allow Cohesity to automatically create one during the backup configuration.

- If you choose to **Auto Create** the staging bucket: Cohesity automatically creates a staging bucket in the same region as your database(s) when you start a backup operation.
- If you choose to **specify an existing bucket**: You can specify an existing bucket located in the same region as the databases being protected. Using a bucket in a different region is supported but may incur additional Google Cloud Storage charges.

> **Note:** After each protection job run, Cohesity deletes only the temporary data stored in the staging bucket during backup operations. The staging bucket itself is retained and reused for future backup operations to minimize storage costs and avoid cross-region charges.

Protect Firestore Databases

To protect Firestore databases:

1. Navigate to **Data Protection** > **Protection**. Click **Protect** on the top-right of the page and then select **Google Cloud** > **Firestore**.
2. From the **Source** drop-down list, select a registered Google Cloud source, or click **Register Source** to add a new one.
3. In the **Objects** section, choose databases using one of the following views:
   - **Hierarchy View (default)**: Browse objects by backup scope. You can enable **Auto Protect** at the source, project, or region level.
   - **List View**: Select databases from a flat, searchable list.
4. In the **Protection Name** field, enter a name from the Protection Group.
5. In the **Staging Bucket** section, choose one of the following options:
   - **Auto Create**: Cohesity automatically creates a temporary staging bucket in the same region as your database(s). The bucket follows the naming format `cohe-<project-id >-<region-name>`.

     Where:

- `project-id` is the Google Cloud project ID.
- `region-name` is the Google Cloud region where the databases reside.

- **Specify Bucket to Use**: Enter the name of an existing staging bucket in Google Cloud Storage (GCS) that you created for backups.

After each protection job run, Cohesity deletes only the temporary data stored in the staging bucket during backup operations. The staging bucket itself is retained and reused for future backup operations to minimize storage costs and avoid cross-region charges.

6. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, see Manage Protection Policy.
7. In the **Settings** section, configure the following:

Settings	Description
Storage Domain	Select the appropriate Storage Domain. For more information, see Manage Storage Domains.
Start Time	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. > **Note:** This option is not applicable for Firestore data protection. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

8. In the **Additional Settings** section, configure the following:

Additional Settings	Description
Pause Future Runs	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
End Date	Optional. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup Target HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup Target SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Alerts	Optional. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.

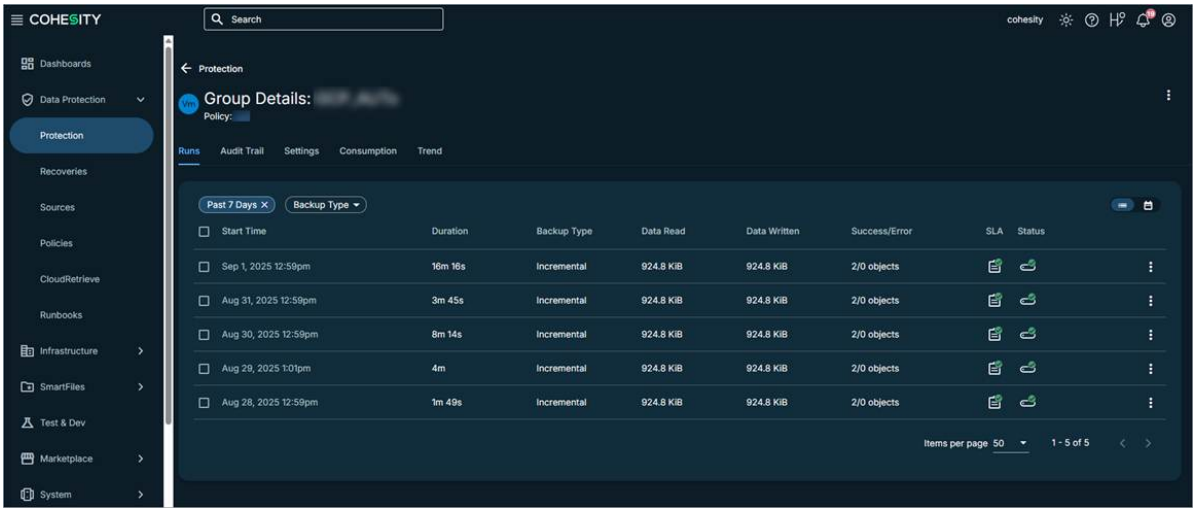
Additional Settings	Description
Priority	Select a priority for the Protection Group execution. The Cohesity cluster supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs
Description	Optional. Enter a brief description about the Protection Group.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.



Manage Firestore Backup Configuration

In the Cohesity cluster, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Object(s) to the Protection Group

You can add new object(s) to the existing Protection Group for backup. The newly added object is backed up from the next protection run.

To add object(s) to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Firestore.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ in the **Objects** section.
5. In the **Objects** section, Click the plus icon (**+**) to enter multiple objects that you plan to back up. click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Firestore.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Firestore.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a protection run:

1. Navigate to **Data Protection** > **Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all associated local and archived snapshots. Replicated snapshots must be deleted from the remote cluster. Snapshots under DataLock cannot be deleted.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Firestore.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
   - Keep the **Delete Snapshots** toggle disabled to delete the Protection Group only.
   - Enable the **Delete Snapshots** toggle to delete the Protection Group and all associated snapshots.
5. Type **YES** to confirm that you want to delete the Protection Group.
6. Click **Delete Group**.

Recover Firestore Databases

You can restore Firestore databases either to their original GCP source or to a different GCP source and region.

Prerequisites

Before you restore Firestore databases, ensure that a staging bucket is available in Google Cloud Storage. You can either use an existing bucket or allow Cohesity to automatically create one during the restore process.

- **If you choose to Auto Create the staging bucket**: Cohesity automatically creates a staging bucket in the same region as your database(s) when you start the recovery.
- **If you choose to specify an existing bucket**: You can specify an existing bucket located in the same region as the recovery target. Using a bucket in a different region is supported but may incur additional Google Cloud Storage charges.

> **Note:** After each recovery job run, Cohesity deletes only the temporary data stored in the staging bucket. The staging bucket itself is retained and reused for future recovery operations to minimize storage costs and avoid cross-region charges.

Recover Firestore Databases

To recover Firestore databases:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **Google Cloud** > **Firestore**.
3. Search for the database by entering characters of the database name, or by specifying the wildcard character *.
4. From the list of search results, select the database to recover.
    - By default, the latest snapshot of the database is selected for recovery.
    - To recover from a different snapshot, hover over the snapshot and click the Edit icon. The **Edit Recovery Point for <database_name>** page appears.
    - By default, snapshots are displayed in **List** mode. You can switch to **Timeline** mode by clicking the **Timeline** tab in the top-right corner of the page.

      To select a snapshot from the **List** mode:

        a. On the **List** tab, snapshots available in the past month are displayed by default.
        b. To view snapshots from a different range, select a date range from the **Date** drop-down list.
        c. Select the snapshot(s) to recover.
        d. By default, the snapshot is recovered from the local Cohesity cluster.
        e. Click **Select Recovery Point** and then go to step 5.

      To select a snapshot from the **Timeline** mode:

        a. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar.
        b. Select the snapshot to be recovered by clicking the corresponding blue dot.
        c. By default, the snapshot is recovered from the local Cohesity cluster.
        d. Click **Select Recovery Point** and then go to step 5.
5. Click **Next: Recover Options**.
6. In the **Recover To** section, select any one of the following options based on your requirements:

Option	Description
Original Location	Restore the database to the same project from which it was backed up. **Note:** Restoring to the original location replaces any existing database with the same name. Type **YES** to confirm.
New Location	Restore the database to an alternate location in a different GCP source. Select a registered GCP source, project, and region. To overwrite an existing database with the same name, enable **Overwrite existing database(s)** and type **YES**. **Note:** Restoring to a new location also replaces any existing database with the same name in the selected region.

7. In **Restore Staging Bucket** section, choose one of the following options:
   - **Auto Create**: Cohesity automatically creates a temporary staging bucket in the same region as your database(s) for the recovery operation. The bucket follows the naming format: `cohe-<project-id>-<region-name>`.

     Where:
     - `project-id` is the Google Cloud project ID.
     - `region-name` is the Google Cloud region where the databases reside.
   - **Specify Bucket to Use**: Enter the name of an existing staging bucket in Google Cloud Storage (GCS) that you created for recovery.

   Cohesity deletes only the temporary data stored in the staging bucket during each recovery operation. The bucket itself is retained and reused for future recovery operations to minimize storage costs and avoid cross-region charges.
8. In the **Recovery Options** section, configure the following options:

Options	Description
Rename	Enter a new name for the database if you want to rename it after recovery.
Task Name	Update the default name of the recovery task.

9. Click **Recover**.

Cloud SQL for MySQL

Cohesity natively integrates with Google Cloud to provide a simple, fast, and cost-effective solution for backup, recovery, and data management of Google Cloud databases, including Cloud SQL for MySQL.

> **Important:** The backup and recovery of Google Cloud Cloud SQL for MySQL is supported only on DataProtect for cloud in GCP (formerly known as GCP NGCE cluster). This is a Controlled Availability feature, contact your Cohesity account team to enable the feature.

This chapter includes the following topics:

Plan and Prepare for Cloud SQL for MySQL Data Protection

To protect Cloud SQL for MySQL databases with the Cohesity cluster, you must register your Google Cloud environment as a source in the Cohesity cluster and perform backup and recovery operations. The following table lists the requirements are grouped into those needed only for source registration and those needed for both backup and restore.

Requirement	When Needed	Details
Service Account	Source registration	Create a dedicated service account in Google Cloud for Cohesity. Assign the required permissions to the service account for Cloud SQL for MySQL protection.
Service Account Key	Source registration	Generate a JSON key for the service account to allow authentication from outside Google Cloud.
Project ID	Source registration	The Google Cloud Project ID of the project associated with the service account.
Virtual Private Cloud (VPC)	Source registration	The name of the Virtual Private Cloud network to connect the Cohesity cluster with Google Cloud.
Subnet	Source registration	The name of the subnet within the VPC for network connectivity.
Network Connectivity	Source registration, backup/restore	Ensure the Cohesity cluster can reach `google.apis.com` over firewall port **443**.

Requirement	When Needed	Details
Allowlisted Domains	Source registration, backup/restore	Allowlist the following FQDNs for source registration and data protection operations: • `https://accounts.google.com/` • `https://www.googleapis.com/` • `https://storage.googleapis.com` • `https://vpcaccess.googleapis.com/` • `https://cloudfunctions.googleapis.com/` • `https://cloudresourcemanager.googleapis.com/`

Required Permissions for Cloud SQL for MySQL Data Protection

The following table lists the permissions and privileges that must be included in a custom role. Assign this role to the service account to enable Cloud SQL for MySQL data protection.

Permission	Purpose
`cloudsql.instances.list`	Allows listing the Cloud SQL instances in the project.
`cloudsql.databases.list`	Allows to retrieve the list of databases.
`cloudsql.databases.get`	Allows to retrieve details of a specific database.
`cloudsql.instances.get`	Allows to retrieve details of a specific Cloud SQL instance.

Create an IAM Custom Role in GCP

To enable Cloud SQL for MySQL data protection, you must create an IAM custom role in Google Cloud and assign it to the service account used by the Cohesity cluster.

For detailed instructions, refer to the following topics in the Google Cloud documentation:

- Create a custom IAM role
- Assign a role to a service account

> **Note:** Before you begin creating IAM custom role, ensure that you have created a dedicated service account in Google Cloud for the Cohesity cluster.

Considerations for Cloud SQL for MySQL Data Protection

Review and understand the following limitations and known issues before you protect Cloud SQL for MySQL databases:

- **Full Database Backups Only**: Incremental backups are not supported. Each backup captures the complete contents of the selected database.
- **Database-Level Restores**: You can restore individual databases and choose to rename or overwrite them. Restoring an entire MySQL server is not supported.
- **Direct Database Connection**: Cohesity connects directly to the MySQL server using the database credentials you provide. These credentials are required for performing backup and recovery operations, as well as for retrieving the size of the databases on the server.
- **Version Downgrade Not Supported**: Restoring a backup taken from a higher Cloud SQL for MySQL database version to a lower version is not supported.

Register and Manage Google Cloud Source

To protect your Cloud SQL for MySQL databases, you need to register your Google Cloud environment as a source on the Cohesity cluster. After registering your Google Cloud environment as a source, you can:

- Update the Google Cloud source configuration.
- Refresh the source details.
- Unregister the Google Cloud source from the Cohesity cluster.

Register Google Cloud as a Source

Before registering Google Cloud as a source, make sure you have completed all prerequisite tasks and reviewed the considerations.

To register Google Cloud source:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Register** at the top-right of the page and then select **Cloud Platforms** > **Google Cloud Platform**.
3. In the **Register GCP Source** dialog box, perform the following:

1. Configure the following:

Field	Description
GCP Project ID	The Google Cloud Project ID of the project associated with the service account.
Virtual Private Cloud (VPC)	The name of the VPC network that connects the Cohesity cluster to Google Cloud.
Subnet	The subnet within the VPC for network connectivity.

2. Under the **Authentication Method** section, choose any one of the following:
   - **Upload JSON Key File** - Upload the service account JSON key file. You can either drag and drop the file or click to upload the JSON file.
   - **Enter Email and Private Key** - Manually enter the service account email address and private key associated with the service account.
3. Click **Register**.

The Cohesity cluster authenticates with Google Cloud using the provided service account credentials (JSON key or email and private key). Once authenticated, it automatically discovers all projects that the service account can access, as well as all supported workloads such as Cloud SQL for MySQL databases within those projects.

The discovered workloads appear under **Data Protection** > **Sources**, and when you open the registered Google Cloud source, each workload type is displayed on its own tab.

Update the Google Cloud Source Configuration

After registering Google Cloud as a source in the Cohesity cluster, you may have updated your environment in one or more of the following ways:

- Changed the project associated with the service account
- Updated VPC or subnet details
- Generated a new JSON key file for the service account

You can update the Google Cloud registration details provided during the source registration with the latest Google Cloud configuration details.

To edit the Google Cloud source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Google Cloud source and select **Edit**.

3. In the **Edit GCP Source** page, update the required configurations.
4. Click **Update**.

Refresh Google Cloud Source

You can refresh the Google Cloud source configuration and fetch the latest changes on your Google Cloud environment.

To refresh the Google Cloud source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Google Cloud source and select **Refresh**.

Unregister Google Cloud Source

If you plan to stop taking the backup of your Google Cloud source, you can unregister the Google Cloud source from the Cohesity Cluster.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the Google Cloud source.

To unregister the Google Cloud source:

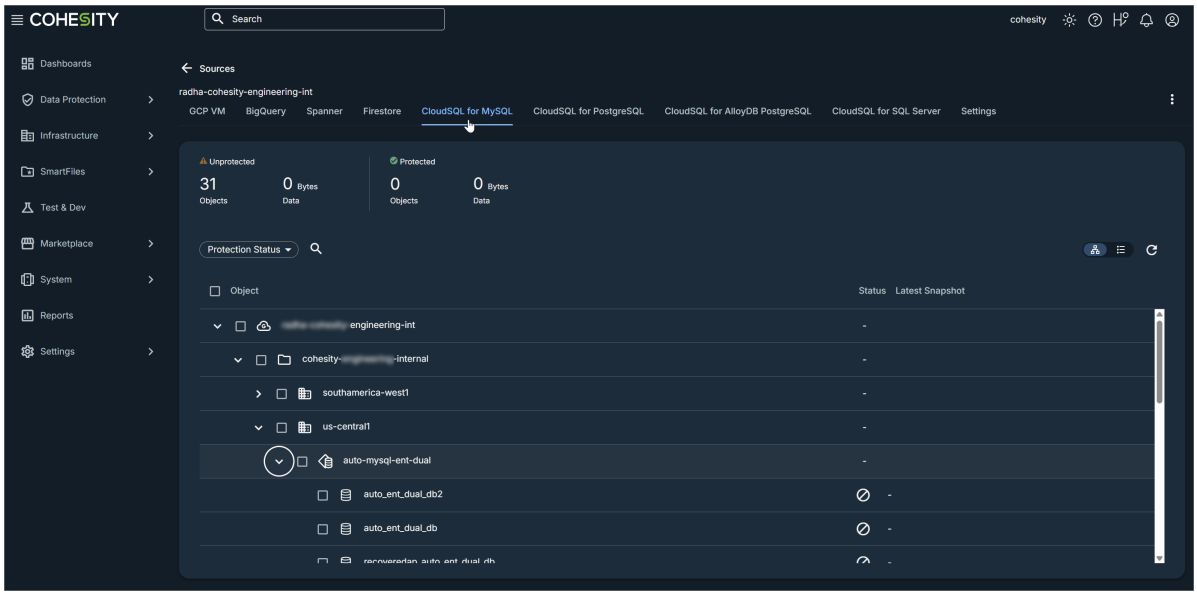
1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Google Cloud source and select **Unregister**.

Backup Cloud SQL for MySQL Databases

After registering your Google Cloud source in the Cohesity cluster, it uses the provided service account credentials (JSON key or email and private key) to authenticate with Google Cloud.

Once authenticated, it automatically discovers all projects that the service account can access, as well as all supported workloads such as Cloud SQL for MySQL databases within those projects. The discovered workloads appear under **Data Protection** > **Sources**. When you open the registered Google Cloud source, each workload type is displayed on its own tab. Select the **Cloud SQL for MySQL** tab to view all the discovered databases.

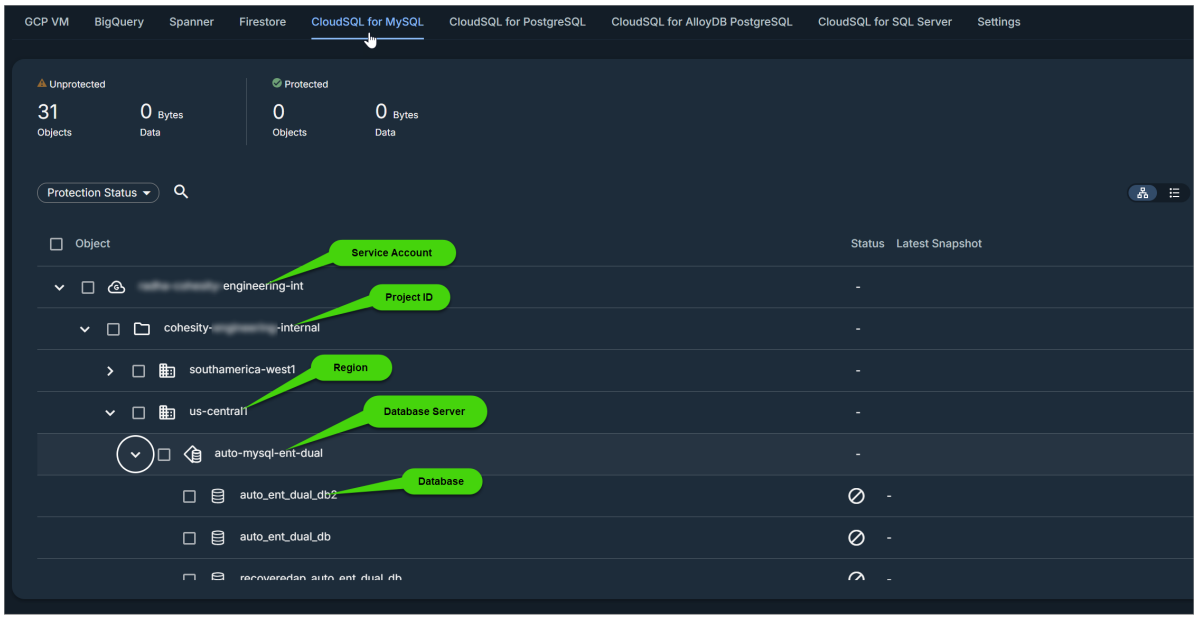
The **Cloud SQL for MySQL** tab displays the entity hierarchy for the Cloud SQL for MySQL environment, allowing you to navigate from the project level down to individual databases.



Cloud SQL for MySQL Entity Hierarchy

The following hierarchy describes how Cloud SQL for MySQL entities are organized and displayed in the Cohesity cluster:

Structure	Description
Service Account	The Google Cloud service account configured for the Cohesity cluster to perform Cloud SQL for MySQL backup and recovery operations.
Project ID	The Google Cloud Project ID that the service account has permissions to access.
Region	The Google Cloud region configuration where the MySQL server is hosted.
Database Server	The MySQL server available for backup and recovery.
Database	The individual Cloud SQL for MySQL database that can be backed up or restored.



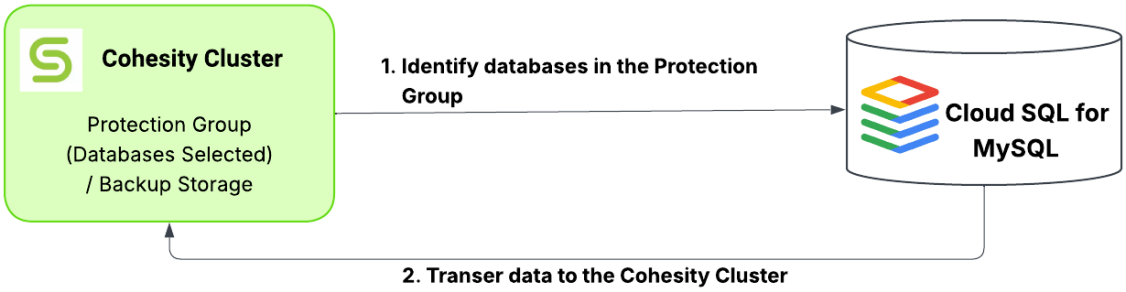
Backup Scope by Cloud SQL for MySQL Hierarchy

Cohesity cluster allows you to back up Cloud SQL for MySQL databases at different levels of the hierarchy. You can choose to back up:

- **Individual database**: Back up a single database.
- **Multiple databases within a region**: Back up selected databases from the same region.
- **Region level**: Back up all databases within a specific region.
- **Multiple databases across regions**: Back up selected databases from different regions.
- **Project level**: Back up all databases in all regions within the specified Project ID.

Cloud SQL for MySQL Backup Process

When you run a protection job for Cloud SQL for MySQL, the Cohesity cluster performs a full backup of the databases specified in the Protection Group. The Cohesity cluster connects to the selected Cloud SQL instance using the database credentials you provided during source registration and uses standard MySQL backup utilities, such as `mysql` and `mysqldump`, to export the complete database contents to the cluster.



Supported Backup Types

Cohesity supports only full backups for Cloud SQL for MySQL databases. Incremental backups are not supported.

Protect Cloud SQL for MySQL

In the Cohesity cluster, Google Cloud Cloud SQL for MySQL databases are protected using a Protection Group and a Protection Policy. The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select standard or custom policy to use when creating a Protection Group. For more information, see Manage Protection Policy.

Prerequisites

Before you protect Cloud SQL for MySQL databases, ensure that you add the database credentials required to authenticate and connect to the MySQL server. These credentials allow the Cohesity cluster to establish a secure connection, perform the database dump, and complete backup and recovery operations.

Add Database Credentials

You must add credentials at least at the Cloud SQL for MySQL server level. You can also add credentials at any higher level in the hierarchy, such as the region. Credentials added at a higher level automatically apply to all objects beneath it.

The Cohesity cluster searches for credentials in a bottom-up manner, starting from the specific entity (for example, a server) and moving up the hierarchy until valid credentials are found. When multiple credentials exist, the credentials closest to the MySQL server take precedence.

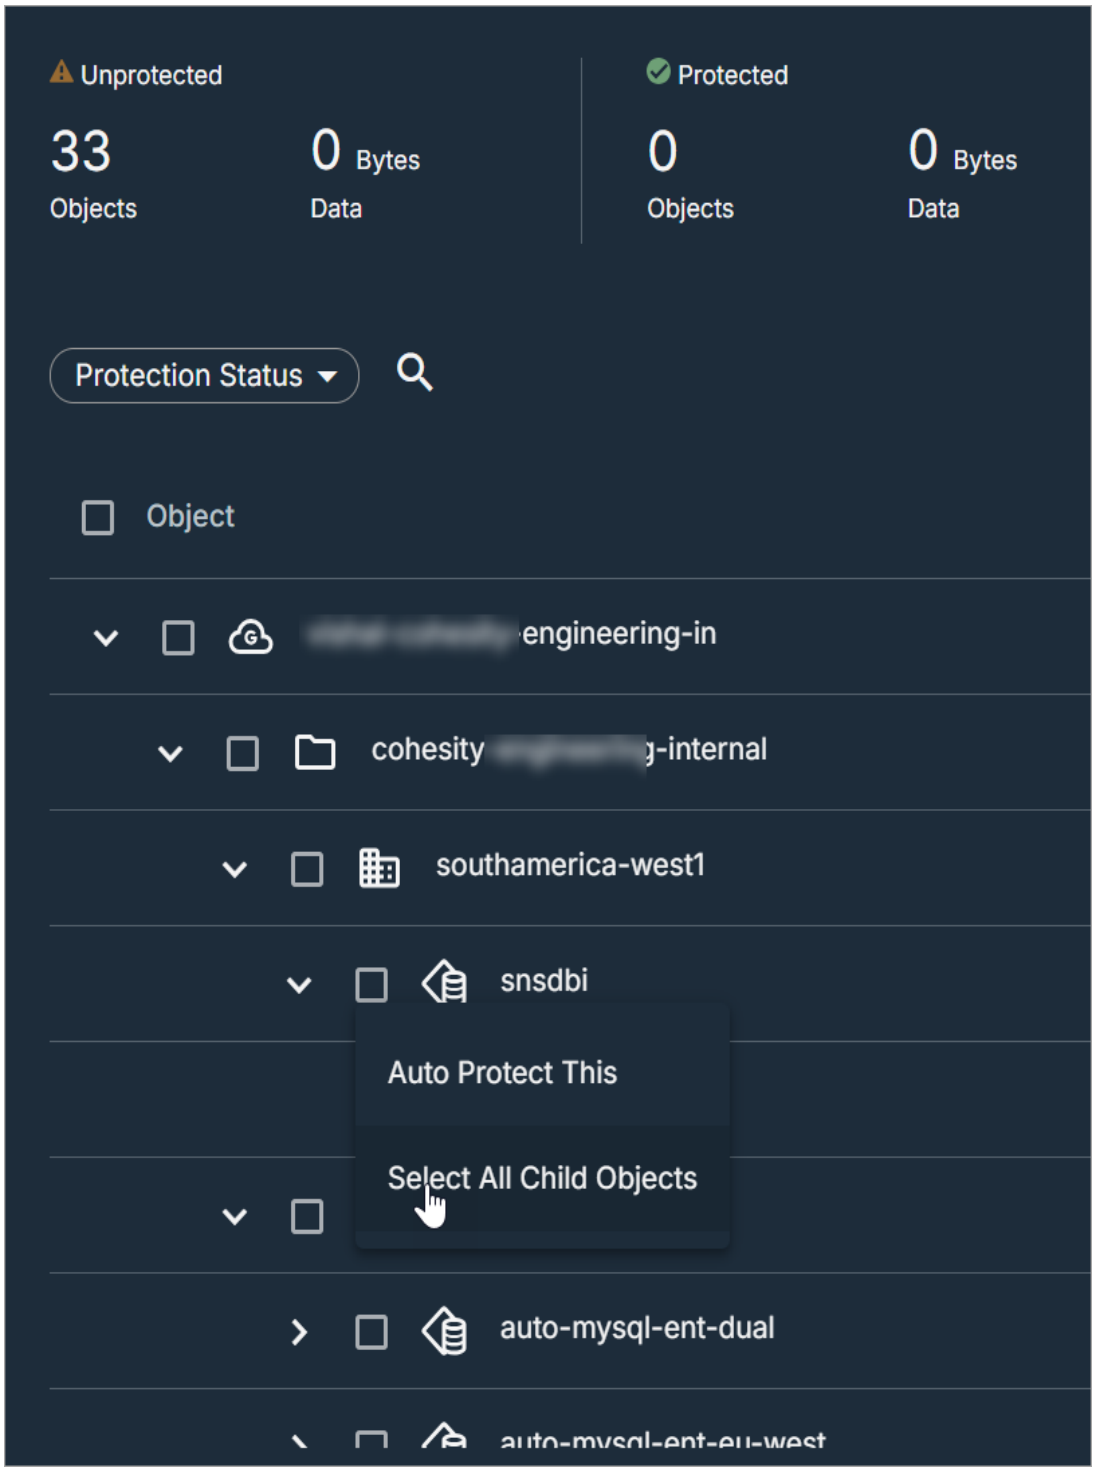
For example:

- If **region-1** has a set of credentials and **server-1** under that region has its own, the Cohesity cluster uses the credentials on **server-1** to authenticate to **server-1**.

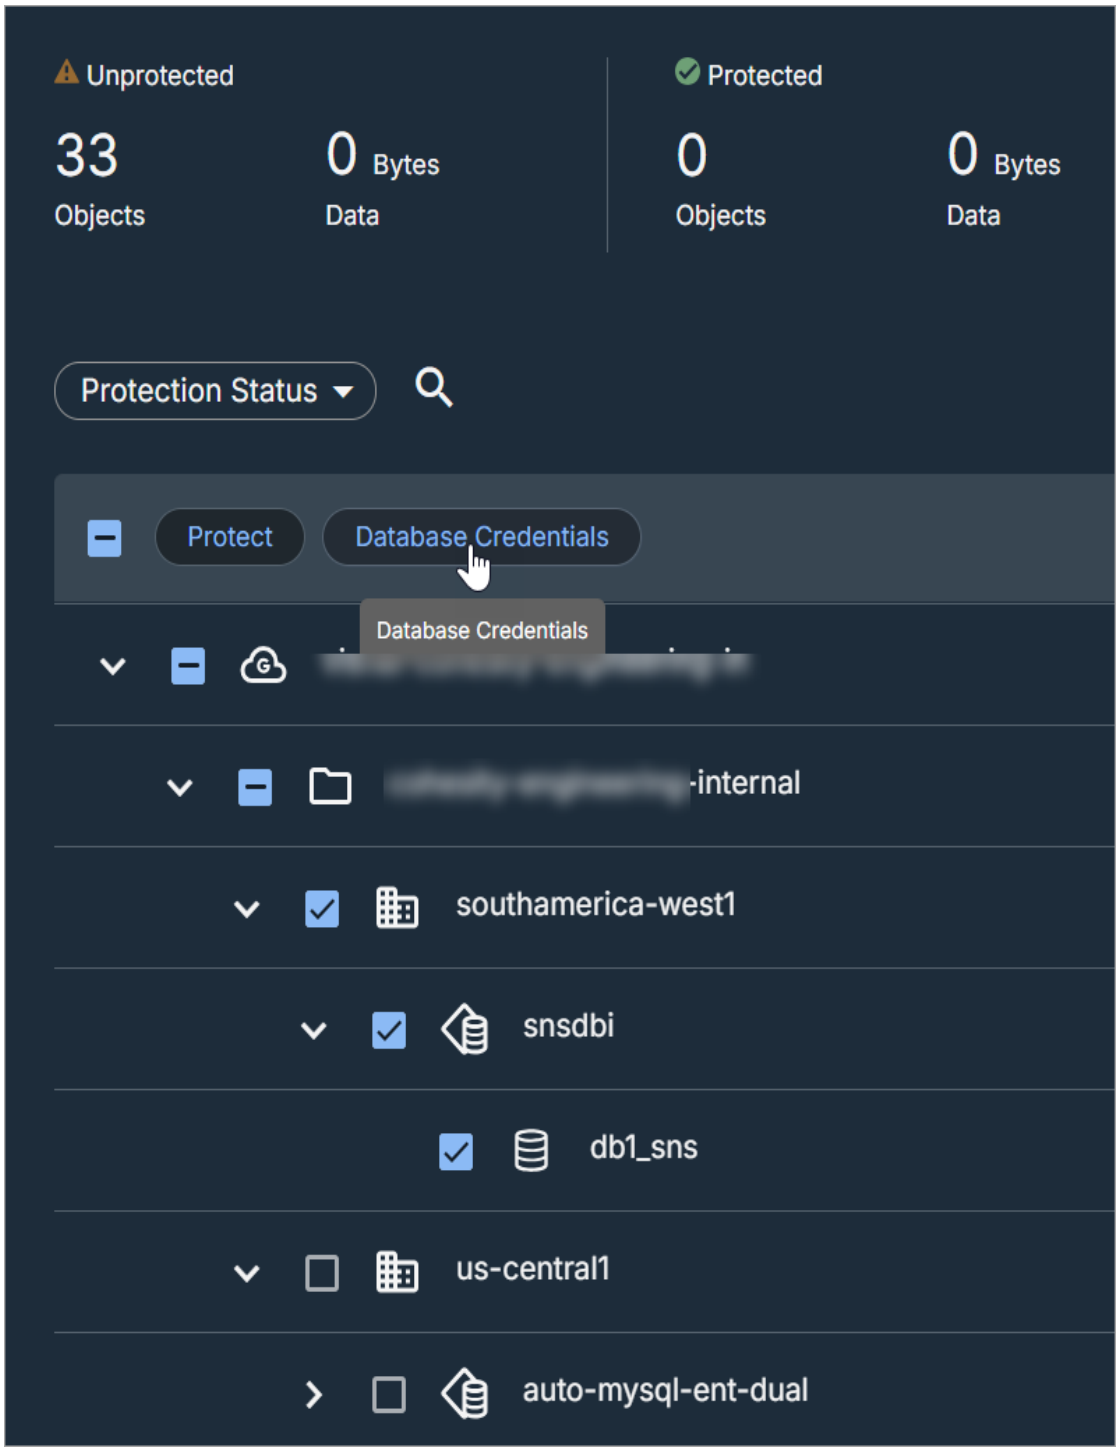
- Another server, **server-2**, under the same region, the Cohesity cluster uses the region-level credentials for authentication because that is the closest level where credentials are specified.

To add database credentials:

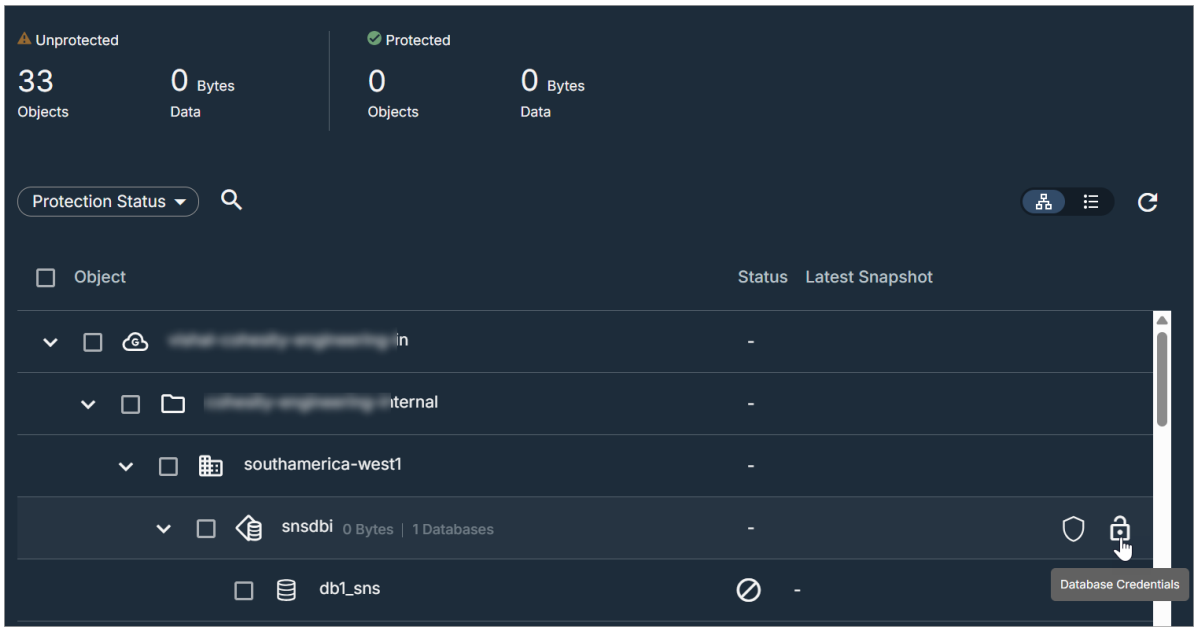
1. Navigate to **Data Protection** > **Sources**, locate the registered Google Cloud source, and click on it.
2. Click the **Cloud SQL for MySQL** tab.
3. Choose one of the following options:
    - Select the checkbox next to the MySQL server and click **Select All Child Objects**.



Then, click **Database Credentials** at the top left corner.



- Click the next to the required MySQL server.



4. In the **Database Credentials** dialog box, enter the MySQL server **username** and **password**, and click **Save**.

Protect Cloud SQL for MySQL Databases

To protect Cloud SQL for MySQL databases:

1. Navigate to **Data Protection** > **Protection**. Click **Protect** on the top-right of the page and then select **Google Cloud** > **Cloud SQL for MySQL**.
2. From the **Source** drop-down list, select a registered Google Cloud source, or click **Register Source** to add a new one.
3. In the **Objects** section, choose databases using one of the following views:
   - **Hierarchy View (default)**: Browse objects by backup scope. You can enable **Auto Protect** at the source, project, or region level.
   - **List View**: Select databases from a flat, searchable list.
4. In the **Protection Name** field, enter a name from the Protection Group.
5. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, see Manage Protection Policy.

6. In the **Settings** section, configure the following:

Settings	Description
Storage Domain	Select the appropriate Storage Domain. For more information, see Manage Storage Domains.
Start Time	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. > **Note:** This option is not applicable for Cloud SQL for MySQL data protection. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

7. In the **Additional Settings** section, configure the following:

Additional Settings	Description
Pause Future Runs	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
End Date	Optional. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.

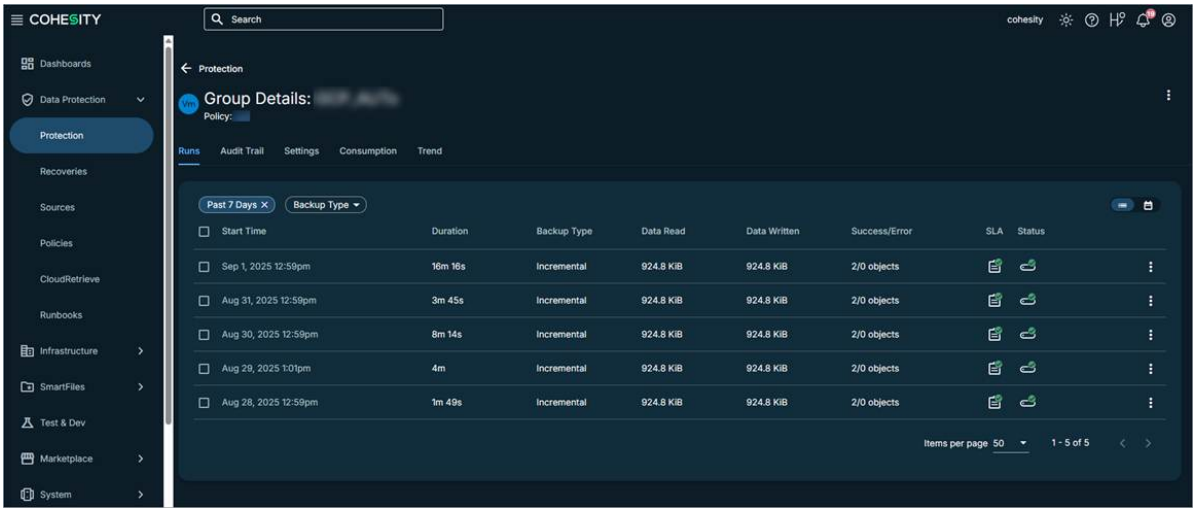
Additional Settings	Description
QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup Target HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup Target SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Alerts	Optional. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.
Priority	Select a priority for the Protection Group execution. The Cohesity cluster supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs
Description	Optional. Enter a brief description about the Protection Group.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.



Manage Cloud SQL for MySQL Backup Configuration

In the Cohesity cluster, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Object(s) to the Protection Group

You can add new object(s) to the existing Protection Group for backup. The newly added object is backed up from the next protection run.

To add object(s) to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Cloud SQL for MySQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ in the **Objects** section.

5. In the **Objects** section, Click the plus icon (**+**) to enter multiple objects that you plan to back up. click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Cloud SQL for MySQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Cloud SQL for MySQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a protection run:

1. Navigate to **Data Protection** > **Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all associated local and archived snapshots. Replicated snapshots must be deleted from the remote cluster. Snapshots under DataLock cannot be deleted.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Cloud SQL for MySQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
   - Keep the **Delete Snapshots** toggle disabled to delete the Protection Group only.
   - Enable the **Delete Snapshots** toggle to delete the Protection Group and all associated snapshots.
5. Type **YES** to confirm that you want to delete the Protection Group.
6. Click **Delete Group**.

Recover Cloud SQL for MySQL Databases

You can restore Cloud SQL for MySQL databases either to their original GCP source or to a different GCP source and region.

Prerequisites

To recover Cloud SQL for MySQL databases, add the database credentials for the target Cloud SQL MySQL databases server if you plan to restore it to a new location.

Recover Cloud SQL for MySQL Databases

To recover Cloud SQL for MySQL databases:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **Google Cloud** > **Cloud SQL for MySQL**.
3. Search for the database by entering characters of the database name, or by specifying the wildcard character *.
4. From the list of search results, select the database to recover.
    - By default, the latest snapshot of the database is selected for recovery.
    - To recover from a different snapshot, hover over the snapshot and click the Edit icon. The **Edit Recovery Point for <database_name>** page appears.
    - By default, snapshots are displayed in **List** mode. You can switch to **Timeline** mode by clicking the **Timeline** tab in the top-right corner of the page.

      To select a snapshot from the **List** mode:

        a. On the **List** tab, snapshots available in the past month are displayed by default.

        b. To view snapshots from a different range, select a date range from the **Date** drop-down list.

        c. Select the snapshot(s) to recover.

        d. By default, the snapshot is recovered from the local Cohesity cluster.

        e. Click **Select Recovery Point** and then go to step 5.

      To select a snapshot from the **Timeline** mode:

        a. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar.

        b. Select the snapshot to be recovered by clicking the corresponding blue dot.

c. By default, the snapshot is recovered from the local Cohesity cluster.

d. Click **Select Recovery Point** and then go to step 5.

5. Click **Next: Recover Options**.
6. In the **Recover To** section, select any one of the following options based on your requirements:

Option	Description
Original Location	Restore the database to the same project from which it was backed up. > **Note:** Restoring to the original location replaces any existing database with the same name. Type **YES** to confirm.
New Location	Restore the database to an alternate location in a different GCP source. Select a registered GCP source, project, and region. To overwrite an existing database with the same name, enable **Overwrite existing database(s)** and type **YES**. > **Note:** Restoring to a new location also replaces any existing database with the same name in the selected region.

7. In the **Recovery Options** section, configure the following options:

Options	Description
Rename	Enter a new name for the database if you want to rename it after recovery.
Task Name	Update the default name of the recovery task.

8. Click **Recover**.

Cloud SQL for PostgreSQL

Cohesity natively integrates with Google Cloud to provide a simple, fast, and cost-effective solution for backup, recovery, and data management of Google Cloud databases, including Cloud SQL for PostgreSQL.

> **Important:** The backup and recovery of Google Cloud Cloud SQL for PostgreSQL is supported only on DataProtect for cloud in GCP (formerly known as GCP NGCE cluster). This is a Controlled Availability feature, contact your Cohesity account team to enable the feature.

This chapter includes the following topics:

Plan and Prepare for Cloud SQL for PostgreSQL Data Protection

To protect Cloud SQL for PostgreSQL databases with the Cohesity cluster, you must register your Google Cloud environment as a source in the Cohesity cluster and perform backup and recovery operations. The following table lists the requirements are grouped into those needed only for source registration and those needed for both backup and restore.

Requirement	When Needed	Details
Service Account	Source registration	Create a dedicated service account in Google Cloud for Cohesity. Assign the required permissions to the service account for Cloud SQL for PostgreSQL protection.
Service Account Key	Source registration	Generate a JSON key for the service account to allow authentication from outside Google Cloud.
Project ID	Source registration	The Google Cloud Project ID of the project associated with the service account.
Virtual Private Cloud (VPC)	Source registration	The name of the Virtual Private Cloud network to connect the Cohesity cluster with Google Cloud.
Subnet	Source registration	The name of the subnet within the VPC for network connectivity.
Network Connectivity	Source registration, backup/restore	Ensure the Cohesity cluster can reach `google.apis.com` over firewall port **443**.

Requirement	When Needed	Details
Allowlisted Domains	Source registration, backup/restore	Allowlist the following FQDNs for source registration and data protection operations: • `https://accounts.google.com/` • `https://www.googleapis.com/` • `https://storage.googleapis.com` • `https://vpcaccess.googleapis.com/` • `https://cloudfunctions.googleapis.com/` • `https://cloudresourcemanager.googleapis.com/`
Database User	Backup and restore	Cohesity requires PostgreSQL user credentials to perform backup and recovery operations on Cloud SQL for PostgreSQL databases. You can use the PostgreSQL instance admin user or create a dedicated database user with the required privileges for backup and recovery operations.

Required Permissions for Cloud SQL for PostgreSQL Data Protection

The following table lists the permissions and privileges that must be included in a custom role. Assign this role to the service account to enable Cloud SQL for PostgreSQL data protection.

Permission	Purpose
`cloudsql.instances.list`	Allows listing the Cloud SQL instances in the project.
`cloudsql.databases.list`	Allows to retrieve the list of databases.
`cloudsql.databases.get`	Allows to retrieve details of a specific database.
`cloudsql.instances.get`	Allows to retrieve details of a specific Cloud SQL instance.

Create a Custom Database User

Cohesity requires PostgreSQL user credentials to retrieve database size information and perform backup and recovery operations. You can use the PostgreSQL instance admin credentials or create a dedicated database user with the required privileges and provide those credentials to the Cohesity cluster.

These credentials allow the Cohesity cluster to establish a secure connection to the PostgreSQL instance, perform database dumps, and complete backup and recovery operations.

To create a custom database user:

1. Log in to the PostgreSQL instance using a user with administrative privileges.
2. Create a database user by running the following command:

```
CREATE USER <username> WITH PASSWORD '<password'>;
```

3. Assign the following permissions to the database user.

```
GRANT cloudsqlsuperuser,pg_read_all_data,pg_write_all_data TO
<username>;
ALTER USER <username> WITH CREATEDB;
ALTER USER <username> WITH BYPASSRLS;
```

Create an IAM Custom Role in GCP

To enable Cloud SQL for PostgreSQL data protection, you must create an IAM custom role in Google Cloud and assign it to the service account used by the Cohesity cluster.

For detailed instructions, refer to the following topics in the Google Cloud documentation:

- Create a custom IAM role
- Assign a role to a service account

> **Note:** Before you begin creating IAM custom role, ensure that you have created a dedicated service account in Google Cloud for the Cohesity cluster.

Considerations for Cloud SQL for PostgreSQL Data Protection

Review and understand the following limitations and known issues before you protect Cloud SQL for PostgreSQL databases:

- **Security Privileges Not Restored**: Restoring database security privileges is not supported.
- **Owner and Privilege Options**: You can use the `-no-owner` and `-no-privileges` options during restore. The metadata captured during backup is displayed as the owner and ACL details in the restore activity logs.
- **Missing Roles Do Not Block Restore**: The restore operation does not fail if the owner or role from the source does not exist on the destination instance.
- **Post-Restore Role Assignment**: After restore, the database is assigned to the role configured in the Cohesity cluster for the destination instance.
- **Manual Ownership Updates**: You must manually update database ownership after the restore, if required.
- **Unsupported Characters in Database Names**: The restore workflow does not support the following characters in database names: `, @, \, [, ], !, #, %, ^,`

```
., ,, &, *, (, ), <, >, ?, /, |, }, {, ~, :, ', ", ;, +, =, -
```

- **Uppercase Usernames Not Supported**: Uppercase usernames are not supported for users added after the PostgreSQL server is created.
- **Temporary Objects May Cause Backup Failures**: Full or differential incremental backups may fail if temporary objects exist. Remove temporary objects manually and retry the backup.
- **Version Downgrade Not Supported**: Restoring a backup taken from a higher Cloud SQL for PostgreSQL database version to a lower version is not supported.

Register and Manage Google Cloud Source

To protect your Cloud SQL for PostgreSQL databases, you need to register your Google Cloud environment as a source on the Cohesity cluster. After registering your Google Cloud environment as a source, you can:

- Update the Google Cloud source configuration.
- Refresh the source details.
- Unregister the Google Cloud source from the Cohesity cluster.

Register Google Cloud as a Source

Before registering Google Cloud as a source, make sure you have completed all prerequisite tasks and reviewed the considerations.

To register Google Cloud source:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Register** at the top-right of the page and then select **Cloud Platforms** > **Google Cloud Platform**.
3. In the **Register GCP Source** dialog box, perform the following:
    1. Configure the following:

Field	Description
GCP Project ID	The Google Cloud Project ID of the project associated with the service account.
Virtual Private Cloud (VPC)	The name of the VPC network that connects the Cohesity cluster to Google Cloud.
Subnet	The subnet within the VPC for network connectivity.

    2. Under the **Authentication Method** section, choose any one of the following:

- **Upload JSON Key File** - Upload the service account JSON key file. You can either drag and drop the file or click to upload the JSON file.
- **Enter Email and Private Key** - Manually enter the service account email address and private key associated with the service account.

3. Click **Register**.

The Cohesity cluster authenticates with Google Cloud using the provided service account credentials (JSON key or email and private key). Once authenticated, it automatically discovers all projects that the service account can access, as well as all supported workloads such as Cloud SQL for PostgreSQL databases within those projects.

The discovered workloads appear under **Data Protection** > **Sources**, and when you open the registered Google Cloud source, each workload type is displayed on its own tab.

Update the Google Cloud Source Configuration

After registering Google Cloud as a source in the Cohesity cluster, you may have updated your environment in one or more of the following ways:

- Changed the project associated with the service account
- Updated VPC or subnet details
- Generated a new JSON key file for the service account

You can update the Google Cloud registration details provided during the source registration with the latest Google Cloud configuration details.

To edit the Google Cloud source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Google Cloud source and select **Edit**.
3. In the **Edit GCP Source** page, update the required configurations.
4. Click **Update**.

Refresh Google Cloud Source

You can refresh the Google Cloud source configuration and fetch the latest changes on your Google Cloud environment.

To refresh the Google Cloud source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Google Cloud source and select **Refresh**.

Unregister Google Cloud Source

If you plan to stop taking the backup of your Google Cloud source, you can unregister the Google Cloud source from the Cohesity Cluster.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the Google Cloud source.

To unregister the Google Cloud source:

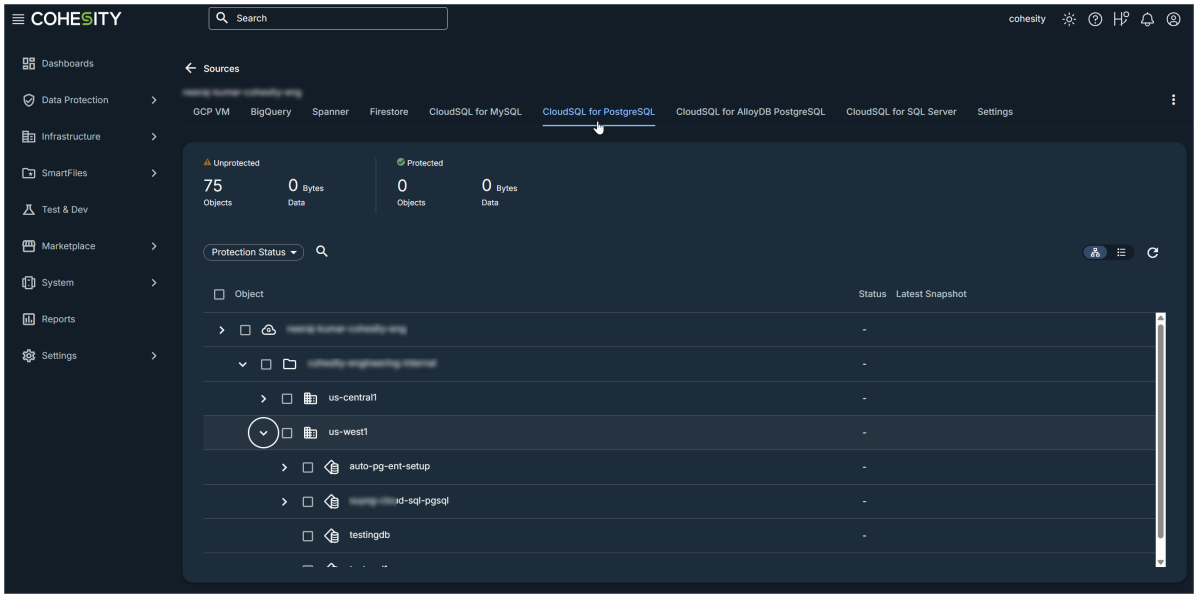
1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Google Cloud source and select **Unregister**.

Backup Cloud SQL for PostgreSQL Databases

After registering your Google Cloud source in the Cohesity cluster, it uses the provided service account credentials (JSON key or email and private key) to authenticate with Google Cloud.

Once authenticated, it automatically discovers all projects that the service account can access, as well as all supported workloads such as Cloud SQL for PostgreSQL databases within those projects. The discovered workloads appear under **Data Protection** > **Sources**. When you open the registered Google Cloud source, each workload type is displayed on its own tab. Select the **Cloud SQL for PostgreSQL** tab to view all the discovered databases.

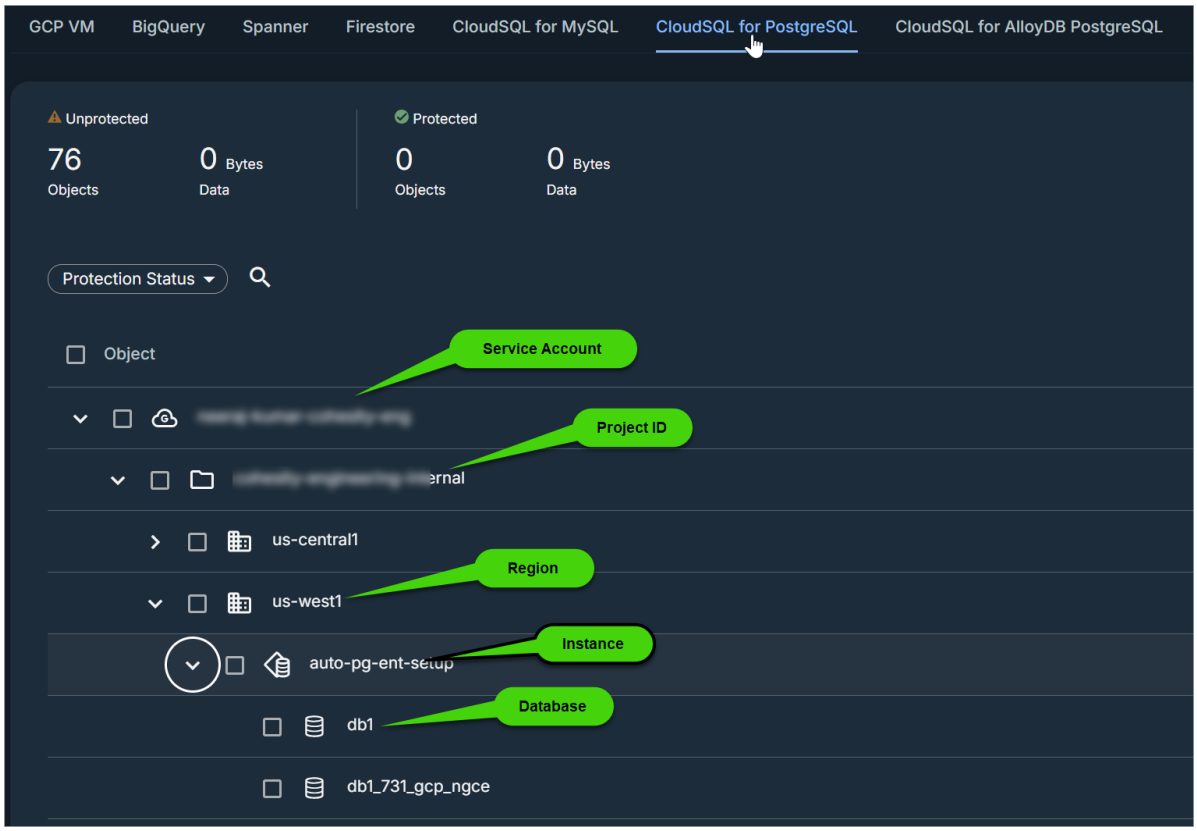
The **Cloud SQL for PostgreSQL** tab displays the entity hierarchy for the Cloud SQL for PostgreSQL environment, allowing you to navigate from the project level down to individual databases.



Cloud SQL for PostgreSQL Entity Hierarchy

The following hierarchy describes how Cloud SQL for PostgreSQL entities are organized and displayed in the Cohesity cluster:

Structure	Description
Service Account	The Google Cloud service account configured for the Cohesity cluster to perform Cloud SQL for PostgreSQL backup and recovery operations.
Project ID	The Google Cloud Project ID that the service account has permissions to access.
Region	The Google Cloud region configuration where the PostgreSQL instance is hosted.
Instance	The PostgreSQL instance available for backup and recovery.
Database	The individual Cloud SQL for PostgreSQL database that can be backed up or restored.



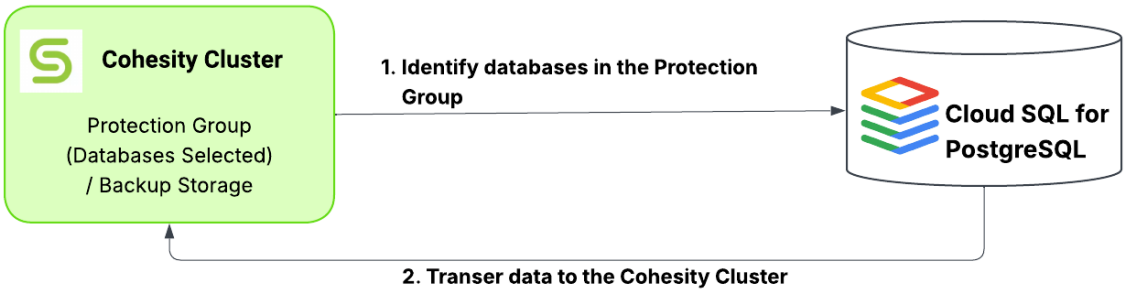
Backup Scope by Cloud SQL for PostgreSQL Hierarchy

Cohesity cluster allows you to back up Cloud SQL for PostgreSQL databases at different levels of the hierarchy. You can choose to back up:

- **Individual database**: Back up a single database.
- **Multiple databases within a region**: Back up selected databases from the same region.
- **Region level**: Back up all databases within a specific region.
- **Multiple databases across regions**: Back up selected databases from different regions.
- **Project level**: Back up all databases in all regions within the specified Project ID.

Cloud SQL for PostgreSQL Backup Process

When you run a protection job for Cloud SQL for PostgreSQL, the Cohesity cluster performs a full backup of the databases specified in the Protection Group. The Cohesity cluster connects to the selected Cloud SQL instance using the database credentials you provided during source registration and uses standard PostgreSQL backup utilities, such as `PostgreSQL` and `pgdump`, to export the complete database contents to the cluster.



Supported Backup Types

Cohesity supports only full backups for Cloud SQL for PostgreSQL databases. Incremental backups are not supported.

Protect Cloud SQL for PostgreSQL

In the Cohesity cluster, Google Cloud Cloud SQL for PostgreSQL databases are protected using a Protection Group and a Protection Policy. The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select standard or custom policy to use when creating a Protection Group. For more information, see Manage Protection Policy.

Prerequisites

Before you protect Cloud SQL for PostgreSQL databases, ensure that you add the database credentials required to authenticate and connect to the PostgreSQL server. These credentials allow the Cohesity cluster to establish a secure connection, perform the database dump, and complete backup and recovery operations.

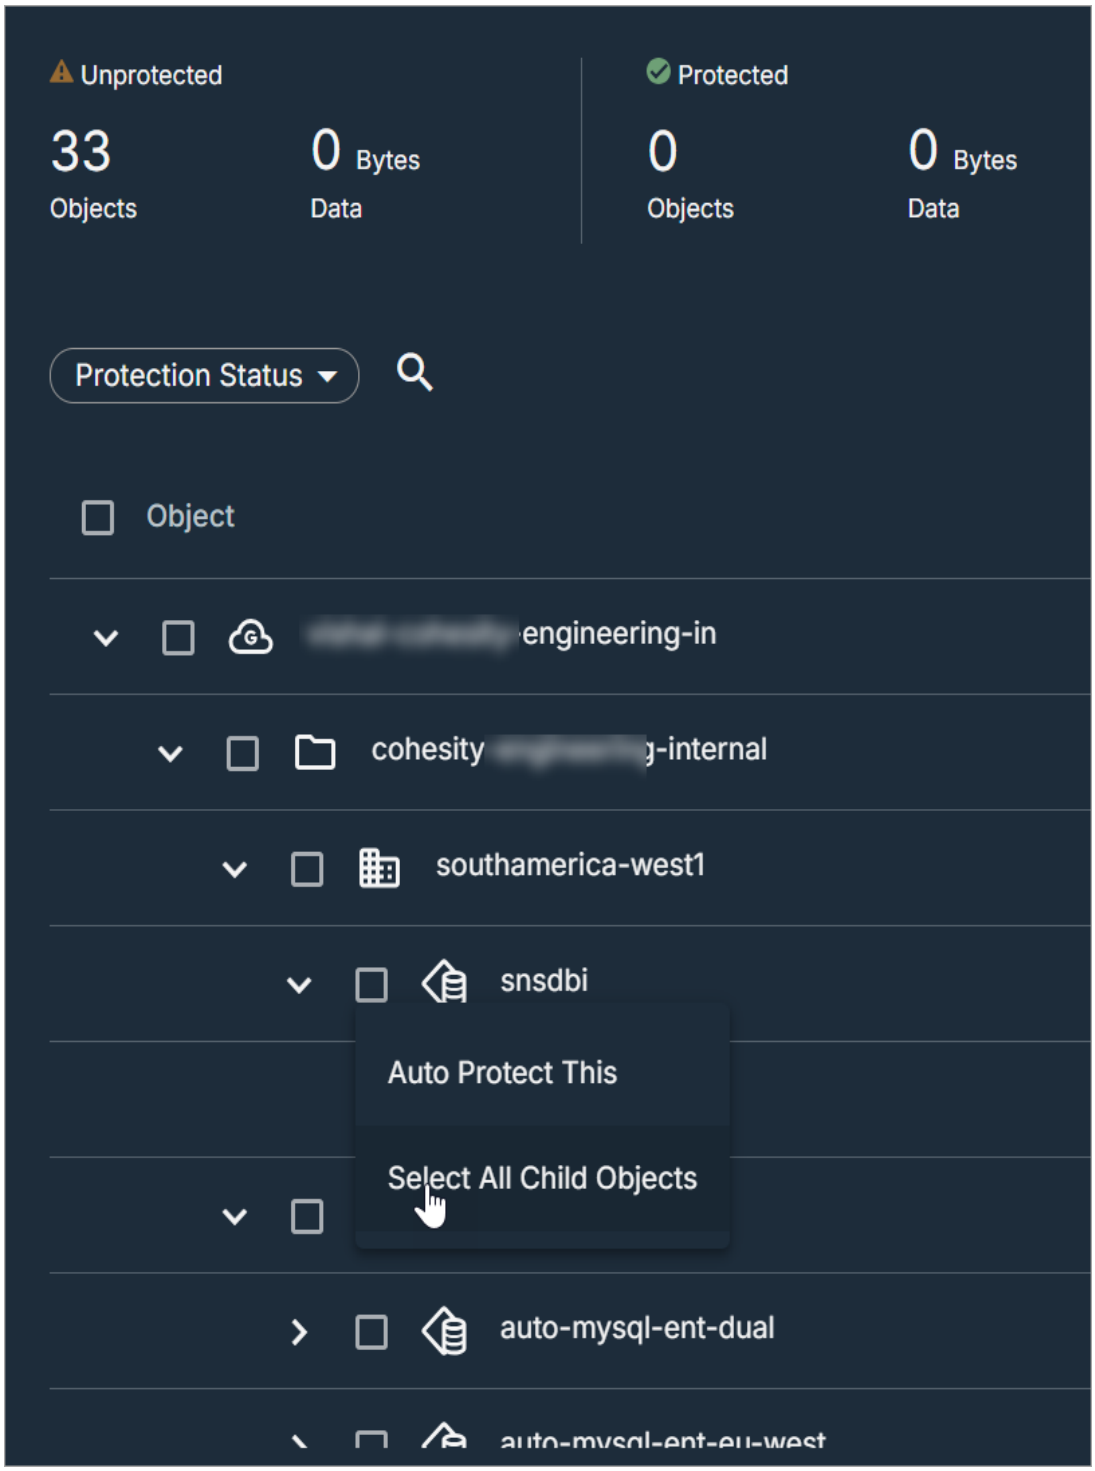
Add Database Credentials

You must add credentials at least at the Cloud SQL for PostgreSQL server level. You can also add credentials at any higher level in the hierarchy, such as the region. Credentials added at a higher level automatically apply to all objects beneath it. When multiple credentials exist in the hierarchy, the credentials closest to the PostgreSQL server take precedence. For example:

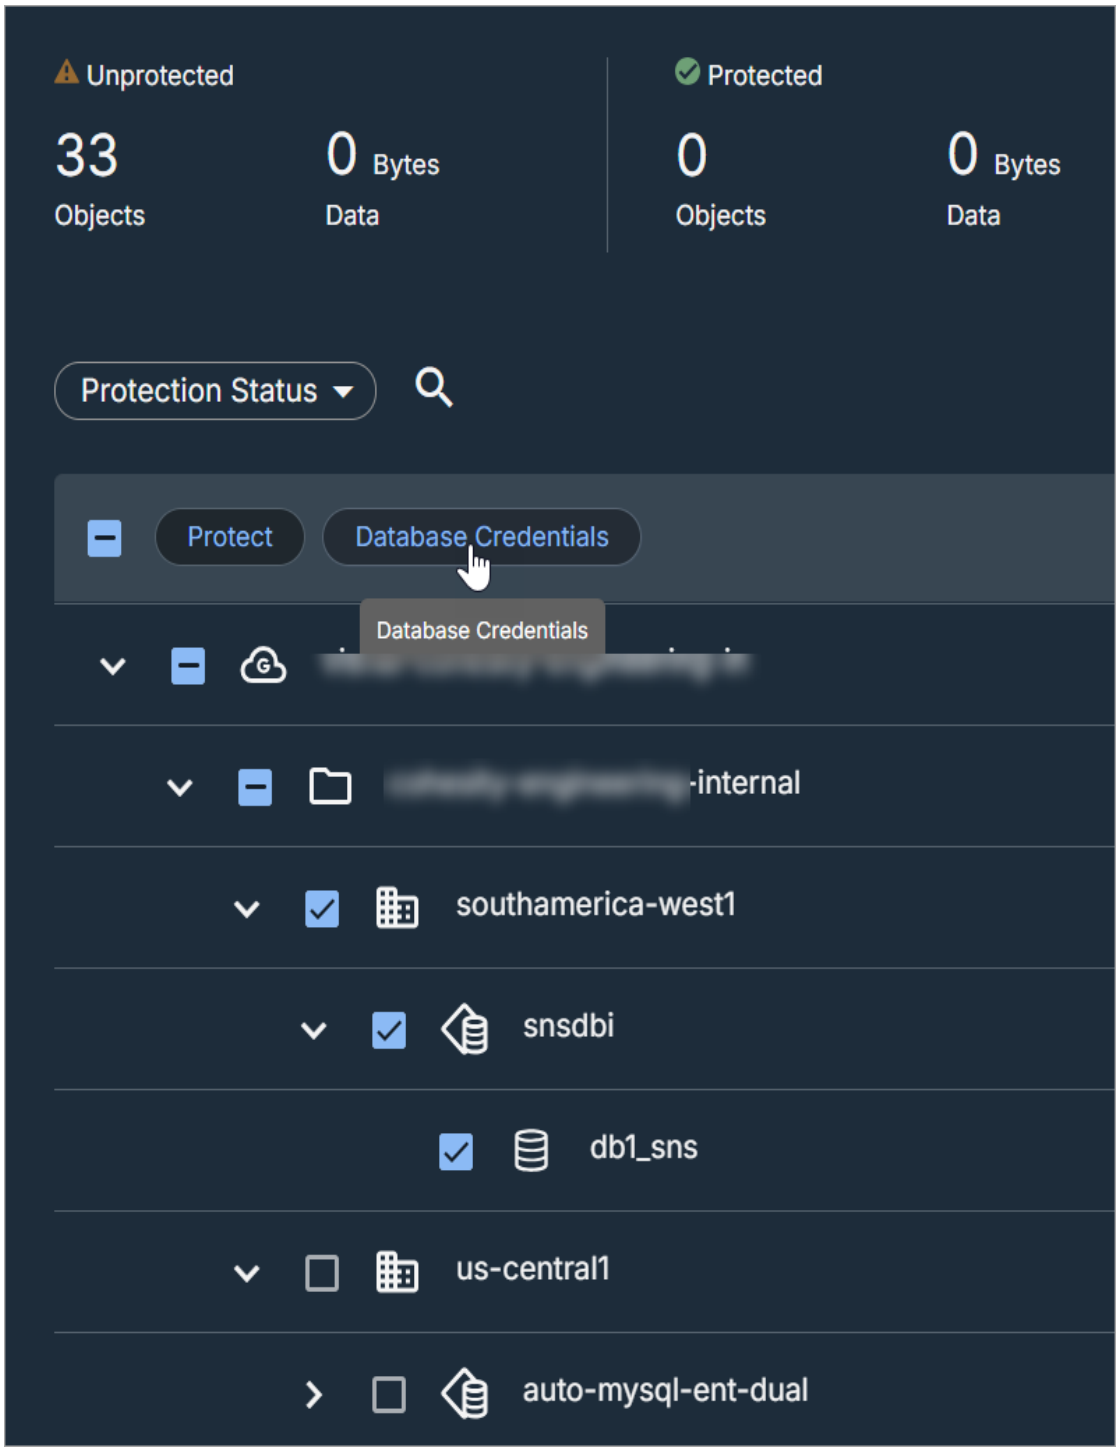
- If **region-1** has a set of credentials and **server-1** under that region has its own, the Cohesity cluster uses the credentials on **server-1** to authenticate to **server-1**.
- Another server, **server-2**, under the same region, the Cohesity cluster uses the region-level credentials for authentication because that is the closest level where credentials are defined.

To add database credentials:

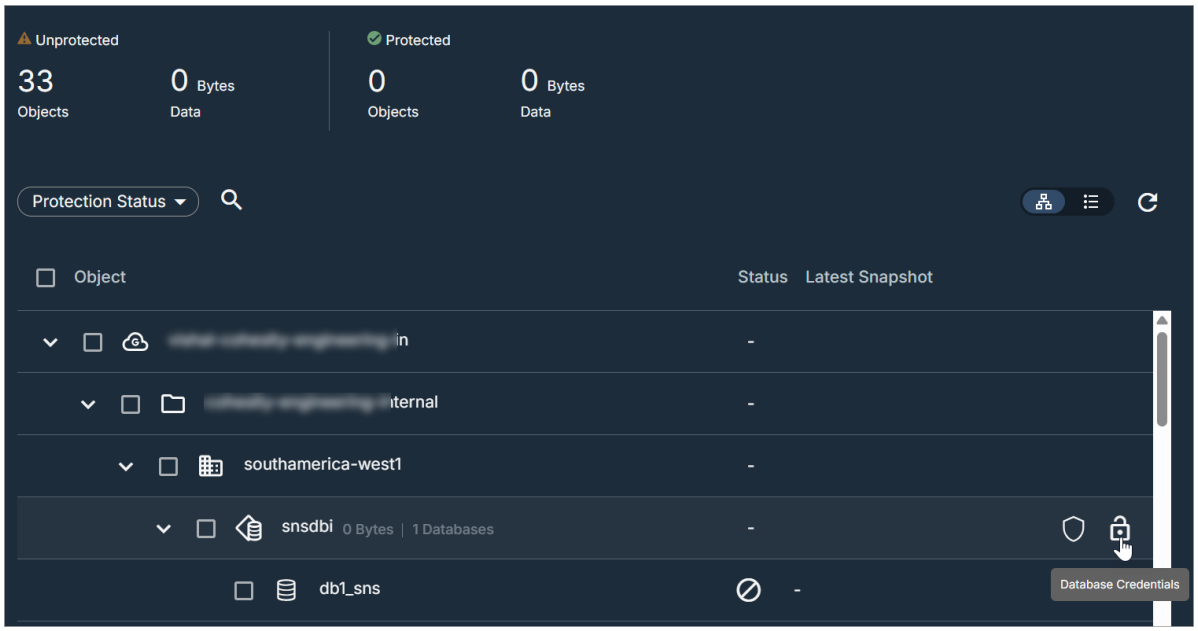
1. Navigate to **Data Protection** > **Sources**, locate the registered Google Cloud source, and click on it.
2. Click the **Cloud SQL for PostgreSQL** tab.
3. Choose one of the following options:
    - Select the checkbox next to the PostgreSQL instance and click **Select All Child Objects**.



Then, click **Database Credentials** at the top left corner.



- Click the next to the required PostgreSQL instance.



4. In the **Database Credentials** dialog box, enter the PostgreSQL instance **username** and **password**, and click **Save**.

Protect Cloud SQL for PostgreSQL Databases

To protect Cloud SQL for PostgreSQL databases:

1. Navigate to **Data Protection** > **Protection**. Click **Protect** on the top-right of the page and then select **Google Cloud** > **Cloud SQL for PostgreSQL**.
2. From the **Source** drop-down list, select a registered Google Cloud source, or click **Register Source** to add a new one.
3. In the **Objects** section, choose databases using one of the following views:
   - **Hierarchy View (default)**: Browse objects by backup scope. You can enable **Auto Protect** at the source, project, or region level.
   - **List View**: Select databases from a flat, searchable list.
4. In the **Protection Name** field, enter a name from the Protection Group.
5. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, see Manage Protection Policy.

6. In the **Settings** section, configure the following:

Settings	Description
Storage Domain	Select the appropriate Storage Domain. For more information, see Manage Storage Domains.
Start Time	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. > **Note:** This option is not applicable for Cloud SQL for PostgreSQL data protect ion. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

7. In the **Additional Settings** section, configure the following:

Additional Settings	Description
Pause Future Runs	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
End Date	Optional. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.

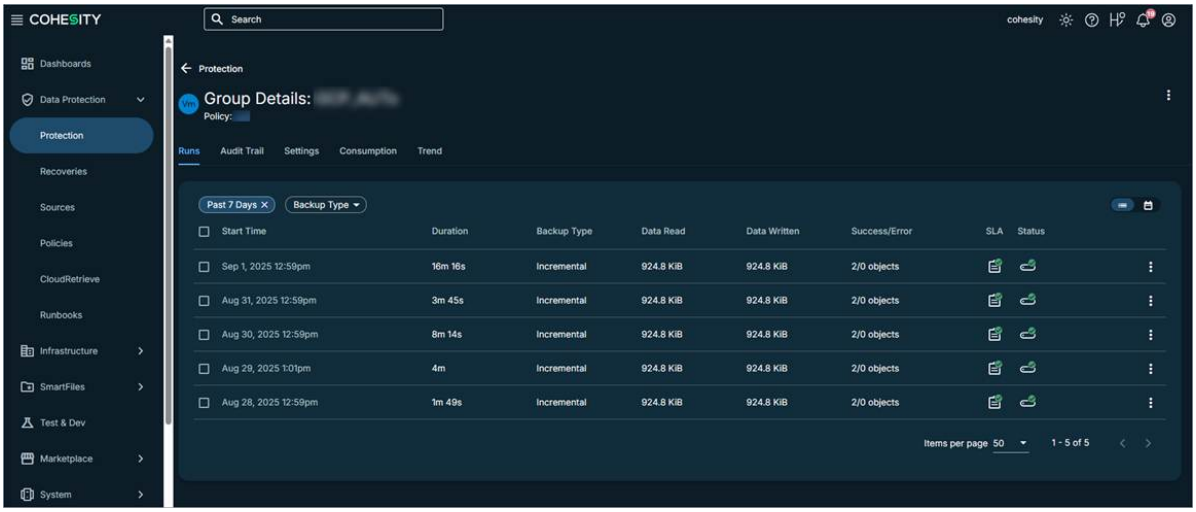
Additional Settings	Description
QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup Target HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup Target SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Alerts	Optional. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.
Priority	Select a priority for the Protection Group execution. The Cohesity cluster supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs
Description	Optional. Enter a brief description about the Protection Group.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.



Manage Cloud SQL for PostgreSQL Backup Configuration

In the Cohesity cluster, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Object(s) to the Protection Group

You can add new object(s) to the existing Protection Group for backup. The newly added object is backed up from the next protection run.

To add object(s) to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Cloud SQL for PostgreSQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ in the **Objects** section.

5. In the **Objects** section, Click the plus icon (**+**) to enter multiple objects that you plan to back up. click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Cloud SQL for PostgreSQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Cloud SQL for PostgreSQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a protection run:

1. Navigate to **Data Protection** > **Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all associated local and archived snapshots. Replicated snapshots must be deleted from the remote cluster. Snapshots under DataLock cannot be deleted.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Cloud SQL for PostgreSQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
   - Keep the **Delete Snapshots** toggle disabled to delete the Protection Group only.
   - Enable the **Delete Snapshots** toggle to delete the Protection Group and all associated snapshots.
5. Type **YES** to confirm that you want to delete the Protection Group.
6. Click **Delete Group**.

Recover Cloud SQL for PostgreSQL Databases

You can restore Cloud SQL for PostgreSQL databases either to their original GCP source or to a different GCP source and region.

Prerequisites

To recover Cloud SQL for PostgreSQL databases, add the database credentials for the target Cloud SQL PostgreSQL instance if you plan to restore it to a new location.

Recover Cloud SQL for PostgreSQL Databases

To recover Cloud SQL for PostgreSQL databases:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **Google Cloud** > **Cloud SQL for PostgreSQL**.
3. Search for the database by entering characters of the database name, or by specifying the wildcard character *.
4. From the list of search results, select the database to recover.
    - By default, the latest snapshot of the database is selected for recovery.
    - To recover from a different snapshot, hover over the snapshot and click the Edit icon. The **Edit Recovery Point for <database_name>** page appears.
    - By default, snapshots are displayed in **List** mode. You can switch to **Timeline** mode by clicking the **Timeline** tab in the top-right corner of the page.

      To select a snapshot from the **List** mode:

        a. On the **List** tab, snapshots available in the past month are displayed by default.

        b. To view snapshots from a different range, select a date range from the **Date** drop-down list.

        c. Select the snapshot(s) to recover.

        d. By default, the snapshot is recovered from the local Cohesity cluster.

        e. Click **Select Recovery Point** and then go to step 5.

      To select a snapshot from the **Timeline** mode:

        a. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar.

        b. Select the snapshot to be recovered by clicking the corresponding blue dot.

c. By default, the snapshot is recovered from the local Cohesity cluster.

d. Click **Select Recovery Point** and then go to step 5.

5. Click **Next: Recover Options**.
6. In the **Recover To** section, select any one of the following options based on your requirements:

Option	Description
Original Location	Restore the database to the same project from which it was backed up. **Note:** Restoring to the original location replaces any existing database with the same name. Type **YES** to confirm.
New Location	Restore the database to an alternate location in a different GCP source. Select a registered GCP source, project, and region. To overwrite an existing database with the same name, enable **Overwrite existing database(s)** and type **YES**. **Note:** Restoring to a new location also replaces any existing database with the same name in the selected region. If you want to restore the database to a different instance within the same GCP source, you must use this option.

7. In the **Recovery Options** section, configure the following options:

Options	Description
Rename	Enter a new name for the database if you want to rename it after recovery.
Task Name	Update the default name of the recovery task.

8. Click **Recover**.

Cloud SQL for AlloyDB PostgreSQL

Cohesity natively integrates with Google Cloud to provide a simple, fast, and cost-effective solution for backup, recovery, and data management of Google Cloud databases, including Cloud SQL for AlloyDB PostgreSQL.

> **Important:** The backup and recovery of Google Cloud Cloud SQL for AlloyDB PostgreSQL is supported only on DataProtect for cloud in GCP (formerly known as GCP NGCE cluster). This is a Controlled Availability feature, contact your Cohesity account team to enable the feature.

This chapter includes the following topics:

Plan and Prepare for Cloud SQL for AlloyDB PostgreSQL Data Protection

To protect Cloud SQL for AlloyDB PostgreSQL databases with the Cohesity cluster, you must register your Google Cloud environment as a source in the Cohesity cluster and perform backup and recovery operations. The following table lists the requirements are grouped into those needed only for source registration and those needed for both backup and restore.

Requirement	When Needed	Details
Service Account	Source registration	Create a dedicated service account in Google Cloud for Cohesity. Assign the required permissions to the service account for Cloud SQL for AlloyDB PostgreSQL protection.
Service Account Key	Source registration	Generate a JSON key for the service account to allow authentication from outside Google Cloud.
Project ID	Source registration	The Google Cloud Project ID of the project associated with the service account.
Virtual Private Cloud (VPC)	Source registration	The name of the Virtual Private Cloud network to connect the Cohesity cluster with Google Cloud.
Subnet	Source registration	The name of the subnet within the VPC for network connectivity.
Network Connectivity	Source registration, backup/restore	Ensure the Cohesity cluster can reach `google.apis.com` over firewall port **443**.

Requirement	When Needed	Details
Allowlisted Domains	Source registration, backup/restore	Allowlist the following FQDNs for source registration and data protection operations: • `https://accounts.google.com/` • `https://www.googleapis.com/` • `https://storage.googleapis.com` • `https://vpcaccess.googleapis.com/` • `https://cloudfunctions.googleapis.com/` • `https://cloudresourcemanager.googleapis.com/`
Database User	Backup and restore	Cohesity requires PostgreSQL user credentials to perform backup and recovery operations on AlloyDB for PostgreSQL databases. You can use the AlloyDB cluster admin user or create a dedicated database user with the required privileges for backup and recovery operations.

Required Permissions for Cloud SQL for AlloyDB PostgreSQL Data Protection

The following table lists the permissions and privileges that must be included in a custom role. Assign this role to the service account to enable Cloud SQL for AlloyDB PostgreSQL data protection.

Permission	Purpose
`alloydb.clusters.list`	Allows you to view a list of all AlloyDB clusters in your project.
`alloydb.clusters.get`	Enables you to retrieve detailed information about a specific AlloyDB cluster.
`alloydb.instances.get`	Grants the ability to list all AlloyDB instances within a cluster.
`alloydb.instances.list`	Allows you to access detailed information about a specific AlloyDB instance.

Create a Custom Database User

Cohesity requires PostgreSQL user credentials to discover databases in an AlloyDB for PostgreSQL cluster, retrieve database size information, and perform backup and recovery operations. You can use the AlloyDB cluster admin credentials or create a dedicated database user with the required privileges and provide those credentials to the Cohesity cluster.

These credentials allow the Cohesity cluster to establish a secure connection to the AlloyDB cluster, perform database dumps, and complete backup and recovery operations.

To create a custom database user:

1. Log in to the AlloyDB for PostgreSQL cluster using a user with administrative privileges.

   ```
   Create a database user by running the following command:
   ```

2. CREATE USER <username> WITH PASSWORD '<password'>;
3. Assign the following permissions to the database user.

   ```
   GRANT alloydbsuperuser, pg_read_all_data, pg_write_all_data TO
   <username>;
   ALTER USER <username> WITH CREATEDB;
   ALTER USER <username> WITH BYPASSRLS;
   ```

Create an IAM Custom Role in GCP

To enable Cloud SQL for AlloyDB PostgreSQL data protection, you must create an IAM custom role in Google Cloud and assign it to the service account used by the Cohesity cluster.

For detailed instructions, refer to the following topics in the Google Cloud documentation:

- Create a custom IAM role
- Assign a role to a service account

> **Note:** Before you begin creating IAM custom role, ensure that you have created a dedicated service account in Google Cloud for the Cohesity cluster.

Considerations for Cloud SQL for AlloyDB PostgreSQL Data Protection

Review and understand the following limitations and known issues before you protect Cloud SQL for AlloyDB PostgreSQL databases:

- **Security Privileges Not Restored**: Restoring database security privileges is not supported.
- **Owner and Privilege Options**: You can use the `-no-owner` and `-no-privileges` options during restore. The metadata captured during backup is displayed as the owner and ACL details in the restore activity logs.
- **Missing Roles Do Not Block Restore**: The restore operation does not fail if the owner or role from the source does not exist on the destination instance.
- **Post-Restore Role Assignment**: After restore, the database is assigned to the role configured in the Cohesity cluster for the destination instance.
- **Manual Ownership Updates**: You must manually update database ownership after the restore, if required.

- **Unsupported Characters in Database Names**: The restore workflow does not support the following characters in database names: `, @, \, [, ], !, #, %, ^, ., ,, &, *, (, ), <, >, ?, /, |, }, {, ~, :, ', ", ;, +, =, -`
- **Uppercase Usernames Not Supported**: Uppercase usernames are not supported for users added after the AlloyDB PostgreSQL instance is created.
- **Temporary Objects May Cause Backup Failures**: Full or differential incremental backups may fail if temporary objects exist. Remove temporary objects manually and retry the backup.
- **Version Downgrade Not Supported**: Restoring a backup taken from a higher Cloud SQL for AlloyDB PostgreSQL database version to a lower version is not supported.

Register and Manage Google Cloud Source

To protect your Cloud SQL for AlloyDB PostgreSQL databases, you need to register your Google Cloud environment as a source on the Cohesity cluster. After registering your Google Cloud environment as a source, you can:

- Update the Google Cloud source configuration.
- Refresh the source details.
- Unregister the Google Cloud source from the Cohesity cluster.

Register Google Cloud as a Source

Before registering Google Cloud as a source, make sure you have completed all prerequisite tasks and reviewed the considerations.

To register Google Cloud source:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Register** at the top-right of the page and then select **Cloud Platforms** > **Google Cloud Platform**.
3. In the **Register GCP Source** dialog box, perform the following:

1. Configure the following:

Field	Description
GCP Project ID	The Google Cloud Project ID of the project associated with the service account.
Virtual Private Cloud (VPC)	The name of the VPC network that connects the Cohesity cluster to Google Cloud.
Subnet	The subnet within the VPC for network connectivity.

2. Under the **Authentication Method** section, choose any one of the following:
   - **Upload JSON Key File** - Upload the service account JSON key file. You can either drag and drop the file or click to upload the JSON file.
   - **Enter Email and Private Key** - Manually enter the service account email address and private key associated with the service account.
3. Click **Register**.

The Cohesity cluster authenticates with Google Cloud using the provided service account credentials (JSON key or email and private key). Once authenticated, it automatically discovers all projects that the service account can access, as well as all supported workloads such as Cloud SQL for AlloyDB PostgreSQL databases within those projects.

The discovered workloads appear under **Data Protection** > **Sources**, and when you open the registered Google Cloud source, each workload type is displayed on its own tab.

Update the Google Cloud Source Configuration

After registering Google Cloud as a source in the Cohesity cluster, you may have updated your environment in one or more of the following ways:

- Changed the project associated with the service account
- Updated VPC or subnet details
- Generated a new JSON key file for the service account

You can update the Google Cloud registration details provided during the source registration with the latest Google Cloud configuration details.

To edit the Google Cloud source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Google Cloud source and select **Edit**.

3. In the **Edit GCP Source** page, update the required configurations.
4. Click **Update**.

Refresh Google Cloud Source

You can refresh the Google Cloud source configuration and fetch the latest changes on your Google Cloud environment.

To refresh the Google Cloud source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Google Cloud source and select **Refresh**.

Unregister Google Cloud Source

If you plan to stop taking the backup of your Google Cloud source, you can unregister the Google Cloud source from the Cohesity Cluster.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the Google Cloud source.

To unregister the Google Cloud source:

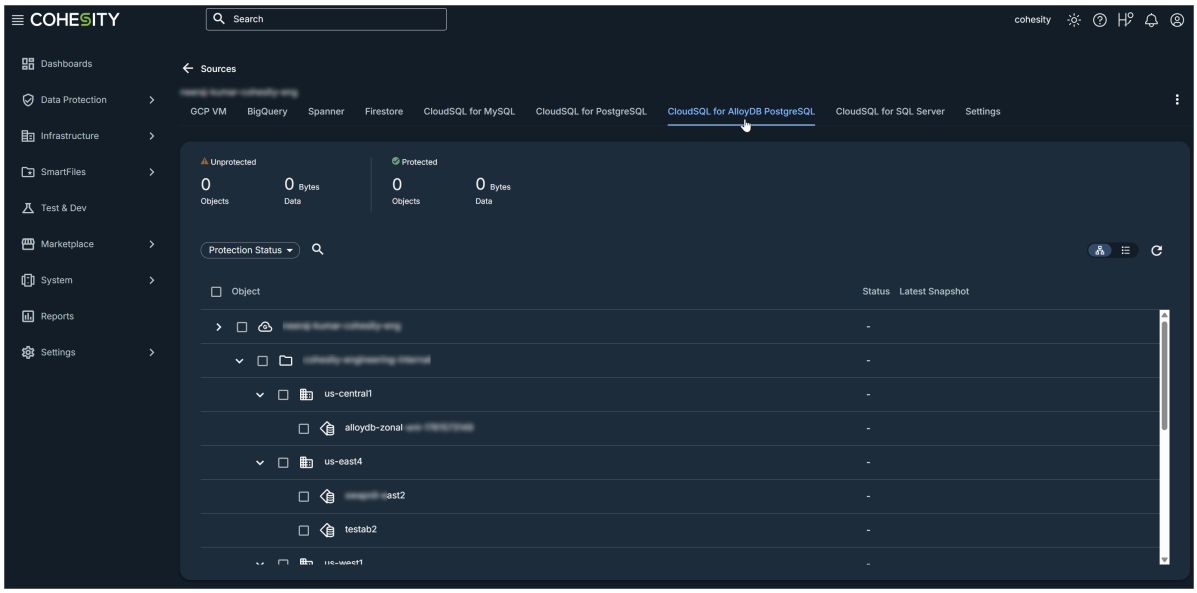
1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Google Cloud source and select **Unregister**.

Backup Cloud SQL for AlloyDB PostgreSQL Databases

After registering your Google Cloud source in the Cohesity cluster, it uses the provided service account credentials (JSON key or email and private key) to authenticate with Google Cloud.

Once authenticated, it automatically discovers all projects that the service account can access, as well as all supported workloads such as Cloud SQL for AlloyDB PostgreSQL databases within those projects. The discovered workloads appear under **Data Protection** > **Sources**. When you open the registered Google Cloud source, each workload type is displayed on its own tab. Select the **Cloud SQL for AlloyDB PostgreSQL** tab to view all the discovered databases.

The **Cloud SQL for AlloyDB PostgreSQL** tab displays the entity hierarchy for the Cloud SQL for AlloyDB PostgreSQL environment, allowing you to navigate from the project level down to individual databases.

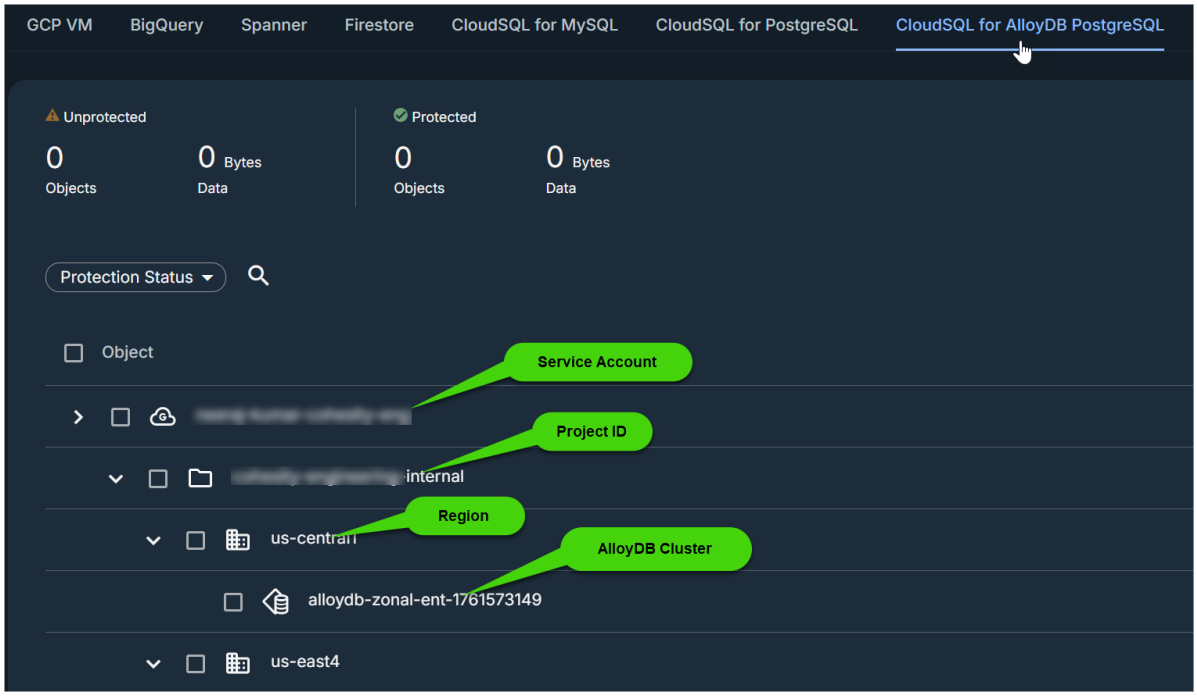


Cloud SQL for AlloyDB PostgreSQL Entity Hierarchy

The following hierarchy describes how Cloud SQL for AlloyDB PostgreSQL entities are organized and displayed in the Cohesity cluster:

Structure	Description
Service Account	The Google Cloud service account configured for the Cohesity cluster to perform Cloud SQL for AlloyDB PostgreSQL backup and recovery operations.
Project ID	The Google Cloud Project ID that the service account has permissions to access.
Region	The Google Cloud region where the CloudSQL for AlloyDB PostgreSQL cluster reside.
AlloyDB Cluster	The CloudSQL for AlloyDB PostgreSQL cluster available for backup and recovery.

Structure	Description
Database	The databases that can be selected for backup and recovery. **Note:** Databases appear only after the required credentials are applied on the AlloyDB cluster.



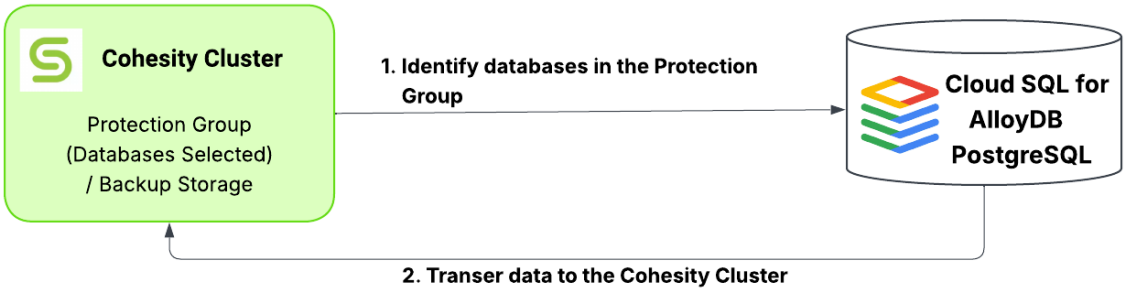
Backup Scope by Cloud SQL for AlloyDB PostgreSQL Hierarchy

Cohesity cluster allows you to back up Cloud SQL for AlloyDB PostgreSQL databases at different levels of the hierarchy. You can choose to back up:

- **Individual database**: Back up a single database.
- **Multiple databases within a region**: Back up selected databases from the same region.
- **Region level**: Back up all databases within a specific region.
- **Multiple databases across regions**: Back up selected databases from different regions.
- **Project level**: Back up all databases in all regions within the specified Project ID.

Cloud SQL for AlloyDB PostgreSQL Backup Process

When you run a protection job for Cloud SQL for AlloyDB PostgreSQL, the Cohesity cluster performs a full backup of the databases specified in the Protection Group. The Cohesity cluster connects to the selected Cloud SQL instance using the database credentials you provided during source registration and uses standard PostgreSQL backup utilities, such as `pgdump`, to export the complete database contents to the cluster.



Supported Backup Types

Cohesity supports only full backups for Cloud SQL for AlloyDB PostgreSQL databases. Incremental backups are not supported.

Protect Cloud SQL for AlloyDB PostgreSQL

In the Cohesity cluster, Google Cloud Cloud SQL for AlloyDB PostgreSQL databases are protected using a Protection Group and a Protection Policy. The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select standard or custom policy to use when creating a Protection Group. For more information, see Manage Protection Policy.

Prerequisites

Before you protect Cloud SQL for AlloyDB PostgreSQL databases, ensure that you add the database credentials required to authenticate and connect to the AlloyDB cluster. These credentials allow the Cohesity cluster to establish a secure connection, perform the database dump, and complete backup and recovery operations.

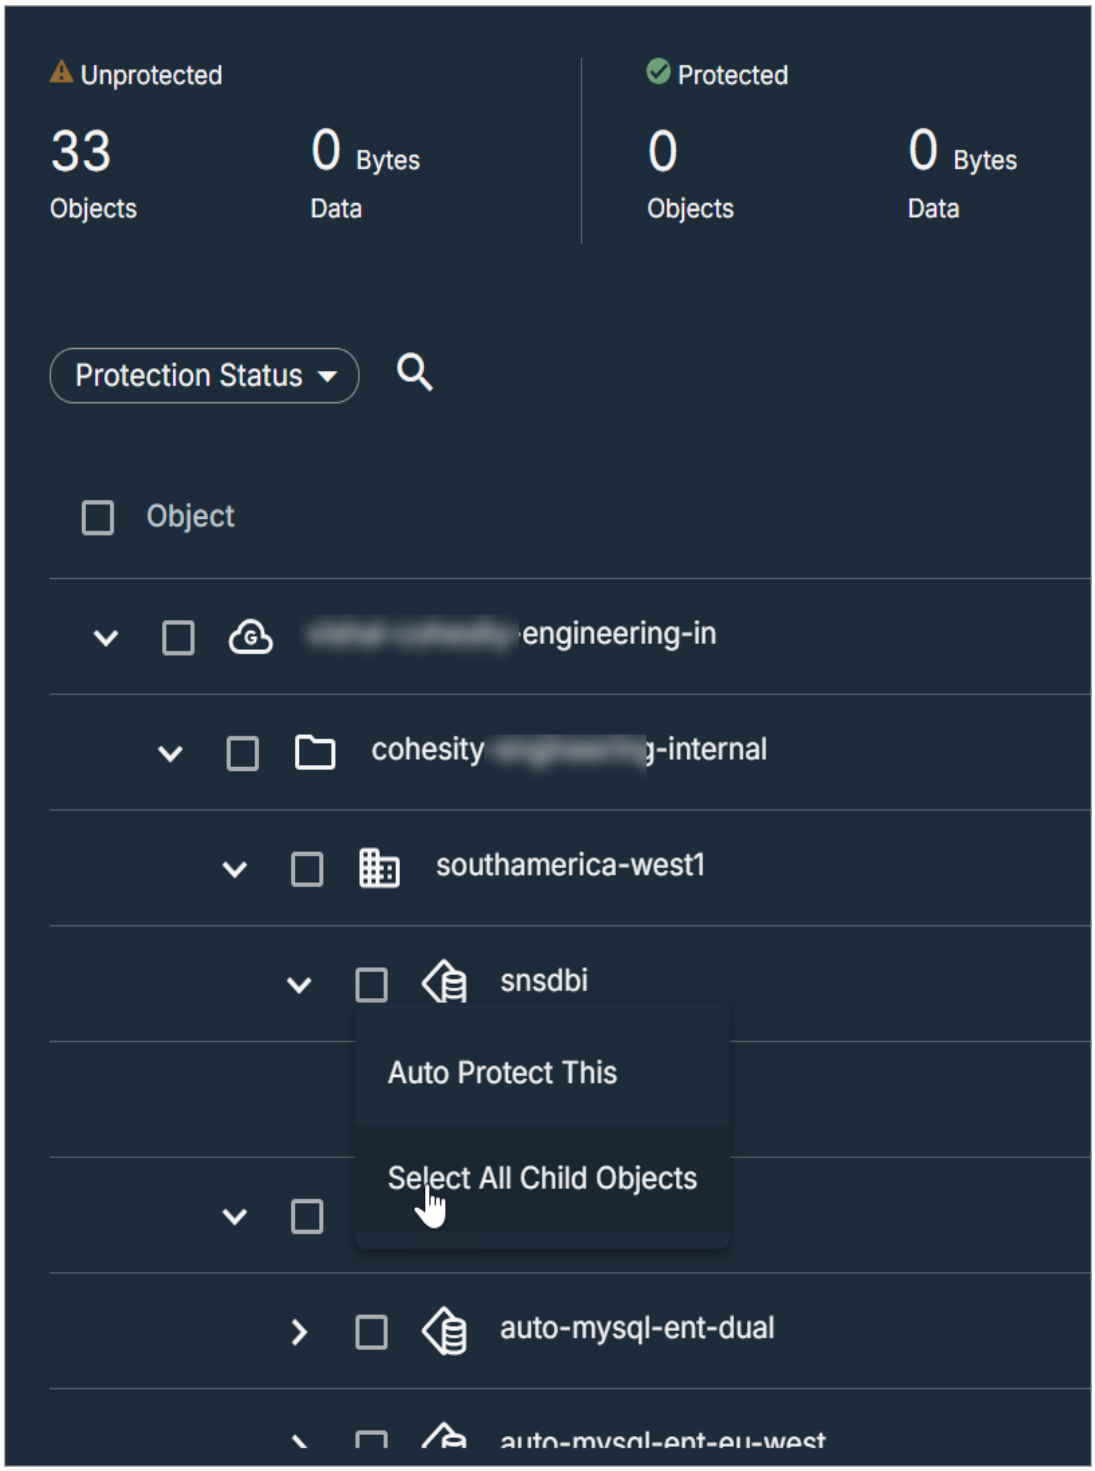
Add Database Credentials

You must add credentials at least at the Cloud SQL for AlloyDB cluster level. You can also add credentials at any higher level in the hierarchy, such as the region. Credentials added at a higher level automatically apply to all objects beneath it. When multiple credentials exist in the hierarchy, the credentials closest to the AlloyDB cluster take precedence. For example:

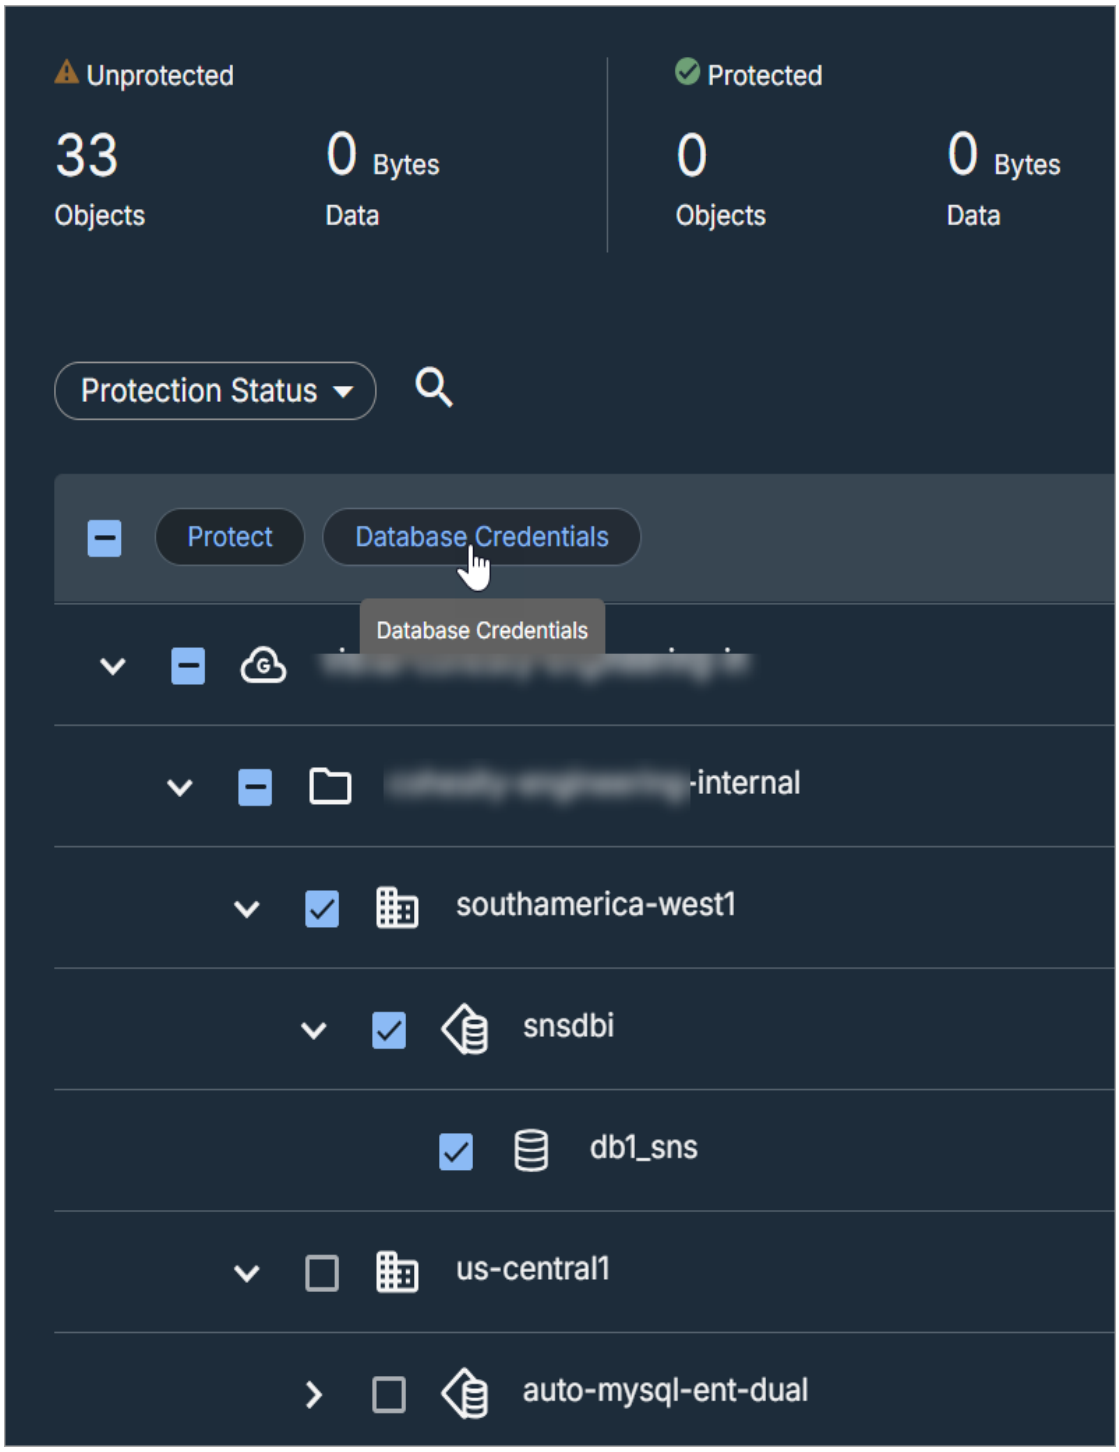
- If **region-1** has a set of credentials and **cluster-1** under that region has its own, the Cohesity cluster uses the credentials on **cluster-1** to authenticate to **cluster-1**.
- Another cluster, **cluster-2**, under the same region, the Cohesity cluster uses the region-level credentials for authentication because that is the closest level where credentials are defined.

To add database credentials:

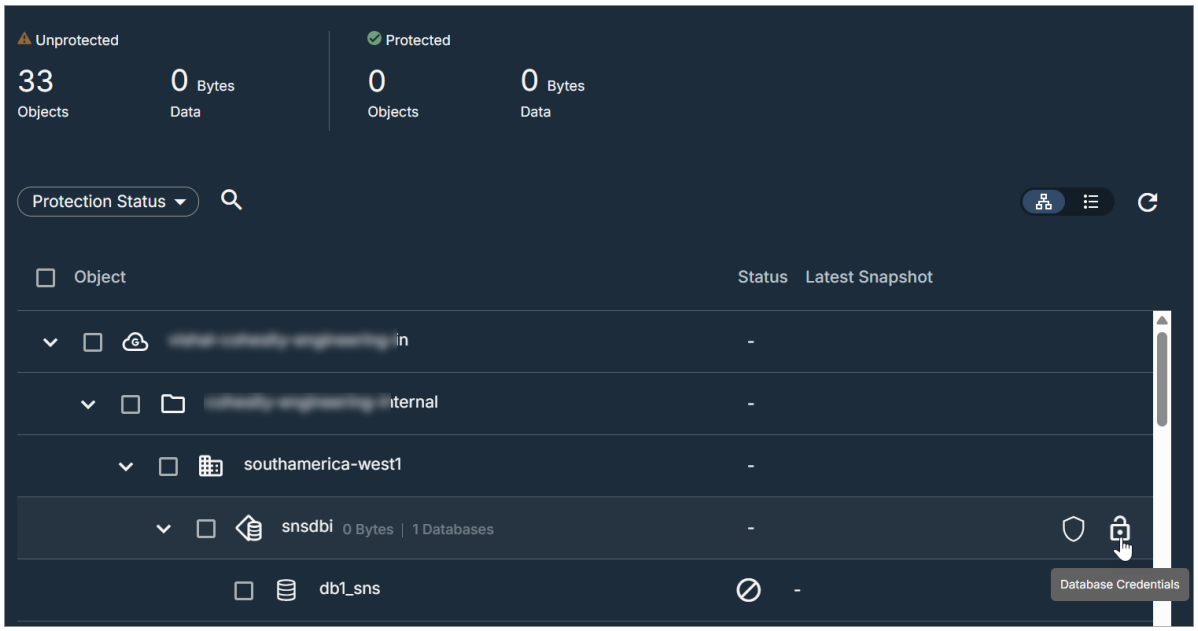
1. Navigate to **Data Protection** > **Sources**, locate the registered Google Cloud source, and click on it.
2. Click the **Cloud SQL for AlloyDB PostgreSQL** tab.
3. Choose one of the following options:
    - Select the checkbox next to the AlloyDB cluster and click **Select All Child Objects**.



Then, click **Database Credentials** at the top left corner.



- Click the next to the required AlloyDB cluster.



4. In the **Database Credentials** dialog box, enter the AlloyDB cluster **username** and **password**, and click **Save**.

Protect Cloud SQL for AlloyDB PostgreSQL Databases

To protect Cloud SQL for AlloyDB PostgreSQL databases:

1. Navigate to **Data Protection** > **Protection**. Click **Protect** on the top-right of the page and then select **Google Cloud** > **Cloud SQL for AlloyDB PostgreSQL**.
2. From the **Source** drop-down list, select a registered Google Cloud source, or click **Register Source** to add a new one.
3. In the **Objects** section, choose databases using one of the following views:
   - **Hierarchy View (default)**: Browse objects by backup scope. You can enable **Auto Protect** at the source, project, or region level.
   - **List View**: Select databases from a flat, searchable list.
4. In the **Protection Name** field, enter a name from the Protection Group.
5. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, see Manage Protection Policy.

6. In the **Settings** section, configure the following:

Settings	Description
Storage Domain	Select the appropriate Storage Domain. For more information, see Manage Storage Domains.
Start Time	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. > **Note:** This option is not applicable for Cloud SQL for AlloyDB PostgreSQL dat a protection. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

7. In the **Additional Settings** section, configure the following:

Additional Settings	Description
Pause Future Runs	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
End Date	Optional. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.

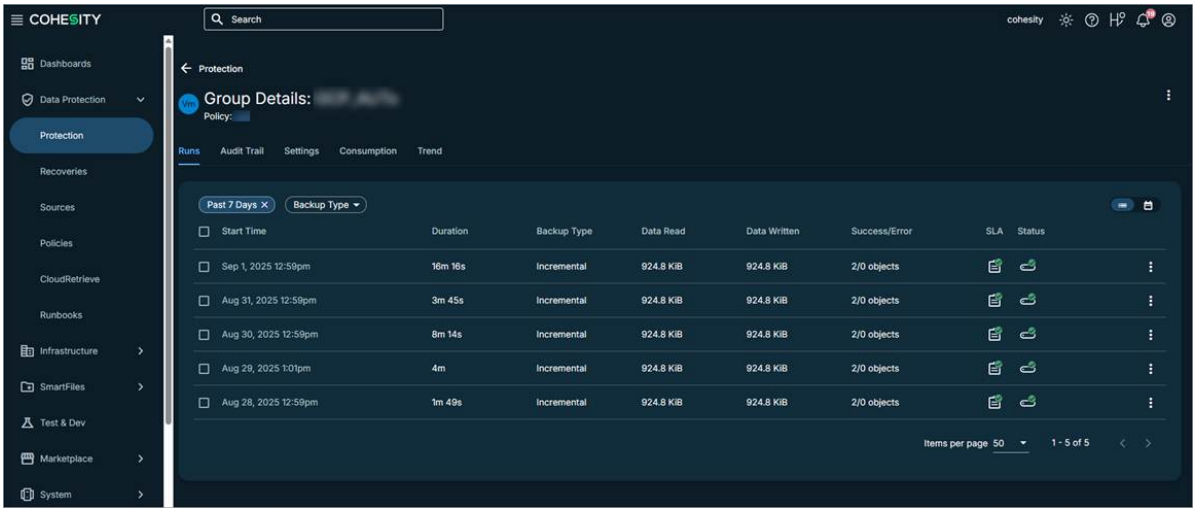
Additional Settings	Description
QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup Target HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup Target SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Alerts	Optional. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.
Priority	Select a priority for the Protection Group execution. The Cohesity cluster supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs
Description	Optional. Enter a brief description about the Protection Group.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.



Manage Cloud SQL for AlloyDB PostgreSQL Backup Configuration

In the Cohesity cluster, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Object(s) to the Protection Group

You can add new object(s) to the existing Protection Group for backup. The newly added object is backed up from the next protection run.

To add object(s) to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Cloud SQL for AlloyDB PostgreSQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ in the **Objects** section.

5. In the **Objects** section, Click the plus icon (**+**) to enter multiple objects that you plan to back up. click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Cloud SQL for AlloyDB PostgreSQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Cloud SQL for AlloyDB PostgreSQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a protection run:

1. Navigate to **Data Protection** > **Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all associated local and archived snapshots. Replicated snapshots must be deleted from the remote cluster. Snapshots under DataLock cannot be deleted.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Cloud SQL for AlloyDB PostgreSQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
   - Keep the **Delete Snapshots** toggle disabled to delete the Protection Group only.
   - Enable the **Delete Snapshots** toggle to delete the Protection Group and all associated snapshots.
5. Type **YES** to confirm that you want to delete the Protection Group.
6. Click **Delete Group**.

Recover Cloud SQL for AlloyDB PostgreSQL Databases

You can restore Cloud SQL for AlloyDB PostgreSQL databases either to their original GCP source or to a different GCP source and region.

CloudSQL for AlloyDB PostgreSQL Recovery Process

When you run a recovery job for Cloud SQL for AlloyDB PostgreSQL, Cohesity restores the database(s) specified in the recovery job. The Cohesity cluster connects to the selected Cloud SQL instance using the database credentials you provide after source registration and imports the backup data into the target instance.

Cohesity retrieves the backup from Cohesity-managed storage, transfers the backup files to the recovery target, and uses standard PostgreSQL restore utilities, such as `pg_restore`, to import the database contents into the target instance.

Prerequisites

To recover Cloud SQL for AlloyDB PostgreSQL databases, add the database credentials for the target Cloud SQL AlloyDB PostgreSQL instance if you plan to restore it to a new location.

Recover Cloud SQL for AlloyDB PostgreSQL Databases

To recover Cloud SQL for AlloyDB PostgreSQL databases:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **Google Cloud** > **Cloud SQL for AlloyDB PostgreSQL**.
3. Search for the database by entering characters of the database name, or by specifying the wildcard character *.
4. From the list of search results, select the database to recover.
    - By default, the latest snapshot of the database is selected for recovery.
    - To recover from a different snapshot, hover over the snapshot and click the Edit icon. The **Edit Recovery Point for <database_name>** page appears.
    - By default, snapshots are displayed in **List** mode. You can switch to **Timeline** mode by clicking the **Timeline** tab in the top-right corner of the page.

      To select a snapshot from the **List** mode:

        a. On the **List** tab, snapshots available in the past month are displayed by default.

        b. To view snapshots from a different range, select a date range from the **Date** drop-down list.

        c. Select the snapshot(s) to recover.

d. By default, the snapshot is recovered from the local Cohesity cluster.

e. Click **Select Recovery Point** and then go to step 5.

To select a snapshot from the **Timeline** mode:

a. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar.

b. Select the snapshot to be recovered by clicking the corresponding blue dot.

c. By default, the snapshot is recovered from the local Cohesity cluster.

d. Click **Select Recovery Point** and then go to step 5.

5. Click **Next: Recover Options**.
6. In the **Recover To** section, select any one of the following options based on your requirements:

Option	Description
Original Location	Restore the database to the same project from which it was backed up. **Note:** Restoring to the original location replaces any existing database with the same name. Type **YES** to confirm.
New Location	Restore the database to an alternate location in a different GCP source. Select a registered GCP source, project, and region. To overwrite an existing database with the same name, enable **Overwrite existing database(s)** and type **YES**. **Note:** Restoring to a new location also replaces any existing database with the same name in the selected region.

7. In the **Recovery Options** section, configure the following options:

Options	Description
Rename	Enter a new name for the database if you want to rename it after recovery.
Task Name	Update the default name of the recovery task.

8. Click **Recover**.

Cloud SQL for SQL Server

Cohesity natively integrates with Google Cloud to provide a simple, fast, and cost-effective solution for backup, recovery, and data management of Google Cloud databases, including Cloud SQL for SQL Server.

> **Important:** The backup and recovery of Google Cloud Cloud SQL for SQL Server is supported only on DataProtect for cloud in GCP (formerly known as GCP NGCE cluster). This is a Controlled Availability feature, contact your Cohesity account team to enable the feature.

This chapter includes the following topics:

Plan and Prepare for Cloud SQL for SQL Server Data Protection

To protect Cloud SQL for SQL Server databases with the Cohesity cluster, you must register your Google Cloud environment as a source in the Cohesity cluster and perform backup and recovery operations. The following table lists the requirements are grouped into those needed only for source registration and those needed for both backup and restore.

Requirement	When Needed	Details
Service Account	Source registration	Create a dedicated service account in Google Cloud for Cohesity. Assign the required permissions to the service account for Cloud SQL for SQL Server protection.
Service Account Key	Source registration	Generate a JSON key for the service account to allow authentication from outside Google Cloud.
Project ID	Source registration	The Google Cloud Project ID of the project associated with the service account.
Virtual Private Cloud (VPC)	Source registration	The name of the Virtual Private Cloud network to connect the Cohesity cluster with Google Cloud.
Subnet	Source registration	The name of the subnet within the VPC for network connectivity.
Network Connectivity	Source registration, backup/restore	Ensure the Cohesity cluster can reach `google.apis.com` over firewall port **443**.

Requirement	When Needed	Details
Allowlisted Domains	Source registration, backup/restore	Allowlist the following FQDNs for source registration and data protection operations: • `https://accounts.google.com/` • `https://www.googleapis.com/` • `https://storage.googleapis.com` • `https://vpcaccess.googleapis.com/` • `https://cloudfunctions.googleapis.com/` • `https://cloudresourcemanager.googleapis.com/`
Staging Bucket for Backup and Restore	Backup/Restore	You must have a staging bucket in Google Cloud Storage to enable backup and restore operations for Cloud SQL for SQL Server databases. • **Auto Create**: Cohesity can automatically create a staging bucket when you configure backup and recovery for Cloud SQL for SQL Server databases. • **Manual Create**: You can manually create one or more staging buckets in Google Cloud Storage. Use different staging buckets for protecting different databases or for recovery operations. Each bucket can be in the same or a different region as the database. **Note:** Using a bucket in a different region than the database may incur additional Google Cloud Storage costs.

Required Permissions for Cloud SQL for SQL Server Data Protection

The following table lists the permissions and privileges that must be included in a custom role. Assign this role to the service account to enable Cloud SQL for SQL Server data protection.

Type	Permission	Purpose
Google Cloud Storage	`storage.buckets.create`	Allows creating new Google Cloud Storage (GCS) buckets within the project.
	`storage.buckets.get`	Ability to retrieve the metadata of a specific Cloud Storage bucket
	`storage.buckets.getIamPolicy`	Ability to read the Identity and Access Management (IAM) policy of a specific Cloud Storage bucket.
	`storage.buckets.setIamPolicy`	Ability to set the Identity and Access Management (IAM) policy (ACLs) for a specific Cloud Storage bucket.
	`storage.objects.create`	Ability to create new objects (files) within a specified Cloud Storage bucket
	`storage.objects.delete`	Ability to delete objects (files) from a Cloud Storage bucket.
	`storage.objects.get`	Ability to read the data and metadata of an object stored in a Cloud Storage bucket.
	`storage.objects.list`	Ability to list the objects (files) within a specified Cloud Storage bucket.
Cloud SQL for SQL Server	`cloudsql.databases.get`	Ability to retrieve metadata for a specific database within a Cloud SQL instance.
	`cloudsql.databases.list`	Allows listing all databases inside a Cloud SQL instance.
	`cloudsql.instances.export`	Allows initiating an export operation on a Cloud SQL instance.
	`cloudsql.instances.get`	Allows reading configuration details for a Cloud SQL instance, such as version, region, and settings.
	`cloudsql.instances.import`	Allows starting an import operation on a Cloud SQL instance.
	`cloudsql.instances.list`	Allows listing all Cloud SQL instances in the project.

Create an IAM Custom Role in GCP

To enable Cloud SQL for SQL Server data protection, you must create an IAM custom role in Google Cloud and assign it to the service account used by the Cohesity cluster.

For detailed instructions, refer to the following topics in the Google Cloud documentation:

- Create a custom IAM role
- Assign a role to a service account

> **Note:** Before you begin creating IAM custom role, ensure that you have created a dedicated service account in Google Cloud for the Cohesity cluster.

Create Staging Bucket on Google Cloud Storage

To enable Cloud SQL for SQL Server data protection with the Cohesity cluster, you need a staging bucket in Google Cloud Storage. The staging bucket is used to temporarily store exported Cloud SQL for SQL Server databases during backup and recovery operations.

You can choose one of the following options when setting up the staging bucket:

- **Auto Create**: Cohesity can automatically create a staging bucket for you as part of the backup configuration workflow in the Cohesity cluster.
- **Create Manually**: Manually create and specify an existing Google Cloud Storage bucket to be used for staging.

> **Note:** Create one or more staging buckets in Google Cloud Storage. You can use different staging buckets for protecting different databases or for recovery operations. Each bucket can be in the same or a different region as the database. Note that using a different region may incur additional Google Cloud Storage costs.

Manually Create a Staging Bucket

To manually create a staging bucket:

1. In the **Google Cloud** console, go to the Cloud Storage **Buckets** page.
2. Click **Create**.
3. On the **Create a bucket** page, provide the following information. After completing each section, click **Continue** to proceed:
    1. **Get started**: Enter a unique name for the staging bucket. Follow naming guidelines to ensure compatibility.

2. **Choose where to store your data**: Select either **Region** or **Multi-region** as the location type.
3. **Choose how to store your data**: Select **Set a default class**, then choose **Standard** as the default storage class.
4. **Choose how to control access to objects**:
    - Enable **Enforce public access prevention**.
    - Select **Uniform as the access control model**.
5. **Choose how to protect object data**:
    - Under **Data protection**, enable **Soft delete policy (For data recovery)** and select **Use default retention duration**.
    - Under **Data encryption**, select **Google-managed encryption key** as the encryption method.
6. Click **Create**.

Considerations for Cloud SQL for SQL Server Data Protection

Review and understand the following limitations and known issues before you protect Google Cloud Cloud SQL for SQL Server databases.

Review and understand the following limitations and known issues before you protect Cloud SQL for SQL Server databases:

- **Logical Backups Only**: Snapshot-based backups are not supported.
- **Backup Coverage**: Only user databases are supported. Backups of read-only databases or databases running in single-user mode are not supported.
- **Recovery Behavior**: Databases can be recovered only as new databases. Cross-region and cross-account recoveries are not supported.
- **Version Downgrade Not Supported**: Restoring a backup taken from a higher Cloud SQL for SQL Server database version to a lower version is not supported.

Register and Manage Google Cloud Source

To protect your Cloud SQL for SQL Server databases, you need to register your Google Cloud environment as a source on the Cohesity cluster. After registering your Google Cloud environment as a source, you can:

- Update the Google Cloud source configuration.
- Refresh the source details.
- Unregister the Google Cloud source from the Cohesity cluster.

Register Google Cloud as a Source

Before registering Google Cloud as a source, make sure you have completed all prerequisite tasks and reviewed the considerations.

To register Google Cloud source:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Register** at the top-right of the page and then select **Cloud Platforms** > **Google Cloud Platform**.
3. In the **Register GCP Source** dialog box, perform the following:
    1. Configure the following:

Field	Description
GCP Project ID	The Google Cloud Project ID of the project associated with the service account.
Virtual Private Cloud (VPC)	The name of the VPC network that connects the Cohesity cluster to Google Cloud.
Subnet	The subnet within the VPC for network connectivity.

    2. Under the **Authentication Method** section, choose any one of the following:
        - **Upload JSON Key File** - Upload the service account JSON key file. You can either drag and drop the file or click to upload the JSON file.
        - **Enter Email and Private Key** - Manually enter the service account email address and private key associated with the service account.
    3. Click **Register**.

The Cohesity cluster authenticates with Google Cloud using the provided service account credentials (JSON key or email and private key). Once authenticated, it automatically discovers all projects that the service account can access, as well as all supported workloads such as Cloud SQL for SQL Server databases within those projects.

The discovered workloads appear under **Data Protection** > **Sources**, and when you open the registered Google Cloud source, each workload type is displayed on its own tab.

Update the Google Cloud Source Configuration

After registering Google Cloud as a source in the Cohesity cluster, you may have updated your environment in one or more of the following ways:

- Changed the project associated with the service account
- Updated VPC or subnet details
- Generated a new JSON key file for the service account

You can update the Google Cloud registration details provided during the source registration with the latest Google Cloud configuration details.

To edit the Google Cloud source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Google Cloud source and select **Edit**.
3. In the **Edit GCP Source** page, update the required configurations.
4. Click **Update**.

Refresh Google Cloud Source

You can refresh the Google Cloud source configuration and fetch the latest changes on your Google Cloud environment.

To refresh the Google Cloud source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Google Cloud source and select **Refresh**.

Unregister Google Cloud Source

If you plan to stop taking the backup of your Google Cloud source, you can unregister the Google Cloud source from the Cohesity Cluster.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the Google Cloud source.

To unregister the Google Cloud source:

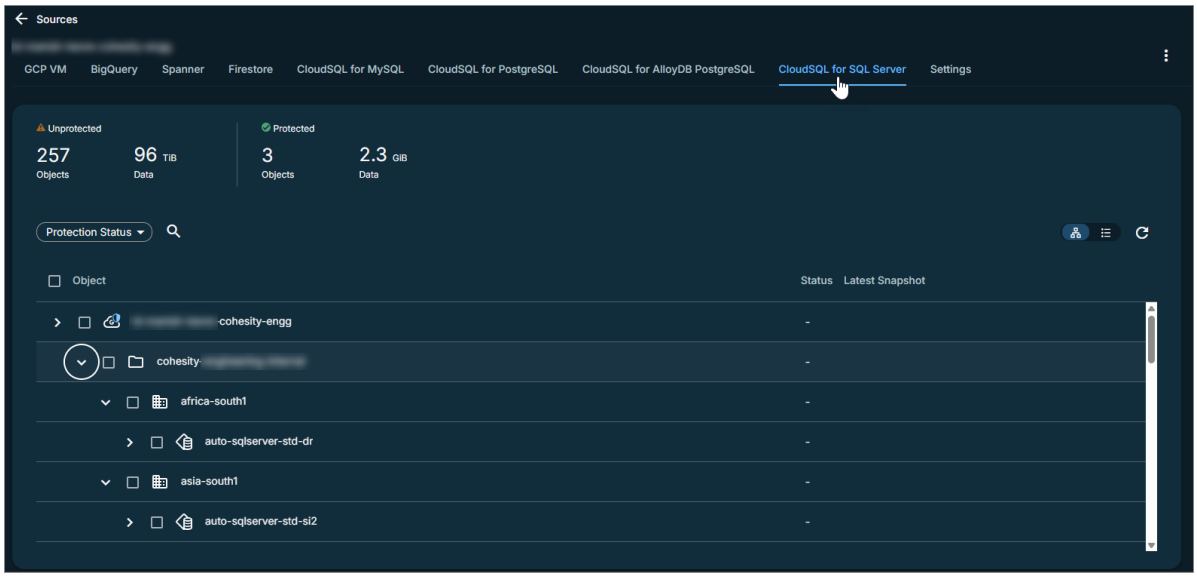
1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Google Cloud source and select **Unregister**.

Backup Cloud SQL for SQL Server Databases

After registering your Google Cloud source in the Cohesity cluster, it uses the provided service account credentials (JSON key or email and private key) to authenticate with Google Cloud.

Once authenticated, it automatically discovers all projects that the service account can access, as well as all supported workloads such as Cloud SQL for SQL Server databases within those projects. The discovered workloads appear under **Data Protection** > **Sources**. When you open the registered Google Cloud source, each workload type is displayed on its own tab. Select the **Cloud SQL for SQL Server** tab to view all the discovered databases.

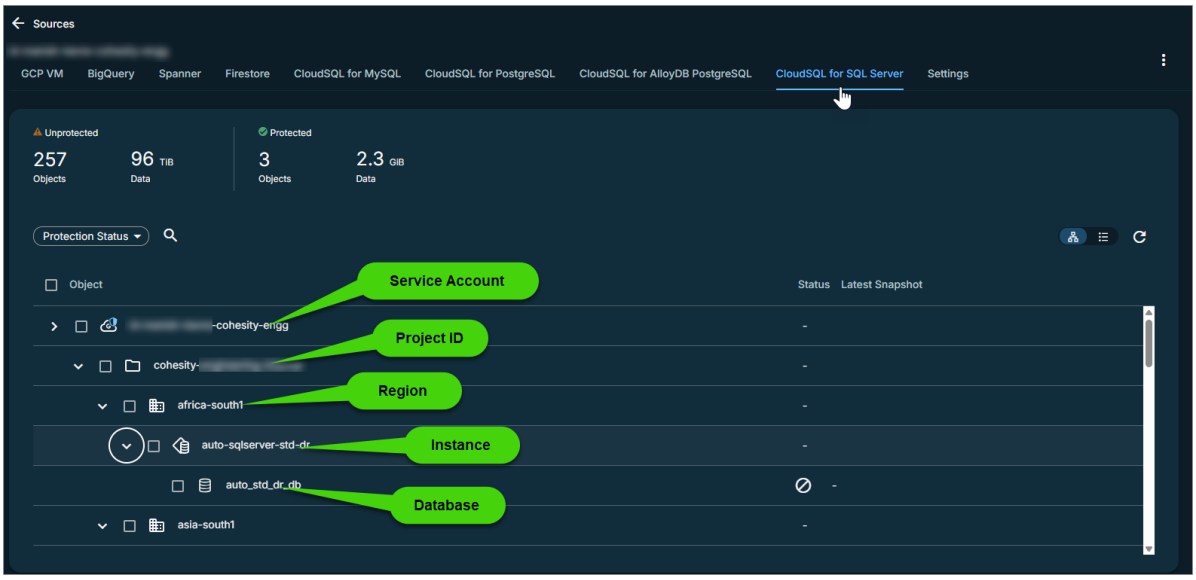
The **Cloud SQL for SQL Server** tab displays the entity hierarchy for the Cloud SQL for SQL Server environment, allowing you to navigate from the project level down to individual databases.



Cloud SQL for SQL Server Entity Hierarchy

The following hierarchy describes how Cloud SQL for SQL Server entities are organized and displayed in the Cohesity cluster:

Structure	Description
Service Account	The Google Cloud service account configured for the Cohesity cluster to perform Cloud SQL for SQL Server backup and recovery operations.
Project ID	The Google Cloud Project ID that the service account has permissions to access.
Region	The Google Cloud region where the Cloud SQL for SQL Server databases are hosted.
Instance	The Cloud SQL for SQL Server instance available for backup and recovery.
Database	The database that can be selected for backup and recovery.



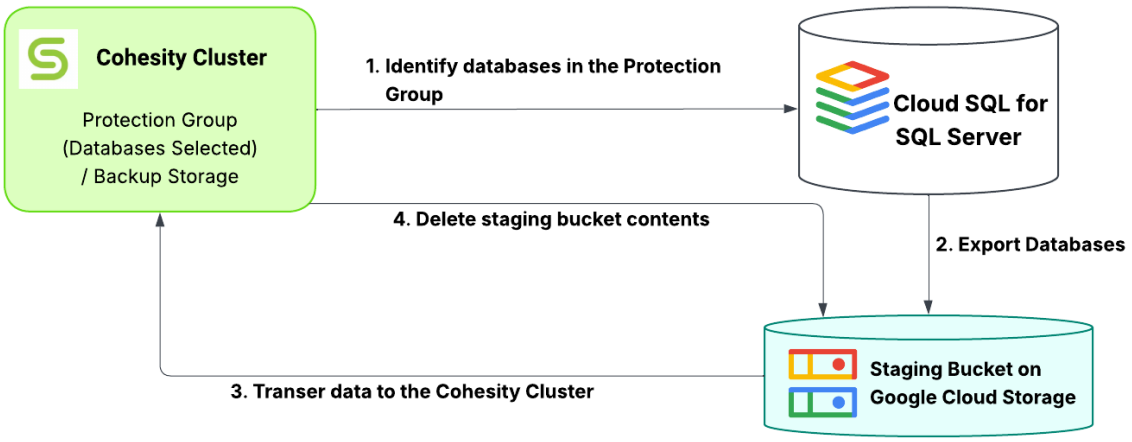
Backup Scope by Cloud SQL for SQL Server Hierarchy

Cohesity cluster allows you to back up Cloud SQL for SQL Server databases at different levels of the hierarchy. You can choose to back up:

- **Individual database**: Back up a single database.
- **Multiple databases within a region**: Back up selected databases from the same region.
- **Region level**: Back up all databases within a specific region.
- **Multiple databases across regions**: Back up selected databases from different regions.
- **Project level**: Back up all databases in all regions within the specified Project ID.

Cloud SQL for SQL Server Backup Process

When you run a protection job in the Cohesity cluster to back up Cloud SQL for SQL Server databases, the databases specified in the Protection Group are first exported from Cloud SQL for SQL Server to a staging bucket in Google Cloud Storage. The Cohesity cluster then copies the data from the staging bucket to the cluster. After the backup completes successfully, the contents of the staging bucket are deleted to free up storage.



Supported Backup Types

Cohesity supports both full backup and incremental backups for Cloud SQL for SQL Server databases.

Protect Cloud SQL for SQL Server

In the Cohesity cluster, Google Cloud Cloud SQL for SQL Server databases are protected using a Protection Group and a Protection Policy. The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select standard or custom policy to use when creating a Protection Group. For more information, see Manage Protection Policy.

Prerequisites

Before you protect Cloud SQL for SQL Server databases, ensure that:

- A staging bucket exists in Google Cloud Storage (GCS) for storing exported data during backups. You can:
  - If you choose to **Auto Create** the staging bucket:

    Cohesity automatically creates a staging bucket in the same region as your database(s) when you start a backup operation.
  - If you choose to **specify an existing bucket**:

    You can specify an existing bucket located in the same region as the databases being protected. Using a bucket in a different region is supported but may incur additional Google Cloud Storage charges.

> **Note:** After each protection job run, Cohesity deletes only the temporary data stored in the staging bucket during backup operations. The staging bucket itself is retained and reused for future backup operations to minimize storage costs and avoid cross-region charges.

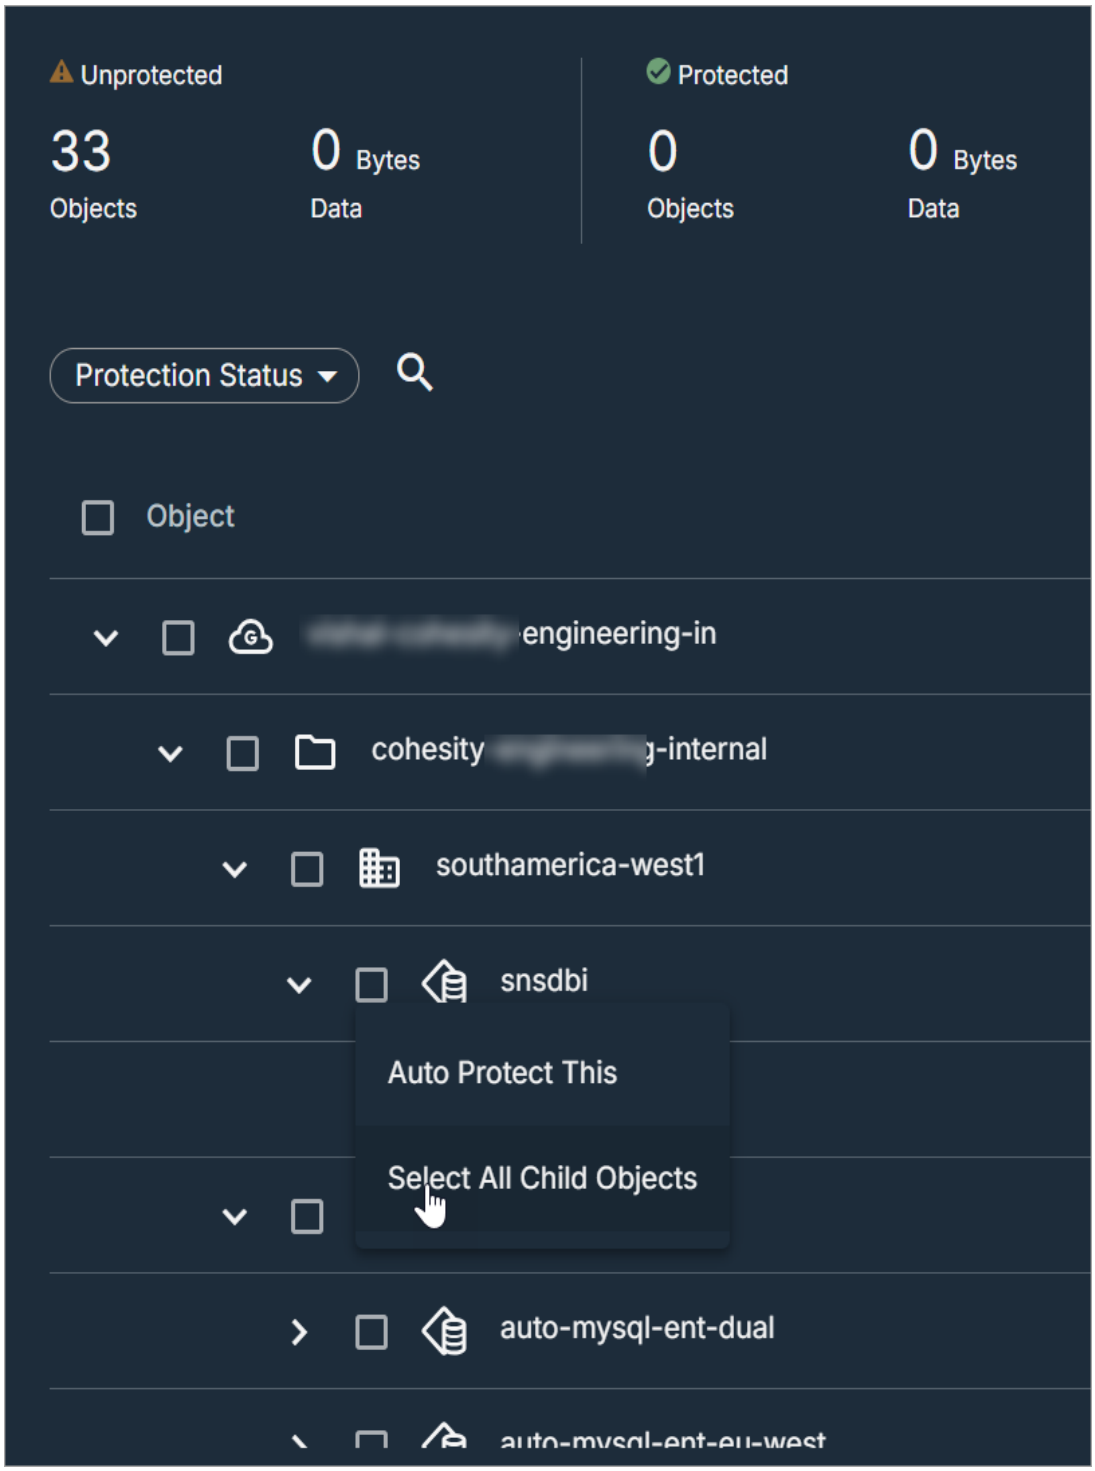
- Add the database credentials required for the Cohesity cluster to authenticate and connect to the SQL server instance. These credentials allow the Cohesity cluster to establish a secure connection, perform the database dump, and complete backup and recovery operations.

Add Database Credentials

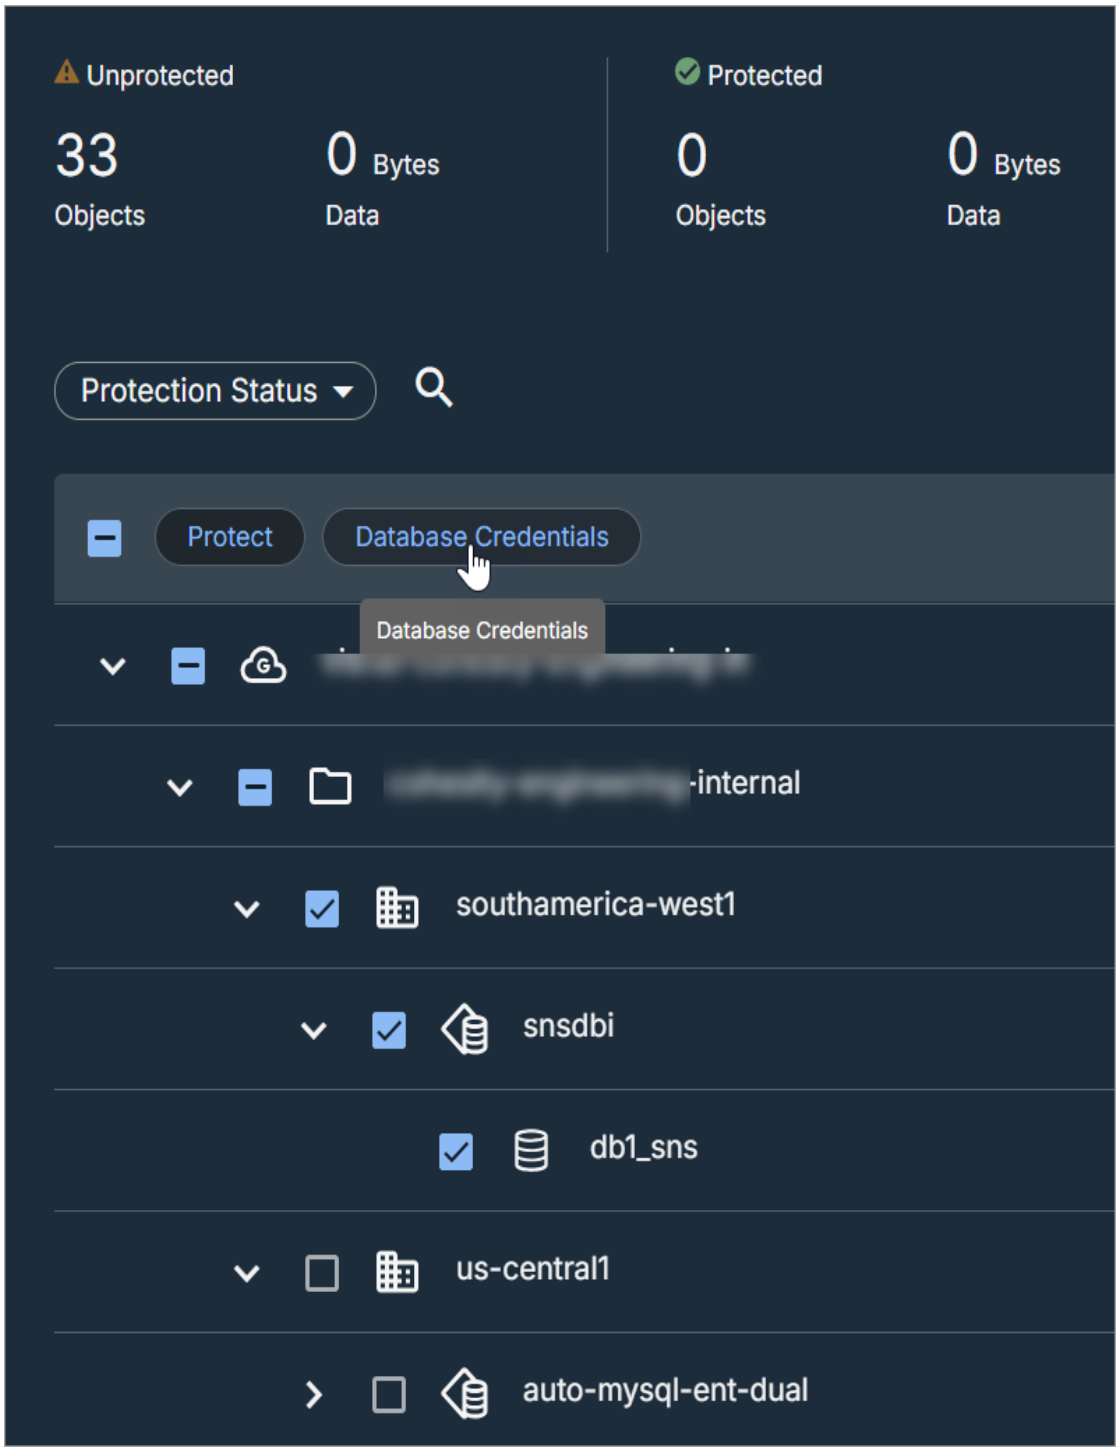
You must add the credentials at the Cloud SQL for SQL Server instance level. The same credentials are used whenever the Cohesity cluster connects to the database for backup or restore.

To add the database credentials:

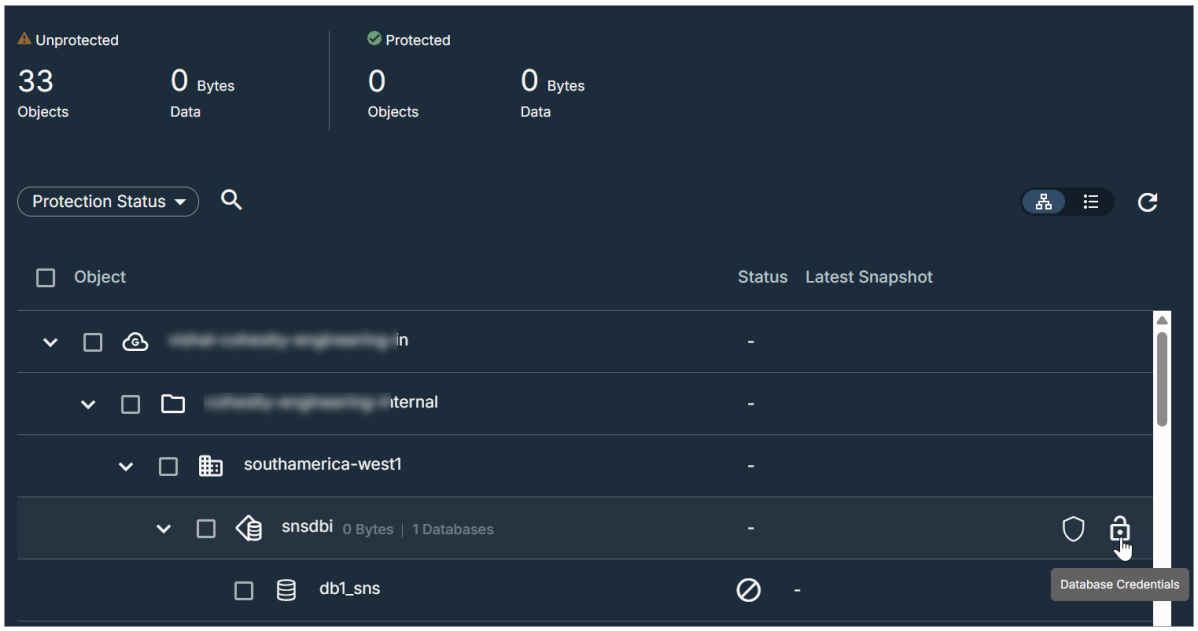
1. Navigate to **Data Protection** > **Sources**, locate the registered Google Cloud source, and click on it.
2. Click the **Cloud SQL for SQL Server** tab.
3. Choose one of the following options:
    - Select the checkbox next to the Cloud SQL for SQL Server instance and click **Select All Child Objects**.



Then, click **Database Credentials** at the top left corner.



- Click the next to the required Cloud SQL for SQL Server instance.



4. In the **Database Credentials** dialog box, enter the Cloud SQL for SQL Server instance **username** and **password**, and click **Save**.

Protect Cloud SQL for SQL Server Databases

To protect Cloud SQL for SQL Server databases:

1. Navigate to **Data Protection** > **Protection**. Click **Protect** on the top-right of the page and then select **Google Cloud** > **Cloud SQL for SQL Server**.
2. From the **Source** drop-down list, select a registered Google Cloud source, or click **Register Source** to add a new one.
3. In the **Objects** section, choose databases using one of the following views:
   - **Hierarchy View (default)**: Browse objects by backup scope. You can enable **Auto Protect** at the source, project, or region level.
   - **List View**: Select databases from a flat, searchable list.
4. In the **Protection Name** field, enter a name from the Protection Group.
5. In the **Staging Bucket** section, choose one of the following options:
   - **Auto Create**: Cohesity automatically creates a temporary staging bucket in the same region as your database(s). The bucket follows the naming format `cohe-<project-id >-<region-name>`.

     Where:
     - `project-id` is the Google Cloud project ID.
     - `region-name` is the Google Cloud region where the databases reside.

- **Specify Bucket to Use**: Enter the name of an existing staging bucket in Google Cloud Storage (GCS) that you created for backups.

After each protection job run, Cohesity deletes only the temporary data stored in the staging bucket during backup operations. The staging bucket itself is retained and reused for future backup operations to minimize storage costs and avoid cross-region charges.

6. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, see Manage Protection Policy.
7. In the **Settings** section, configure the following:

Settings	Description
Storage Domain	Select the appropriate Storage Domain. For more information, see Manage Storage Domains.
Start Time	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).

8. In the **Additional Settings** section, configure the following:

Additional Settings	Description
Pause Future Runs	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.

Additional Settings	Description
End Date	Optional. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup Target HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup Target SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Alerts	Optional. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.

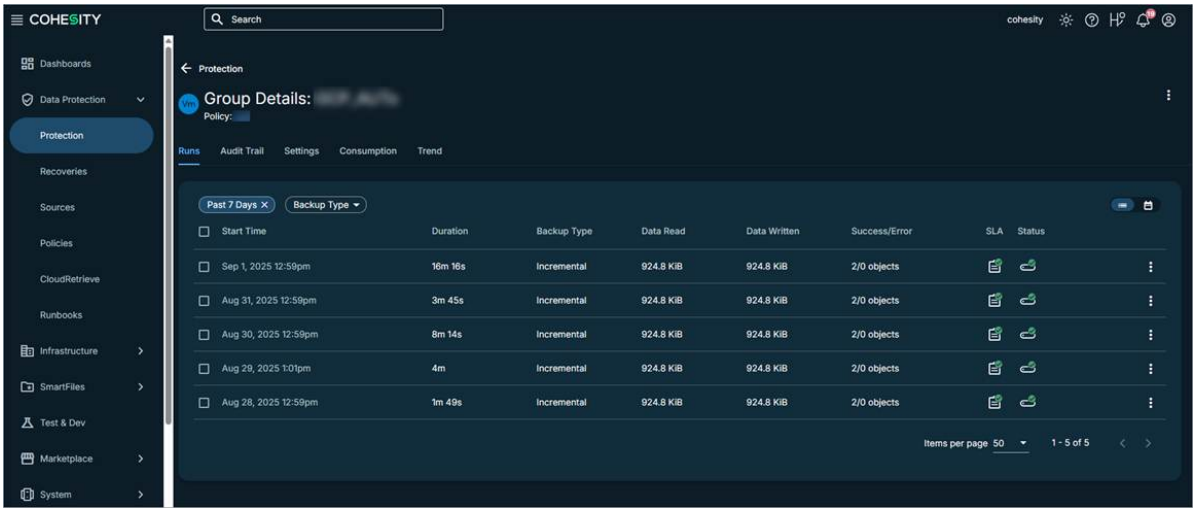
Additional Settings	Description
Priority	Select a priority for the Protection Group execution. The Cohesity cluster supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs
Description	Optional. Enter a brief description about the Protection Group.

View Protection Group Details

After creating a Protection Group, you can view key details including:

- Status of protection runs
- Audit trails
- Storage consumption
- Configuration settings
- Protection run trends

To access these details, navigate to **Protection** and click the Protection Group you created.



Manage Cloud SQL for SQL Server Backup Configuration

In the Cohesity cluster, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Object(s) to the Protection Group

You can add new object(s) to the existing Protection Group for backup. The newly added object is backed up from the next protection run.

To add object(s) to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Cloud SQL for SQL Server.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ in the **Objects** section.
5. In the **Objects** section, Click the plus icon (**+**) to enter multiple objects that you plan to back up. click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Cloud SQL for SQL Server.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Cloud SQL for SQL Server.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a protection run:

1. Navigate to **Data Protection** > **Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all associated local and archived snapshots. Replicated snapshots must be deleted from the remote cluster. Snapshots under DataLock cannot be deleted.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Cloud SQL for SQL Server.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Keep the **Delete Snapshots** toggle disabled to delete the Protection Group only.
    - Enable the **Delete Snapshots** toggle to delete the Protection Group and all associated snapshots.
5. Type **YES** to confirm that you want to delete the Protection Group.
6. Click **Delete Group**.

Recover Cloud SQL for SQL Server Databases

You can restore Cloud SQL for SQL Server databases either to their original GCP source or to a different GCP source and region.

Cloud SQL for SQL Recovery Process

When you run a recovery job in the Cohesity cluster, one or more selected Cloud SQL for SQL databases backups are exported to a Google Cloud Storage staging bucket. The staging bucket temporarily stores the exported data before it is ingested into Cloud SQL for SQL deployment.

After the export completes, Google Cloud automatically copies the data from the staging bucket to the Cloud SQL for SQL deployment. Once ingestion is successful, the contents of the staging bucket are then automatically deleted to free up storage and reduce costs.

Prerequisites

Before you restore Cloud SQL for SQL Server databases, ensure the following:

- A staging bucket is available in Google Cloud Storage. You can either use an existing bucket or allow Cohesity to automatically create one during the restore process.
    - If you choose to **Auto Create** the staging bucket:

      Cohesity automatically creates a staging bucket in the same region as your database(s) when you start the recovery.
    - If you choose to **specify an existing bucket**:

You can specify an existing bucket located in the same region as the recovery target. Using a bucket in a different region is supported but may incur additional Google Cloud Storage charges.

> **Note:** After each recovery job run, Cohesity deletes only the temporary data stored in the staging bucket. The staging bucket itself is retained and reused for future recovery operations to minimize storage costs and avoid cross-region charges.

- **If recovering to a new location**: Ensure that you have added the database credentials for the Cloud SQL for SQL Server instance to which the data will be restored.

Recover Cloud SQL for SQL Server Databases

To recover Cloud SQL for SQL Server databases:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **Google Cloud** > **Cloud SQL for SQL Server**.
3. Search for the database by entering characters of the database name, or by specifying the wildcard character *.
4. From the list of search results, select the database to recover.
   - By default, the latest snapshot of the database is selected for recovery.
   - To recover from a different snapshot, hover over the snapshot and click the Edit icon. The **Edit Recovery Point for <database_name>** page appears.
   - By default, snapshots are displayed in **List** mode. You can switch to **Timeline** mode by clicking the **Timeline** tab in the top-right corner of the page.

     To select a snapshot from the **List** mode:

     a. On the **List** tab, snapshots available in the past month are displayed by default.

     b. To view snapshots from a different range, select a date range from the **Date** drop-down list.

     c. Select the snapshot(s) to recover.

     d. By default, the snapshot is recovered from the local Cohesity cluster.

     e. Click **Select Recovery Point** and then go to step 5.

     To select a snapshot from the **Timeline** mode:

a. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar.
b. Select the snapshot to be recovered by clicking the corresponding blue dot.
c. By default, the snapshot is recovered from the local Cohesity cluster.
d. Click **Select Recovery Point** and then go to step 5.

5. Click **Next: Recover Options**.
6. In the **Recover To** section, select any one of the following options based on your requirements:

Option	Description
Original Location	Restore the database to the same project from which it was backed up. **Note:** Restoring to the original location replaces any existing database with the same name. Type **YES** to confirm.
New Location	Restore the database to an alternate location in a different GCP source. Select a registered GCP source, project, and region. To overwrite an existing database with the same name, enable **Overwrite existing database(s)** and type **Yes**. **Note:** Restoring to a new location also replaces any existing database with the same name in the selected region.

7. In **Restore Staging Bucket** section, choose one of the following options:
   - **Auto Create**: Cohesity automatically creates a temporary staging bucket in the same region as your database(s) for the recovery operation. The bucket follows the naming format: `cohe-<project-id>-<region-name>`.

     Where:
     - `project-id` is the Google Cloud project ID.
     - `region-name` is the Google Cloud region where the databases reside.
   - **Specify Bucket to Use**: Enter the name of an existing staging bucket in Google Cloud Storage (GCS) that you created for recovery.

   Cohesity deletes only the temporary data stored in the staging bucket during each recovery operation. The bucket itself is retained and reused for future recovery operations to minimize storage costs and avoid cross-region charges.

8. In the **Recovery Options** section, configure the following options:

Options	Description
Rename	Enter a new name for the database if you want to rename it after recovery.
Task Name	Update the default name of the recovery task.

9. Click **Recover**.

Chapter 10: S3-Compatible Storage

S3-compatible storage is a cloud storage system or service that supports the Amazon S3 (Simple Storage Service) API. Cohesity provides enterprise-grade backup and recovery of S3-compatible storage.

Plan and Prepare for S3-Compatible Storage Protection

Before you protect your S3-compatible storage, ensure you have met the prerequisites and reviewed the considerations.

Supported S3-Compatible Storage

For the list of supported S3-compatible Storage, see Supported Software.

Ports Used for Communication

Ensure the port used by the S3-compatible is open for communication with the Cohesity cluster.

S3-Compatible Storage Source	Port
Dell EMC ECS	9021
Pure Storage Flashblade	443
NetApp StorageGrid	443
IBM Cloud Object Storage	443
MinIO	9000

You need to mention these ports when registering the S3-compatible with the Cohesity cluster.

Considerations

- Cohesity does not support:
  - Auto-protection of S3-compatible bucket.
  - Backup and recovery of metadata and tags for S3-compatible buckets.
  - Recovery of S3-compatible bucket to AWS S3 bucket.
  - Browse and recover an object in an S3-compatible bucket. However, you can recover multiple objects by specifying the object prefix in the recovery task under the S3 Prefixes to Recover option.
  - The backup of older versions of the S3-compatible versioned bucket. Only the latest version of the versioned S3-compatible bucket is backed up.
  - Backup and recovery of user-defined metadata and Tags.
- While creating the Protection Group for Dell EMC ECS, the UI displays only up to 1,000 buckets from the S3-compatible storage for selection.
- Cohesity supports all object stores that are compatible with the Amazon S3 API version dated 2006-03-01.

Register and Manage S3-Compatible Storage

To protect your S3-compatible storage bucket, you need to register your S3-compatible storage as a source on the Cohesity cluster. After registration, you can manage the source on the Cohesity cluster in the following ways:

- Update the S3-compatible storage source configuration.
- Refresh the source details.
- Unregister the S3-compatible storage source from the Cohesity cluster.

Before you Begin

Before you register S3-compatible storage as a source on the Cohesity cluster, ensure that you:

1. Review the requirements, considerations, and best practices.
2. Perform the prerequisite tasks.

For more information, see Plan and Prepare for S3-Compatible Storage Protection.

Register S3-compatible storage as a Source

Perform the following steps to register S3-compatible storage as a source:

1. In the product UI, select **Data Protection** > **Sources**.
2. Click Register on the top-right of the page and then select **S3 Compatible**.

   The Register S3-compatible Source page appears.
3. Provide the following information, and then click **Register**:
   - **Endpoint**: The IP address or Fully Qualified Domain Name (FQDN) of S3-compatible storage.

     > **Note:** Do not include 'http://' or 'https://'.
   - **Port**: The S3-compatible port that Cohesity communicates with.
   - **Access Key ID**: Access key ID used to access the storage.
   - **Secret Access Key**: Secret access key address to access the storage.

When registration finishes, a new entry appears on the Sources page. You can now create a Protection Group to back up S3-compatible buckets. For more information, see Protect S3-Compatible Storage.

Update the S3-Compatible Source Configuration

You can update the S3-compatible storage source details that you had provided during the registration process with the latest S3-compatible storage configuration.

To edit the S3-compatible storage source configuration:

1. Select **Data Protection** > **Sources**.
2. Click the actions menu next to the AWS source and select **Edit**.
3. In the **Edit S3 Compatible Storage Source** page, update the respective configurations.
4. Click **Update**.

Refresh the S3-Compatible Storage Source

You can refresh the S3-compatible storage source configuration and fetch the latest changes on the S3-compatible storage source.

To refresh the AWS source configuration:

1. Select **Data Protection** > **Sources**.
2. Click the actions menu next to the S3-compatible storage source and select **Refresh**.

Unregister S3-Compatible Storage Source

If you plan to stop taking backups of the S3-compatible storage, you can unregister the S3-compatible storage source from the Cohesity cluster. Before you unregister, you must delete all the Protection Groups associated with the S3-compatible storage source. For more information, see Delete the Protection Group.

To unregister the S3-compatible storage source on the Cohesity cluster:

a. Select **Data Protection** > **Sources**.

b. Click the actions menu next to the S3-compatible storage source and select **Unregister**.

c. Click **Unregister**.

Protect S3-Compatible Storage

Once you register the S3-compatible storage source with the Cohesity cluster, you can create a Protection Group to back up the S3 buckets of the S3-compatible storage. A Protection Group uses the schedules and settings defined in the protection policy to determine when and how backups are captured, archived, or replicated.

A Protection Policy is a reusable set of settings that define how and when objects are protected and replicated. You can select which standard or custom policy to use when creating a Protection Group. For more information, see Manage Policies.

Before you Begin

Before you protect an S3-compatible storage as a source on the Cohesity cluster, ensure that you:

1. Review the requirements, considerations, and best practices.
2. Perform the prerequisite tasks.
3. Register the S3-compatible storage as source with the Cohesity cluster.

Protect S3-Compatible Storage Buckets

Perform the following steps to protect the S3-compatible storage buckets:

1. Select **Data Protection** > **Protection**.
2. Click **Protect** on the top-right of the page and then click **Protect** > **S3 Compatible**.

   The New Protection page appears.
3. Click **Add Objects**, and from the **Registered Source** drop-down list, select the S3-compatible source that contains the buckets you want to back up. You can also

register a S3-compatible source with the Cohesity cluster so you can protect it.

To register a new S3-compatible source, click Register Source from the drop-down. For more information, see Register and Manage S3-Compatible Storage.

4. From the buckets, select the buckets you want to back up.
5. Click **Continue**.
6. Provide a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.
7. From the Policy drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, see Create or Edit a Standard Policy.
8. Select **More Options** to configure additional settings and continue with the next steps. Else, click **Protect**.
9. Optionally, from the **Protection Group** field, you can select an existing Protection Group. By selecting an existing Protection Group, the additional settings configured in the existing Protection Group will be applied to this Protection Group. To select an existing Protection Group, perform the following steps or else, go to step 10:
    a. From the **Protection Grou**p field, enable **Existing Group**.
    b. Select an existing Protection Group from the **Group** drop-down list.
    c. Click **Protect**.
10. Select the appropriate Storage Domain. For more information, see Create or Edit Storage Domains.
11. In the **Start Time** field, the default time zone is the browser's time zone. You can change the time zone of the job by selecting a different time zone.
12. In the **SLA** field, select the expected time to complete either a full backup or incremental backup.
    - **Incremental**: Enter the number of minutes you expect an incremental protection run to complete. An incremental backup captures only the differences (changed blocks) since the last protection run.
    - **Full**: Enter the number of minutes you expect a full backup protection run to complete. A full backup captures the entire object (all blocks).
13. If you need to change any of the additional settings on the Protection Group page, click the down arrow icon next to the **Advance Settings** and click **Edit** of the respective field. For more information, see Additional Settings.
14. Click **Protect**.

Additional Settings

Additional Settings	Description
Pause Future Runs	Toggle on this option to stop protection runs of the Protection Group from executing. Once you enable this option, no protection runs will be scheduled for this Protection Group.
End Date	Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts prior to this date runs until completion even if it completes after this date.
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of jobs exceeds the ability to process jobs, this will be the priority of implementation of the jobs: • High • Medium • Low
QoS Policy	Select an appropriate quality of service (QoS) policy. **Note:** Cohesity recommends specifying **Backup HDD**, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Cancel Runs at Quiet Time Start	(Available only if the selected policy has at least one Quiet Time) When enabled, all the protection runs that are currently executing will cancel when the Quiet Time period starts. By default, this setting is disabled, meaning that after a protection run starts, it continues to execute even when a Quiet Time period starts. However, new protection runs will not start during a Quiet Time.

Additional Settings	Description
Alerts	Select one or more of the following Alerts On settings if you want alerts to be created for the following triggers: • **SLA Violation**: Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, seeAlerts. • **Failure**: Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **Success**: Create an informational alert when the Protection Group completes successfully. Emails are not sent when informational alerts are created. To send emails when alerts are triggered for the Protection Group, in the **Email Recipients** field, add the email addresses of the recipients.
Description	Enter a brief description about the Protection Group.

Policy Settings for S3-Compatible Storage

The following table lists the applicable policy settings for S3-compatible storage:

Field	Description
Primary Copy	Select **Local** from the drop-down to keep the primary copy data on the Cohesity cluster. Select any external target for performing CloudArchive Direct wherein the primary copy of the data is stored on the external targets. For more information, see CloudArchive Direct.
DataLock	If applicable, add a DataLock for compliance and regulatory requirements, to ensure that your protected data, including local backups, archives, and replication, cannot be modified until the DataLock expiration. Once applied, a DataLocked Snapshot will be deleted only after its retention period expires. A DataLock prevents all users, including those who have the Data Security role in Cohesity, from modifying or deleting any Snapshots that were generated by the Protection Groups that use this Policy. Only users with the Data Security role can add, modify, or remove a DataLock from a Policy.
Scheduled Backup	Defines when backups are captured, how long they are retained and the type of backup to capture.
Extended Retention	Add this to retain a subset of snapshots (backups) for longer than defined by the protection schedule.

Field	Description
Retry Options	Use this option to customize the retry settings for capturing Snapshots. By default, Cohesity attempts to capture Snapshots three times before the Protection Group fails. The default time between retries is five minutes. You can customize the number of retries and how long to wait between each attempt.
Periodic full backup	Use this option to choose when to run a periodic full backup.
Quiet Times	Quiet Times defines time periods when new protection runs are not started. For example, you might want to configure hourly backups that run during weekdays but not on Saturday or Sunday. Quiet Times only prevents new protection runs from starting during the specified time period. The protection runs that started before the quiet time period will be dependent on the quiet time settings configured in the additional settings of the protection Group. For example, if a protection run starts at 12:45 AM on Saturday morning and there is a weekend quiet time period that starts at 1 AM on Saturday morning, the protection run will continue to run past 1 AM. No new protection runs are started during the quiet time period.
Replication	To replicate snapshots to another cluster, click the **Replication** icon from the floating menu. The copied snapshots are stored in the storage domain of the remote cluster. .
Archival	To add an archive schedule, click **archival** icon from the floating menu.

Use an Existing Protection Policy

You can use an existing Protection Policy protecting S3-compatible storage If you are selecting an existing protection policy, then the following options are ignored if they are already configured in the protection policy:

- Log Backup (Databases)
- Add BMR Backup (Physical Server)
- CloudSpin

Manage S3-Compatible Backup Configuration

In Cohesity, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

You cannot update the registered S3-compatible storage and the assigned Storage Domain in the Protection Group settings.

Add S3-Compatible Storage Buckets to the Protection Group

You can add new S3-compatible storage buckets to an existing Protection Group for backup. The newly added buckets are backed up from the next protection run, and it will be a full backup.

To add S3-compatible storage buckets to the Protection Group:

1. Select **Data Protection** > **Protection**.
2. On the Protection page, select the Protection Group that you created for protecting the S3-compatible storage.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** field, click the **Edit** icon.
5. Select the S3-compatible storage buckets you want to add to the Protection Group.
6. Click **Save Selection** > **Save**.

The newly added S3-compatible storage buckets will be backed in the next scheduled protection run.

Remove S3-Compatible Storage Buckets from the Protection Group

From the Edit Protection page, you can remove S3-compatible storage buckets from the Protection Group that you do not want to back up in the next protection run.

To remove the S3-compatible storage buckets from the Protection Group:

1. Select **Data Protection** > **Protection**.
2. On the Protection page, select the Protection Group that you created for protecting the S3-compatible storage buckets.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** field, click the **Edit** icon.
5. Unselect the S3-compatible storage buckets that you want to remove from the Protection Group.
6. Click **Save**.

The removed S3-compatible storage buckets will not be backed in the next scheduled protection run.

Edit Existing Protection Policy

You can edit the existing Protection Policy that is attached to the Protection Group based on your requirement. In the Protection Policy, you can edit the settings listed in the Create or Use an Existing Protection Policy.

To the policy settings:

1. Select **Data Protection** > **Protection**.
2. On the Protection page, select the Protection Group that you had created for S3-compatible storage buckets.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the Edit Protection page, in the **Policy** field, click **Edit**.

   The Edit Policy page appears.
5. Edit the settings listed in the Create or Use an Existing Protection Policy and then click **Save**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

You can attach a new Protection Policy to your Protection Group. The new policy is applied to the Protection Group in the next scheduled protection run.

1. Select **Data Protection** > **Protection**.
2. On the Protection page, select the Protection Group that you created for protecting the S3-compatible storage buckets.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the Edit Protection page, from the drop-down list in the policy field, select a new Protection Policy for the Protection Group.
5. Click **Save**.

Start an On-Demand Protection Run

You can instantly start a protection run of the Protection Group that you have created to backup S3-compatible storage buckets. It provides you options to back up all the objects or only selected objects in the Protection Group. If the policy associated with the Protection Group:

- Supports multiple backup types, you can select an incremental or full backup.
- If configured with replication targets, you can select those targets.
- If configured with archival targets, you can select those targets.

To start a protection run:

1. Select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for protecting the S3-compatible storage buckets.
3. Click the action icon next to the Protection Group and select **Run Now**.
4. In the pop-up window, perform the following:

a. In the Backup drop-down list, select any one of the following:
   - Backup all Objects in the Protection Group
   - Backup only selected Objects in the Protection Group
   - All objects that failed last run

b. In the **Backup Type** drop-down list, select the backup type.

c. In the **Replicate** section, select the replication target, the retention duration, and enable the **Replicate only fully successful runs** checkbox if you want to replicate the data only after a successful protection run.

d. In the Archive section, select the archive target, the retention duration, and enable the **Archive only fully successful runs** checkbox if you want to archive the data only after a successful protection run.

5. Click **Run**.

Pause Future Protection Runs

You can stop the protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Select **Data Protection** > **Protection**.
2. On the Protection page, select the Protection Group that you created for protecting the S3-compatible storage buckets.
3. Click the action icon next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run.**Pause Future Runs**.

To resume a paused protection run:

1. Select **Data Protection** > **Protection**.
2. On the Protection page, select the Protection Group that you had paused.
3. Click the action icon next to the Protection Group and select **Resume**.

Delete the Protection Group

Cohesity provides the following ways to delete the Protection Group associated with the AS3-compatible storage buckets:

- **Delete Protection Group Only**: Delete only the Protection Group. Any local snapshots and or archived snapshots stored on the external targets that were captured by this Protection Group are not deleted

- **Delete Protection Group and Snapshots**: Delete the Protection Group and all Snapshots, any local Snapshots captured by this Protection Group and stored on this cluster are deleted. In addition, any archived Snapshots stored on external targets that were captured by this Protection Group are also deleted.

To delete the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you created for protecting the S3-compatible storage buckets.
3. Click the action icon next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group**? dialog box, select any one of the following options:
    - **Delete Protection Group Only**
    - **Delete Protection Group and Snapshots**

If the current Protection Group is replicating snapshots to a remote cluster or archiving snapshots to an external target, you should cancel these replication or archive tasks before deleting the Protection Group. For instructions, see Cancel Replication and Archive Copy Tasks of a Protection Group Run.

If the Protection Group is replicating to a remote cluster, the inactive job created on the remote cluster is not deleted. In addition, the snapshots that were replicated (copied) to the remote cluster by this job are not deleted. You can log in to the remote cluster to delete the snapshots and the inactive job.

Recover S3-Compatible Storage Buckets

After you protect your S3-compatible storage, you can recover them to their original location or a new location using Cohesity.

Recover S3-Compatible Storage Buckets to the Original Location

To recover your protected S3-compatible storage buckets to their original location:

1. Navigate to **Data Protection** > **Recoveries**.

    Click **Recover** on the top-right of the page and then select **S3 Compatible** as the recovery source.
2. Search for a S3-compatible storage bucket or Protection Group that contains the snapshots to recover from by entering characters of the S3 bucket name, Protection Group name, or by specifying the wildcard character *.

    You can optionally filter the search results by source, Protection Group, or date.

3. From the list of search results, select an S3-compatible storage bucket you want to recover.

   By default, the latest snapshot is selected for recovery.

   To recover from a different snapshot, perform the following steps:

   a. From the selected lists, click the edit icon.

      The Edit recovery point for <S3bucket_name> page appears. By default, the page displays the latest snapshot available.

   b. Optionally, you can also select a snapshot from a different date by performing one of the following:

      - Selecting the date from the **Choose a date** drop-down list. Once you select the date, the Edit recovery point page displays the available snapshots on the specified date.
      - Clicking the **List** tab. The List tab displays all the available snapshots of the selected S3-compatible storage bucket.

   c. Select the snapshots to be recovered.

      By default, the snapshot is recovered from the local cluster.

   d. Optionally, you can also select snapshots archived to the cloud by clicking the cloud icon if available in the **Location** option.

   e. Click **Select Recovery Point** and then go to step 5.

4. Click **Next: Recover Options**.
5. Under **Recover To**, select **Original Location**.
6. Enable **Overwrite Existing Bucket** if you want to recover the S3-compatible storage bucket by overwriting the original S3-compatible storage bucket. By default, this option is disabled.

   If the data in the source S3 object and target S3 are the same, then the target S3 will not be updated even if the Overwrite Existing Bucket option is enabled. If the target bucket is versioned and the S3 object name of the target and the source match, then a new version of the S3 object will be created.

7. In the **Target Prefix** field, add prefix value to the names of the S3 objects that are recovered by this task.
8. Select your **Recovery Options**:

   - **S3 Prefixes to Recover**: To perform granular recovery of the S3-compatible bucket, enable the Turn ON to recover specific prefixes option and provide the prefix of the objects to be recovered.

     For example, `Finance/statement/document`

     You can click the add icon to provide multiple prefixes.

The maximum number of prefixes that you can provide per recovery task is 100.

- **Task** : Change the default name of the recovery task.

9. Click **Recover**.

Cohesity begins to restore the selected S3-compatible bucket.

Recover S3-Compatible Storage Buckets to New Location

To recover your protected S3-compatible storage buckets to a new location:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click Recover on the top-right of the page and then select S3-compatible as the recovery source.
3. Search for a S3 bucket or Protection Group that contains the snapshots to recover from by entering characters of the S3 bucket name, Protection Group name, or by specifying the wildcard character *.
4. From the list of search results, select an S3-compatible storage bucket you want to recover.

   By default, the latest snapshot is selected for recovery.

   To recover from a different snapshot, perform the following steps:

   a. From the selected lists, click the **edit** icon.

      The Edit recovery point for <S3bucket_name> page appears. By default, the page displays the latest snapshot available.

   b. Optionally, you can also select a snapshot from a different date by performing one of the following:

      - Selecting the date from the **Choose a date** drop-down list. Once you select the date, the Edit recovery point page displays the available snapshots on the specified date.
      - Clicking the **List** tab. The List tab displays all the available snapshots of the selected S3-compatible storage bucket.

   c. Select the snapshots to be recovered.

      By default, the snapshot is recovered from the local cluster.

      Optionally, you can also select snapshots archived to the cloud by clicking the cloud icon if available in the **Location** option.

   d. Click Select **Recovery Point** and then go to step 5.

5. Click **Next: Recover Options**.
6. Under **Recover To**, select **New Location** and provide the following information:

- **Register Source**: Select a registered S3-compatible source as the new recovery destination.
- **Region**: Select a destination region.
- **Bucket**: Select the S3-compatible bucket to which you want to recover.

7. Enable **Overwrite Existing Bucket** if you want to recover the S3-compatible bucket by overwriting the original S3-compatible bucket. By default, this option is disabled.

   If the data in the source S3 object and target S3 are the same, then the target S3 will not be updated even if the **Overwrite Existing Bucket** option is enabled. If the target bucket is versioned and the S3 object name of the target and the source match, then a new version of the S3 object will be created.
8. In the **Target Prefix fi**eld, add prefix value to the names of the S3 objects that are recovered by this task.
9. Select your **Recovery Options**:
   - **S3 Prefixes to Recover**: To perform granular recovery of the S3-compatible bucket, enable the Turn ON to recover specific prefixes option and provide the prefix of the objects to be recovered.

     For example, `Finance/statement/document`

     You can click the add icon to provide multiple prefixes.

     The maximum number of prefixes that you can provide per recovery task is 100.
   - **Task Name**: Change the default name of the recovery task.
10. Click **Recover**.

Cohesity begins to restore the selected S3-compatible bucket.

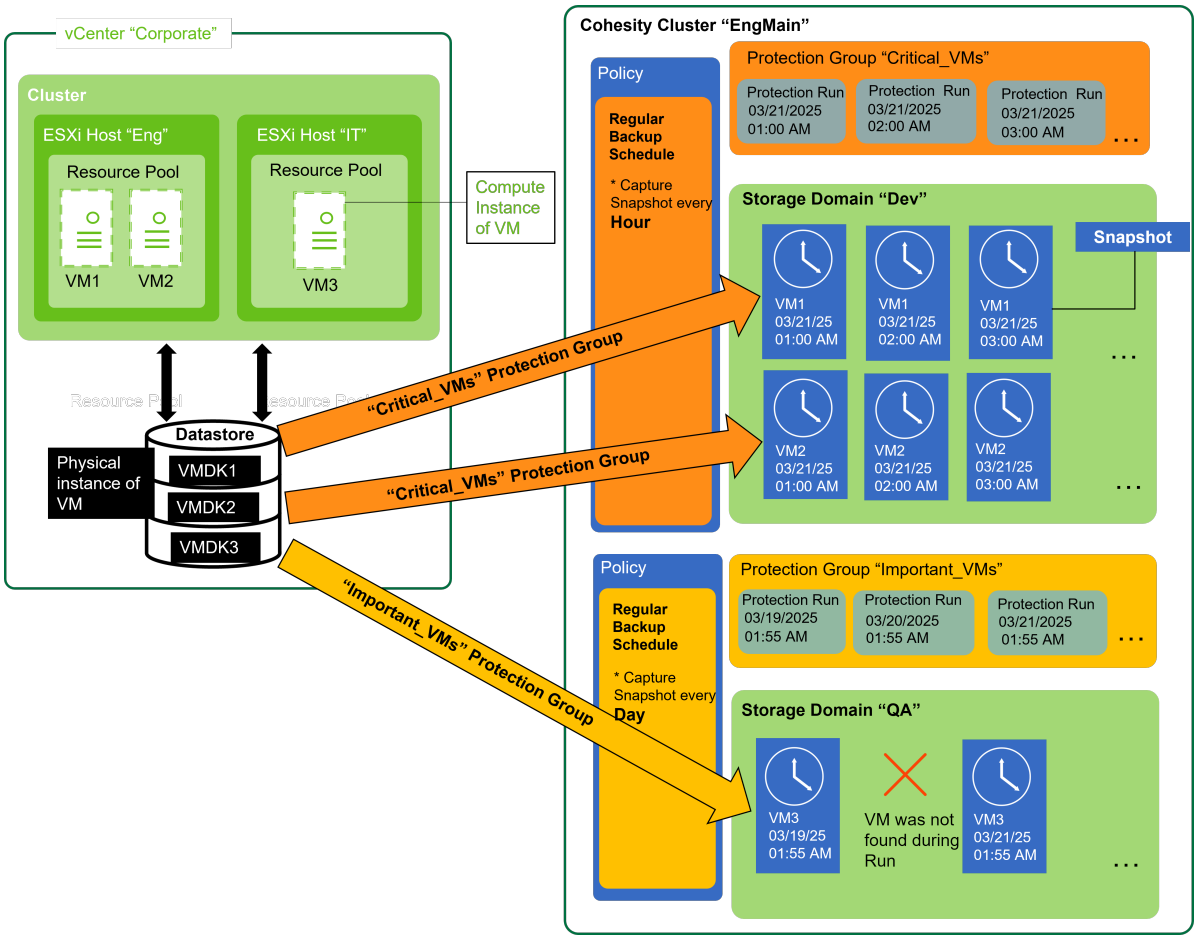
Chapter 11: Virtual Machines

Cohesity unifies fragmented data protection solutions for virtualized environments. With Cohesity, organizations no longer need to deal with complex and expensive protection solutions that result in multiple infrastructure silos and copies of data.

Cohesity supports backing up Virtual Machines (VMs) from different hosts in a single Protection Group. Protection Groups can run repetitively on a schedule.

To learn more about the relationship between Protection Groups and Policies, see Manage Protection Policy. For instructions on how to use the Cohesity Dashboard to back up VMs, see Manage Protection Groups.

For example, you could create a Protection Group with a protection schedule that backs up all critical VMware VMs every hour as represented by the *Critical* Protection Group in the following figure and a second Protection Group that backs up important systems every night as represented by the *Important* Protection Group in the following figure. Note that the Critical Protection Group is a mix of VMs from the Engineering ESXi Host and the IT ESXi Host.



During a Protection Group Run, Snapshots of the VMs are saved on the Cohesity cluster with a date and time stamp. If a VM is unavailable when the Protection Group runs, a Snapshot is not created for that VM in the Protection Group as shown by the 03/20/2015 01:55 AM protection run in the Important Protection Group. In this example, a Snapshot of VMDK3 is not created by the 03/20/2015 01:55 AM protection run because VM3 was unavailable when the Protection Group ran. If the VM becomes available at a later date, the next time the Protection Group runs a Snapshot of the VM is included in the Protection Group as shown by the 03/21/2015 01:55 AM Protection Group Run for the Important Protection Group.

For instructions on how to use the Cohesity Dashboard to back up VMs, see Add or Edit a Protection Group for Virtual Servers.

About Encrypted VM Backup

Cohesity supports backing up VMware VMs encrypted by a VMware storage policy. A single Protection Group can back up both encrypted and unencrypted VMs.

The VMware user account designated for data protection requires the following additional privileges to back up encrypted VMs:

- Cryptographic Operations > Add Disk
- Cryptographic Operations > Direct Access
- Cryptographic Operations > Encrypt
- Cryptographic Operations > Encrypt new

A Protection Group performs the following actions:

1. Connects to the vCenter using an account with the proper privileges.
2. Takes a snapshot of encrypted VMs.
3. Decrypts and backs up data to the cluster.
4. Optionally, the backed-up data is encrypted.

The recovered VM from the backup will be decrypted. You must re-enable encryption after recovery by applying an appropriate storage policy.

Plan and Prepare for VM Protection

This topic provides information on minimum permissions, prerequisites and considerations to protect VMware VMs and Hypervisors with the Cohesity cluster.

Minimum Permissions

Ensure you have the required minimum permissions to register VMware VMs and Hypervisors as a source with the Cohesity, and to perform backup and recovery. For more information, see Ensure Adequate Privileges for Cohesity on the Source.

Support Matrix

Before you register your VMware VMs and Hypervisors with the Cohesity cluster, ensure that Cohesity supports the VMware VMs and Hypervisor versions. For more information, see Supported Software.

Ports Used for Communication

Ensure all necessary ports are open in the firewall between the Cohesity cluster and VMware VMs and Hypervisors. For more information, see Manage Firewall Ports.

Prerequisites and Considerations

Standalone ESXi Hosts

Review the following considerations:

- Throttling
- SQL backup, clone or restore
- File recovery to source
- Instant volume mount
- You must manually configure Storage vMotion.

VMware Snapshots

Prerequisite

Cohesity and VMware recommend limiting the number of delta files in a snapshot chain. For more information, see Best practices for virtual machine snapshots in the VMware environment (1025279). You may want to consider disk consolidation.

Considerations

The Cohesity cluster creates snapshots of VMware VMs. The limitations that apply to VMware snapshots also apply to Cohesity cluster snapshots. These limitations are described in VMware Snapshot limitations.

Review the following snapshot considerations:

- During Protection Group runs, the Cohesity cluster can report `The virtual machine requires manual consolidation` alerts when attempts to consolidate data in VMs fails due to VMware issues such as locking issues and timeouts. During the next run, the Cohesity cluster will attempt to consolidate the data in each VM but if the cluster is unable to consolidate the data in a VM, the cluster will continue to report `The virtual machine requires manual consolidation` alerts and skip backing up those VMs with this issue. However, the rest of the VMs in the Protection Group will be backed up. For the Cohesity cluster to start backing up the VMs with this issue, you must perform a manual workaround as described in the Unable to delete the virtual machine snapshot due to locked files (2017072) Knowledge Base issue. Cohesity recommends attempting consolidation by right-clicking the VM and selecting **Snapshot >Consolidate** as explained in the note of step#2. If that does not fix the problem, try restarting the management agents on the ESXi hosts where the VMs are running as described in step#5 and right-click the VM and select **Snapshot >Consolidate** as explained in the note of step#2.
- Registering a VMware source or protecting VMware VMs on Wide Area Networks (WAN) is not supported. Cohesity recommends using a Cohesity cluster (Virtual or Cloud Edition) with LAN connectivity to the vCenter and ESXi Host to register and protect the VMs.
- Registering a vCenter source and using it for Data Protection on multiple Cohesity clusters is not recommended. Cohesity clusters running in parallel may deplete vCenter's resources (such as API sessions, API calls, network bandwidth, computing power, memory, IO resources, number of tasks, and much more) as resource usage is not coordinated across Cohesity clusters. If you want to protect portions of your

vCenter, Cohesity suggests registering the corresponding Standalone ESXi host(s) to the Cohesity clusters rather than registering the entire vCenter.

- Creating snapshots of fault-tolerant VMs is not supported by VMware vSphere or the Cohesity cluster. Cohesity clusters will not display fault-tolerant VMs among the list of protectable VMs discovered from the vCenter.
- Creating snapshots of VMs with PCI vSphere DirectPath I/O devices is not supported by VMware vSphere or the Cohesity cluster.
- Creating snapshots of VMs with SR-IOV (Single Root I/O Virtualization) is not supported by the Cohesity cluster.
- When a VM with independent disks is protected, the independent disks are automatically skipped and the rest of the disks are backed up. After recovering or cloning these VMs from a Cohesity backup, you must manually attach the independent disks.
- Recovery of a VMware VM to a different vCenter does not attach tags of the original VM to the restored VM.
- If a Protection Group fails with the following error: "Failed with error: kVSphereError, detail: [Cannot complete the operation because the file or folder already exists]", see Unable to create snapshot: Operation failed because file already exists or Cannot complete the operation because the file or folder [DatastoreName] VMname/VMname.vmx already exists (308942) for information about a possible resolution.
- If the backup of a standalone ESXi host fails with one of the following errors:
  - "The operation is not allowed in the current state."

    This may be caused if ESXi is in maintenance mode.
  - "Backup task failed with error: [kInvalidLogin]: SOAP 1.1 fault: "":ServerFaultCode[no subcode] "Permission to perform this operation was denied." Detail:"

    This means the same ESXi host was registered on vCenter in "lockdown" mode.
- VMware folder-based protection is currently qualified with vCenter 6.7, 6.5, 6.0 and 5.5 only.
- If a Protection Group backs up multiple vApps, each vApp must be recovered individually.
- VMware does not support taking the snapshots or backups of the VMs having RDM (physical and virtual) on Shared Bus.
- Cohesity recommends increasing the default HTTPS connection limit after upgrading to vSphere 7.0 and later. For details, see the KB article.

- VMware Site Recovery Manager (SRM) creates placeholder VMs that are used for disaster recovery of the vCenter. Although Cohesity clusters display these placeholder VMs, the option to select or add them to a Protection Group is disabled.
- Review the following considerations when leveraging Pure Storage snapshots:
  - This feature is supported for vCenter only; it is not supported for standalone ESXi sources.
  - It is not supported for VMware VVols.
- Known VMware limitations when SAN Transport mode is enabled:
  - Protection of VMs on VVol datastores is unsupported.
  - VMware vSAN, a network-based storage solution with direct attached disks, does not support SAN transport.
  - Differential restore of VMware VMs is not supported.
  - Backing up VMware VMs using SAN transport mode cannot be leveraged when VMs have disks in different storage arrays.
  - Backing up VMware VMs using SAN transport mode cannot be leveraged if VMs are hosted on Pure ActiveCluster.
  - VMware SAN transport mode is not supported with Cohesity virtual nodes. To use SAN transport mode for backing up VMware VMs, zoning and granting datastores access to the Cohesity nodes has to be done manually.

  For more information, see the Virtual Disk Development Kit Programming Guide.
- VMware - Storage Array Snapshot
  - VMware VM backup using Leverage Storage Snapshots is not supported for NetApp volumes enabled with Load-Sharing Mirror (LSM).
  - N_Port ID Virtualization (NPIV) Fibre Channel (FC) standard and Virtual World Wide Name (WWN) identifier are not supported when backing up VMware VMs using Leverage Storage Snapshots for Data Protection.

    > **Note:** This consideration is not applicable for IBM FlashSystem storage systems.
- Review the following considerations when leveraging the Nutanix AHV storage snapshots:
  - This feature is supported for vCenter only. It is not supported for standalone ESXi sources.
  - Cohesity does not support application-consistent backups of VMware VMs that leverage Nutanix as the storage snapshot provider.

- Cohesity does not support differential restore of VMware VMs backed by leveraging the storage snapshots.
- If the protection run of VMware VMs is switched from VADP-based backup to storage snapshot-based backup, then the Cohesity cluster will initiate a full backup.
- While performing storage snapshot-based backup, if a VMware VM snapshot is present on the ESXi host, then Cohesity will perform VADP backup.
- Cohesity does not support leveraging storage snapshots for backing up VM templates.

Change Block Tracking

Prerequisite

You must specify a VMware vCenter user that has adequate privileges on the VMware vCenter server. The role assigned to the specified VMware vCenter user should include privileges to turn on Change Block Tracking (CBT) and other privileges required by the Cohesity cluster.

> **Note:** When creating snapshots, the Cohesity cluster attempts to turn on the Change Block Tracking (CBT) to improve performance and reduce disk space usage.

Consideration

For older versions of ESXi 5.5, if Change Block Tracking (CBT) is enabled for a VM and the VM is moved (or migrated) using VMware Storage vMotion, the Change Block Tracking gets reset so when the Cohesity cluster creates the next backup of the VM, a full backup is triggered instead of an incremental backup. For more information see Resetting Changed Block Tracking for VMware vSphere virtual machines (2139574).

Microsoft Hyper-V

Prerequisites

- Any one of the following:
  - Hyper-V version 8.0 or 9.0 VMs running on Windows Server 2019 managed by System Center Virtual Machine Manager (SCVMM) 2016 or 2019.
  - Hyper-V version 8.0 VMs running on Windows Server 2016 managed by SCVMM 2012 R2 or 2016.
  - Hyper-V version 5.0 VMs running on Windows Server 2012 R2 managed by SCVMM 2012 R2 or 2016.
  - Standalone Hyper-V 2019 or 2016 or 2012 R2 host or cluster (cluster can have mixed versions).

- If antivirus software is installed and running on a Hyper-V host, then you must configure several exclusions and options of the antivirus software for optimal operation of Hyper-V and the running virtual machines. For more information, see the Microsoft documentation.

Considerations

- For VMs backed up using RCT (VMs residing on Hyper-V 2016 hosts), disk size must be in multiples of 256 MB.

> **Note:** Hyper-V backups that use VSS snapshots may encounter issues if VSS Legacy Tracing is enabled on the applicable Hyper-V hosts. Disable VSS Legacy Tracing unless it is explicitly required. For more information, refer to the Microsoft documentation.

- Cohesity does not support the backup of Hyper-V VMs with shared disks.
- Deleting the most recent Hyper-V snapshot from the Cohesity cluster causes the object's next Protection Group run to be a full backup instead of incremental.
- Hyper-V 2012 R2 VMs can be protected by only one Cohesity cluster at a time. Backup by multiple clusters of a Hyper-V 2012 R2 VM results in a failure with the following error: [kAgentErrorNotRetryable]: [kInvalid]: FetchVolumeSnapshotInfo called for an incorrect snapshot set id.
- Performing VM instant recovery requires the Cohesity cluster to be joined to the same domain as the Hyper-V cluster.
- When canceling an in-progress instant VM recover task, the created Cohesity SMB internal view must be torn down after VM storage migration is complete.
- A Hyper-V VM that is recovered using instant recovery shows an "Unsupported VM Configuration" status in SCVMM during migration and after migration finishes. After VM migration finishes, you must manually refresh the recovered VM in SCVMM to get it out of this state and make it usable from SCVMM. A VM in the "Unsupported VM Configuration" state, however, can still be accessed directly from the Hyper-V host.
- CBT information on a Hyper-V 2012 R2 host does not persist after a reboot. The next backup after a reboot is full instead of incremental.
- Hyper-V 2012 R2 supports SMB that was already preconfigured to back up Hyper-V VMs using agentless VSS; array-based SMB is not supported. Only VMs residing on Windows Native SMB servers are supported.
- File-level recovery to a Hyper-V VM requires the following:

    - For Windows target VM:
        - Target VM belongs to Active Directory.
        - The Windows Remote Management (WinRM) service is enabled on the target VM: winrm quickconfig.
        - Remote powershell must be enabled from Hyper-V host to VM.
        - The Hyper-V Guest Service Interface is enabled on the target VM: Enable-VMIntegrationService -Name 'Guest Service Interface.
    - For Linux target VM:
        - Cohesity Linux agent must be installed on the target VM.
- Review the following considerations when performing instant volume mount to Hyper-V VMs:
    - Only Windows VMs are supported.
    - Dynamic Disks (LDM and LVM) are not supported.
    - The Bring Disks Online option requires the following:
        - VM must be part of Active Directory, the VM and the Hyper-V host must be in the same AD.
        - Users must execute "winrm quickconfig" to enable winrm on the target VM and remote powershell must be enabled from Hyper-V host to VM.
    - Instant volume mount and file level recovery from Gen 1 to Gen 2 type VMs is not supported.
    - If SCVMM is unregistered from the Cohesity cluster, ensure you tear down all instant volume mounts. Not tearing them down can prevent the VM from being backed up when the source is registered with a different Cohesity cluster.
    - Instant volume mounting Hyper-V 2012 R2 VMs without a SCSI controller is not supported. This is because Hyper-V disallows dynamically adding a SCSI controller, which is required to add the virtual disks.
    - On 2012 R2 VMs, if an instant volume mount disk is attached during a Protection Group, that snapshot cannot be application-consistent. If this occurs, the event viewer may contain a VSS-catastrophic error or similar message.
- Standalone Hyper-V hosts and failover clusters support backing up VMs on SMB, but recovering to SMB volumes is not supported.
- If Hyper-V 2012 R2 VSS group snapshots are enabled, the following limitations apply:
    - All Hyper-V VMs on the same Hyper-V host must belong in the same Protection Group.
    - Each Protection Group can only include Hyper-V VMs belonging to the same Hyper-V host.

- Cloned VMs in a saved state prevent VM tear down.
- The Protection Group for Hyper-V VMs will fail if you select to auto-protect the VMs using more than one tag.
- When recovering Hyper-V VMs with Tags (including custom properties) to an alternate location, the restoration of Tags will be skipped. Tags are only restored when recovered to the original location.
- Consider the following when recovering a VM with a thin-provisioned disk otherwise, the restored VM will have full allocated disk size:
    - The backed-up VM has thin-provisioned disks.
    - The Recovery Type is Instant Recovery.
    - The power state of the VM is On.

Nutanix Acropolis

Prerequisites

- The data services IP address must be set in the AHV cluster.
- A Linux or a Windows agent is required for file or folder recovery.

Considerations

- Backing up a Volume Group (VG) attached to a VM is not supported. The VM is backed up, but the VG is skipped. Similarly, if the VM is recovered, the VG is not attached to the VM.
- AFS NFS shares are not supported.
- The instant recovery of Nutanix Cloud Clusters (NC2) AHV on AWS and Azure is not supported.

Nutanix AHV Prism Central

Considerations

- If any of the Prism Elements have incorrect credentials, a warning will be logged for those credentials, but the other Prism Element sources will still be registered.
- You can recover VMs from one PC to another, as well as recover VMs within the same Prism Central instance, but on a different Prism Element (cluster).
- You cannot perform mass instant recovery across different clusters. All VMs must be recovered to the same cluster for mass instant recovery or done individually.

RHV

Considerations

- Cohesity supports RHV only until version 6.8.1. While you can still protect your RHV sources, the Cohesity Support team will not provide assistance.
- VM tags are not supported.

- File recovery to a VM is not supported.
- Non-data storage domains display as recovery destinations when recovering to an alternate location.
- RHV VM snapshots are not application consistent.

Troubleshooting

- Canceling a recover task may not clean up the VMs that were being recovered.

  Workaround - Delete the VMs manually.
- Original VM console settings are not recovered.

  Workaround - Change them manually after recovery. Some settings cannot be changed with the VM running and may require you to power off the VM or recover with a power off to change before booting.
- The VM object hierarchy may show non-VMs during job creation. These can be ignored.
- When searching for files/folders to recover, the UI shows their Protection Group as "Deleted Job." This can be ignored; the jobs have not been deleted.
- Cohesity does not support the backup of RHV VMs that are using compressed `qcow2` disk images.

  Workaround - Decompress the `qcow2` images using the `qemu-img convert` command.

Register or Edit a Hypervisor Source

After a source is added (registered), its objects are eligible to be protected or backed up on the Cohesity cluster. For example, if a VMware vCenter Server is registered as a source, its VMs are eligible to be backed up.

To register a source to back up:

1. Navigate to **Data Protection > Sources**.
2. Select **Register** > **Virtual Machines**.
3. Select a **Hypervisor Source Type** from the drop-down.
4. Enter the information for your source type.

   VMware: vCenter or Standalone ESXi Host

   > **Tip:** You can also watch the Registering a VMware Source video to learn how to register a VMware vCenter Server or a Standalone ESXi host as a source.

Field Name	Description
Hostname or IP Address	Specify the hostname or IP address (IPv4 or IPv6) of the source that contains the VMs to protect.
Username	You must specify a VMware vCenter user that has adequate privileges on the VMware vCenter server. The role assigned to the specified VMware vCenter user should include privileges to turn on Change Block Tracking (CBT) and other privileges required by the Cohesity cluster. When specifying a Windows Active Directory username, use the following format: <**domain**>\<**username**> or <**username**>@domain. For all other cases, just enter: <**username**>.
Password	Enter the password for the specified user.
CA Certificate	For VMware vCenter only. Toggle this setting on if you want Cohesity to validate the connection to vCenter for operations. Copy and paste certificate content in the field.

Field Name	Description
Latency Based Adaptive Throttling	For VMware vCenter only. Toggle this setting on if you want the Cohesity cluster to adaptively throttle the running of tasks created by the Protection Groups protecting this source. This throttling helps to ensure that the datastores on the source (vCenter Server) are not adversely affected by the Protection Groups. You specify latency thresholds and if the observed latency on the datastore is greater than the specified threshold, the Cohesity cluster throttles the processing of the backup using that datastore as explained below. **Note:** • Enabling throttling can increase how much time a Protection Group run takes to complete, resulting in SLA violations. You may want to increase the SLA for the Protection Group. For more information, see Manage Protection Groups. • Latency-based adaptive throttling is ineffective while leveraging storage array snapshots for VMware backups. Specify the latency thresholds in milliseconds. If you enable throttling, the following two fields appear: • **Latency Threshold for throttling the new tasks of Protection Group Runs**–If the observed latency of a datastore is greater than the specified latency threshold, the Cohesity cluster throttles the processing of new backup tasks using that datastore. Throttling can occur in the middle of a protection run. For example, tasks creating the first snapshots of the protection run could complete without throttling but after the threshold is reached, the tasks creating the remaining Snapshots in the protection run are throttled. • **Latency Threshold for throttling the currently running tasks of Protection Group Runs**–If the observed latency of a datastore is greater than the specified latency threshold, the Cohesity cluster throttles any currently running backup tasks using that datastore. If throttling is enabled, the vCenter user specified for the source must have administrative datastore privileges. When throttling is enabled and the vCenter user has the necessary administrative datastore privileges, the Cohesity cluster enables the collection of Storage IO Control (SIOC) statistics on the datastores if not already enabled. The Cohesity cluster uses the statistics from SIOC to calculate the observed latency of datastores. If throttling and the collection of SIOC statistics were initially enabled and then throttling is disabled, the Cohesity cluster does not change the SIOC collection statistic settings on the datastores.

Field Name	Description
Cap concurrent streams per Datastore	Toggle this setting on if you want to limit the number of streams concurrently backed up per datastore. This helps to reduce any performance impact on the datastore. When registering a vCenter, you can configure the **Number of Streams** for all datastores in the vCenter only. After a vCenter is registered and the datastores in the vCenter are discovered, you can add overrides for individual datastores by clicking **Add Datastore Override**. Select a datastore, toggle on **Cap** and enter the number of **Streams**. If you toggle off **Cap** for a datastore, it is not subject to the vCenter's global concurrent streams cap.
Cap concurrent VM Backups	Toggle this setting on if you want to limit the number of VMs of a vCenter to be backed up concurrently. In the **Number of VM Backups** field, you can set the number of VMs that can be backed up concurrently.
Auto Cancel Backups if Datastore is running low on space	Turn this toggle ON if you want to set the minimum free space that should always be available in the datastore. Once set, Cohesity automatically prevents backups from starting if the datastore does not meet this requirement. Enter the minimum free space needed in the **GiB** or **%** fields. For example, if you enter 10 in the **%** field, 10% of the datastore space will always be available. The percentage option is more flexible because it auto-adjusts when the datastore shrinks or expands, even if a VM has multiple datastores. Which means, if two virtual disks of a VM reside in datastores of size 500 GB and 1 TB each, 10% of free space will apply to both the datastores.

Field Name	Description
Set Last Backup detail	For VMware vCenter only: Toggle this setting ON to set the last backup time and backup status for a VM in vCenter. These are published as custom attributes. By default, the option is turned OFF. When a backup is performed on a vCenter with the feature enabled, the custom attributes "Last Cohesity Backup Attempt Time" and "Last Cohesity Backup Status" will be set or updated to reflect the backup time and status. • **Last Cohesity Backup Attempt** - The exact timestamp when the last backup attempt succeeded. • **Last Cohesity Backup Status** - Status of the last backup for each VM. **Note:** When performing VM-based backups, if the backup is successful but has warnings caused by implicit fallbacks such as failure to utilize storage snapshots or issues with deleting the VM snapshot (which is a time-consuming operation), we will set the last backup status as 'Success' since the VM was successfully backed up. However, if there are errors or warnings due to explicit fallbacks (for example, transitioning from SAN to NBDSSL, or from app consistent to crash consistent), we will update the backup status to accurately reflect the error or warning.
Use VM BIOS UUID to track virtual machines	Toggle this setting on if you want the Cohesity cluster to track VMs using a unique BIOS UUID. You must enable the BIOS UUIDs toggle to support integration with Zerto–a continuous data protection (CDP) product. In addition, you must configure Zerto to preserve the BIOS UUIDs upon recovery. If both products are using BIOS UUIDS to uniquely identify VMs, VMs can be restored by either of the products and the link back to the original VM is not lost. To protect a VM in the vCenter with this toggle on, all VMs must have a unique BIOS UUID. If the Cohesity cluster finds more than one VM with the same BIOS UUIDs, these VMs are not listed when selecting VMs to protect. **Important:** This option must be set when you initially register a vCenter. After the vCenter has been registered, you cannot edit the hypervisor source and change this setting. To configure Zerto to also use BIOS UUIDs, select **Site Settings**. Under **Policies > Replication** select **For incoming replication, copy the BIOS UUID of the protected VM to the recovered VM**.

Field Name	Description
Network for Data Transfer	(Applies only to VMware vCenter) Toggle this option on if you want to configure a secondary network for the backup and copy recovery of VMs on the ESXi host of the VMware vCenter, while also using NBDSSL as the transport mode. By default, this option is turned off. If this option is turned off, the default network will be used for backup and recovery. **Configure a Secondary Network** To configure the secondary network, specify the subnet IP in the **Subnet IP** field and **CIDR prefix** in the CIDR prefix field. When the ESXi host has multiple VMkernel adapters, then Cohesity cluster will use the IP address that belongs to the specified subnet for the backup and recovery of VMs on the ESXi host. To view the updated ESXi hostname to IP address mapping, from the Cohesity Dashboard, select **Settings** > **Cluster** > **Networking** and click the **Host Mapping** tab. > **Note:** When ESXi hosts are registered to VMware vCenter using IP addresses instead of hostnames, Host Mapping does not work. **Add Multiple Subnets** To add multiple subnets, click the **Add** icon, and then specify the subnet IP and CIDR prefix. If you add more than one subnet, then the ESXi IP address selected for host mapping will be the one which matches the first subnet in the order they are provided. Example 1: Consider a VMware vCenter having two ESXi hosts and each ESXi has two VM kernel adapters. ESXi-1: • VM kernel adapter 1: 111.255.190.57 • VM kernel adapter 2: 10.10.33.130 ESXi-2: • VM kernel adapter 1: 111.255.190.51 • VM kernel adapter 2: 10.10.33.120 Consider you have provided the subnet IP as 10.10.33.0 and CIDR as 24. During the backup and restore of VMs under both the ESXi hosts, Cohesity cluster will resolve the hostname of ESXi-1 and ESXi-2 to IP address 10.10.33.130 and 10.10.33.120 respectively since these IP addresses belong to the same subnet you have provided.

Field Name	Description
	Example 2: Consider a VMware vCenter having two ESXi hosts and each ESXi has two VM kernel adapters. ESXi-1: • VM kernel adapter 1: 111.255.190.57 • VM kernel adapter 2: 10.10.33.130 ESXi-2: • VM kernel adapter 1: 111.255.190.51 • VM kernel adapter 2: 10.10.148.40 Consider you have provided the subnet information in the order listed below: 1. Subnet IP: 10.10.33.0 CIDR: 24 2. Subnet IP: 10.10.148.0 CIDR: 24 During the backup and restore of VMs under ESXi-1, the Cohesity cluster will resolve the hostname of ESXi-1 to IP address - 10.10.33.130 since the IP address belongs to 10.10.33.0/24 subnet. Similarly, during the backup and restore of VMs under ESXi-2, the Cohesity cluster will resolve the hostname of ESXi-2 to IP address - 10.10.148.40 since the IP address belongs to 10.10.148.0/24 subnet. **Delete an Added Subnet** To delete an added subnet, click the **cross** icon next to the subnet. When an ESXi host is added or deleted from a VMware vCenter, the corresponding host mapping will be updated during the next source refresh.

Field Name	Description
Detect VM migration across vCenter to Preserve backup chain	Toggle this option on if you want your Cohesity cluster to detect the VMs that are migrated from the current VMware vCenter to another VMware vCenter. With this option enabled: • The VMware vCenter (the VMware vCenter to which the VMs are migrated) hierarchy view (**Data Protection** > **Sources** > <VMware source> **All Objects**) in the Cohesity cluster will display a tag with the label, vCenter Migrated next to the migrated VMs. • When a Protection Group is run on the VMware vCenter to which the VMs are migrated, the Cohesity cluster eliminates the need for a full backup of the migrated VMs as the VMs are protected before the migration. Only an incremental backup is needed. > **Note:** If you are enabling this option to an existing VMware vCenter source, then you must refresh (**Data Protection** > **Sources** > <VMware source> **Action menu**>**Refresh**) the source for this feature to function. For more information, see Detect VM migration across vCenter to Preserve backup chain.

VMware: vCloud Director

Field Name	Description
Hostname or IP Address	Specify the hostname or IP address of the vCloud Director that contains the vCenters to protect.
Username	Specify the local administrator user. The minimum privileges needed to register vCD as a source are: • vCD user • vCenter user • User role that is used within the vCD Extension to start the mapping between the vCD organization and the Cohesity organization • User role that is used within the vCD Extension to complete the mapping between the vCD organization and the Cohesity organization
Password	Enter the password for the specified user.
vCenter Details:	

Field Name	Description
Username	You must specify a VMware vCenter user that has adequate privileges on the VMware vCenter server. The role assigned to the specified VMware vCenter user should include privileges to turn on Change Block Tracking (CBT) and other privileges required by the Cohesity cluster. When specifying a Windows Active Directory username, use the following format: <**domain**>\<**username**> or <**username**>@domain. For all other cases, just enter: <**username**>.
Password	Enter the password for the specified user.
Detect VM migration across vCenter to Preserve backup chain	Toggle this option on if you want your Cohesity cluster to detect the VMs that are migrated from the current VMware vCenter to vCD. With this option enabled: • The vCD (the vCD to which the VMs are migrated) hierarchy view (**Data Protection** > **Sources** > <VMware source> **All Objects**) in the Cohesity cluster will display a tag with the label, vCenter Migrated next to the migrated VMs. • When a Protection Group is run on the vCD to which the VMs are migrated, the Cohesity cluster eliminates the need for a full backup of the migrated VMs as the VMs are protected before the migration. Only an incremental backup is needed. **Note:** If you are enabling this option to an existing vCD source, then you must refresh (**Data Protection** > **Sources** > <VMware source> **Action menu**>**Refresh**) the source for this feature to function. For more information, see Detect VM migration across vCenter to Preserve backup chain.

Hyper-V: SCVMM Server, Standalone Host or Failover Cluster

> **Important:** Before registering SCVMM, you must install the Cohesity agent on the SCVMM server or on an existing proxy endpoint that is connected to an SCVMM server. Registration will fail without the agent installed. Ensure you install the Cohesity agent on any Hyper-V hosts that you want Cohesity to protect. The Cohesity agent version cannot be higher than the Cohesity cluster version. For more information, see Agent Compatibility Within a Cluster. For agent installation steps, see Download and Install the Agent on the SCVMM Server and Download and Install the Agent on Hyper-V Hosts. If a Hyper-V host is managed by SCVMM, do not register that host as a standalone host with the Cohesity cluster. Failover clusters require additional privileges. For more information, see Microsoft Hyper-V.

Field Name	Description
Hostname or IP Address	Specify the FQDN of the SCVMM cluster. Otherwise, you can specify the hostname or IP address of the source that contains the VMs to protect.
Username	Specify a domain user's account that has been granted administrative access to the SCVMM application.
Password	Enter the password for the specified user.
The Cohesity Agent has a different hostname or IP address than this SCVMM	If toggled off, the Cohesity agent is installed on the SCVMM server. If toggled on, the Cohesity agent is installed on an existing proxy endpoint that is connected to an SCVMM server. Specify the **Agent Hostname or IP Address**. The proxy endpoint must already have the VMM Administrator Console installed.
Cap concurrent streams per Datastore	Toggle this setting on if you want to limit the number of streams concurrently backed up per datastore. This helps to reduce any performance impact on the datastore. When registering a Hyper-V SCVMM Server, you can configure the **Number of Streams** for all datastores in the Hyper-V. After a Hyper-V is registered and the datastores in the Hyper-V are discovered, you can add overrides for individual datastores by clicking **Add Datastore Override**. Select a datastore, toggle on **Cap** and enter the number of Streams. If you toggle off **Cap** for a datastore, it is not subject to the Hyper-V's global concurrent streams cap.

Ensure you open necessary firewall ports as described in Manage Firewall Ports.

When editing registration (such as moving the SCVMM proxy agent endpoint to a different proxy or to the SCVMM cluster; or moving from the SCVMM cluster to a proxy), perform the following steps:

1. Copy the old agent registry values from the Cohesity folder and subfolders.
2. When moving to a proxy, paste the registry values to the new endpoint.

   When moving to SCVMM, paste the registry values to the active SCVMM node (RDPing into the SCVMM cluster redirects to the active master node).

Nutanix AHV Prism Central

Field Name	Description
Hostname or IP Address	Specify the hostname or IP address of Nutanix Prism Central.
Prism Central Username	Specify a Prism username that has adequate privileges to perform actions on the source. For more information, see Nutanix Acropolis.
Prism Central Password	Enter the password for the specified user.
Prism Element Username	(*Optional*) **Note:** If the same user account is used for both Prism Central and Prism Element credentials, you do not need to manually re-enter the Prism Element credentials. Specify a Prism element username that has adequate privileges to perform actions on the source. It is used to access the Nutanix Prism element.
Prism Element Password	(*Optional*) Enter the password for the specified user.

Acropolis: Acropolis Standalone Cluster

After you complete the iSCSI configuration and have an iSCSI target set/enabled on the source, verify the iSCSI connectivity between the Cohesity cluster and the source. You can manually log in to one of the configured iSCSI targets from one of the Cohesity cluster nodes.

Field Name	Description
Hostname or IP Address	Specify the hostname or IP address of Nutanix Prism.
Username	Specify a Prism username that has adequate privileges to perform actions on the source. For more information, see Nutanix Acropolis.
Password	Enter the password for the specified user.

GCP

For information on registering GCP, see Register or Edit a GCP Source.

AWS

Create an IAM user that has the required permissions for either backing up VMs or converting and cloning VMware VMs. See AWS and AWS GovCloud Permissions.

Field Name	Description
Access Key ID	Specify the Access Key ID for the new IAM user that was created to back up a AWS Cloud source or convert and clone Amazon EC2 to an AWS Cloud Source. For general information about AWS keys, see Access Keys (Access Key ID and Secret Access Key).
Secret Access Key	Specify the Secret Access Key for the new IAM user that was created to back up a AWS Cloud Source or convert and clone Amazon EC2 to an AWS Cloud Source. For general information about AWS keys, see Access Keys (Access Key ID and Secret Access Key).
ARN	Specify an Amazon Resource Name (ARN) of the IAM user that is used to identify the resources in AWS. For more information, see Amazon Resource Names (ARNs) .

Field Name	Description
Specify Fleet Settings	To understand fleet instances, see Fleet Instances. Enable this option to: • Specify the VPC and subnet in which the EC2 fleet instance should be launched. • Add tags to the EC2 fleet instance. By default, this option is disabled and the EC2 fleet instance is launched in the same VPC and subnet of the Amazon EC2 instances that are to be protected. > **Note:** This option is applicable only for the fleet instance created for backing up Amazon EC2. **Specify the VPC and Subnet** From the **Fleet Instance location** drop-down list select one of the following options to specify the VPC and subnet in which the fleet instance should be launched. • **Same Subnet as protected VMs**: The fleet instance will be launched in the same VPC and subnet of the Amazon EC2 instances that are to be protected. • **Select New**: The fleet instance will be launched in the specified VPC and subnet of the specified region. If the AWS source is not registered with the Cohesity cluster, the cluster cannot detect the AWS region, and the associated VPC and subnets. To configure a new VPC and subnet for the fleet instance, you must first register the source and then update the registered source to specify the VPC and subnet. For more information, see Configure a New VPC and Subnet for Fleet Instance. If you have not selected the **Fleet Instance location** after enabling the **Specify Fleet Settings** option, then the EC2 fleet instance is launched in the same VPC and subnet of the Amazon EC2 instances that are to be protected. **Add a Tag** Tags enable you to categorize and identify your fleet instances. A tag consists of a key and an optional value, both of which you define. To add a tag to the fleet instances, click **Add Tags** and enter a tag key and value. You can add up to 47 tags to a fleet instance. **Delete a Tag** To delete an existing tag, click the **cross** icon next to the tag.

Configure a New VPC and Subnet for Fleet Instance

To launch EC2 fleet instance will be launched in the specified subnet when you back up the Amazon EC2 instance to the Cohesity cluster. To configure a new VPC and subnet for the fleet instance:

1. In the Cohesity Dashboard select **Data Protection** > **Sources**.
2. Navigate the hierarchy to the registered AWS source for which you want to configure a new VPC and subnet for the fleet instance.
3. Click **Edit** next to the **Specify Subnet for Fleet Instance** text , or click the actions menu next to the AWS source and select **Edit**.

   The Edit Source page appears.
4. Enable the **Specify Fleet Settings** option if you have not enabled when registering the AWS source.
5. From the **Fleet Instance Location** drop-down list, select **Select New**.
6. Select a region, and its VPC and subnet in which the fleet instance should be launched.

   > **Note:** As the Amazon EC2 sources are mostly located in one region, you can select the VPC and subnet of only one region.
7. Click **Save**.

Create an IAM role and configure the following parameters for AWS Commercial Cloud Services (C2S):

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

Field Name	Description
Base URL	URL of the Commercial Cloud Services (C2S) server that contains the Amazon storage provided by the C2S agency.
Agency	The name of the agency that is providing the Commercial Cloud Services (C2S) server.
Mission	The account name for accessing the Commercial Cloud Services (C2S) server which is provided by the C2S agency.

Field Name	Description
Role	The IAM role to use when accessing the Amazon storage which is provided by the C2S agency.
Password	The password to read the Client Private Key when accessing the Commercial Cloud Services (C2S) server which is provided by the C2S agency.
Server CA Trusted Certificate	Upload the Certificate Authority Trusted Certificate file to access the Commercial Cloud Services (C2S) server which is provided by the C2S agency.
Client Certificate	Upload the Client Certificate file to access the Commercial Cloud Services (C2S) server which is provided by the C2S agency.
Client Private Key	Upload the Client Private Key file to use when accessing the Commercial Cloud Services (C2S) server which is provided by the C2S agency.
Specify Fleet Settings	Enable this option to: • Specify the VPC and subnet in which the EC2 fleet instance should be launched. • Add tags to the EC2 fleet instance. By default, this option is disabled and the EC2 fleet instance is launched in the same VPC and subnet of the VMs that are to be protected.

Azure

For information about required permissions, see Azure Permissions.

Field Name	Description
Category	Select one of the following options: • **Standard**–Standard Azure. • **Gov**–Azure Government. • **Stack**–Azure Stack Hub. You must specify the authentication type, region, and the domain name. For more information, see Azure Stack Hub.
Subscription ID	This is the subscription ID from which you want to back up data. Log in to the Azure portal. In the left panel, click **Subscriptions**. Copy the SUBSCRIPTION ID from the table.

Field Name	Description
Application ID	The Application ID assigned by Azure during the service principal creation process. For instructions see Get application ID and authentication key in the Microsoft Azure documentation.
Application Key	The Azure Application key generated using Legacy App Registration during the service principal creation process that is used for authentication. For instructions see Get application ID and authentication key in the Microsoft Azure documentation.
Tenant ID	The unique tenant ID assigned by Azure. For instructions see Get tenant ID in the Microsoft Azure documentation. **Note:** The **Tenant ID** field is not displayed for Azure Stack Hub Active Directory Federation Services (AD FS) authentication type.
Stack Type	If you select Stack, select the authentication type: • Azure Active Directory • Active Directory Federation Services Azure Stack Hub uses either Azure Active Directory or AD FS for authentication. AD FS is mostly used for disconnected deployments of Azure Stack Hub. For more information, see Microsoft Azure Stack Hub documentation.
Region	If you select **Stack**, specify the Azure Stack Hub region. For instructions, see Region management in Azure Stack Hub in the Microsoft Azure documentation.
Domain Name	If you select **Stack**, specify the Azure Stack Hub domain name.

RHV: oVirt Manager

> **Note:** Cohesity supports RHV only until version 6.8.1. While you can still register your RHV sources, the Cohesity Support team will not provide assistance.

> **Note:** When you register the oVirt-Manager with a Cohesity cluster, ensure you install the Cohesity agent on the RHV hosts that are joined to the oVirt Manager. The Cohesity agent version cannot be higher than the Cohesity cluster version. For more information, see Agent Compatibility Within a Cluster. For agent installation steps, see Download and Install the Cohesity Agent on RHV Hosts.

To register the oVirt-Manager with a different Cohesity cluster:

1. Unregister the current Cohesity cluster from the oVirt-Manager.

   > **Note:** If you skip this step, protection runs fail in the current Cohesity cluster.

2. Uninstall and reinstall the Cohesity agent on each RHV host.
3. Register the oVirt-Manager with the new Cohesity cluster.

Field Name	Description
Hostname or IP Address	Specify the RHV oVirt Manager hostname or IP address.
Username	Specify a username that has adequate privileges (Cohesity recommends a user with the "admin" role) to perform actions on the source. Use the format: username@profile, for example, admin@internal.
Password	Enter the password for the specified user.

5. Click **Register**.

   When source registration finishes, a new entry appears in the sources table.

Manage Application Registration on a VM

After you register applications with the Cohesity cluster, they can be protected. Currently, MS SQL Server and MS Exchange are supported.

For information about MS SQL, see Set Up Standalone Microsoft SQL Server or Microsoft SQL Server AGs.

For information about MS Exchange, see Register Exchange on a VM.

Edit Application Registration

1. Navigate to **Data Protection > Sources**.
2. Navigate the source hierarchy to the server, mouse over its actions menu and click **Edit Application Registrations**.
3. Edit the desired information.
4. Click **Save**.

Unregister Applications

You can unregister MS SQL Server only if it is not currently protected by an MS SQL Server Protection Group.

1. Navigate to **Data Protection > Sources**.
2. Navigate the source hierarchy to the server, mouse over its actions menu and click **Unregister All Applications**.
3. Click **Unregister**.

Register a Hyper-V Source

To register and back up a Microsoft Hyper-V source, follow the steps described below.

> **Note:**
> - Cohesity does not support the backup of Hyper-V VMs with shared disks.
> - If antivirus software is installed and running on a Hyper-V host, you must configure several exclusions and options for optimal agent operation. For more information, see Antivirus Software Exclusions.

Download and Install the Cohesity Agent on the SCVMM Server

Before registering SCVMM, you must install the Cohesity agent on the SCVMM server or on an existing proxy endpoint that is connected to an SCVMM server.

1. Navigate to **Data Protection > Sources**.
2. Click **Download Cohesity Agent**. Ensure the agent has been downloaded to the appropriate server.
3. As an administrator with local system privileges, run the executable and complete the installation wizard.

   Install the agent without additional components.
4. The agent starts automatically. Now you can register the Hyper-V SCVMM server as a source.

Download and Install the Cohesity Agent on Hyper-V Hosts

Ensure you install the Cohesity agent on any Hyper-V hosts that you want Cohesity to protect.

1. Navigate to **Data Protection > Sources**.
2. Click **Download Cohesity Agent**. Ensure the agent has been downloaded to the appropriate hosts.
3. As an administrator with local system privileges, run the executable and complete the installation wizard.

   For Hyper-V 2016 servers, install the agent without additional components.

   For incremental backups of individual VMs hosted by Hyper-V on Windows Server 2012 R2, install the **File System CBT (Changed Block Tracker)** component.
4. The agent starts automatically.

Guest Windows VM minimum recommended specifications: 2 GB RAM and the equivalent of a 1 GHz processor.

Best practice: For Hyper-V 2016, configure all VMs' Automatic Stop Action to shut down or turn off, instead of save. This results in all powered-on VMs having minimal size .vmrs files. Because Cohesity does not back up .vmrs files that are greater than 10 MB (.vmrs file size, if set to save, scales to the amount of memory assigned to the VM). VMs in the saved state, by definition, generally have .vmrs files greater than 10 MB. This Cohesity Windows Agent registry value entry determines the maximum size of the .vmrs file supported per backup: agent_hyperv_max_vm_config_file_size_mb. Set it to zero to back up .vmrs files of all sizes.

Register a Hyper-V Source with the Cohesity cluster

1. Navigate to **Data Protection > Sources**.
2. Select **Register** > **Virtual Machines**.
3. From the **Select Hypervisor Source Type** drop-down, select the hypervisor source type and complete the fields. The available options are:
   - HyperV: SCVMM Server
   - HyperV: Standalone Host
   - HyperV: Failover Cluster

   For detailed registration steps, see Register or Edit a Hypervisor Source.
1. Click **Register**.

   After registration is completed, ensure the Cohesity cluster is joined to an Active Directory domain as described in Join Active Directory, which is required for Hyper-V VM backup and recovery.

   Now Cohesity can back up any Hyper-V hosts where the Cohesity agent is installed.

User Account Requirements for VM Protection

Specific user account configuration is required for the following operations:

- The user account that is used for auto-deploying agents in a Windows VMware environment must have administrator privileges on the VM where the agent is deployed. The account must have the "sysadmin" Server Role.

  If the Windows Firewall is used, add an inbound rule to accept the Cohesity Agent and TCP connections on local port 50051.
  Port 50051 may have limited requirements. It is needed for application integration, but not required for File-Level Recovery or Instant Volume Mount operations.

If the operation fails with an error indicating insufficient privileges, then check if the user account used for this operation allows remote command execution without a UAC prompt. Otherwise, use a persistent agent or other suitable recovery methods, if applicable.

Register a Storage Snapshot Provider

Cohesity can leverage the snapshots from the following storage snapshot providers:

- Cisco HyperFlex
- Nimble Storage, HPE Alletra 5000, and/or HPE Alletra 6000
- NetApp ONTAP
- Nutanix
- Pure Storage Array
- IBM FlashSystem

You can leverage snapshots only for VMware backups from the preceding storage snapshot providers. To leverage the storage snapshots, you must:

1. Register the snapshot providers with the Cohesity cluster. See the following sections on how to register the above snapshot providers.
2. Enable the **Leverage Storage Snapshots for Data Protection** field and select the storage snapshot provider from the drop-down when creating the Protection Group. For more information, see Add or Edit a Protection Group for Virtual Servers.

Considerations

- You can leverage only one storage snapshot provider for a Protection Group.
- For IBM FlashSystem, Nimble Storage, HPE Alletra 5000, HPE Alletra 6000 and Pure Storage, VMFS datastores are supported.
- For NetApp, NFS 3 and NFS 4.1 datastores are supported.
- Cohesity cannot leverage storage snapshots when VM has disks on volumes of different storage systems.

- The Cohesity cluster periodically queries the registered NetApp source(s) to obtain volume information. The VM protection job does not query NetApp for volume information at the time it is run. If new NetApp volumes were presented to the vCenter as NFS datastores and VMs from such datastores are part of a protection job, you must manually refresh the NetApp source on the Cohesity cluster or wait for the periodic refresh to ensure volume information is updated for leveraging this integration.
- The Cohesity cluster periodically queries the inventory of the vCenter and the Nutanix cluster. The information from these two sources may be out of sync. Therefore, if new VMs have been added or VMs have been moved, you may need to manually refresh the vCenter and Nutanix source on the Cohesity cluster to leverage Nutanix snapshots for VMware backup.
- SAN transport mode is not supported if you are leveraging VMware snapshots from NetApp.
- The leverage storage snapshot feature doesn't work when multitenancy is enabled.
- To complete the storage snapshot, you must register the source with the same IP address or FQDN that is specified in vCenter for the datastore.

Register Cisco HyperFlex

To register Cisco HyperFlex as a storage snapshot provider for VMware, follow the steps described below.

1. Navigate to **Data Protection > Sources**.
2. Click **Register > Storage Snapshot Provider**.
3. From the **Select Snapshot Storage Provider Type** drop-down, select **Storage Snapshot Provider: Hyperflex**.
4. Enter the following information:

Field	Description
Hostname or IP Address	Specify the hostname or IP address of the Cisco HyperFlex system to protect. Cohesity recommends using the HyperFlex Management IP address (SCVM floating IP address). **Note:** You must also register the corresponding VMware vCenter with the Cohesity cluster.
Username	Specify a Cisco HyperFlex admin user to ensure adequate privileges.
Password	Enter the password for the specified user.

5. Click **Register**.

   When registration finishes, a new entry appears in the Sources table.

After registering the snapshot provider, to leverage the VMware snapshots from Cisco HyperFlex, you must enable the **Leverage Storage Snapshots for Data Protection** field and select **HyperFlex** when creating the virtual Server Protection Group. For more information, see create a Protection Group for VMware.

Register Nimble Storage Array, HPE Alletra 5000, and/or HPE Alletra 6000

> **Note:**
> - Registering HPE Alletra 5000 and/or HPE Alletra 6000 as a source is an Early Access feature.
> - You can register Nimble Storage, HPE Alletra 5000, and/or HPE Alletra 6000 for leveraging storage snapshots for VMDKs. Cohesity does not support the backup of Nimble Storage, HPE Alletra 5000, and/or HPE Alletra 6000 storage volumes.

Before registering the Nimble Storage Array as a storage provider, ensure it meets firewall port requirements.

Registering a Nimble Storage as a Storage array makes its LUN (both iSCSI and FC) content eligible to be protected on the Cohesity cluster.

After you complete the iSCSI configuration and have an iSCSI discovery set/enabled on the Nimble array, verify the iSCSI connectivity between the Cohesity cluster and the Nimble array. To verify the connectivity, you can manually log in to one of the configured iSCSI targets on the Nimble array from any one of the Cohesity cluster nodes.

Run the following command to check the iSCSI connectivity:

```
iscsiadm -m discovery -t sendtargets -p <ipaddress>
```

For additional iSCSI commands, see Additional iSCSI commands.

Perform the following steps to register Nimble Storage, HPE Alletra 5000, and/or HPE Alletra 6000 Storage Array:

1. Navigate to **Data Protection > Sources**.
2. Click **Register > SAN**.
3. Select the source type as **Nimble**.

> **Note:** You can register HPE Alletra 5000 and HPE Alletra 6000 by selecting the source type as Nimble.

4. Enter the following information:

> **Note:** You must also register the corresponding VMware vCenter where Storage Array Datastore is mounted with the Cohesity cluster.

Field	Description
Management Host or IP Address	Specify the Management Host or IP Address of the Nimble or HPE Alletra 5000 and HPE Alletra 6000 Storage to register.
Username	Specify the user name used for accessing the Nimble or HPE Alletra 5000 and HPE Alletra 6000 Storage.
Password	Enter the password for the specified user.

5. Click **Register**.

   When registration finishes, a new entry appears in the Sources table.

Additional iSCSI Commands

The table below lists the additional iSCSI commands:

Command	Description
iscsiadm -m node -T <targetname> -p <ipaddress> -l	Use this command to log in to a specific target.
iscsiadm -m node -T <targetname> -p <ipaddress> -u	Use this command to log out from a specific target.
iscsiadm -m node -T< targetname> -p <ipaddress>	Use this command to display the target information.
iscsiadm -m node -s -T <targetname> -p <ipaddress>	Use this command to display the statistics of a target.
iscsiadm -m session	Use this command to display all the current logged-in sessions.

Command	Description
iscsiadm -m discovery -o show	Use this command to display the iSCSI database regarding discovery.
iscsiadm -m node -o show	Use this command to display the targets to log into.
iscsiadm -m session -o show	Use this command to display the sessions logged into.

After registering the snapshot provider, to leverage the VMware snapshots from Nimble Storage, HPE Alletra 5000, and/or HPE Alletra 6000, you must enable the **Leverage Storage Snapshots for Data Protection** field and select **Storage Array/NAS** when creating the virtual Server Protection Group. For more information, see create a Protection Group for VMware.

Using the **Leverage Storage Snapshots for Data Protection** option with the **Leverage SAN Transport for Data Protection** option is not recommended.

To leverage SAN transport for VMware backup only through FC without leveraging storage snapshots for data protection, contact Cohesity Support.

Register NetApp ONTAP

To register NetApp ONTAP as a source as a storage snapshot provider for VMware, follow the steps described below.

Minimum Permissions

Before you register NetApp ONTAP cluster or SVM with Cohesity cluster as a storage snapshot provider for VMware, you must have the required permissions:

Permission for registering NetApp ONTAP cluster as a storage snapshot provider for VMware:

Access-level	Command	Description
All	vserver export-policy	Adds the Cohesity cluster subnet to the export-policy so that Cohesity can mount volumes.
	volume snapshot	Allows fetching, creating, and deleting snapshots for volumes.
	volume	Fetches information about volumes and deletes flex clone.

Access-level	Command	Description
ReadOnly	cluster identity	Fetches information about the cluster.
	network interface	Fetches information about network interfaces to which Cohesity connects for mounting volumes.
	vserver	Fetches information about Vservers.

Permission for registering NetApp ONTAP SVM as a storage snapshot provider for VMware:

Access-level	Command	Description
All	vserver export-policy	Adds the Cohesity subnet to the export policy so that the Cohesity cluster can mount volumes.
	volume snapshot	Allows fetching, creating, and deleting snapshots for volumes.
	volume	Fetches information about volumes and deletes flex clone.
ReadOnly	network interface	Fetches information about network interfaces to which the Cohesity cluster connects for mounting volumes.
	vserver	Fetches information about Vservers.

To register NetApp ONTAP:

1. Select **Data Protection > Sources**.
2. Click **Register > NAS**.

   The Register NAS page appears.
3. From the **NAS Source** drop-down list, select **NetApp**.
4. Enter the following information.

Field Name	Description
NetApp Source Type	The NetApp ONTAP cluster or Vserver to register.
Host or IP Address	The Host or IP address of the NetApp ONTAP cluster or Vserver to register.

Field Name	Description
Username	Username used to access the NetApp ONTAP cluster or Vserver. **Note:** The username used to register the NetApp ONTAP cluster and Vserver is case sensitive.
Password	Enter the password for the specified user.
Back Up SMB Volumes	Not applicable. This field is not applicable for registering NetApp ONTAP as a storage snapshot provider
Filter IPs	Not applicable. This field is not applicable for registering NetApp ONTAP as a storage snapshot provider.

5. Click **Register**.

   When registration finishes, a new entry appears in the Sources table.

After registering the snapshot provider, to leverage the VMware snapshots from NetApp ONTAP, you must enable the **Leverage Storage Snapshots for Data Protection** field and select **Storage Array/NAS** when creating the virtual Server Protection Group. For more information, see create a Protection Group for VMware.

Register Nutanix

To leverage the Nutanix Prism element as the storage snapshot of VMware VMs, you must first register the Nutanix Prism element as a source with the Cohesity cluster. To register Nutanix as a storage snapshot provider for VMware, follow the steps described below:

1. Navigate to **Data Protection > Sources**.
2. Click **Register > Virtual Machines**.

   The Register Virtual Machines page appears.
3. From the **Source Type** drop-down list, select **Acropolis: Other Hypervisors**.
4. Enter the following information:

Field Name	Description
Hostname or IP Address	Specify the hostname or IP address of Nutanix Prism.
Username	Specify a Prism username that has adequate privileges to perform actions on the source. For more information, see Nutanix Acropolis.
Password	Enter the password for the specified user.

5. Click **Register**.

   When registration finishes, a new entry appears on the Sources page.

After registering the snapshot provider, to leverage the VMware snapshots from Nutanix, you must enable the **Leverage Storage Snapshots for Data Protection** field and select **Nutanix** when creating the virtual Server Protection Group. For more information, see create a Protection Group for VMware.

Considerations

Review the following considerations of Nutanix Storage Snapshot:

- Cohesity does not support application-consistent backups of VMware VMs that leverage Nutanix as the storage snapshot provider.
- Cohesity does not support differential restore of VMware VMs backed by leveraging the storage snapshots.
- If the protection run of VMware VMs is switched from VADP-based backup to storage snapshot-based backup, then the Cohesity cluster will initiate a full backup.
- While performing storage snapshot-based backup, if a VMware VM snapshot is present on the ESXi host, then Cohesity will perform VADP backup.
- Cohesity does not support leveraging storage snapshots for backing up VM templates.

Register Pure FlashArray

Before registering or editing a Pure FlashArray, ensure it meets prerequisites, minimum permissions, and firewall port requirements in the Plan and Prepare for Pure FlashArray.

To register Pure FlashArray as a storage snapshot provider for VMware, see Register or Edit a Pure FlashArray.

To leverage the VMware snapshots from Pure FlashArray, you must enable the **Leverage Storage Snapshots for Data Protection** field and select **Pure** when creating the virtual Server Protection Group. For more information, see Add or Edit a Protection Group for Virtual Servers.

To leverage SAN transport for VMware backup only through FC without leveraging storage snapshots for data protection, contact Cohesity Support

Register IBM FlashSystem

To register IBM Storage FlashSystem as a storage snapshot provider for VMware, see Register or Edit an IBM Storage FlashSystem.

To leverage the IBM FlashSystem Storage Snapshots for VMware backups, after registering the IBM FlashSystem, you must also enable the **Leverage Storage Snapshots for Data Protection** field and select **Storage Array/NAS** when creating the virtual Server Protection Group. For more information, see Add or Edit a Protection Group for Virtual Servers.

Register HPE Alletra Storage MP

Before registering the HPE Alletra Storage MP as a storage provider, ensure it meets firewall port requirements.

To register HPE Alletra Storage MP as a storage snapshot provider for VMware, see Register or Edit HPE Alletra Storage MP.

To leverage the HPE Alletra Storage MP for VMware backups, after registering the HPE Alletra, you must also enable the Leverage Storage Snapshots for Data Protection field and select Storage Array/NAS when creating the virtual Server Protection Group. For more information, see Add or Edit a Protection Group for Virtual Servers.

Related Topic

Ensure Adequate Privileges for Cohesity on the Source

Add or Edit a Protection Group for Virtual Servers

Register or Edit a Pure FlashArray.

Add or Edit a Protection Group for Virtual Servers

A Protection Group that protects VMs captures snapshots, which are required for the following tasks:

- clone VMs
- recover VMs
- recover files
- instant volume mount
- replicate snapshots
- archive snapshots

> **Tip:** You can also watch the VMware Protection Groups video to learn how to create a Protection Group.

Before you begin

When you create a Protection Group, you can select an existing source, policy, or storage domain. You can also create them while creating the Protection Group. However, you might find it easier to create them prior to creating the Protection Group, as described in the following topics.

- Register or Edit a Hypervisor Source
- Create or Edit a Standard Policy
- Create or Edit Storage Domains

> **Important:**
> - The options and features available in the following procedure are dependent on the selected source and the Protection Group type. For example if a **Cloud** > **AWS: IAM User** source is selected, the **Cohesity Protection Service** and **Native Snapshot** Protection Group types appear.
> - (Applies only to Hyper-V) To prevent the AVHDX snapshot files from being deleted, merged, or cleaned up after successful backup, Microsoft recommends the following workaround:
>   - Change the Cohesity Windows agent service user account to LOCAL SYSTEM.
>   - Clear all manually set accounts under Log On As A Service/Deny Log On As A Service from both local and group policies.

To add or edit a Protection Group for virtual servers:

1. Navigate to **Data Protection > Protection** and do one of the following:
   - To create a Protection Group—Click **Protect** on the top-right of the page and then select the type of Protection Group.
   - To edit a Protection Group—Click the action icon (⋮) next to the Protection Group and select **Edit**.
2. If you are creating a Protection Group, click **Protect > Virtual Machines**.

   The New Protection page appears.

3. Click **Add Objects**, and from the **Registered Source** drop-down list, select the Virtual server whose VMs you want to protect. You can also Register a new source with the Cohesity cluster by clicking the **Register Source** option.

   Best practice: For environments with Hyper-V 2012 R2 (v5.0) VMs running on 2016 hosts, create separate Protection Groups for Hyper-V 2012 R2 VMs and Hyper-V 2016 (v8.0) VMs. This separation enables the Protection Group s protecting only Hyper-V 2016 VMs to use resilient change tracking (RCT) backup.

   > **Note:** Cohesity can exclude the backup of placeholder VMs in a VMware VMs Protection Group. This is an Early Access feature and you must contact Cohesity Support to enable this feature.

4. Select the source objects to back up or exclude.

   For VMware vCenter, you can also select VM templates as the objects to backup. For VM templates only full backup is performed.

   By default, all objects in the source are excluded as indicated by the unselected check box. Expand the source objects and select the objects you want to include in the Protection Group. A selected check box ( ) indicates the object is selected to be backed up.

   - Indicates an auto protected object.
   - Excluded objects are not protected. The icon indicates that an ancestor of the object is auto protected but this object is explicitly excluded.
   - Excluded objects are not protected. The icon indicates that an ancestor of the object is auto protected but this object is excluded through inheritance (an ancestor is explicitly excluded).
   - Click this icon to view the general information—type, server size, and version of the selected object.
   - vCenter Migrated indicates the VMware VM is migrated from another VMware vCenter.

   When protecting vApp and vApp template, you must enable auto-protect. If you are not enabling auto-protect, then Cohesity cluster will only back up the underlying objects of the vApp and vApp template. When protecting vApp VMs, Cohesity recommends using one protection group exclusively for all VMs within a vApp and not mixing vApp VMs with other VMs.

   Display modes can show VMs in a hierarchy or a flat list of all VMs.

For VMware vSphere 6.0 onwards, AWS, Azure, and Microsoft Hyper-V, you can also display only VMs with specific tags. Click the **Tags** button, select a tag from the drop-down and click **Add**. You can choose to **Auto Protect** or **Exclude** the VMs that have this tag. After clicking **Auto Protect** or **Exclude**, the source tree is updated with your selection. If a VM has multiple tags with **Auto Protect** and **Exclude** applied, exclusion takes precedence. These excluded VMs are also excluded even if a parent object is auto protected.

The **Tags** button will not be displayed if the Cohesity cluster detects that no VMs have tags assigned to them. For the **Tags** button to appear, log in to the hypervisor and assign a tag to at least one VM. Once the tag is assigned to the VMs, you must manually refresh the registered hypervisor in the Cohesity cluster. To refresh the hypervisor, select **Data Protection** > **Sources**, navigate the source hierarchy to the hypervisor server, click the actions menu, and then click **Refresh**.

AHV Prism Central supports tag-based functionality, where the Tags view displays only VMs associated with tag:

1. Navigate to **Data Protection** > **Protection**.
2. From the **Protect** drop-down, select **Virtual Machines**.

   The **New Protection** page appears.
3. Click **Add Objects**, and from the **Registered Source** drop-down list, select a Prism Central VM.
4. Click the **Tags** button. Selecting a value will display all VMs tagged with that particular value.

You can choose to **Auto Protect** or **Exclude** the VMs that have this tag. After clicking **Auto Protect** or **Exclude**, the source tree is updated with your selection. If a VM has multiple tags with **Auto Protect** and **Exclude** applied, exclusion takes precedence. These excluded VMs are also excluded even if a parent object is auto-protected.

Protection Groups of Hyper-V VMs allow auto-protection using multiple selections in the include and exclude lists and multiple tags in each selection.

You can choose which disk to back up or exclude in a Hyper-V VM or Protection Group, VMware VM or Protection Group, or an AHV VM or Protection Group.

To include or exclude disks for a Hyper-V, AHV VM, or VMware when creating a Protection Group:

a. Navigate to **Data Protection** > **Protection**.
b. From the **Protect** drop-down, select **Virtual Machines**.

   The **New Protection** page appears.
c. Click **Add Objects**, and from the **Registered Source** drop-down list, select a VM.

d. In the **Add Objects** dialog, select the checkbox next to that VM and click the Edit ( ) icon.

> **Note:** To enable the **Disk Inclusion/Exclusion** option to an existing Protection Group, click the Edit icon under Objects in the Protection Group settings.

e. In the **Options** dialog, enable **Enable Disk Inclusion/Exclusion**.

f. You can choose to include or exclude the disks. After selecting **Include** or **Exclude**, select the disks from the drop-down.

g. Click **Save**.

Once saved, the **Customized** link appears next to the Edit icon and lets you modify the disk inclusion/exclusion settings.

To include or exclude disks for a Hyper-V, AHV, or VMware Protection Group as a whole:

a. Navigate to **Data Protection** > **Protection**.

b. From the Actions menu (⋮) of the Protection Group, select **Edit**.

c. Under **Additional Settings** of the Protection Group, select **Include** or **Exclude Disks** and enable **Enable Disk Inclusion/Exclusion**.

d. Select **Include** or **Exclude**.

e. Click **+ Add**.

f. Enter the details of the disk:

AHV: Select the Controller Type and enter the Unit Number of the disk. The Unit Number (or Index) is the unique identifier assigned to that disk when it's added to the VM in the Nutanix Prism Web Console.

Hyper-V: Select the Controller Type and enter the Controller Number and Unit Number of the disk. The Controller Number and Unit Number (or Location) are the unique identifiers assigned to the Controller and Disk by the Hyper-V Manager.

VMware VM: Select the Controller Type and enter the Bus Number and Unit Number for each disk. The Bus Number and Unit Number (or Location) are the unique identifiers assigned to the Controller and Disk by VMware.

g. You can add more disks until you have all the disks you want included or excluded for that Protection Group.

h. Click **Protect.**

> **Note: Disk Inclusion** or **Exclusion** settings of a VM take precedence over the settings of its Protection Group.

The VMware user account designated for data protection requires the following additional privileges to back up encrypted VMs:

- Cryptographic Operations > Add Disk
- Cryptographic Operations > Direct Access
- Cryptographic Operations > Encrypt
- Cryptographic Operations > Encrypt new

When configuring an AWS Protection Group, you can search VMs with specific tags, if the VM Protection Group type is **Native Snapshot**.

You can optionally filter the objects displayed.

In the search field, enter part of the object name.

Use the filtering options:

- In the **Filter** drop-down, select one of the following options:
  - **Unprotected**—Displays the servers that are not protected by any Protection Groups in the Cohesity cluster—not protected by Cohesity.
  - **Protected by Cohesity**—Displays the servers that are protected by all the Protection Groups in the Cohesity cluster.
  - **MS SQL Servers**—Displays only object hierarchy objects that contain servers registered as MS SQL Server.
  - **Protected by this Job**—Displays the servers that are currently selected to be backed up by this Protection Group. (This option is only available when editing an existing job.)

  To reset the filter and show all objects, click **Show All**.
- For virtual servers only, the **Expand to** drop-down allows you to expand the object hierarchy to a specific level.

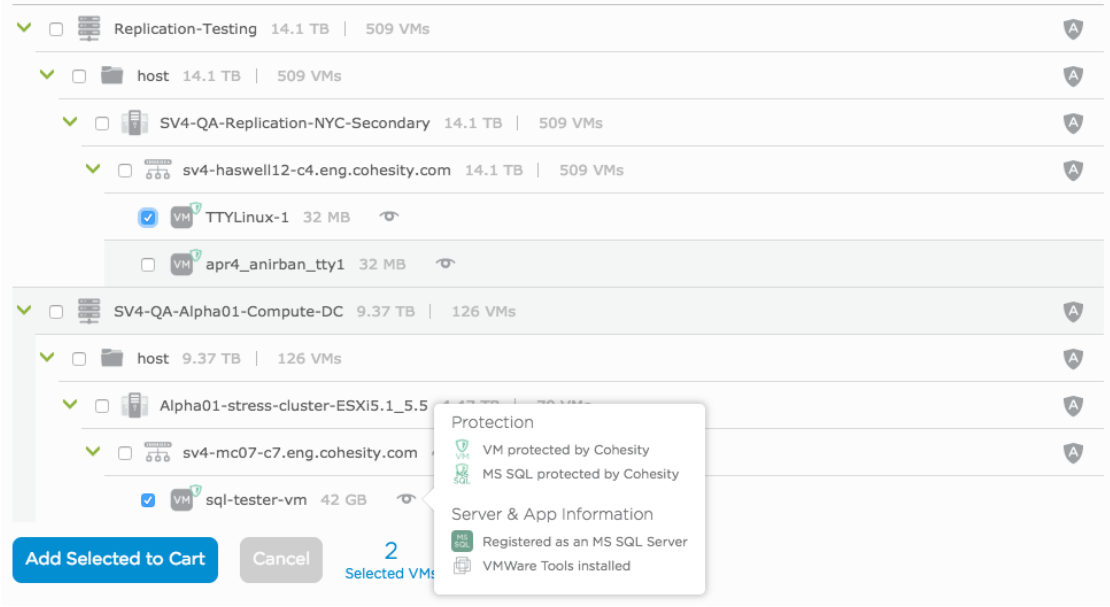
  Selecting the check box adjacent to **Objects** selects all filtered objects.
- For physical servers only, you can choose to show just Windows or Linux servers. All servers are shown by default.

  Selecting the check box adjacent to **Servers** selects all filtered servers.
- Click the arrow adjacent to object (**Expand All**) to expand the entire object hierarchy. Click the arrow again (**Collapse All**) to collapse the entire object hierarchy.

The graphical representations in the table are described below.

- If you are creating a new Protection Group and the shield appears next to the object, this object is already protected by another Protection Group.

- If you are editing an existing Protection Group and the shield appears next to the object and the object is selected ( ), this object will be protected by the current Protection Group. (It may also be protected by another Protection Group.)



- Click the icon to see details about the object.

  MS SQL The MS SQL Server application is registered.

  VMware Tools is installed on the VM. If VMware Tools are installed, this VM can be backed up by an application-consistent Protection Group. For more information, see Creating Application-Consistent Snapshots.

- If the object name is in red, it is inaccessible, invalid, or orphaned. If the object is in one of the specified states when the Protection Group runs, no snapshot is

created. If the object becomes accessible, a snapshot is created the next time the Protection Group runs.

If appropriate for your organization, enable auto protect.

Click to enable auto protect. Any new VMs added to the parent object in the future will automatically be protected by this Protection Group.

Click to disable auto protect for an object. The icon turns red.

> **Note:** A Protection Group that auto-protected VMware VMs will run successfully without any critical failure alerts, even if it has no objects, with the following message in the Protection Run's Details dialog: "Protection Group has no eligible source to back up.".

The object hierarchy is automatically refreshed every four hours. To manually refresh the object hierarchy, select **Data Protection > Sources**, find the source in the list and click .

> **Warning:** You may unintentionally back up cloned VMs with this option. For example, if you select this option for a Protection Group that backs up an ESXi host and that ESXi host is where cloned VMs are created, the new cloned VMs are also backed up the next time the Protection Group runs. You may want to edit the original Protection Group and explicitly exclude the new cloned VMs.

> **Note:** In the Cohesity Dashboard, users with a restricted role (such as operator) cannot access the runs of a Protection Group for leaf objects (such as VMs) that were backed up because a higher level object (such as a datacenter) was auto-protected, even if that user has permissions to access those leaf objects. Cohesity supports assigning permissions to leaf level object such as VMs. Cohesity currently does not support assigning permissions to higher level objects such as a datacenter and since auto-protection is applied higher level objects, access is denied.

5. Click **Continue** to go back to the New Protection page.

6. Select **Protection Group** and in the **Name** field, enter a name from the Protection Group.
7. **Protection Group Type:** This option is available only if the selected source is a cloud source that supports backing up with both agents or native snapshotting.

   Select a Protection Group type:

   - **Cohesity Protection Service**— A Cohesity cluster supports backing up VMs in a cloud service (such as Azure or AWS) using an agent. You must install an agent on the VMs with this option.

     For more information, see and .
   - **Native Snapshot**—A Cohesity cluster supports backing up VMs in a cloud service (such as AWS) using the native snapshotting of the cloud service. An agent does not need to be installed for this option.

     For more information, see AWS Backup Use Cases.
   - **Snapshot Manager**—A Cohesity cluster supports the backup of VMs in a cloud service (Azure and AWS) using the Cloud Snapshot Manager APIs of the cloud service. For more information, see AWS Backup Use Cases.
8. Select **Policy** and from the **Policy** drop-down list, select an existing protection policy or create a new one by selecting **New Policy**. For more information, see Create or Edit a Standard Policy.
9. Select **Storage Domain** and select an existing storage domain or create a new one by selecting Add Storage Domain.
10. Selection one of the following options:
    - **Protect**: Select this option if you want to complete the Protection Group creation without changing or configuring any of the additional settings.
    - **More Options**: Select this option and go to step 12 if you want to change or configure any of the additional settings.
11. **Start Time:** Indicates when the Protection Group should run. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting.

    The default time zone is the browser's time zone. You can change the time zone by selecting a different time zone.
12. **End Date:** Optional. Toggle on and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
13. **QoS Policy:** Select an appropriate quality of service (QoS) policy.

    > **Note:** Cohesity recommends specifying **Backup HDD**, which is the default.

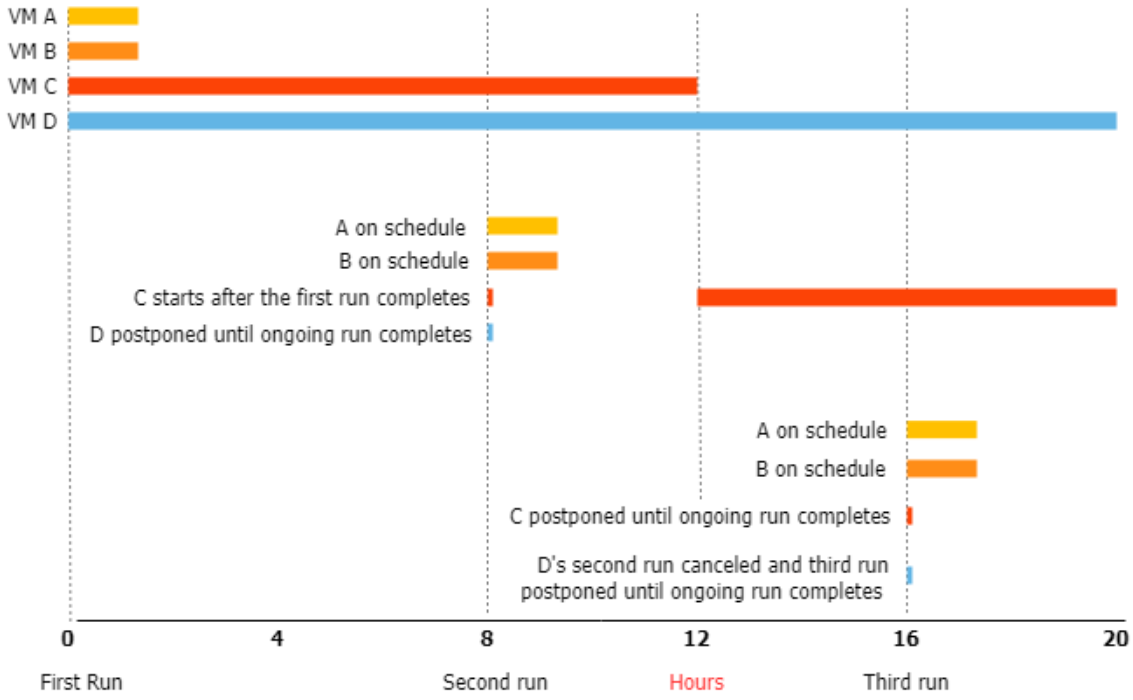
- **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group.
- **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups.
- **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy.
- **TestAndDev High:** The Cohesity cluster writes the data to an SSD drive for this Protection Group. The I/Os with this QoS policy are given higher priority compared to other QoS policies. Use this policy for workloads that require lower I/O latency.

14. **Defer Incomplete Objects in Concurrent Runs**: (Applies only to VMware VMs) A Protection Group can protect both small (for example, 1 GB VM) and large VMs (for example, 1 TB VM). While a short VM usually completes its protection runs within a few minutes, a large VM might take longer and still be running when it's time for the next run. By default, when it's time to start the next run, the Cohesity cluster checks for any in-progress protection run in that Protection Group. If there are in-progress protection runs (typically a large VM), the Cohesity cluster cancels the next run for that Protection Group, causing the small VMs to also miss that run and the SLA. When the **Defer Incomplete Objects in Concurrent Runs** option is enabled, if there is an in-progress protection run, the Cohesity cluster postpones the subsequent run only for that VM. The postponed run resumes as soon as the current run is completed. The protection runs of the remaining VMs (typically small VMs) in that Protection Group are not affected and run on schedule.

    For example, Protection Group PG1 runs every 8 hours to protect VMs A, B, and C. When the first protection run starts, A and B complete running in a few minutes. VM C, a large VM, needs 12 hours to complete running. If **Defer Incomplete Objects in Concurrent Runs** is disabled for PG1, when it’s time for the second run, the Cohesity cluster cancels the second run in all three VMs because C is still in progress. However, the third run completes in all three VMs. Because C is a large VM, A and B miss every alternate run.

If **Defer Incomplete Objects in Concurrent Runs** is enabled for PG1, when it's time for the second run, the Cohesity cluster starts the second run in A and B but postpones the run in C. C's second run resumes when its first run completes. As a result, A, B, and C do not miss any scheduled runs.

If PG1 also protects VM D, another large VM, which needs 20 hours to complete, when it's time for the second run, the Cohesity cluster postpones D's second run. When it's time for the third run, because D's first run is still in progress, the Cohesity cluster cancels its second run but postpones its third run. D's next run will resume automatically when its ongoing run completes.



When the Cohesity cluster cancels the backup task of an object (such as D) in the Protection Group (such as PG1), the **Protection Group Details** page displays the following message at the corresponding protection run:

```
"Failed to back up some of the objects in the protection run as they
are already backed in another protection run. ".
```

At the corresponding task (D's second backup task), the following message is displayed:

```
"cancelled the backup task of this object as it is already being backup
up by another protection run."
```

Enabling the **Defer Incomplete Objects in Concurrent Runs** option helps you meet the defined SLAs, and improves the efficiency of the scheduled runs, thereby enhancing the backup performance.

> **Note: Defer Incomplete Objects in Concurrent Runs** can be enabled for runs with replication or archiving enabled.

15. **Leverage Storage Snapshots for Data Protection**: Toggle on to leverage storage array-based snapshots of supported Storage Snapshot Providers such as Cisco HyperFlex, HPE Nimble Storage, HPE Alletra 6000, NetApp ONTAP, Nutanix Prism element, Pure Flash Array, and IBM FlashSystem.

    Enabling this option greatly reduces the persistence time of VADP snapshots, thereby minimizing VM stuns and snapshot consolidation issues. The storage array-based snapshots can be leveraged only if the Storage Snapshot Provider is registered with the Cohesity cluster. For details on how to register, see Register a Storage Snapshot Provider.

Note:

- Disk exclusions in a VM is not supported if the **Leverage Storage Snapshots for Data Protection** option enabled.
- Using the **Leverage Storage Snapshots for Data Protection** option with the **Leverage SAN Transport for Data Protection** option is not recommended.
- The protection run may not be able to leverage storage snapshots for the backup of all VMs within the Protection Group; for example, when a VM has one or more Virtual RDM disks.
- The leverage storage snapshot feature doesn't work when multitenancy is enabled.

16. **Leverage SAN Transport for Data Protection**: Cohesity supports SAN transport for Fibre Channel (FC) and iSCSI-based storage arrays and datastores that contain such storage arrays. Turn on this option to enable the SAN transport mode over FC or iSCSI for backing up VMware VMs to the Cohesity cluster.

    To use the SAN transport mode over FC, ensure the following pre-requirements:

    - Fibre channel is installed and zoned appropriately between the Cohesity cluster and the primary storage.

    To use the SAN transport mode over FC and iSCSI, ensure the following pre-requirement:

    - Volumes are mapped appropriately between the Cohesity cluster, ESXi hosts, and the primary storage.

> **Note:**
> - Using the **Leverage SAN Transport for Data Protection** option with the **Leverage Storage Snapshots for Data Protection** option is not recommended.
> - This option is valid for storage arrays supported by VMware. Cohesity has tested this with Pure Flash Array, HPE Nimble Storage Array, and IBM Storage FlashSystem configurations.
> - VMware SAN transport mode is not supported with Cohesity virtual nodes. To use SAN transport mode for backing up VMware VMs, zoning and granting datastores access to the Cohesity nodes has to be done manually.

You can turn on the **Allow NBDSSL Transport Fallback** toggle if you do not want to enforce strict SAN transport mode for backing up VMware to the Cohesity cluster. With toggle enabled, backup will not fail if the SAN transport is not available. If you disable this toggle, backup will fail if the SAN transport mode is unavailable.

> **Note:** NBDSSL is the default transport mode for On-Prem vCenter backups. The fallback to NBD if NBDSSL fails is no longer supported.

> **Note:** Ensure that the storage array connects to the primary environment (host) and the Cohesity node over the same protocol (FC on both ends or iSCSI on both ends). Cohesity does not support SAN transport for SAS (Serial Attached SCSI) based storage arrays.

17. **Exclude Disks**: (*Applies only to VMware VM*) By default, all the volumes on a selected server are protected. Toggle on to select disks to exclude for all VMs is this Protection Group. Provide the type of controller, bus number and unit number for each disk to exclude. Excluded disks are not backed up and are not recovered during VM recovery.

> **Note:** If you exclude a disk that is part of a striped volume, the Cohesity cluster does not index the volume even if **Indexing** is toggled on for this Protection Group. You will not be able to search for or recover individual files in that volume.

18. **Include Disks**: (*Applies only to VMware VM*) By default, all the volumes on a selected server are protected. Toggle on to select disks to exclude for all VMs is this Protection Group. Provide the type of controller, bus number, and unit number for each disk to include. Only the specified disks are backed up and recovered during VM recovery.
19. **Exclude Physical RDM Volumes**: (*Applies only to VMware VM*) VMware vSphere Storage APIs cannot be used to snapshot physical compatibility RDM disks. Enable this option to allow the backup of VMs by excluding physical compatibility RDM disks. If you disable this option, the backup of VMs with physical compatibility RDM disks will fail. Excluded disks are not backed up and are not recovered during VM recovery. Cohesity recommends you to use agent-based backups to protect data on the physical RDM disks.

    > **Note:**
    > - VMware does not support taking the snapshot or backup of the VMs having RDM (physical and virtual) on Shared Bus.
    > - Backup of Virtual compatibility RDM disks is supported and does not depend on the **Exclude Physical RDM Volumes** toggle setting.

20. **Protection Type**: It provides the following options.
    1. **Auto**: Select this option to automatically identify the mode based on the version of virtual machines in the protection job. If there is a VM that does not support RCT, then the VSS backup approach is used for all the VMs in that protection job.
    2. **VSS**: Select this option to use Hyper-V VSS Writer as the backup approach.
    3. **RCT**: Select this option to use Hyper-V WMI Based Backup as the backup approach. Resilient Change Tracking (RCT) is available on Windows Server 2016 or later and the version of the virtual machine should be 8.0 or later.
21. **App Consistent Backup**: (*Applies only for VMware, Hyper-V, and AHV VMs*) Enable if you want the guest operating systems of all the VMs in the Protection Group to be quiesced before snapshots of these VMs are created. When this option is selected, the Cohesity cluster requests the VMware vSphere/AHV software to create a quiesced VM snapshot by invoking VMware Tools/Nutanix Guest Tools (installed on the guest operating systems of the VM). The VMware Tools/Nutanix Guest Tools requests that applications on the guest OS quiesce their state so that application-consistent snapshots can be created. Quiescing of VMs before capturing snapshots ensures the integrity of the data saved in the snapshots.

    If the Cohesity cluster fails to capture an app-consistent snapshot, you can use the **Take a Crash Consistent backup if unable to perform an App Consistent**

backup option to capture a crash-consistent snapshot. The option is available only if the **App-Consistent backups option** is enabled.

For example, the Cohesity cluster may fail to perform an app-consistent backup for the following reasons: when VMware Tools/Nutanix Guest Tools is not installed on the VM, the VM (VMware) is powered off, or if the VM cannot be quiesced. If the **Take a Crash Consistent backup if unable to perform an App Consistent backup** is enabled in that Cohesity cluster, a crash-consistent snapshot is captured.

> **Note:** App-consistent backups apply to VMs only. For physical servers, Windows is app-consistent by default and Linux is crash-consistent. For more information, see Creating Application-Consistent Snapshots.

22. **Indexing:** Indexing is enabled by default and required for file recovery. The Cohesity cluster will scan all the files in the Protection Group and create an internal index that can be used later by a recover task to locate files by name.

    For information about customizing indexing, see Customize Indexing.

23. **Cloud Migration:** Enable this option to support the cloud migration of VMs between hypervisors (such as vCenter) servers and cloud services for failover and failback. Cohesity agents must be installed on the Windows VMs prior to backing up the snapshots on the on-premises Cohesity cluster. For more information, see Disaster Recovery of VMs Using AWS Cloud Edition.

    After enabling cloud migration, you can download the Cohesity Agent directly from the Cohesity Dashboard.

24. **CDP Synchronous Replication**: Displayed only if the selected policy has **Continuous Data Protection** and **Replication** enabled.

    Before you enable this field, you must enable **Encryption** in the remote Cohesity cluster to which the snapshots will be replicated. For details on how to enable **Continuous Data Protection** and **Encryption**, see the Create a Protection Policy section in Cohesity CDP for VMware.

    Toggle on to enable CDP synchronous replication and achieve near-zero RPO (Recovery Point Objective) on the DR target site (remote cluster). Once enabled, real-time I/Os of the VM are streamed to the remote Cohesity cluster and are available for immediate recovery. Enabling Synchronous Replication minimizes the risk of data loss to near-zero for your mission-critical applications during an outage.

    Synchronous replication is expensive in terms of storage because the protected data is replicated almost immediately to the remote cluster.

25. **Cancel Runs at Quiet Time Start**: Available only if the selected policy has at least one quiet time period. Toggle it on to specify that all currently executing protection runs should abort if a quiet time period specified for the Protection Group starts. By

default this toggle is off, which means after a protection run starts, it continues to execute even when a quiet time period specified for this protection run starts. However, a new protection run will not start during a quiet time period.

26. **Alerts:** Optional. Select one or more of the following settings if you want alerts to be created for the following triggers:
    - **Success:** Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created.
    - **Failure:** Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created.
    - **SLA Violation:** Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created.

    For more information, see Alerts.
27. **Priority:** Select a priority for the Protection Group execution. Cohesity supports concurrent backups, but if the number of Protection Groups exceeds the ability to process them, those with **High** priority are given the highest priority to execute, **Medium** the second-highest priority, and **Low** the lowest priority.
28. **Email Recipients**: You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the Protection Group.

    > **Note:**
    > The connection to the SMTP Server must be enabled to send email notification. You can enable the SMTP Server connection in the configuration settings page (Cohesity UI > **Settings** > **Summary** > **Configure** > **Enable SMTP Server**).

29. **SLA:** The service-level agreement (SLA) defines the expected time to complete either a full backup or incremental backup. The backup completion time depends on the Windows volume size on AD, objects changed between incremental backups, network speed, and other Protection Groups running on the Cohesity cluster.
    - **Incremental:** Enter the number of minutes you expect an incremental protection run to complete. An incremental backup captures only the differences (changed blocks) since the last protection run.
    - **Full:** Enter the number of minutes you expect a full backup protection run to complete. A full backup captures the entire object (all blocks).
30. **Pause Future Runs**: Enable this option to pause future protection runs for the Protection Group.
31. **Description:** Optional. Click the plus sign and enter a description for the Protection Group.

32. Click **Protect**.

    The Protection page is displayed and includes the new Protection Group.

> **Note:**
> - If a server is being backed up and files will also be recovered to that same server, the file recovery task starts after the backup is completed. The converse is also true; if files are being recovered to a server and that same server will be backed up, the backup starts after the file recovery is completed.
> - For a File-Based backup, the "Protected" and "Protected Size" fields on the source page for physical sources are updated after the source refresh.

Protection for NVRAM files

The NVRAM (non-volatile random-access memory) file of a VMware VM stores the boot drive setting and, in the case of multiple disks, the boot order. As VMware recommends, Cohesity automatically backs up the NVRAM file when backing up its VM.

> **Note:** It is important to back up the NVRAM file if you created the VM with the Virtual Trusted Platform Module (vTPM).

Supported Workloads

Cohesity supports the backup and recovery of NVRAM files when backing up VMware VMs.

NVRAM backup and recovery is available for VMC, VCD, Storage Array Snapshot Arrays, Snapshot Integration, Archival, Replication, and Cloud Spins.

Troubleshooting with NVRAM Files

Errors

You might run into the following error scenarios when protecting VMware VMs:

- The backup of the VM(s) is successful, but the status of the protection run is set to “warning” and the VM fails to start.
- The VM(s) recovery is successful, but the VM fails to start.
- If the NVRAM file is missing for a recovered VM (which can happen if the backup was taken before upgrading the Cohesity cluster to 7.1), VMware will create a new NVRAM file with default settings. While this new file would suffice to start any VM, the VM

might not start if the BIOS or UEFI settings were customized before recovery. For example, if you've modified the OS boot path, this setting will not be present in the newly created NVRAM file causing the VM to not start.

Solution

Follow these steps to start the VM by replacing its NVRAM file with the downloaded NVRAM file:

1. Navigate to **Data Protection** > **Recoveries**.
2. Select **Recover** and then choose **Virtual Machines** from the menu.
3. Select the VM whose NVRAM file you want to download.
4. Perform one of the following:
    1. If you've protected the NVRAM file, click the Actions Menu (⋮) of that VM and select **Download NVRAM File**. The NVRAM file is downloaded to your local system.
    2. If you have not protected the NVRAM file, download the NVRAM file from the original VM in the vCenter.
5. Ensure the name of the downloaded NVRAM file is the same as the NVRAM file in the recovered VM.
6. Replace the NVRAM file in the recovered VM with the NVRAM file downloaded in step 4.
7. Restart the VM.

Considerations

- If you are protecting a VM equipped with vTPM, enable the *Cryptographer.ManageKeyServers* privilege in the vCenter for the user account registered with Cohesity.
- If you are recovering a VM equipped with vTPM using a different KMS or replacing the current KMS with a new one, the vTPM VMs may not start after the recovery process, even if the new KMS has the same name.
- The supported maximum size of the NVRAM file is 10 MB. Contact your Cohesity account team if your NVRAM files are larger than 10 MB.
- Restoring the NVRAM file from the encrypted VMs is not supported, except for vTPM encryption.

Protection for vSphere DataSets files

The VM configuration files and vSphere DataSets files are stored together, and a reference to the DataSet (.dsd) is written into the virtual machine configuration file (.vmx). The datasets of the VM are stored within the DataSets file. The DataSets files are denoted with a

.dsd extension and are stored alongside the VM configuration files. The maximum size of the DataSets file is 300 MB.

Cohesity clusters now automatically back up the VM's DataSets file while protecting a VM and also allow you to recover the DataSets file.

DataSets file functionality is available in vSphere 8.0 and requires the VM to be running virtual hardware version 20.

Supported Workloads

Cohesity supports the backup and recovery of DataSets files when backing up VMware VMs.

vSphere DataSets file backup and recovery is available for VADP, Storage Array Snapshot Arrays, and HCI integration.

Troubleshooting with DataSets files

Errors

You might run into the following error scenarios when protecting VMware VMs:

- The backup task will raise a warning if the DataSets files are not backed up sccessfully.
- The restore task will raise a warning if the DataSets files are not restored successfully.

Considerations

- The maximum size of a DataSets file can be up to 300 MB. In most cases, the DataSets file size will be a few MBs. Contact your Cohesity account team if the files exceed 300 MB.
- Restoring the DataSets file from the encrypted VMs is not supported, except for vTPM encryption.

AHV Virtual Trusted Platform Module (vTPM)

You can now back up Virtual Trusted Platform Module (vTPM) metadata for AHV VMs. During backup, Cohesity records whether vTPM was enabled on the VM. vTPM configuration is backed up and restored only if it is enabled on the source VM at the time the backup is taken. This ensures that the original vTPM configuration is preserved.

vTPM metadata is backed up and restored to ensure the security configuration of VMs. vTPM metadata does not include any cryptographic keys or other data stored within the vTPM.

> **Note:** Ensure to manually back up the important cryptographic data stored in the vTPM. the cryptographic data stored in the vTPM module is important, it must be manually backed up by the user.

Manage the VMware VM Backup Configuration

In Cohesity Data Cloud, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

> **Note:** You cannot update the registered VMware VMs and the assigned Storage Domain in the Protection Group settings.

Add VMware VMs to the Protection Group

You can add new VMware VMs to the existing Protection Group for backup. The newly added VMware VMs are backed up from the next protection run and it will be a full backup.

Perform the following steps to add VMware VMs to the Protection Group:

1. Select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you created for VMware VM.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** field, click the edit icon.
5. Select the VMware VM you want to add to the Protection Group.
6. Click **Save Selection** > **Save**.

The newly added VMware VMs are backed in the next scheduled protection run.

Remove VMware VMs from the Protection Group

From the Edit Protection page, you can remove VMware VMs from the Protection Group that you do not want to back up in the next protection run.

Perform the following steps to remove VMware VMs from the Protection Group:

1. Select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you created for VMware VM.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** field, click the edit icon.
5. Unselect the VMware VM you want to remove from the Protection Group.
6. Click **Save Selection** > **Save**.

Enable or Disable Auto Protect

The Auto Protect option enables you to automatically protect the new VMware VMs that are added to the selected parent VMware host. However, you cannot enable auto-protect at the server-level containing both Read-Write volumes and Data-Protect volumes.

Perform the following steps to enable auto protect:

1. Select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you created for VMware VM.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** field, click the edit icon.
5. Click the shield icon to enable Auto Protect.
6. Click **Save Selection** > **Save**.

When this option is enabled on the parent VMware VM, all the VMware VMs that are added to the parent VMware VM in the future are automatically added to the Protection Group and are protected from the next protection run.

For example, you create a Protection Group that backs up a VMware VM. The Protection Group runs for two weeks and then a new volume is added to the VMware VM. The next time the Protection Group runs, if the object hierarchy has been refreshed on the Cohesity cluster, the new volume is also backed up even though the new volume has not been explicitly selected to be included in the Protection Group. The object hierarchy is automatically refreshed every four hours. To manually refresh the object hierarchy, select **Data Protection > Sources**, find the source in the list, and click . To exclude an object from Auto Protect, click .

- Indicates an Auto Protected object.
- Excluded objects that are not protected. The icon indicates that an ancestor of the object is Auto Protected but this object is explicitly excluded.

Edit Existing Protection Policy

You can edit the existing Protection Policy that is attached to the Protection Group based on your requirement.

Perform the following steps to edit the policy settings:

1. Select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you created for VMware VM.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Policy** field, click the **Edit Policy** icon .

   The **Edit Policy** page appears
5. Edit the settings and then click **Save**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

You can attach a new Protection Policy to the Protection Group. The new policy is applied to the Protection Group in the next scheduled protection run.

Perform the following steps to attach a new protection policy to the Protection Group:

1. Select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you created for VMware VM.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, from the **Policy** drop-down, select a new Protection Policy for the Protection Group.
5. Click **Save**.

Start an On-demand Protection Run

You can instantly start a protection run of the Protection Group that you have created to back up VMware VMs. It provides you options to back up all the objects, only selected objects, or failed objects in the Protection Group. If the policy associated with the Protection Group:

- Supports multiple backup types, you can select an incremental or full backup.
- Is configured with replication targets, you can select those targets.
- Is configured with archival targets, you can select those targets.

Perform the following steps to start an on-demand protection run:

1. Select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you created for VMware VM.

3. Click the actions menu (⋮) next to the Protection Group and select **Run Now**.
4. In the pop-up window, perform the following:
    1. From the **Backup** drop-down list, select any one of the following:
        - **All objects in the Protection Group**.
        - **All objects that failed last run**.
        - **All objects that succeeded last run**.
        - **Selected objects in the protection run**.
    2. In the **Backup Type** drop-down list, select the backup type.
    3. Optional. In the **Replicate** section, select the replication target and the retention duration or click **Add** to add the replication target and the retention duration. Also, select **Replicate only fully successful runs** to replicate the data only from the completed protection runs.
    4. Optional. In the **Archive** section, click **Add** to add the external target to which you want to archive the data and the retention duration. Also, select **Archive only fully successful runs** checkbox to archive the data only from the completed protection runs.
5. Click **Backup Now**.

Pause Future Protection Runs

You can pause future protection runs for the Protection Group. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

Perform the following steps to pause the future protection runs:

1. Select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you created for VMware VM.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired then a full backup is triggered

Perform the following steps to resume paused protection runs:

1. Select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you paused.

3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity Data Cloud provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Delete only the Protection Group. Any local snapshots and or archived snapshots stored on the external targets that were captured by this Protection Group are not deleted.
- **Delete Protection Group and Snapshots**: Delete the Protection Group and all snapshots, any local snapshots captured by this Protection Group and stored on this cluster are deleted. In addition, any archived snapshots stored on external targets that were captured by this Protection Group are also deleted.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

Perform the following steps to delete the Protection Group:

1. Select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you created for VMware VM.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Delete Protection Group Only
    - Delete Protection Group and Snapshots

If the current Protection Group is replicating snapshots to a remote cluster or archiving snapshots to an external target, you should cancel these replication or archive tasks before deleting the Protection Group. For instructions, see Cancel Replication and Archive Copy Tasks of a Protection Run.

If the Protection Group is replicating to a remote cluster, the failover job created on the remote cluster is not deleted. In addition, the snapshots that were replicated (copied) to the

remote cluster by this job are not deleted. You can log in to the remote cluster to delete the snapshots and the failover job.

Creating Application-Consistent Snapshots

Cohesity supports application-consistent backup for VMware, Nutanix Acropolis, and Hyper-V. By enabling application-consistent backups for a Protection Group, the guest-operating systems of all the VMs in the Protection Group will be quiesced before snapshots of these VMs are created.

Application-Consistent Snapshots for VMware VMs

Toggle **App-Consistent backups** for a Protection Group if you want the guest operating systems of all the VMs in the job to be quiesced before snapshots of these VMs are created. If this option is selected, the Cohesity cluster makes a request to the VMware vSphere software to create a quiesced VM snapshot by invoking VMware Tools (installed on the guest operating systems of the VM). The VMware Tools requests that applications on the guest OS quiesce their state so application-consistent snapshots can be created. This quiescing of VMs prior to capturing snapshots ensures the integrity of the data saved in the snapshots. App-consistent backups apply to VMs only. For physical servers, Windows is app-consistent by default and Linux is crash-consistent.

Snapshots created without quiescing are known as Crash-Consistent Snapshots.

When the **App-Consistent backups** toggle is on, all the guest Operating Systems of the protected Objects (VMs) in this Protection Group must have VMware Tools installed. The Cohesity Dashboard prevents you from saving the Protection Group if any selected VMs do not have VMware Tools installed.

If the **App-Consistent backups** toggle is on, the **Take a Crash Consistent backup if unable to perform an App Consistent backup** toggle is available. Toggle it on if you want the Cohesity cluster to capture a crash-consistent snapshot if the Cohesity cluster fails to capture an app-consistent snapshot. For example, the Cluster may be unable to perform an app-consistent backup when VMware Tools is not installed on the VM, the VM is powered off, or the VM cannot be quiesced. If the **Take a Crash Consistent backup if unable to perform an App Consistent backup** toggle is off and the Cohesity cluster is unable to perform an app-consistent backup of a VM, a snapshot is not captured.

If the **App-Consistent backups** option is selected for a Protection Group and the Job is protecting Linux VMs, the Cohesity cluster invokes the VMware vSphere software to create the Snapshot. For a Linux VM, the VMware vSphere software *always* reports that the VM was not quiesced because Linux does not provide a system quiescing mechanism like Windows VSS. Because of this VMware behavior, the Cohesity cluster does not check and report on the quiescing return status for Linux VMs. However, other status are checked and reported, for example if Snapshots of VMs are not created, the protection run fails.

If the **App-Consistent backups** option is selected for the Job, when the Cohesity cluster calls VMware vSphere software to quiesce Linux or Windows VMs, if quiesce custom pre-freeze and post-thaw scripts can be found in the correct locations, these scripts are run as part of the quiescing and create Snapshot process. For more information, see the appropriate documentation for the Operating System type:

- Running custom quiescing scripts inside Windows virtual machine with ESX 3.5 Update 2 and later (1006671) Knowledge Base Article
- Configuring Custom Quiesce Scripts for Linux Virtual Machines

Application-Consistent Snapshots for AHV VMs

Toggle App-Consistent backups for a Protection Group if you want the guest operating systems of all the AHV VMs in the Protection Group to be quiesced before snapshots of these VMs are created. If this option is selected, the Cohesity cluster makes a request to the AHV software to create a quiesced VM snapshot by invoking the Nutanix Guest Tools (installed on the guest operating systems of the VM). When you invoke the Nutanix Guest Tools, the VSS and application-consistent snapshot applications are automatically enabled. With these applications enabled, the application-consistent snapshots for all the VMs that support VSS are taken using the Nutanix native in-guest VmQuiesced Snapshot Service (VSS) agent.

Snapshots created without quiescing are known as Crash-Consistent Snapshots.

When the **App-Consistent backups** toggle is on, all the guest Operating Systems of the protected Objects (VMs) in this Protection Group must have Nutanix Guest Tools installed. The Cohesity Dashboard prevents you from saving the Protection Group if any selected VMs do not have Nutanix Guest Tools installed.

If the App-Consistent backups toggle is on, the **Take a Crash Consistent backup if unable to perform an App Consistent backup** toggle is available. Toggle it on if you want the Cohesity cluster to capture a crash-consistent snapshot if the Cohesity cluster fails to capture an app-consistent snapshot. For example, the Cluster may be unable to perform an app-consistent backup when Nutanix Guest Tools is not installed or running on the VM, or the VM cannot be quiesced. If the **Take a Crash Consistent backup if unable to perform an App Consistent backup** toggle is off and the Cohesity cluster is unable to perform an app-consistent backup of a VM, a snapshot is not captured.

If the **App-Consistent backups** option is selected for the Protection Group, when the Cohesity cluster calls AHV software to quiesce Linux or Windows VMs, if quiesce custom pre-freeze and post-thaw scripts can be found in the correct locations, these scripts are run as part of the quiescing and create Snapshot process. For more information, see the Nutanix Documentation.

Application-Consistent Snapshots for Hyper-V VMs

Enable **App-Consistent backups** for a Protection Group if you want the guest operating systems of all the Hyper-V VMs in the Protection Group to be quiesced before snapshots of

these VMs are created. If this option is selected, the Cohesity cluster makes a request to the Hyper-V software to create Application Consistent checkpoints.

When the **App-Consistent backups** toggle is ON, all the guest Operating Systems of the protected Objects (VMs) in this Protection Group must have:

- Hyper-V Integration Services installed. For more information, see Hyper-V Integration Services.
- Production Checkpoints enabled. For more information, see Enable Production Checkpoints.

If the Cohesity cluster fails to capture an app-consistent snapshot, you can use the **Take a Crash Consistent backup if unable to perform an App Consistent backup toggle to capture a crash-consistent snapshot** option. This option is available only if the **App-Consistent backups** toggle is ON. For example, the Cohesity cluster may be unable to perform an app-consistent backup for the following reasons: when Hyper-V Integration Services is not installed or running on the VM, or the VM cannot be quiesced. If the **Take a Crash Consistent backup if unable to perform an App Consistent backup** toggle is ON for that Cohesity cluster, a crash-consistent snapshot is captured.

Cancel Protection Run at Object Level

You can now cancel the protection run of individual objects within a Protection Group created for **VMware vCenter**.

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

Protection Group States at Granular Level

A Protection Group run can be in the following states:

- Protection Group is in progress; where the backup of the objects is in progress.
- Protection Group is progress but the backup of a few objects is in failed status.
- Protection Group is completed; where the backup of a few objects is failed and a few are success and is waiting in the retry interval time.

> **Note:** Retry is the time you set for the Cohesity cluster to attempt backup before the Protection Group fails. Retry interval time is defined in the Protection Policy along with retry attempts.

- Retry attempts are over and the Protection Group is completed with Success or Failed status.

The protection run cancellation at the object level is applicable for the first three states mentioned above. You cannot cancel the protection run at the object level if the Protection Group run is complete and the retry attempts are over.

Cancel Protection Run at Object Level

To cancel the protection run of individual objects within a Protection Group, perform the following steps:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group.

   The Protection page displays the protection runs of the Protection Group.
3. Select the in-progress protection run from which you want to cancel the protection run of the individual objects.

   The Run details page displays the list of objects that are protected in the protection run.
4. Perform one of the following actions based on your requirement:

   - To cancel the protection run of individual objects, click the actions menu (⋮) next to the object and then click **Cancel VM**.
   - To cancel the protection run of multiple objects, select the checkboxes next to the objects and click on the cross icon that appears on the column heading of the Run details page.

Considerations

Consider the following points when canceling the protection run of the objects when the protection run is in progress:

- If you are canceling the protection run of the objects that are being backed up, then the protection run of these objects will get canceled immediately.
- If you are canceling the protection run of the objects whose backups are failed, then the protection run of these objects will get canceled in the next retry attempt. The next retry attempt will happen once the current protection run is complete and retry interval is over.
- If you are canceling the protection run of the failed objects during the retry interval time (while the protection run is waiting for the next retry), then the protection run of these objects will get canceled immediately.

  For example, consider the following scenario:

A Protection Group is created for backing up 10 objects. The retry time set is 5 minutes. During the protection run,

- 5 objects (V1, V2, V3, V4, V5) are already backed up and status is success.
- 3 objects (V6, V7, V8) are being backed up and the status is in progress.
- 2 objects (V9, V10) are failed in backing up and status is failed.

Now, if you cancel the protection run of V6, V7, or V8 objects then the protection run of these objects will get canceled immediately.

If you cancel the protection run of V9 or V10 objects then the protection run of these objects will get canceled in the next retry attempt. The next retry attempt will happen 5 minutes after the current protection run is complete.

If the protection run of V6, V7, and V8 is complete and you cancel the protection run of V9 and V10 during the retry interval time of 5 minutes, then the protection run of these objects would get canceled immediately and the next retry attempt will happen immediately for V9 and V10.

Migrate VMware VMs Using Cohesity

All the VMs that need to be migrated must be protected using one or more Protection Groups in Cohesity. When the initial backup run is started for the Protection Group, Cohesity first performs a full backup of the source VMs. Once the initial backup is completed, you can initiate the migration for the source VMware VMs. As a part of the migration, Cohesity creates a standby VM on the target vCenter for each source VM being migrated and restores the backed-up data to these standby VMs. Now, whenever there is an incremental backup, Cohesity migrates only the incremental backed-up data to standby VMs. When you decide to complete the migration, Cohesity will migrate the latest incremental backed-up data to standby VMs and then will stop syncing the data. You can power on the standby VMs once the migration is complete. This reduces the downtime of the VM migration as the cutover time (time between powering off the source VMs and powering on the standby VMs) is minimal.

Perform Migration for VMware VMs

To perform migration for VMware VMs:

1. Register both the source VMware vCenter (where the source VMs reside) and the target VMware vCenter (where the VMs need to be migrated) with the Cohesity cluster. For more information, see Register or Edit a Hypervisor Source.
2. Create a Protection Group for backing up the source VMware VMs. For more information, see Add or Edit a Protection Group for Virtual Servers.
3. Initiate VMware VM Migration.
4. Finalize VM Migration.

Initiate VMware VM Migration

When you initiate the VMware VM migration, Cohesity will first create standby VMs and then migrate or restore the backed-up data to the standby VMs. After that, whenever there is an incremental backup, Cohesity will sync this incremental backed-up data with the standby VM.

To initiate VM migration:

1. In the Cohesity Dashboard, select **Data Protection** > **Recovery** > **Virtual Machines** > **Migrate Virtual Machine (VMware only)**.
2. Search for Protected Object (VM) or Protection Group by entering characters of the VM name, Protection Group name, or by specifying the wildcard character *.

   A list of VMs is displayed.

   You can optionally filter the search results by Source, Protection Group, Storage Domain, or Date.
3. From the list of search results, select one or more VMs that need to be migrated. You can also select Protection Groups.

   > **Note:**
   > - If you have selected a Protection Group, then all the VMs backed up in the latest protection run of this Protection Group will be selected for migration and the option to select those VMs individually will be greyed out in the search result list.
   > - You can only select Protection Groups and VMs with snapshots stored in the same Storage Domain and belonging to the same source. Once you select a VM or Protection Group, the **Storage Domain** and **Source** filters will automatically get locked.
4. Click **Next: Migration Options**.
5. Provide the following **Migration Target** options:
   1. **Register Source**: Select a registered source to migrate the VMs to.
   2. **Resource Pool**: Select a Resource Pool to store the migrated VMs.

      > **Note:** When protecting a VMware source, if you select a Resource Pool that is not part of the ESX cluster, all datastores in the vCenter are displayed. Ensure you select a datastore that is part of the selected Resource Pool.

3. **Data Stores**: Select the target datastore. The VM files (such as VMDK files) extracted from the VMs are stored in the selected datastore.
4. **VM Folder**: Optionally select a logical VM folder in the data center in which to create the VMs.

6. Provide details for the following **Options**:
    1. **Network**: From the drop-down menu, select a network to attach the virtual Network Interface Card (vNIC) to a new network. The new network might be a standard port group or a distributed port group. For VMware VMs, the selected Network port group will be attached to all the network interfaces of the VMs being migrated.
    2. **Rename**: Add prefix and/or suffix strings to the names of the VMs that will be migrated by this task. For example, you could specify Prefix Test_ and Suffix _QA to the VM name WinOS and when the VM is migrated, the new VM that is created is called Test_WinOS_QA.
    3. **Cluster Interface**: By default, the **Auto Select** option is enabled and the migration task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the **Interface Group** drop-down.
    4. **Task Name**: Change the default name of the migration task.
7. Click **Start Migrating**.

The migration task is initiated. To complete the migration, see Finalize VM Migration.

Finalize VM Migration

You can finish the migration at any point in time by selecting the **Finalize Migration** option on the recoveries page. When you finalize the migration, Cohesity will migrate the latest incremental backed-up data to the standby VMs and then will stop syncing the data further. You can optionally choose to power on the standby VMs once the migration is complete.

To complete the migration, perform the following steps:

1. On the recoveries page, select the migration task you initiated.

    The Migrate VM page appears. The page displays the last synced snapshot details and the sync status.
2. Click **Finalize Migration** on the top right of the page to complete the migration task.
3. In the Finalize Migration screen, you can choose to **power on VMs after migration**.
4. Click **Finalize Migration**.

Sync Objects

When you initiate VM migration, Cohesity will automatically sync the data from the source VMs to the standby VMs. You can also manually sync the data from the source VMs to the standby VMs if required.

To manually sync the data:

1. On the recoveries page, select the migration task you initiated.
    - To manually sync all the objects (VMs) selected for migration:
        a. Click the actions menu on the top-right of the page.
        b. Select **Sync All Objects**.
    - To manually sync individual objects selected for migration:
        a. Click the sync icon available for the individual VM.

Cancel VM Migration

You can cancel the migration task that you initiated earlier.

To cancel the migration task, on the recoveries page, select the migration task you initiated earlier.

- To cancel the migration of all the objects selected for migration:
    a. Click the actions menu on the top-right of the page.
    b. Select **Cancel Migration**.
    c. Confirm your action by clicking **Cancel Migration**.
- To cancel the migration of individual objects selected for migration:
    a. Click the delete icon available for the individual VM.
    b. Confirm your action by clicking **Cancel Migration**.

> **Note:** Canceling the VM migration task will not delete the standby VMs that are already created.

Consideration

- The migration target has to be a VMware vCenter.
- During Replication, an inactive copy of the Protection Group is created on the remote Cohesity cluster. Migration of VMware VMs protected by such inactive Protection Groups is not supported. For details on Replication, see About Replication.

Protect Migrated VMs or vCD

The VMs of a VMware vCenter Server that are being protected by a Cohesity Protection Group might migrate to another VMware vCenter or vCD for any of the following reasons:

- Upgrade or maintenance activity.
- Inplace vCenter upgrade.
- Inventory deletion and re-import into same or another vCenter
- Failover and Failback and so on.
- Migration of workloads from vCenter to VCD.

If the VMware vCenter to which the VMs are migrated is already registered with the Cohesity cluster, then by default, the Cohesity cluster discovers these VMs as new VMs on the VMware vCenter Server. However, if you enable the **Detect VM migration across vCenter to Preserve backup chain** option while registering or in the registered VMware vCenter source (from which the VM is migrated), then:

- Cohesity discovers these VMs as migrated VMs on the VMware vCenter to which the VMs are migrated.
- When a Protection Group is run on the VMware vCenter to which the VMs are migrated, Cohesity eliminates the need of taking a full backup of the migrated VMs if they were already protected before the migration, and continues to take an incremental backup.
- On the Cohesity cluster, the migrated VMs are displayed with a tag with the name, **vCenter Migrated**.

For information on enabling **Detect VM migration across vCenter to Preserve backup chain** option, see Register or Edit a Hypervisor Source.

If the VMs of a VMware vCenter protected by the Cohesity cluster are migrated to a vCD, which is already registered with the Cohesity cluster, then Cohesity DataPlatform preserves the backup history of these migrated VMs. This feature eliminates the need to take a full backup of the migrated VMs when a Protection Group is run on the vCD to which the VMs are migrated. For information on enabling **Detect VM migration across vCenter to Preserve backup chain** option, see Detect VM migration across vCenter to Preserve backup chain.

View Migrated VMs Original Source

From VMware vCenter to another VMware vCenter

To view the migrated VMs original source:

1. In the Cohesity cluster, select **Data Protection** > **Sources**.
2. Select the VMware vCenter to which the VMs are migrated and then select the **All Objects** tab.

   The objects of the VMware vCenter appear in a Hierarchical view. The VMs that are migrated from another VMware vCenter are displayed with the tag name, **vCenter Migrated** displayed.

3. Click the eye icon displayed next to the VM. The **Virtual Machine Details** pop-up window displays the original VMware vCenter source name and the migration timestamp.

From VMware vCenter to vCD

To view the migrated VMs original source:

1. In the Cohesity cluster, select **Data Protection** > **Sources**.
2. Select the vCD to which the VMs are migrated and then select the **All Objects** tab.

   The objects of the vCD appear in a Hierarchical view. The VMs that are migrated from another VMware vCenter are displayed with the tag name **vCenter Migrated** displayed.
3. Click the eye icon displayed next to the VM. The **Virtual Machine Details** pop-up window displays the original VMware vCenter source name and the migration timestamp.

Consideration

Considerations when protecting migrated VMs

From VMware vCenter to another VMware vCenter:

- The backups of the first Protection Group created to protect the migrated VMs are always incremental. Backups of subsequent Protection Groups created to protect the migrated VMs are incremental by default. Contact your Cohesity account team if you want full backups from the subsequent Protection Groups.

  For example, Protection Group J1 is the first Protection Group created to protect the migrated VMs A and B. Following this, Protection Group J2 is also created to protect VMs A and B. J1 backups are always incremental. J2 backups are incremental by default and can be converted to full backups by contacting your Cohesity account team.
- If you want to recover the snapshot of the VM that was taken before migration, then while recovering, you must select the VM that is protected by the Protection Group created for the VMware vCenter source from which the VMs were migrated.
- If you want to recover the snapshot of the VM that was taken after migration, then while recovering, you must select the VM that is protected by the Protection Group created for the VMware vCenter source to which the VMs are migrated.
- You can enable the **Detect VM migration across vCenter to Preserve backup chain** option for an existing registered source by editing the source. If you are enabling this option to an existing VMware vCenter source, then you must refresh (**Data Protection** > **Sources** > <VMware source> **Action menu**>**Refresh**) the source for this feature to function. Ensure that the source VMware vCenter is

reachable till you refresh the target VMware vCenter.

- If your Cohesity cluster does not identify all the migrated VMs or incorrectly identifies VMs as migrated, contact your Cohesity account team.
- To perform incremental backup for any other scenario, contact your Cohesity account team.

From VMware vCenter to another vCD:

- The migration target has to be a vCD.
- During Replication, an inactive copy of the Protection Group is created on the remote Cohesity cluster. Migration of VMware VMs protected by such inactive Protection Groups is not supported. For details on Replication, see About Replication.
- Considerations when protecting migrated VMs:
  - The backups of the first Protection Group created to protect the migrated VMs are always incremental. Backups of subsequent Protection Groups created to protect the migrated VMs are incremental by default. Contact your Cohesity account team if you want full backups from the subsequent Protection Groups.

    For example, Protection Group J1 is the first Protection Group created to protect the migrated VMs A and B. Following this, Protection Group J2 is also created to protect VMs A and B. J1 backups are always incremental. J2 backups are incremental by default and can be converted to full backups by contacting your Cohesity account team.
  - If you want to recover the snapshot of the VM that was taken before migration, then while recovering, you must select the VM that is protected by the Protection Group created for the VMware vCenter source from which the VMs were migrated.
  - If you want to recover the snapshot of the VM that was taken after migration, then while recovering, you must select the VM that is protected by the Protection Group created for the vCD source to which the VMs are migrated.
  - You can enable the **Detect VM migration across vCenter to Preserve backup chain** option for an existing registered source by editing source. If you are enabling this option to an existing VCD source, then you must refresh (**Data Protection** > **Sources** > <**VMware source**> **Action menu**>**Refresh**) the source for this feature to function. Ensure that the source VMware vCenter is reachable till you refresh the target VCD.
  - If your Cohesity cluster does not identify all the migrated VMs or incorrectly identifies VMs as migrated, contact your Cohesity account team.
  - To perform incremental backup for any other scenario, contact your Cohesity account team.

Cohesity CDP for VMware

To protect your VMware VMs, you can optionally choose to leverage the Continuous Data Protection (CDP) option available on the Cohesity Data Cloud. Cohesity's CDP provides near-zero RPOs for your applications.

Every change to the VM (IOs) is captured and replicated to the Cohesity cluster. This provides a continuous window of protection allowing you to restore a VM to a selected point-in-time within the configured CDP window.

Cohesity uses the VMware API for I/O Filtering (VAIO) based solution for providing Continuous Data Protection. In this process, Cohesity deploys an I/O Filter in a vSphere environment. The scope of the filter installation is at a cluster level (also known as ClusterComputeResouce) within the vCenter. Once the filter installation is complete, an I/O Filter is attached to the VM marked for protection. This filter intercepts all the real-time IOs of the VM and sends the IOs to the Filter Daemon running on the ESXi host. The Filter Daemon continuously replicates the IOs to the Cohesity cluster (IO Journal) based on the VM Storage Policy attached to the VM.

In releases earlier than 7.0, the Cohesity cluster automatically deploys the VAIO filter on the ESXi host clusters. From release 7.0 onwards, Cohesity provides an additional option to download the VAIO from the Cohesity cluster and upload it to an HTTP server to deploy it manually on the ESXi host clusters using the vSphere IO filter installation APIs. For details, see Deploy the VAIO Filter Manually.

You can either manually create or update an existing VM Storage Policy and then attach it to the VMs or Cohesity will automatically create and attach the VM Storage Policy to the VMs you want to perform continuous data protection.

If you are manually attaching the VM Storage Policy, then ensure to:

- Attach a Storage Policy to the VMs before a CDP-enabled Protection Group is created for these VMs.
- While creating the VM Storage Policy, select the **Enable host based rules** checkbox in the **Policy structure** tab and create rules for Replication data service under **Host based services** with the following settings:
  - **Provider**: cohfilter
  - **vCenterUUID**: <vCenterUUID>
  - **CohesityID**: <ClusterId:IncarnationId>
  - **CohesityClusterEndpoint**: <endpoint>:20004
  - **HeartbeatInterval**: 30

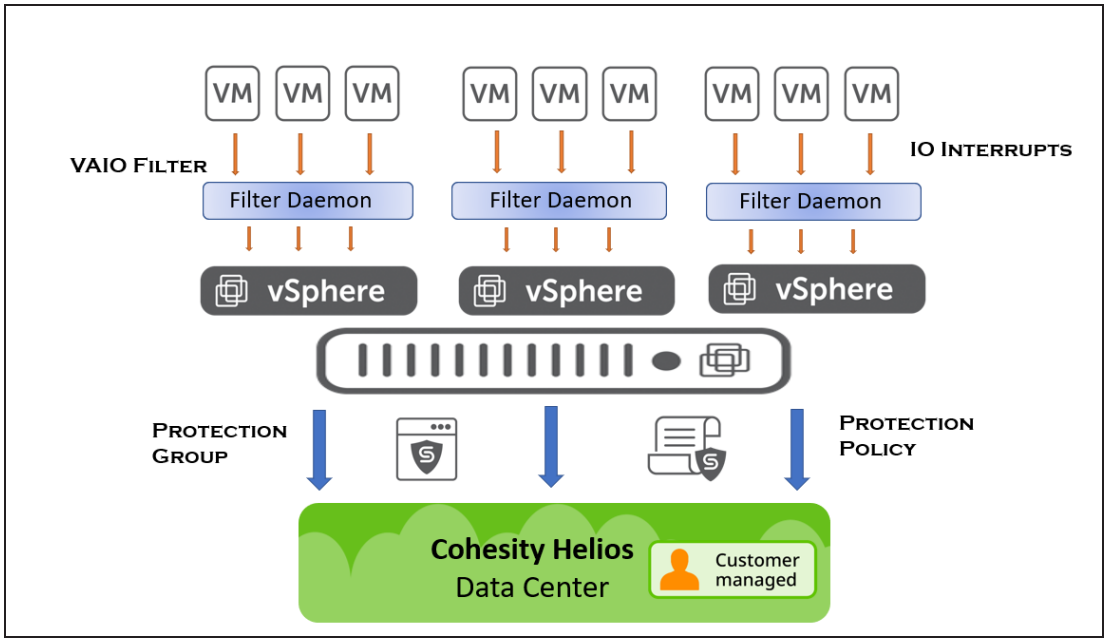
> **Note:** You can view the default Storage Policy created by Cohesity on the VMware vCenter as a reference for the above settings.

During the backup process, all the IOs of a workload will be saved in a write-ahead-log (WAL), and is used to recover the applications at any point-in-time as long as all the previous IOs are available. If any IOs are missed during the CDP, then a VADP backup is triggered, and the CDP backup process is re-initialized. For better RTO, the hydrated snapshots of the VMs are also captured to the Cohesity cluster every 15 minutes.

Core Components

This section lists the core components of the Cohesity CDP.

- **I/O Filter**: An I/O Filter is run per VM on the ESXi host as part of the Virtual Machine Executable (VMX) process. It intercepts the IOs of a VM synchronously in real-time and replicates those IOs to the Cohesity cluster.
- **I/O Filter Daemon**: An I/O Filter Daemon, also implemented using VAIO, provides more resources to perform replication, caching, batching, and other operations. It runs in the ESXi host environment and communicates with individual VM's I/O Filters over a Unix socket. An I/O Filter Daemon is ideal for replicating collected IOs from VMs over the network asynchronously.
- **Cohesity Data Cloud**: The CDP service starts on all the Cohesity cluster nodes and receives the Filter Daemon requests.



CDP Requirements for VMware vCenter

If you are enabling CDP for near-zero RPO, ensure that the VMware vCenter meets these additional requirements:

Requirements	Details
ESXi version	VMware ESXi 8.0.3, 8.0.1, 7.0 U3, 7.0 U2, 7.0 U1, 7.0, 6.7 U3, 6.7 U2, 6.7 U1, 6.7, 6.5 U3, 6.5 U2
Memory required per VM disk	1 GB (from the heap)
Memory required by Daemon	4 GB
ESXi Hosts	All the ESXi hosts within the Cluster Compute Resource should be on the same VLAN.
Upgrade filter	For automatic upgrades or uninstallation of filters, a VMware cluster should have Distributed Resource Scheduler (DRS) enabled with shared storage.

CDP Related Permissions

For CDP, in addition to the required VMware vCenter Related Permissions, you must also require the following VMware privileges:

Privilege Level		Permissions Required	Description
Host	Configuration	Maintenance	To move hosts automatically to maintenance mode to uninstall CDP filter.
		Query patch	To deploy CDP Filter to the host.
Profile-driven Storage		Profile-driven storage update	To create and update Storage profiles to enable CDP for virtual machines.
		Profile-driven storage view	To view defined storage capabilities and storage profiles in order to manage CDP.

Enable Cohesity CDP on VMs

To enable CDP on VMs, create a new protection policy and attach the Continuous Data Protection option to the policy. Within the CDP option specify the retain point in time configuration, and associate this policy with the VM’s Protection Group.

After associating the protection policy with the Protection Group, the protection run will first initiate a full VADP-based backup and, in the process, attach the I/O Filter to the ESXi host. An incremental protection run follows the initial full backup, and the VM's continuous

protection will begin from this point on. You can view all the continuously protected VMs from the same Dashboard page.

Steps

Perform these tasks to enable CDP for VMs:

1. Create a Protection Policy with the **Continuous Data Protection** option.
2. Associate this policy with the VMs' Protection group that you plan to protect using CDP. See Add or Edit a Protection Group for Virtual Servers.

Create a Protection Policy

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. Also, for Disaster Recovery, you can add CDP and replication for the Protection Group using the Protection Policy.

To create a Protection Policy with CDP & Replication:

1. Navigate to **Data Protection** > **Policies**.
2. Click **Create Policy** located at the top right of the page.

   The Create Protection Policy page appears.
3. In the **Policy Name** field, specify a protection policy name. The name can contain alphanumerics, underscores, hyphens, periods, and spaces. This field is required and can be changed later.
4. In the **Incremental Backup** field, specify when backups are captured, and how long they are retained.
5. Click **More Options**.
6. Click the **Continuous Data Protection** option from the floating menu. In the **Retain Point in Time for** field, enter a number and select Minute, Hour, or Day from the drop-down. This value defines the period the Cohesity cluster will retain the captured CDP logs. You can use this option to restore the VM applications to a point-in-time as opposed to periodic snapshots available with regular protection runs.

   When CDP is enabled for a protection policy, VM IOs are captured continuously and streamed in real time to the local cluster. As a result, data protected by CDP-enabled policies are available on the local cluster with near-zero RPO.
7. Click the **Replication** icon to replicate snapshots with CDP to another Cohesity cluster. The copied snapshots are stored in the storage domain of the remote cluster. (The storage domain, however, is specified in the Protection Group.) The replication schedule for copying Snapshots cannot be more often than the protection schedule for capturing Snapshots. For example if Snapshots are captured hourly, the Cohesity cluster cannot replicate them every 30 minutes but it can replicate them hourly or any value over one hour.

When **Continuous Data Protection** and **Replication** are enabled, VM IOs are captured real-time and replicated periodically (every 15 minutes by default) on the remote cluster.

a. **Replicate to**: Select either a Remote Cluster or AWS.

   From the drop-down, select either a cluster source or an AWS S3 storage source to replicate snapshots. If you select an S3 storage object, you also need to select a region.

   You can also register a new cluster to replicate to by selecting **Register Remote Cluster**.

   From Cohesity release 7.0 onwards, you can enable **CDP Synchronous Replication** for a Protection Group. Once enabled, VM IOs of every VM in that Protection Group are streamed directly to the remote cluster (continuous streaming, not periodic).

   As a result, Synch Replication makes data available for immediate (near-zero RPO) recovery. For details on enabling **CDP Synchronous Replication**, see Add or Edit a Protection Group for Virtual Servers section.

   > **Note:** Irrespective of whether you use an existing remote cluster or register a new one, you must enable the **Encryption** toggle in the remote cluster if you have enabled the **CDP Synchronous Replication** field in the Protection job to replicate the real-time IOs and logs to the remote cluster synchronously. For details on the **CDP Synchronous Replication** field, see Add or Edit a Protection Group for Virtual Servers. For detailed instructions on registering a remote cluster and enabling encryption, see Create a Connection to the Remote Cohesity Cluster.

b. **Retain for xx days**: Specify how long the snapshots are retained on the remote cluster.

To add additional replication schedules, repeat these steps. To replicate to multiple Cohesity clusters, create multiple replication schedules with different replication targets.

If you specify multiple replication schedules with the same replication target that replicate the same set of snapshots but with different retention periods, the snapshots are retained for the longest time period. For example if you define two replication schedules with the same replication target that retain the same set of snapshots but one schedule specifies a 90-day retention period and the other schedule specifies a 180 day retention period, the set of snapshots is retained for 180 days.

8. Click **Save**.

The policy is immediately available to use in Protection Groups. If you want to configure

additional policy settings, see Create or Edit a Standard Policy.

> **Note:** If replication is enabled for CDP, then the blackout window option in the policy would not be honored.

Recovery

You can perform a point-in-time recovery of VMs, files and folders, Virtual Disks, and IVM of a CDP-based Protection Group s by selecting the points in the timeline bar on the recovery page. This timeline will also show when the VADP backups were taken. So, the user can optionally recover from the VADP snapshots as well. For detailed instructions on recovering VMs, files and folders, Virtual Disks, and IVM, see Recover Virtual Machines.

Deploy the VAIO Filter Manually

From release 7.0 onwards, you can deploy the VAIO filter manually on the ESXi host cluster. To deploy the VAIO filter, use the VMware vSphere IOFilterManager APIs that can be accessed through the vCenter MOB interface.

The vibURL required to deploy the VAIO filter is generated by downloading the VAIO installer from the Cohesity cluster and directly hosting the VAIO installer on an HTTP server accessible from the vCenter server and the ESXi hosts where the VAIO filter needs to be installed.

Prerequisites

- Ensure the VMware vCenter meets the CDP requirements.
- Ensure the VMware vCenter meets the conditions and permissions required to install the I/O filers in its ESXi host clusters.
- Uninstall existing I/O Filters from the ESXi hosts and the ESXi host clusters.

> **Note:** The VAIO filter can only be installed on the ESXi host cluster and not on the ESXi host.

Download the VAIO Filter from the Cohesity cluster

To download the VAIO filter from the Cohesity cluster:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Cohesity Agent Download**.
3. In the **CDP VMware IO Filter** field of the **Download Agents** dialog, perform the following:

1. Use the drop-down that displays the default ESXi version, **6.7**, to pick the ESXi version of the host in which you want VAIO deployed. Clicking on the drop-down displays both **6.7** and **7.0**. Select **6.7** or **7.0** based on the following:
   - If all the ESXi hosts in the cluster are of versions earlier than 7.0, choose **6.7**.
   - If all the ESXi hosts in the cluster are of versions later than 7.0, choose **7.0**.

     > **Note:** If your cluster has 6.7 and 7.0 ESXi hosts, contact your Cohesity account team to enable this option.

2. Click the **Download** icon ( ).

The VAIO filter's installer (the VIB-vSphere Installation Bundle) is downloaded to your local system. Generate the vibURL required to deploy the VAIO filter in the vCenter MOB interface by directly hosting the downloaded installer on an HTTP server accessible from the vCenter server and the ESXi hosts where the VAIO filter needs to be installed. Your Cohesity cluster can also act as the HTTP web server.

Generate the URL from the Cohesity cluster

To generate the URL for the VAIO filter:

1. Construct the URL as follows:

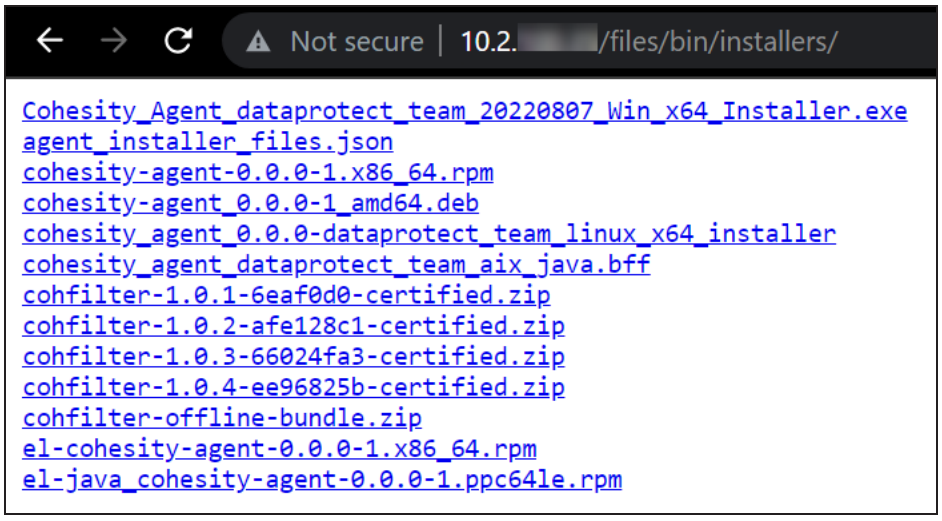
   Format

   ```
   <URL of the HTTP server or the Cohesity cluster>/files/bin/installers/
   ```

   Example

   ```
   http://10.2.111.11/files/bin/installers/
   ```

   When you enter the constructed URL in the address bar of the browser, all the I/O filters available on the Cohesity cluster are displayed.



2. From the displayed list, decide which I/O filter to download based on the ESXi version of the host in which you want VAIO deployed:
   - If all the ESXi hosts in the cluster are of versions earlier than 7.0, choose *cohfilter-1.0.4-ee96825b-certified.zip*
   - If all the ESXi hosts in the cluster are of versions 7.0 or later, choose *VMW-esx-7.0.0-coh-cohfilter-1.0.3-44d0c2a2-certified.zip*
   - The same driver version is applicable for both ESXi 7.0 and 8.0.x.
3. To copy the link to the clipboard, right-click the I/O filter and select **Copy Link Address**.

   You use the copied link address to install the VAIO filter in the VMware MOB interface.

Install Cohesity CDP I/O Filter on VMware vSphere Manually

Prerequisites

- **Cohesity I/O Filter Bundle**
  To obtain the HTTP URL I/O filter bundle, follow the steps outlined in Generate the URL from the Cohesity cluster.
- **Cluster MOID**
  Identify the Managed Object ID (MOID) of the target vSphere cluster where the I/O filter will be installed.

To install the Cohesity CDP I/O Filter on VMware vSphere manually:

1. Access the VMware MOB.
   a. Open a web browser and navigate to the vCenter MOB interface using the following URL format *https://<vcenter-url>/mob*.
   b. Log in with a vCenter user account that has the necessary privileges.

2. Navigate to **IOFilterManager**.
    a. On the MOB home page, click on the value associated with the content property.
    b. On the next page, click the link for **IOFilterManager**.
3. Initiate I/O filter installation.
    a. On the **IOFilterManager** page, locate and click the **InstallIoFilter_Task** method.
    b. A new window will appear when the method is invoked. Enter the following parameters:
        i. **vibURL (string)**: Enter the full HTTP URL of the staged Cohesity I/O filter bundle .zip file.
        ii. **cluster (ManagedObjectReference:ClusterComputeResource)**: Enter the clusterMOID of the target cluster (for example, domain-c10).
    c. Click the **Invoke Method** to start the installation.
4. Monitor the Installation.
    a. After invoking the method, the MOB displays a task ID.
    b. Click the returned task ID to view task details. Monitor the status field to track progress.
    c. The installation completes successfully when the task status changes to success.

Steps to Verify Installation

To confirm installation at the ESXi cluster level and driver installation on each host:

1. Access the cluster user interface.
2. Navigate to the ESXi cluster where the I/O filter has been installed.
3. Click on the **Configure** tab.
4. Select **IO Filters**.
5. **Verification**: If you see an entry that begins with *cohfilter*, the installation was successful at the ESXi cluster level.

Upgrade CDP I/O Filter

To upgrade the Cohesity I/O Filter from the Cohesity cluster:

1. Navigate to **Data Protection** > **Sources**.

    The Sources page displays a list of sources registered with the Cohesity cluster.
2. Select the VMware vCenter Server that has CDP enabled for its protected objects.

    The Protected Objects tab displays the list of protected objects.

3. Select the All Objects tab and select the Physical Hierarchy View.
4. Navigate to a CDP-protected ClusterComputeResource. Optionally you can use the filter option available on the page to view the protected ClusterComputeResource.

   An upgrade icon ( ) is displayed next to the CDP-protected object if an I/O Filter upgrade is available.

5. Click the upgrade icon ( ) next to the protected object, and then select **Upgrade CDP I/O Filter**.

   The Upgrade CDP I/O Filter page appears.
6. Click **Continue**.

> **Note:**
> - Cohesity will upgrade the I/O Filters on all the ESXi hosts and VMs belonging to the same VMware ESXi cluster of the selected object.
> - Cohesity will perform the upgrade of the I/O Filter on the ESXi hosts only if the ESXi hosts in the cluster are in maintenance mode. Cohesity will withhold the upgrade till the ESXi hosts go to maintenance mode.

Uninstall CDP I/O Filter

Ensure these prerequisites are met before you uninstall the Cohesity I/O Filters attached to VMs on the ESXi hosts:

- If the VMs are not migrated to another cluster that has a VM Storage Policy with Cohesity I/O Filter, then ensure that the Cohesity I/O Filter is not attached to any VMs.
- This procedure requires the ESXi hosts to be in maintenance mode. You should shut down the VMs to put the ESXi hosts in maintenance mode.
- If the ESXi hosts are set up with DRS mode, then moving an ESXi host in maintenance mode migrates the VMs to another ClusterComputeResource which has the same filter installed. You can perform a rolling uninstallation to remove the I/O Filter associated with all the hosts to remove the filter definition at the cluster level.

After detaching the I/O Filter from all the VMs, it is recommended to remove the VM Storage Policy from the vSphere created by the Cohesity cluster.

To uninstall the Cohesity I/O Filter from the Cohesity cluster:

1. Navigate to **Data Protection > Sources**.

   The Sources page displays a list of sources registered with the Cohesity cluster.

2. Select the VMware Cluster that has CDP enabled for its protected objects.

   The Protected Objects tab displays the list of protected objects.
3. Select the **All Objects** tab, and select the Physical Hierarchy View.
4. Navigate to a CDP-protected object. Optionally you can use the filter option available on the page to view the protected object.

   A filter icon ( ) with the following message displayed next to the CDP-protected object if an I/O Filter upgrade is available.

   ```
   Uninstall CDP IO Filter
   ```
5. Click the icon ( ) next to the protected object, and then select **Uninstall CDP IO Filter**.

   The uninstall CDP IO Filter page appears.
6. Click **Continue**.

> **Note:** Once initiated, the Cohesity VMware I/O filter installation will continue to completion until CDP is removed from a protection policy.

Considerations

- If a new host is added to the Cluster Compute Resource of the VMware vCenter, CDP will be auto-deployed on the newly added host and the I/O Filter Daemon will start running on it.
- The Cohesity cluster will continue to protect the CDP-enabled VMs that are moved (or migrated) to another ESXi host using VMware Storage vMotion.
- You can perform a point-in-time recovery of VMs, files and folders, Virtual Disks, and IVM of a CDP-based Protection Groups by selecting the points in the timeline bar on the recovery page. This timeline will also display when the VADP backups were taken and you can optionally recover from the VADP snapshots. For detailed instructions on recovering VMs, files and folders, Virtual Disks, and IVM, see Recovery.
- If you are manually attaching the VM Storage Policy, then ensure to:
  - Attach a Storage Policy to the VMs before a CDP-enabled Protection Group is created for these VMs.
  - While creating the VM Storage Policy, select the **Enable host based rules** checkbox in the **Policy structure** tab and create rules for Replication data service under **Host based services** with the following settings:

  - **Provider**: cohfilter
  - **vCenterUUID**: <vCenterUUID>
  - **CohesityID**: <ClusterId:IncarnationId>
  - **CohesityClusterEndpoint**: <endpoint>:20004
  - **HeartbeatInterval**: 30

> **Note:** You can view the default Storage Policy created by Cohesity on the VMware vCenter as a reference for the above settings.

- If there is no VM Storage Policy attached to the VMs, then when the Protection Group is run, Cohesity will automatically create and attach the VM Storage Policy required for CDP.
- A CDP-enabled Protection Group supports a maximum of 25 VMs per node and 40 VMs per ESXi host, in each Cohesity cluster. Attempts to create Protection Groups that exceed this limit fail with the following error messages:

```
The limit on the number of CDP-protected VMs from an ESXi host is being exceeded on the host.
```

```
The maximum number of VMware VMs supported on this cluster for CDP is <number of nodes in the Cohesity cluster times 25>
```

- If the Storage Policy attached to the VM does not have the correct CDP attributes configured, then a corresponding error message is displayed for that VM on the CDP status page (**Protection> CDP** > **Protected Objects**).
- Do not make any updates to the Cohesity-managed I/O Filter or the VM Storage Policy directly from vCenter as this will cause the CDP to fail.
- CDP will stop if the FQDN of the Cohesity cluster is changed after the CDP protection runs are configured for a VMware VM. To reenable CDP, update the new FQDN in the CDP Storage policy and reapply the policy on all the VMs associated with that policy.
- If a Protection Group is deleted or paused, then you must either manually detach the VM Storage Policies that were manually attached or update the Storage Policies to remove the CDP attributes. Once you resume the Protection Group, you can reattach the VM Storage Policies with CDP attributes.
- If the time stamp on the Cohesity cluster and the workload VM are not in sync, then the CDP protection window displayed in the Cohesity cluster will be inaccurate.
- You can select point-in-time restore only for individual VMs and not for a Protection Group.
- The performance of your vCenter server might be impacted if many VMs are added to a CDP policy at once.

- Cohesity clusters monitor the I/O throughput of CDP-enabled objects continuously. The guardrails help you track the resource utilization, performance, and stability of the Cohesity cluster.

  When the I/O throughputs exceed the pre-defined thresholds, appropriate alert messages are displayed under the Message column of the Protection Run details page.

  - **CDP disabled for a set duration**. If the I/O throughput of an object sporadically increases above the threshold, causing a resource scarcity on the Cohesity cluster, CDP is disabled for a duration determined by Cohesity.

    Alert Message

    CDP was temporarily disabled at <hh:mm> because of High IO Throughput. It will be enabled automatically after <default period set by Cohesity>.

    CDP is automatically re-enabled once the time duration set by Cohesity expires. To modify the time duration set by Cohesity, contact your Cohesity account team.

  - **CDP disabled temporarily**: If the I/O throughput of a CDP-enabled object exceeds the threshold for a prolonged period, CDP is disabled until you enable it again.

    Alert Message

    CDP disabled at <hh:mm> PM because of continuous high I/O throughput. Please review the I/O throughput of an entity.

    Disabling CDP ensures the sustainability of the Cohesity cluster and prevents the objects that exceed the thresholds from affecting the other objects in the Cohesity cluster.

    When CDP is disabled with the preceding message, it is not enabled unless you manually enable it. You can review the I/O throughput of such entities and re-enable CDP if you like. You may also contact your Cohesity account team for more details.

- CDP protection is not supported for the VMware VMs residing in the vVol datastores.
- For CDP-enabled VMware VMs that use vSAN-based datastores, you must attach the storage policy manually. For details, see CDP Offline Storage Attach for vSAN Datastores.
- With ESXi 8.0.x versions, the automatic installation of the filter driver does not work as expected.

Failover Protection Group for VMs

> **Note:** Failover of Protection Groups is only supported for VMware VMs.

When a Protection Group with a replication schedule starts replicating snapshots from a primary Cohesity cluster to a remote Cohesity cluster, a Protection Group in Failover Ready state is created on the remote Cohesity cluster. If the original capturing Cohesity cluster and/or the original Source are down because there is a planned maintenance outage or a disaster destroys them, you can failover the Protection Group in Failover Ready state and deactivate the original task on the capturing Cohesity cluster. As part of the Failover, you are prompted to optionally recover the VMs from the replicated snapshots stored on the remote Cohesity cluster.

> **Note:** When you create a Protection Group on a Cohesity cluster with a replication schedule after the first snapshot is replicated, a Failover Ready copy of the Protection Group is created on the remote Cohesity cluster that is receiving the snapshot. For more information on Failover Ready, see About Failover Ready. You can failover the Protection Group of VMs. You cannot failover the Protection Group of Views or SQL Servers. You can, however, clone replicated Views and restore SQL Servers. For more information, see Failover a Protection Group.

During Failover, the following actions occur:

1. **Disaster at Source** - On the primary Cohesity cluster, the backup job fails to capture the snapshots of the source.
2. **Replication Fails** - As the source is down or unreachable, the replication job fails to replicate the snapshots onto the remote Cohesity cluster. The Failover Ready for VMs on the remote Cohesity cluster is activated and causes the rejection of the incoming replicated snapshots created by the associated job on the primary Cohesity cluster.
3. **Failover VMs** - You are prompted to optionally recover the VMs from the replicated snapshots on the remote Cohesity cluster to a new source.

The state of a Protection Group may also become "Failover Ready" when an active Protection Group is deactivated. For more information, see About Failover Ready.

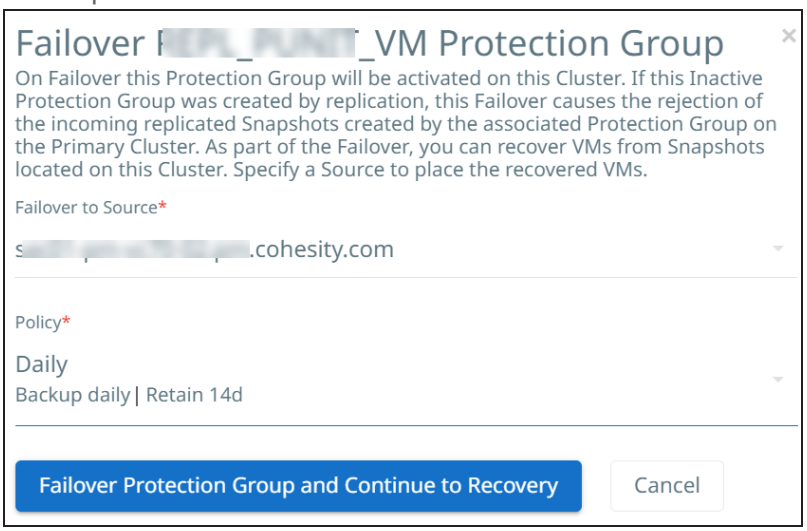
For more information about what happens during a Failover, see Failover from Replicated Copies.

For more information on disaster recovery of VMs using the Cloud Edition, see Back Up VMs to On-Prem, Replicate and Failover to AWS Cloud.

To Failover a Protection Group on the remote Cluster:

1. Navigate to **Data Protection > Protection**.
2. Find the Protection Group in the Failover Ready state in the list, click on the actions menu ⋮, and select **Failover**.

3. Select a source to place the recovered VMs and click **Failover Job and Continue to Recovery**.



4. Set Recover Options for VM Failover.
5. View VM Failover Confirmation.
6. Deactivate Original VM Protection Group. The Failover of the Protection Group in the Cohesity Dashboard does not automatically deactivate the original task on the original cluster that captured the snapshots. To deactivate, you must follow the instructions in Deactivate Original VM Protection Group
7. Restore VM Protection Group to Running. The Failover of the Protection Group in the Cohesity Dashboard does not automatically restore the task to running on the new cluster. To restore the task to a running state, you must follow the instructions in Restore VM Protection Group to Running.

Set Recover Options for VM Failover

In this section, you select the recover options while recovering VMs as part of the Failover of an Inactive Protection Group.

To set recover options:

1. Toggle **Rename Recovered VMs** on if you want to add Prefix and/or Suffix strings to the VM names of the new VMs created by this task. For example, you could specify Prefix `Test_` and Suffix `_QA` to the VM name `WinOS` and when the VM is recovered, the new VM that is created is called `Test_WinOS_QA`.
2. Select the appropriate **Recovery Location** option
   - **Recover back to original location**—Select this option to recover the VM files (such as the VMDK files) to their original datastores and create new instances of the VMs in the original location in the original source. For more information, see Recover to the Original Location.

- **Recover to a new location**—Select this option to recover the VM files (such as the VMDK files) to an alternate datastore and create new instances of the VMs in a new location of a registered Source. For more information, see Recover to a New Location. For details about virtualization or cloud platform-specific options, see the respective section.
  - Acropolis
    a. **Source:** Select a registered Source to recover the VMs to.
    b. **Storage Container:** Select a storage container to store the recovered VMs.
  - AWS
    a. **Source:** Select a registered Source to recover the VMs to.
    b. **Region:** Select a region in the project to recover the VMs.
    c. **VPC:** Select an Amazon Virtual Private Cloud (VPC) to store the recovered VMs.
    d. **Subnet:** Select a subnet in the Amazon VPC to store the recovered VMs.
    e. **Key Pair:** Select an Amazon key pair that has permission to log in to the recovered VMs.
    f. **Network Security Group:** Select the associated network security group.
  - Azure
    a. **Source:** Select a registered Source to recover the VMs to.
    b. **Resource Group, Storage Account:** Select the corresponding Resource Group and Storage Account to which the recovery has to be done.
    c. **Storage Container:** Select the storage container in which page blobs will be created.
    d. **Virtual Network:** Select the virtual network where the VM must be placed.
    e. **Subnets:** Subnets in the virtual network where VMs must be placed.
  - GCP
    a. **Source:** Select a registered Source to recover the VMs to.
    b. **Project:** Select a Google Cloud Platform (GCP) project to recover the VMs to.
    c. **Region:** Select a region in the project to recover the VMs to.

d. **Availability Zone:** Select an availability zone in GCP to recover the VMs.

e. **VPC:** Select a Virtual Private Cloud (VPC) to store the recovered VMs.

- Hyper-V
  a. **Source:** Select a registered Source to recover the VMs to.
  b. **Compute:** Select the compute host for the recovered VMs.
  c. **Volume:** Select a volume to store the recovered VMs.

  When recovering to a standalone Hyper-V host as a new location, SMB volumes are not supported locations.
- RHV
  a. **Source:** Select a registered Source to recover the VMs to.
  b. **Data Center:** Select a data center to store the recovered VMs.
  c. **Cluster:** Select an RHV to store the recovered VMs.
  d. **Storage Domain:** Select an RHV storage domain to store the recovered VMs.
- VMware
  a. **Source:** Select a registered Source to recover the VMs to.
  b. **Resource Pool:** Select a Resource Pool to store the recovered VMs.

  > **Note:** When protecting a VMware Source, if you select a Resource Pool that is not part of the ESX cluster, all datastores in the vCenter are displayed. Ensure you select a datastore that is part of the selected Resource Pool. If you select the wrong datastore, storage migration fails, but the VM remains attached to the ESX Host and runs from the Cohesity datastore. You can manually migrate the VM to the desired datastore at a later time.

  c. **Datastore:** Select one or more available target datastores. The VM files (such as VMDK files) extracted from the Snapshots are stored in the selected datastores. The number of target datastores you select must be equal to or less than the number of VMs selected for recovery.

Cohesity also displays each datastore's amount of free space and total capacity. For more information about recovering VMs to multiple datastores, see Recover VMs to Multiple Datastores.

> **Note:** Not applicable when recovering to a standalone ESX host. After recovery, VMs continue to run on the Cohesity datastore because Storage vMotion is not supported.

d. **VM Folder** Optionally select a logical VM folder in the datacenter in which to create the VMs.

> **Note:** Not applicable when recovering to a standalone ESX host.

- vCloud Director
  a. **Source:** Select a registered vCloud Director source to which you plan to recover the VMs or vApp.
  b. **Organization VDC:** Select the target organization VDC.
  c. **vApp:** Optional. Select the target vApp. If not specified, VMs are recovered as standalone VMs inside the target organization VDC.
  d. **Storage Profile:** Select the target Storage Profile. The Cohesity cluster chooses any compliant datastore associated with the Storage Profile to store the VM files. If you are recovering multiple VMs, the Cohesity cluster chooses one or more datastores associated with the Storage Profile.

3. Select the appropriate **Recovery Type** option.
   - **Instant Recovery**: if you select this option, the VM(s) will be usable instantly in the target environment and will be moved to target storage later. The VM can be used in production during Instant Recovery when data is copied to the VM from the Cohesity cluster. In such scenarios, the VM performance may be low as the Storage vMotion is still in progress.

     When recovering VMware VMs, by default, the selected VM is always instantly available after recovery.

     > **Note:** For instant recovery to Standalone ESXi, the VM(s) will be available immediately in the target environment and will have to be moved to the target storage manually.

- **Copy Recovery**: You can select this recovery type for **VMware** sources only. If you select this option, the recovered VMs will be usable in the target environment only after all the data is copied from Cohesity to the target storage. Once the restore is complete, the VM will be available to use and the performance of the VM will be normal.

  > **Note:** You should have `VirtualMachine.Config.Rename` permission on your user account to use this recovery option.

  Considerations when using the Copy Recovery option to recover VMware sources

  - This is the only option to recover data from VMware cloud solutions.
  - Copy recovery is not supported on Hybrid Extender deployments. Only vCenter and stand-alone ESXi hosts are supported.

4. Specify the networking options.
   The network options displayed depend on the Recovery Location option that was selected.

   - **Keep original**—For each recovered VM, keep the original virtual Network Interface Cards (vNICs) and attach them to the original network connections. This option is only supported when VMs are recovered back to their original location.
   - **Start Connected**—For each recovered VM, connect to the original or new network when the VM reboots. If this option is not selected, the VMs are not connected to any network on reboot.
   - **Detach network**—For each recovered VM, the virtual Network Interface Card (vNIC) is removed from the VM.
   - **Attach to a new network**—For each recovered VM, attach the virtual Network Interface Card (vNIC) to a new network. The new network might be a standard port group or a distributed port group.

     When recovering VMware VMs, the selected Network port group will be attached to all the network interfaces of the VMs being recovered.

     When recovering Hyper-V VMs, the selected virtual switch will be attached to all the network interfaces of the VMs being recovered.

> **Note:**
> - Recovering a network attached CentOS VM on VMware or Hyper-V does not attach the VM to the network. Attach the VM to the network manually.
> - If the VMware Resource Pool is not part of the ESX cluster, all networks available to the Datacenter are displayed. Ensure you select a network available to the selected Resource Pool. If you select the wrong network, VM creation and recovery will fail.

5. **Auto Select:** When enabled, the recovery task automatically selects the correct VLAN.
6. Select **Instant Recovery** if you want to change the Hyper-V recovery mechanism so that VMs become available instantaneously after recovery. Applicable to Hyper-V only.

   Select **Preserve VMs UUID** if you want to preserve the UUID for the recovered VMs. Applicable to Hyper-V only.
7. Select **Leave recovered VMs powered off** if you want the recovered VMs to remain powered off after they are created.

   If you recover VMs from a Storage Domain that has Cloud Tier enabled, Cohesity recommends leaving the VMs powered off.
8. Select **Continue recovery even if errors occur when recovering VMs** if you want the Recover task to continue even if errors occur when recovering the VMs. For example, if one of the VMs cannot be created, the Cluster will still attempt to create the other VMs. If this is unselected, then the Recover task is discontinued only if VM creation fails, so if VM creation succeeds, but VM storage migration fails, the task continues.
9. In the Selected Objects section, click **Show VMs** to view the VMs associated with the Failover Job. By default, the VM Snapshots of the last Run of the Job are recovered.

   Click Edit ( ) to select Snapshots captured by a different protection run.
10. Click **Finish**.

The next step is View VM Failover Confirmation.

View VM Failover Confirmation

In this step, you can view a summary of the options for the current Failover task and a list of objects that will be recovered by the task.

The next step is to Deactivate Original VM Protection Group

Deactivate Original VM Protection Group

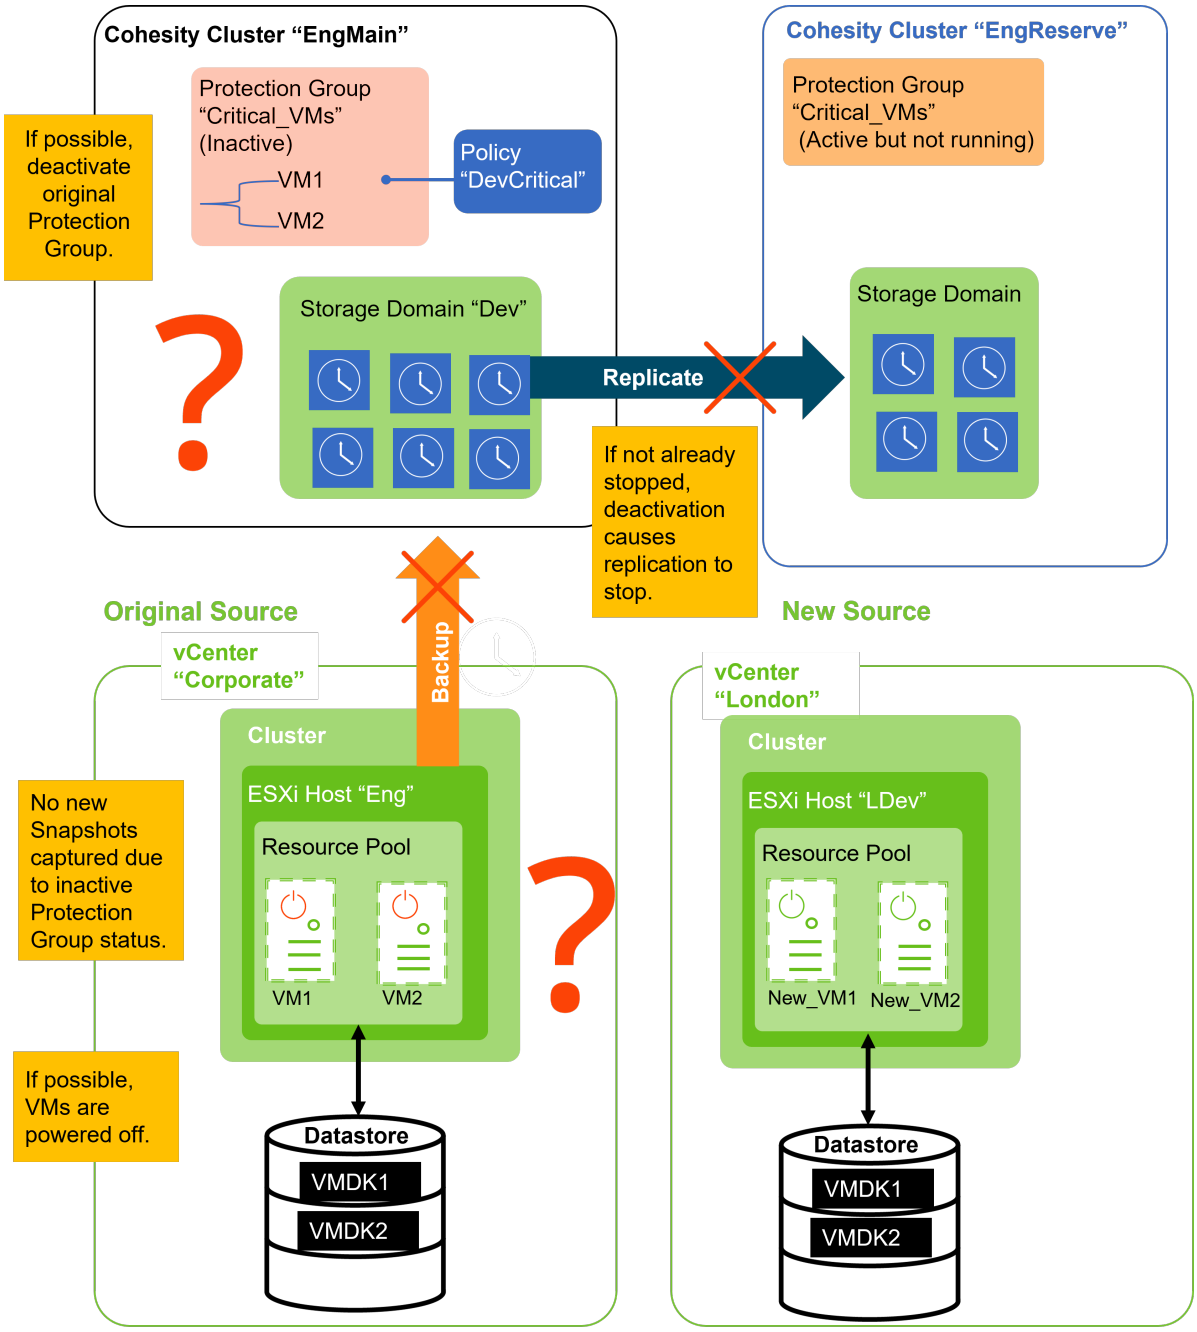
Only Protection Groups that are protecting VMs can be deactivated. Protection Groups that are protecting a view cannot be deactivated.

> **Note:** If possible, deactivate the original Protection Group on the original capturing Cohesity cluster. If the original Cohesity cluster that captured the Snapshots is down or unreachable, you may be unable to deactivate the Protection Group.

The example below shows the deactivation of a Protection Group protecting VMs. Deactivating a Protection Group protecting SQL Servers is similar but not all details are the same. For example, the transaction logs are not described or pictured.

During deactivation, the following actions occur:

1. Snapshots are no longer captured by the original Protection Group on the original capturing Cohesity cluster. However, the existing snapshots captured by the Protection Group remain in the storage domain. They are not deleted.
2. Snapshots created by the Protection Group are no longer replicated to the receiving (remote) Cohesity cluster. (If you have already initiated the failover procedure, the replication has already stopped.)
3. You can optionally choose that the VMs on the original source be powered off. The VMs and the VM files, however, are not deleted. (The Cohesity cluster may be unable to power off the VMs if the original source is down or unreachable.)



To deactivate the original Protection Group:

1. Log in to the Cohesity cluster where the original Protection Group was running.
2. Navigate to **Data Protection > Protection**.
3. Find the original Protection Group in the list, click on the actions menu ⋮ and select **Deactivate**.
4. Click **Deactivate and Power off VMs**, or click **Deactivate Only** if you do not want

to power off the VMs.

5. Optionally delete the VMs and VM files using the VMware vSphere client.

Restore VM Protection Group to Running

You can restore the Protection Group activated by the Failover, by assigning a new policy to the Protection Group and selecting Objects (VMs) to back up. These actions restore the Protection Group to a running state on the new cluster. To learn more, see Restore Activated Protection Group.

To restore the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, find the inactive Protection Group (created by replication).
3. From the Actions menu (⋮) of that Protection Group, select **Resume**.

This is the last step in the Failover process.

Viewing VM Snapshot Types

Cohesity records Snapshot consistency information (Application-Consistent, Crash-Consistent, Not Powered On) for each VM that the Cluster backs up. You can view this information on the Run Details page. For information about creating App-Consistent backups, see Creating Application-Consistent Snapshots.

To view a VM's Snapshot type:

1. On the Protection Group page, click the name of the Job that captured the Snapshot.
2. On the Job Details page, click the protection run that you want details for.
3. On the Run Details page, mouse over a VM to see its Snapshot type. A message may also provide additional details about the Snapshot type.

When you create a Recover or Clone task, a Snapshot's type is viewable when selecting the Snapshot to Recover or Clone. To view a VM's consistency information, click Edit. If one type displays, this means all VMs in the snapshot are that type. If the Mixed type displays, this means the snapshot contains VMs of different types, such as crash-consistent and not powered on. You can display individual VMs to see each VM's type.

Note the following about Application-Consistent Backups:

Enabling or disabling the Application-Consistent option for an Incremental (CBT) Protection Group results in the creation of full snapshots (instead of incremental snapshots) during the next Protection Group run.

Truncate Logs in Microsoft Exchange Servers on VMs

Cohesity supports the ability to truncate the Microsoft Exchange email server transaction logs after a successful backup of a Windows server that hosts the Exchange email server. After the Cohesity cluster successfully captures a snapshot during a Protection Group, the Cohesity cluster truncates the Exchange transaction logs on the server.

Cohesity has qualified truncating logs for the following Microsoft Exchange servers running on virtual servers:

- Microsoft Exchange 2019 running on supported Windows servers (Standalone and DAG)
- Microsoft Exchange 2016 running on supported Windows servers (Standalone and DAG)
- Microsoft Exchange 2013 running on supported Windows servers (Standalone and DAG)
- Microsoft Exchange 2010 SP3 running on supported Windows servers (Standalone and DAG)

While selecting VMs to protect, you can toggle **Exchange Log Truncation** on for individual VMs where Exchange is registered with the Cohesity cluster.

> **Note:** Cohesity supports log truncation of Microsoft Exchange servers on VMware VMs only.

If **Exchange Log Truncation** is on and the Windows server has an Exchange server but the log truncation fails, an error is reported. However, the backup can successfully complete.

If **App-Consistent Backups** is on for the Protection Group and **Exchange Log Truncation** is on for some VMs in the job, the backup of these VMs is crash-consistent. However, these VMs contain VSS snapshots that were backed up while the Exchange server was quiesced (in an app-consistent state). You can restore this app-consistent VSS snapshot using the Microsoft VSS tools. Note that other applications in these VMs are not quiesced when VSS snapshots are backed up. These other applications were captured in the crash-consistent state in the VSS snapshot.

> **Note:**
> - Exchange log truncation does not require an additional adapter, but Exchange must be registered on the VM you want to protect.
> - **App-Consistent Backups** must be toggled on if you want to protect an Exchange VM.

Register Exchange on a VM

1. Navigate to **Data Protection > Sources**.
2. Navigate the hierarchy to the VM that is running Exchange.
3. Mouse over the VM's actions menu and click **Register Applications**.
4. Select the Cohesity agent to use, either **Installed Agent** or **Auto-Deployed Agent**.
5. Select MS Exchange.
6. Click **Register**.

   The VM's application and agent information displays when you click the icon.

Enable or Disable Exchange Log Truncation

To enable or disable Exchange Log Truncation, please perform the steps below:

1. Navigate to **Data Protection** > **Protection**.
2. Click the Protection Group (VM that is running Exchange).
3. Click the **Settings** tab.
4. Click **Virtual Machines** and then click **Edit** from the list of objects.
5. Toggle on or off **Exchange Log Truncation**.
6. Click **Save**.
7. Click **Protect**.

Configuring Custom Quiesce Scripts for Linux Virtual Machines

If the **Create App-Consistent backups** option is selected for a Protection Group that are protecting Linux Virtual Machines and quiesce custom pre-freeze and post-thaw scripts can be found on Linux VMs in the locations documented below, these scripts are run during the quiesce and create Snapshot process.

> **Warning:** The quiesce scripts must be able to be run by VMware Tools.

Script Name and Directory Location	Description	Example
`/usr/sbin/pre-freeze-script`	Script is run before the Snapshot is created.	Create a custom script that quiesces applications running on the Linux Guest OS before the Snapshot of the VM is created.
`/usr/sbin/post-thaw-script`	Script is run after the Snapshot has been created.	Create a custom script that restarts applications on the Linux Guest OS after the Snapshot of the VM is created. The script restarts applications that were quiesced by the pre-freeze script.

> **Note:** These are the script locations for Linux VMs. The script locations for Windows are documented in Running custom quiescing scripts inside Windows virtual machine with ESX 3.5 Update 2 and later (1006671) Knowledge Base Article.

Recover Virtual Machines

The VMs that are backed up onto the Cohesity cluster can be recovered as VMs, virtual disks, files and folders. You can also perform instant mount volume of the VMs.

Recover Files or Folders

Cohesity provides the ability to recover files and folders from a snapshot created earlier by a Protection Group. Files and folders can be recovered to their original location (limitations apply to physical servers and specific operating systems) or to a newly specified location, which can be within the original source or a different one. You can choose to retain the recovered files' and folders' original (at the time of the backup) permissions and attributes. You can also download files and folders from selected snapshots that were created by a Cohesity Protection Group.

To learn more, see About File Recovery.

For more information about the recovery options:

- Recover Files or Folders to the Original Location
- Recover Files or Folders to a New Location

Windows VMs

- If the Storage Replica feature is enabled on a Windows server with GPT disks, then file recovery (using the Cohesity agent) or IVM recovery to the original location is not supported. Cohesity recommends the following alternatives:
  - For file-level recovery, consider one of the following:
    - Recover to an alternate location.
    - Recover using VMware tools.
    - Use the Download Files option.
  - For IVM recovery, recover to an alternate location instead.
- After making system configuration changes to a Windows 8 or Windows 2012 System VM, such as renaming an existing drive letter or adding a new disk, these changes may not immediately take effect due to a Windows registry refresh issue. To force the drive letters to be updated on the VM, reboot the system in the VM. This issue affects how files are indexed by the Cohesity cluster and displayed while browsing the contents of the VM in the Cohesity Dashboard.
- Considerations when recovering to physical servers that run:
  - Windows 2012 or later - None
  - Windows 2008 R2 - Upto 2040 GB. Larger recoveries not supported.

  If the OS does not support your recovery, you must recover to an alternate physical server running Windows 2012 Server or later, or use downloads.
- Windows behavior (giving each user its own set of mapped networked drives) prevents recovering to an SMB share that was mounted by a different user.
- Recovering files/folders with names longer than 200 characters may return an error. This limitation is due to Windows behavior when handling files/folders with long names.
- File-based recovery to Windows VMs does not support hardlinks and alternate data streams.

Linux VMs

- For Linux VMs, Cohesity supports file recovery from LVM volumes. One LVM volume can consume more than one loop back device, so Linux VMs may support fewer than 8 volumes when configured with the default number of loop devices.
- For Linux Logical Volume Manager (LVM), if all the disks for a volume group are not found by the Cohesity cluster, the Cohesity cluster will not process that volume group. As a result of that, no volumes of this volume group will be recognized or indexed by the Cohesity cluster.

- When recovering a Linux file, the Cohesity Linux Agent runs the following commands in sudo:
  - mount
  - umount
  - findmnt
  - timeout
  - blkid
  - lsof
  - ls
  - rsync
  - losetup
  - dmsetup
  - lvs
  - vgs
  - lvcreate
  - lvremove
  - lvchange
- Recovering files to Linux VMs is not supported in the following cases:
  - When run as a non-root user that does not have sudo access.
  - If `ALL=(ALL) NOPASSWD:ALL` is not set for the recover user in the /etc/sudoers file.
  - Recovering to Linux VMs requires requiretty to be disabled for the recover user in the /etc/sudoers file, otherwise recovery will fail.To disable requiretty for a recover user, add the following line in the /etc/sudoers file, where <USERNAME> is the name of the recover user with sudo access:

    ```
    Defaults:<USERNAME> !requiretty
    ```

  - The recovery directory path length is greater than 4096 characters.
  - There is not enough space in /tmp for Cohesity to push linux_agent.
- For RHEL7, if Open VM Tools is installed instead of VMware Tools, TMPDIR may not point to /tmp. When recovering to location "/tmp/<SOME_DIRECTORY>", files may be recovered to a different location.

  Example: If the recovery location is '/tmp/DIR1', files are recovered to a different location, such as '/tmp/systemd-private-c74aea179e9a43c789a19306d880274f-vmtoolsd.service-9GhOBD/tmp/DIR1'

VMware

- File level recovery for VMware ESXi environments does not support RAID-5 volumes on dynamic disks. Simple, striped, spanned and mirrored volumes on dynamic disks are supported.

VMware Tools

If you use VMware Tools for recovery, ensure the destination VM meets the following conditions:

- The VM is powered on.
- The most recent version of VMware Tools is installed and running on the VM.
- open-vm-tools can be used on the supported Linux releases; open-vm-tools, if used, must be installed and running.
- The user account used to access the VM must be a local user with write permissions for that VM.
- Ensure you run VMware tools in sync with the vCenter and ESXi host versions. For compatibility of VMware Tools with guest operating systems, see the VMware article.
- The use of VMware tools for file-level recovery from a deduplicated Windows volume is not supported.

Considerations

If you recover files and folders of VMware VMs using VMware Tools, then consider the following:

- A VMware Tools service restart during a Recovery operation may disrupt Recovery. If the VMware Tools service restarts during a Recovery operation, the following error message is returned: The guest operations agent could not be contacted. After multiple retries to contact the guest operations agent, an error message stating that it started the copy but it could not get the status is returned. Go to the recovery location to verify whether the operation succeeded.
- The maximum recovery speed is 1-2 Mbps due to a known VMware limitation. For more details, see the VMware article.
- Ensure port 443 is open on the ESXi host that hosts the target VM. For more details, see Manage Firewall Ports.
- Cohesity recommends that you *not* use VMware Tools if the size of the recovered files or folders exceeds 10 GB or 10,000 files.
- For Windows VMs:
    - ACLs cannot be restored even if you have enabled the **Preserve File/Folder Attributes** option. Only the VM data will be restored.

    - Recovery of reparse points (such as shared folders, mount points, or junction points) cannot be restored.
    - When using the VMware Tools option for FLR on Windows VMs, some ACLs cannot be recovered due to limitations in the VMware API.
- For Linux VMs:
    - The **Preserve File/Folder Attributes** option restores only basic user, group, world permissions, and timestamps. Advanced permissions and file attributes such as ACLs are not restored.
    - Permissions for guest files and folders are retained only when the user running the restore operation has permission to change the group ownership on the restored files and folders. If the user does not have change group ownership permissions, the restore operation will fail. In this case, retry the operation without enabling the **Preserve File/Folder Attributes** option.
    - VMware APIs do not support the creation of files in the root folder.
    - VMware APIs cannot restore symbolic links.
    - Restoring files to a folder is not supported if the user account doesn't have write permission to that folder (even if the user has sudo permissions). Cohesity recommends using a root user or a user account with write privileges to the target folder.
    - If you restore files and folders using a guest user account that does not have permission to change file/folder ownership, the restored files are owned by the guest user account used to perform the restore. If you restore files and folders using a guest user account that has permission to change file/folder ownership, the restored files are owned by (or the ownership is retained by) the guest user account used to create the files and folders.
    - When a parent folder is restored all of its sub folders are restored also; Empty folders can be restored only when the parent folder is restored.
    - Restoring hard links is supported; hard links restored with their source files use the same index node (inode).
    - If a Windows VM includes volumes created from a storage pool (Microsoft Storage spaces), FLR is not supported.

Hyper-V

File level recovery for Hyper-V requires the following:

- For Windows target VMs:
    - The VM must be part of an Active Directory (AD). The Hyper-V host must also be in the same AD as the target VM.
    - Remote powershell is enabled from Hyper-V host to VM.

    - The Hyper-V Guest Service Interface is enabled on the target VM: Enable-VMIntegrationService -Name 'Guest Service Interface.
    - The Windows Remote Management (WinRM) service is enabled on the target VM. Users must execute the "winrm quickconfig" command to enable WinRM on the target VM.
- For Linux target VMs:
    - Cohesity Linux agent is installed on the target VM.

Nutanix AHV

File or folder level recovery of VMs in a Nutanix Acropolis Hypervisor requires a Linux or Windows Cohesity agent installed on the target VM. For details on how to install a Cohesity agent on a Nutanix VM, see Download and Install the Agent on Nutanix AHV.

Troubleshooting

- **Error**: When recovering files or folders, the virtual disks are part of the target VM. These virtual disks are attached as SCSI disks that can be any of the supported adapter types: LSI Logic Parallel, LSI Logic SAS or VMware Paravirtual. During this step, you may encounter the following error: "Disk adapter with required slots - <n> is not available. Try creating a new adapter". Here, <n> is the number of virtual disks that are being attached. This can occur if the VM's disk adapter does not have the required number of slots (one SCSI adapter can support 15 virtual disks).

  Solution:Attempt the operation *after* creating a new SCSI adapter. Additionally, the number of virtual disks where files and folders are being recovered from is limited to 15 at a time. Remove some files (or folders) and retry the recovery.
- **Error**: If LVM is not configured, running a protection job fails with the “No LVM volume found in idbmantasdev” error.

  Solution: For details on how to resolve this issue, see the Registering or running a Linux protection job fails when no LVM volumes are detected KB article.

Limitations

- You can download files and folders from selected snapshots that were created by a CohesityProtection Group. However, only items that were indexed when the snapshot was created can be downloaded. Recovering and searching for files and folders in snapshots created by other backup software is not supported.
- Indexing, file recovery and browsing files and folders on VMs are not supported for drives with disk-level encryption (such as BitLocker). On physical Servers, however, these workflows are supported.
- Encrypted folders that have been renamed or deleted cannot be recovered.
- Encrypted VMs are not indexed.
- Recovering files to a VM where vMotion is in process is not supported.

- File recovery is not supported for ReFS volumes in these environments: physical, VMware, Hyper-V and AHV.
- Downloading files and folders from tape archive locations is not supported.
- Recovering files and folders from VMs to physical servers and from physical servers to VMs is not supported.
- The downloadable zip file can contain regular files and folders only; symlinks are not supported. When unzipping the downloaded files/folders, use a zip utility that supports the ZIP64 format.
- If you perform point-in-time recovery of a file that is deleted within the CDP restore window, then the file-level recovery fails with the following error message:

```
Error while obtaining volume information for the file <File_path> -
[kInvalid]: Failed to get the local path for file: <file_path>
```

Recover Files or Folders to the Original Location

To recover files and folders to the original server:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** located at the top right of the page and then select **Files or Folders**.

   The Recover Files or Folders page appears.
3. Select any one of the following options to search for the file or folder:
   - **Files and Folders**: Allows you to search and recover files using file or folder names from any backup available on the Cohesity cluster.
   - **Browse or Specify Path for Search**: Allows you to search and recover files using the name of the server or Protection Group from any backup available on the Cohesity cluster.

If you select...	Then...
Files and Folders	1. Enter characters of the file name, path, or by specifying the wildcard character *. A list of items displays. You can optionally filter the search results by object type, source, object, Protection Group, Storage Domain, files only, or folders only. > **Note:** When entering the path of a Windows VM, be sure to reformat as shown in the example: Instead of *C:\Windows\System32\winevt* use *C:/Windows/System32/winevt/*. 2. From the list of search results, select the required files or folders to recover. 3. By default, the latest snapshot is selected for recovery. To recover from a different snapshot: > **Note:** The option to change the recover point is not available if multiple items were selected for recovery. 1. From the selected list, mouse over the snapshot, and then click the **edit** icon.  The Edit recovery point page appears.  2. By default, only the snapshots that are indexed are displayed. To display all the available snapshots, toggle off the **Show Indexed Snapshots**

If you select...	Then...
	Only option. 3. Select a date range and the snapshot point for recovery. 4. By default, the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud (icon) by clicking this icon if available in the **Location** option. 5. When recovering from an archive, consider the following points: • The archive (external target) must be currently registered for the task to succeed. • (*Applies only for cloud archive incremental with periodic full*) Provisioned Capacity Units (PCU) are required for all file-level recoveries. Provisioned capacity ensures that your retrieval capacity for expedited retrievals is available when needed. Each unit of capacity guarantees that at least three expedited retrievals can be performed every five minutes and provides up to 150 MB/s of retrieval throughput. 4. Click **Select Recovery Point** and go to step 4.

If you select...	Then...
Browse	1. Enter the full or partial server or Protection Group name. You can by specify the wildcard character *. You can also optionally filter the search results by object type, source, object, Protection Group, Storage Domain. 2. From the list of search results, select the object whose files or folders are to be recovered. 3. By default, the latest snapshot is selected for recovery. To recover from a different snapshot, click the snapshots drop-down in the top-left corner and select the snapshot you need. 4. **Browse on Indexed Data**: Toggle on this setting to browse the indexed data. It helps to speed up browsing of recovery data. By default, it only displays the files and folders that are indexed. Hidden files, folders, paths such as /usr, /var, /sys , /Windows, /ProgramData etc. are excluded from indexing. To display all the available files and folders, including hidden files and folders toggle off the **Browse on Indexed Data** setting. **Note:** • Changing the snapshot after selecting the items (files or folder) removes the selected items from the cart. • Enabling or disabling the **Browse on Indexed Data** option after selecting the items (files or folder) removes the selected items from the cart. • Deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process. 5. Browse to the file or folder that you want to recover by clicking a folder and subfolders. 6. Click **Save**. 7. After saving the selection, if you want to recover from a different snapshot or change the location from where the snapshot is recovered, perform the following steps: 1. From the selected list, mouse over the snapshot, and click the edit icon. 2. The Edit recovery point page appears. 3. By default, only the snapshots that are indexed are displayed. To display

If you select...	Then...
	all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. 4. Select a date range and the snapshot point for recovery. 5. By default, the snapshot is recovered from the local Cohesity cluster. You can also select a snapshot archived to the cloud (icon) by clicking this icon if available in the **Location** option. When recovering from an archive, consider the following points: • The archive (external target) must be currently registered for the task to succeed. • (*Applies only for cloud archive incremental with periodic full*) Provisioned Capacity Units (PCU) are required for all file-level recoveries. Provisioned capacity ensures that your retrieval capacity for expedited retrievals is available when needed. Each unit of capacity guarantees that at least three expedited retrievals can be performed every five minutes and provides up to 150 MB/s of retrieval throughput. 8. Click **Select Recovery Point** and go to step 4.

The Cohesity cluster attempts to index all files and folders to a drive on both Windows and Linux systems. If the Cohesity cluster is unable to find mount point information about files or directories, it indexes and displays these files and directories in the `lvol_N` directory, where `N` is a unique number such as `1`.

On Windows systems, if the Cohesity cluster finds the mount point information about files and directories, it indexes and displays these files and directories with a drive letter such as `C:`.

Linux LVM indexing supports the following LVM types only: Linear, Striped, Mirrored, Mirrored + Striped, Thin. On Linux systems, how files and directories are indexed and displayed is dependent on the conditions specified in the following table.

Server Type	Volume Type	

Linux Virtual Machine	Simple Volume	The Cohesity cluster detects mount points for entries in the `/etc/fstab` file with the following formats:
		`UUID=ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc /mnt ext4 auto 0`
		`UUID="ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc" /mnt ext4 auto 0`
		If the Cohesity cluster can detect a mount point, it indexes and displays files and directories in the volume with the mount point that was specified in the `/etc/fstab` file. For these example entries, files and directories are indexed with the `/mnt` mount path, such as `/mnt/example/test.txt`.
		If the Cohesity cluster cannot detect a mount point, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

Linux Virtual Machine	LVM Volume	The Cohesity cluster detects mount points for entries in the `/etc/fstab` file with the following formats:
		`UUID=ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc /mnt ext4 auto 0`
		`/dev/mapper/VG1-root /mnt ext4 defaults 1 1`
		`/dev/VG1/root /mnt ext4 defaults 1 1`
		If the Cohesity cluster can detect a mount point, it indexes and displays files and directories in the volume with the mount point specified in the `/etc/fstab` file. For these example entries, files and directories are indexed with the `/mnt` mount path, such as `/mnt/example/test.txt`.
		If the Cohesity cluster cannot detect a mount point, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

Linux Physical	LVM Volume	The Cohesity agent can only return mount data when the volume is mounted on the Linux physical Server. If the volume is mounted, the Cohesity cluster indexes and displays files and directories in the volume with the mount point such as `/mnt/example/test.txt`. If the volume is not mounted, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

4. Once you select the files and folder to recover, select one of the following options:

- **Next Recover Option**: If you select this option, then continue with the step 5 to configure the file recovery options.
- **Download Files**: If you are recovering a single file, this option downloads the file to your browser's download folder. For all other selections, this creates a recover task. When the task is completed, from the Recoveries page, click the task name and then click **Download Files** to download the generated zip file.

  Character replacement explanation for : and \ in file and directory names in zip files

  If the original file or directory name contains a ':', it is replaced with '_COLON_' in the archive.
  Example:
  - The original name is "a:b" then the archived name is "a_COLON_b"
  - The original name is "a:b:c" then the archived name is "a_COLON_b_COLON_c"

  If the original file or directory name contains a '\', it is replaced with '_BACK_SLASH_' in the archive.
  Example:
  - The original name is "x\y" then the archived name is "x_BACK_SLASH_y"
  - The original name is "x\y\z" then the archived name is "x_BACK_SLASH_y_BACK_SLASH_z"

5. From the **Recover To**, select **Original Server** to recover the files or folders to the original server.
6. (Applies only if you are recovering files and folders of a VMware VM). Select one of the following **Restore Method** options and provide the required information:
   - **Auto Deploy Cohesity Agent**: Select this option to automatically deploy the Cohesity Agent on the target VM. This allows you to use local or domain credentials to access the target VM. For Windows VMs, the following considerations are applicable:
     - If you use local user credentials, that user must be a local administrator on the server.
     - If you use domain user credentials, ensure that the username is entered in the format <domain/username>. The user must either be a domain administrator or a member of the Domain Administrators group on the server. Additionally, make sure that User Account Control (UAC) is disabled for the user.
   - **Use Existing Cohesity Agent**: Select this option to use the existing Cohesity Agent deployed on the target VM.

> **Note:** To recover files and folders of VMware VMs using Cohesity Agent, VMware tools must be installed and running on the target VM.

- **Use VMware Tools**: Select this option to use the VMware Tools for recovery. You have to enter the credentials required to access the target VM. If you are using domain credentials to access a target VM, then you should provide the username in the format <domain/username>. Ensure to install the VMware Tools on the target VM.

7. To recover to a different location in the original server, disable the **Recover to Original Path** option, and then provide the location to which the files or folders are to be recovered in the **Recover To** field. By default, the files and folders will be recovered to the original location.

> **Note:** For Hyper-V FLR, you must provide guest OS credentials on the user interface during the recovery workflow.

8. Optional. Edit the default settings of the following **Recovery options**:
   - **Overwrite Existing File/Folder**: By default, this option is enabled to overwrite the existing files and folders. Disable this option to create the files and folders in the specified location. Any duplicate files are skipped.

     Example for a Windows alternate location with **Overwrite Existing File/Folder** enabled and the target already exists:

     Files to be recovered: "C:\foo\1.txt", "C:\foo\test\1.txt", "C:\bar", "C:\foo\bar". Specified alternate location: "C:\restore". At the end of the copy, the target folder looks like this:

     - C:\restore\1.txt
     - C:\restore\cohesity<taskid>_0\1.txt
     - C:\restore\bar
     - C:\restore\cohesity<taskid>_1\bar

     If **Overwrite Existing File/Folder** is enabled, recovering a file to source when the file is in use may cause the open file to be overwritten. Whether overwriting occurs depends on the application using the file.
   - **Preserve File/Folder Attributes**: By default, this option is enabled and the ACLs, permissions, and timestamps are preserved for all files and folders. If you disable this option, then ACLs and permissions are not preserved. If recovering both folders and files, then folders will receive the new timestamps, but files retain their original timestamps. If recovering only, files, then files will receive

the new timestamps.

- **Continue on Error**: Enable this option if you want to continue the recovery even if one of the objects encounters an error. By default, this option is disabled and the recovery operation will fail if one of the objects encounters an error.
- **Cluster Interface**: By default, the Auto Select option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the Interface Group drop-down.
- **Task Name**: Change the default name of the recovery task.

9. Click **Recover**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Recover Files or Folders to a New Location

To recover files and folders to a new server:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** at the top right of the page and then select **Files or Folders**.

   The Recover Files or Folders page appears.
3. Select any one of the following options to search for the file or folder:
   - **Files and Folders**: Allows you to search and recover files using file or folder names from any backup available on the Cohesity cluster.
   - **Browse or Specify Path for Search**: Allows you to search and recover files using the name of the server or Protection Group from any backup available on the Cohesity cluster.

If you select...	Then...
Files and Folders	1. Enter characters of the file name, path, or by specifying the wildcard character *. A list of items displays. You can optionally filter the search results by object type, source, object, Protection Group, Storage Domain, files only, or folders only. > **Note:** When entering the path of a Windows VM, be sure to reformat as shown in the example: Instead of *C:\Windows\System32\winevt* use *C:/Windows/System32/winevt/*. 2. From the list of search results, select the required files or folders to recover. 3. By default, the latest snapshot is selected for recovery. To recover from a different snapshot: > **Note:** The option to change the recover point is not available if multiple items were selected for recovery. 1. From the selected list, mouse over the snapshot, and then click the **edit** icon. The Edit recovery point page appears. 2. By default, only the snapshots that are indexed are displayed. To display all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. 3. Select a date range and the snapshot point for recovery. 4. By default, the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud (icon) by clicking this icon if available in the **Location** option. When recovering from an archive, consider the following points: • The archive (external target) must be currently registered for the task to succeed. • (*Applies only for cloud archive incremental with periodic full*) Provisioned Capacity Units (PCU) are required for all file-level recoveries. Provisioned capacity ensures that your retrieval capacity for expedited retrievals is available when needed. Each unit of capacity guarantees that at least three expedited retrievals can be performed every five minutes and provides up

If you select...	Then...
	to 150 MB/s of retrieval throughput. 4. Click **Select Recovery Point** and go to step 4.

If you select...	Then...
Browse	1. Enter the full or partial server or Protection Group name. You can by specify the wildcard character *. You can also optionally filter the search results by object type, source, object, Protection Group, Storage Domain. 2. From the list of search results, select the object whose files or folders are to be recovered. 3. By default, the latest snapshot is selected for recovery. To recover from a different snapshot, click the snapshots drop-down in the top-left corner and select the snapshot you need. 4. **Browse on Indexed Data**: Toggle on this setting to browse the indexed data. It helps to speed up the browsing of recovery data. By default, it only displays the files and folders that are indexed. Hidden files, folders, paths such as /usr, /var, /sys , /Windows, /ProgramData etc. are excluded from indexing. To display all the available files and folders, including hidden files and folders toggle off the **Browse on Indexed Data** setting. **Note:** • Changing the snapshot after selecting the items (files or folder) removes the selected items from the cart. • Enabling or disabling the **Browse on Indexed Data** option after selecting the items (files or folder) removes the selected items from the cart. • Deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process. 5. Browse to the file or folder that you want to recover by clicking a folder and subfolders. 6. Click **Save**. 7. After saving the selection, if you want to recover from a different snapshot or change the location from where the snapshot is recovered, perform the following steps: 1. From the selected list, mouse over the snapshot, and click the edit icon. 2. The Edit recovery point page appears. 3. By default, only the snapshots that are indexed are displayed. To display

If you select...	Then...
	all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. 4. Select a date range and the snapshot point for recovery. 5. By default, the snapshot is recovered from the local Cohesity cluster. You can also select a snapshot archived to the cloud (icon) by clicking this icon if available in the **Location** option. When recovering from an archive, consider the following points: • The archive (external target) must be currently registered for the task to succeed. • (*Applies only for cloud archive incremental with periodic full*) Provisioned Capacity Units (PCU) are required for all file-level recoveries. Provisioned capacity ensures that your retrieval capacity for expedited retrievals is available when needed. Each unit of capacity guarantees that at least three expedited retrievals can be performed every five minutes and provides up to 150 MB/s of retrieval throughput. 8. Click **Select Recovery Point** and go to step 4.

The Cohesity cluster attempts to index all files and folders to a drive on both Windows and Linux systems. If the Cohesity cluster is unable to find mount point information about files or directories, it indexes and displays these files and directories in the `lvol_N` directory, where `N` is a unique number such as `1`.

On Windows systems, if the Cohesity cluster finds the mount point information about files and directories, it indexes and displays these files and directories with a drive letter such as `C:`.

Linux LVM indexing supports the following LVM types only: Linear, Striped, Mirrored, Mirrored + Striped, Thin. On Linux systems, how files and directories are indexed and displayed is dependent on the conditions specified in the following table.

Server Type	Volume Type	

Linux Virtual Machine	Simple Volume	The Cohesity cluster detects mount points for entries in the `/etc/fstab` file with the following formats:
		`UUID=ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc /mnt ext4 auto 0`
		`UUID="ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc" /mnt ext4 auto 0`
		If the Cohesity cluster can detect a mount point, it indexes and displays files and directories in the volume with the mount point that was specified in the `/etc/fstab` file. For these example entries, files and directories are indexed with the `/mnt` mount path, such as `/mnt/example/test.txt`.
		If the Cohesity cluster cannot detect a mount point, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

Linux Virtual Machine	LVM Volume	The Cohesity cluster detects mount points for entries in the `/etc/fstab` file with the following formats:
		`UUID=ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc /mnt ext4 auto 0`
		`/dev/mapper/VG1-root /mnt ext4 defaults 1 1`
		`/dev/VG1/root /mnt ext4 defaults 1 1`
		If the Cohesity cluster can detect a mount point, it indexes and displays files and directories in the volume with the mount point specified in the `/etc/fstab` file. For these example entries, files and directories are indexed with the `/mnt` mount path, such as `/mnt/example/test.txt`.
		If the Cohesity cluster cannot detect a mount point, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

Linux Physical	LVM Volume	The Cohesity agent can only return mount data when the volume is mounted on the Linux physical Server. If the volume is mounted, the Cohesity cluster indexes and displays files and directories in the volume with the mount point such as `/mnt/example/test.txt`. If the volume is not mounted, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

4. Once you select the files and folder to recover, select one of the following options:

- **Next Recover Option**: If you select this option, then continue with the step 5 to configure the file recovery options.
- **Download Files**: If you are recovering a single file, this option downloads the file to your browser's download folder. For all other selections, this creates a recover task. When the task is completed, from the Recoveries page, click the task name and then click **Download Files** to download the generated zip file.

  Character replacement explanation for : and \ in file and directory names in zip files

  If the original file or directory name contains a ':' , it is replaced with '_COLON_' in the archive.
  Example:
  - The original name is "a:b" then the archived name is "a_COLON_b"
  - The original name is "a:b:c" then the archived name is "a_COLON_b_COLON_c"

  If the original file or directory name contains a '\', it is replaced with '_BACK_SLASH_' in the archive.
  Example:
  - The original name is "x\y" then the archived name is "x_BACK_SLASH_y"
  - The original name is "x\y\z" then the archived name is "x_BACK_SLASH_y_BACK_SLASH_z"

5. From the **Recover To**, select **New Server** to recover the files or folders to a new location.
6. From the **Registered Source** drop-down menu, select a registered server to which you want to recover the files and folders. You can also register a new source by clicking **Register Source** from the **Source** drop-down menu.
7. From the **Target** (for VM and physical server) or **Volume** (for NAS) drop-down menu, select a VM or volume to which the files and files are to be recovered.

   > **Note:** For recovering files and folders of a VMware VM, ensure that VMware Tools are installed and running on the target VM. The target list displayed includes only VMs with VMware Tools installed and running.

8. (Applies only if you are recovering files and folders of a VMware VM). Select one of the following **Restore Method** options and provide the required information:
   - **Auto Deploy Cohesity Agent**: Select this option and provide the username and password of the target VM to automatically deploy the Cohesity Agent on the target VM.

- **Use Existing Cohesity Agent**: Select this option to use the existing Cohesity Agent deployed on the target VM.

  > **Note:** To recover files and folders of VMware VMs using Cohesity Agent, VMware tools must be installed and running on the target VM.

- **Use VMware Tools**: Select this option to use the VMware Tools for recovery. You have to enter the credentials required to access the target VM. If you are using domain credentials to access a target VM, then you should provide the username in the format <username@domain.com>. Ensure to install the VMware Tools on the target VM.

9. In the **Recover To** field, change the default location to which the files or folders are recovered. By default, the files and folders are recovered to the **/tmp/** directory for VMs.

   For NAS, an example path on an alternate location could be /tmp/recover. You can recover encrypted files/folders to their original location only.

   Example for Windows alternate location:

   - D:\cohesity_restore\1.txt
   - D:\cohesity_restore\bar

   These requirements may need to be met to recover files to a Windows VM.

   If recovering to a standalone Hyper-V host or cluster, you must add the guest VM to the reverse lookup zone in the DNS server to complete the recovery successfully.

   Files to be recovered: "C\foo\1.txt" and "C:\1stfloor\bar". Specified alternate location: "D:\cohesity_restore". At the end of the copy, the target folder looks like this:

   > **Note:** For Hyper-V FLR, you must provide guest OS credentials on the user interface during the recovery workflow.

10. Optional. Edit the default settings of the following **Recovery options**:

    - **Overwrite Existing File/Folder**: By default, this option is enabled to overwrite the existing files and folders. Disable this option to create the files and folders in the specified location. Any duplicate files are skipped.

      Example for a Windows alternate location with **Overwrite Existing File/Folder** enabled and the target already exists:

      Files to be recovered: "C:\foo\1.txt", "C:\foo\test\1.txt", "C:\bar", "C:\foo\bar". Specified alternate location: "C:\restore". At the end of the copy, the target folder looks like this:

  - C:\restore\1.txt
  - C:\restore\cohesity<taskid>_0\1.txt
  - C:\restore\bar
  - C:\restore\cohesity<taskid>_1\bar

  If **Overwrite Existing File/Folder** is enabled, recovering a file to source when the file is in use may cause the open file to be overwritten. Whether overwriting occurs depends on the application using the file.
- **Preserve File/Folder Attributes**: By default, this option is enabled and the ACLs, permissions, and timestamps are preserved for all files and folders. If you disable this option, then ACLs and permissions are not preserved. If recovering both folders and files, then folders will receive the new timestamps, but files retain their original timestamps. If recovering only, files, then files will receive the new timestamps.
- **Continue on Error**: Enable this option if you want to continue the recovery even if one of the objects encounters an error. By default, this option is disabled and the recovery operation will fail if one of the objects encounters an error.
- **Cluster Interface**: By default, the Auto Select option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the Interface Group drop-down.
- **Task Name**: Change the default name of the recovery task.

11. Click **Recover**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Recover VMs

Cohesity provides the ability to recover Protected Objects (such as VMs) from a Snapshot created earlier by a Protection Group. You can recover VMs from a Cohesity cluster or a currently registered archive. You can recover VMs to their original location or a new location.

Follow these procedures to recover VMs from a Cohesity cluster:

- Recover VMs to the Original Location
- Recover VMs to a New Location

> **Tip:** You can also watch the VMware VM Recovery video to learn how to recover a VMware VM to an original or new location.

To learn more about recovering VMs, see About Recovering VMs.

Considerations

Note the following about Recovering VMs:

VMware

- If VMs with the same VM name (but different relative VMDK paths) are cloned, the Cohesity cluster retains the original VM name for one VM and renames the rest by adding _X to the end of the VM names, where X is an increasing number such as 1, 2, or 3. For example, if you clone three VMs called QA, the Cluster names the VMs as QA, QA_1, and QA_2. However, cloning VMs with the same relative path is not supported.
- During VM Recovery or the Cloning of VMs, the Cohesity cluster stores the VMDK and VMX files in different directories on the Cohesity datastore (View), due to a VMware vSphere issue. The VMDK files are placed in the *taskname*/*vmname* directory and the VMX files are placed in the *vmname* directory, where *taskname* is the Task Name you specify for the Recover task and the *vmname* is the name of the VM. For example, if a Clone is created with the Task Name of `QA` that creates clones of the VMs called `Build` and `Test`, the VMDK and VMX files are stored in the following directories in the Cohesity datastore (View): `QA/Build/Build.vmdk`, `QA/Test/Test.vmdk`, `Build/Build.vmx` and `Test/Test.vmx`. However, when recovering a VM, after bringing up the VM on the Cohesity datastore (View), the Cohesity cluster does a Storage vMotion migration of the VM back to its original primary datastore. After the Storage vMotion migration completes, both the VMX and VMDK files end up in the *vmname* directory and the VMDK files are no longer stored in the *taskname* directory. This VM recovery example assumes that the VMDK files were originally located in the default directory (and not in some special directory) when the backup was performed.
- The Cohesity cluster supports the backup, recovery, and cloning of linked clones of VMs. However, the linking between the VMs is not preserved, and full snapshots of the VMs are created. In a single recover task, you can recover a single linked clone VM but not multiple linked clone VMs.
- Virtual RDM disks are recovered as flat disks.
- Data in CDROM or floppy drives attached to a VM snapshot are not recovered or cloned.
- Currently, when a VM with multiple NICs is cloned or recovered to an alternate location, Cohesity creates the VM with only one NIC. This will be fixed in a future release.
- Cohesity supports recovery only from VM to VM. Recovering VM to physical server and vice-versa is not supported.
- When recovering VMs using Cohesity clusters with the Organizations (multitenancy) feature enabled, empty datastores will not be displayed in the **Datastores** drop-down of the **Recover To** dialog if you use an Organization (Tenant) account.

- Till 6.7, the default value is 8 and from 7.0, the default value is 32. If an ESXi Host already has the maximum number of NFS datastores mounted, the Cohesity View (datastore) will not mount on the ESXi Host during the cloning or recovery. For more information including instructions on increasing the limit, see VMware KB Article.
- During the recovery of a single VM that has multiple networks or datastores, VMware does not check if the VM and the ESXi Host's network and datastore are compatible when assigning the VM to the ESXi Host, causing the recovery to fail.
- When the Cohesity cluster clones a VM, the vCenter server selects an ESXi host from the specified resource pool to host the new VM. However, if the vSphere version of the selected ESXi host is incompatible with the VMware vSphere version of the original VM, cloning fails with the following error: A component of the virtual machine is not accessible on the host.
- If the recovered VM belongs to a local datastore, migration might fail because VMware does not register the local datastore to all ESXi Hosts within the resource pool.
- If the recovered VM belongs to a datastore that is not mounted on all ESXi Hosts in the resource pool, migration might fail because VMware does not check the compatibility of the ESXi Host (within the resource pool) with the given datastore while registering the VM.

VMware vCloud Director (vCD)

- When recovering VMs to their original location, with the original location being VMware vCloud Director, the recovery succeeds, but it is not instant. The Cohesity cluster recovers the VMs to the VMware vCenter and then directs the vCloud Director to perform a non-instant import of the VMs.

  > **Note:** If the VM size is immense, then the non-instant VM import operation performed by the vCloud Director might get timed out. If you observe this issue, contact VMware to increase the vCD timeout duration during VM import.

- When vApp VMs are recovered to an alternate location, they can be recovered to the specified Resource Pool only and the user must then move the VMs to the desired vApp.
- Cloning VMs within a vApp is not currently supported; they will be cloned under a specified Resource Pool similar to regular VMs.

Azure VMware Solution (AVS)

- VM recovery from VMware source to AVS and vice-versa:
  - Only copy recovery from the VMware source to AVS is supported.
  - From AVS to VMware source, both copy recovery and instant recovery are supported.
  - Recovering a VM from an AVS source to any other heterogeneous source is not supported.
  - Only copy recovery is supported for a VM backed up from the AVS environment.

    > **Note:** Recoveries between VMware source environments and AVS may fail due to potential incompatibilities between the two platforms.

- Test and dev clone of VM backed up from the AVS environment is not supported.
- VMDK recovery and IVM are not supported for a VM backed up from the AVS environment.

Nutanix AHV VMs

Instant recovery of Nutanix AHV VMs is only supported on the IPv4 network interface.

RHV

Cohesity supports RHV only until version 6.8.1. While you can still protect and recover your RHV sources, the Cohesity Support team will not provide assistance.

Troubleshooting

- VM recovery from a higher vCenter version such as 6.7 (source) to a lower vCenter version (target) such as 5.5 might fail with an "`Unexpected element tag`" error. To learn how to resolve the issue, see the KB article.
- For some conditions, the VMware vSphere reports an error that there is a mismatch between the actual Content ID of the Parent VM and the Parent Content ID stored by the Child VM. To learn how to resolve the issue, see the VMware KB article.
- If recovery to a vSAN datastore (destination) fails with the error message such as the following, see the VMware section in the Support Matrix to ensure your vSAN version is supported:

  ```
  [Code 13] You do not have access rights to this file
  ```

- VMware does not support SAN transport for data stores with Clustered VMDK enabled. For details, see the VDDK Release Notes. To use SAN transport, Cohesity recommends that you not enable Clustered VMDK when you create a data store or disable it if it's set already. If you must use data stores with Clustered VMDK, use NDBSSL transport instead of SAN.

- If "Clustered VMDK" is disabled and the VDDK version on the vCenter server is 7.0.1 or later and SAN transport-based protection runs are failing with the "`Cannot use SAN transport to write to the datastore (<datastore name>) which is marked "clusteredVmdkSupported`," error:
  - Use NBDSSL mode for the protection runs on the affected data stores.
  - Upgrade the Cohesity cluster to a 6.8.1 or later version which uses VDDK version 7.0.3.

Recover VMs to the Original Location

You recover the data stored in the VMs and the configuration files of the VMs (for example, VMDK files which store the configuration of VMware VMs) to their original datastores and create new instances of the VMs in the original location in the original source.

Before you can recover VMs to its original location, snapshots of those VMs must exist on the Cohesity cluster. To create Snapshots, create and run a Protection Group.

To recover VMs to its original location:

1. Navigate to **Data Protection > Recoveries**.
2. Click on **Recover** located at the top right of the page and then select **Virtual Machines > VMs**.

   The Virtual Machines page appears.
3. Search for a Protected Object (VM) or Protection Group that contains the snapshots to recover from by entering characters of the VM name, Protection Group name, or by specifying the wildcard character *.

   A list of VMs displays.

   You can optionally filter the search results by Source, Protection Group, Storage Domain, or Date.
4. From the list of search results, select one or more VMs or Protection Groups that contain the snapshots to recover.

> **Note:**
> - If you have selected a Protection Group, then all the VMs backed up in the latest protection run of this Protection Group will be selected for recovery and the option to select those VMs individually will be greyed out in the search result list.
> - You can only select Protection Groups and VMs with snapshots stored in the same Storage Domain and belonging to the same source. Once you select a VM or Protection Group, the **Storage Domain** and **Source** filters will automatically get locked.

5. In the **VM Protection Group Selection** dialog box, review the list of Virtual Machines in the Protection Group and click **Confirm**. This pop-up is displayed for vCenter, Standalone ESXi Host, and vCloud Director.
6. By default, the latest snapshot of the VMs is selected for recovery. To recover from a different snapshot, perform the following steps depending on the object selected:

> **Note:** In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

To choose a different snapshot for a...	Then...
Protection Group	1. From the selected lists, mouse over the snapshot, and then click the **edit** icon. 2. From the Protection Run drop-down menu, select the snapshot from which you want to recover the VMs. By default the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. 3. Click **Select Recovery Point** and then go to step 6.

To choose a different snapshot for a...	Then...
VM	From the selected lists, mouse over the snapshot, and then click the edit icon. The Edit recovery point for <VM_name> page appears. By default, the option to select the snapshot is displayed in **Timeline** mode. You can also choose to view the option in **List** mode by clicking the List tab in the top-right corner of the page. • To select a snapshot from the Timeline mode: a. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar. b. Select the snapshot to be recovered by clicking the corresponding blue dot. For CDP, select the point-in-time restore. You can specify the exact point-in-time recovery by sliding the timeline bar. c. By default, the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. d. Click **Select Recovery Point** and then go to step 6. • To select a snapshot from the **List** mode: a. Select the List tab from the top-right corner of the Edit recovery point for <VM_name> page. By default, the page displays the snapshots available in the last one month. b. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range. c. Select the snapshots to be recovered. d. By default, the snapshot is recovered from the local Cohesity cluster. You can also select snapshots archived to the cloud by clicking the cloud (

To choose a different snapshot for a...	Then...
	) icon if available in the **Location** option. e. Click **Select Recovery Point** and then go to step 6.

7. Click **Next: Recover Options**.
8. From the **Recover To** options, select **Original Location** to recover the VM to the original location.
9. (*Applies only to VMware and Acropolis*) Select the **Recovery Type**:

> **Note:**
> - You should have the `VirtualMachine.Config.Rename` permission on your user account to use this recovery option.
> - For VMware VMs, Virtual RDM disks are recovered as flat disks.

- **Instant Recovery**: The VMs will be instantly available after recovery in the target location. The data will be moved to the target storage later. The VM can be used in production during Instant Recovery when data is copied to the VM from the Cohesity cluster. In such scenarios the VM performance may be low as the Storage vMotion is still in progress.

  If you choose to keep the VM in a powered-off state when initiating instant recovery, wait for the Storage vMotion to complete before powering the VM on. Cohesity recommends that you choose Copy Recovery for powered-off VMs for better performance.

  > **Note:** For instant recovery to Standalone ESXi, the VM(s) will be available immediately in the target environment and must moved to the target storage manually.

- **Copy Recovery**: The VMs will be available in the target location only after all the data is copied to the target storage from the source location (Cohesity cluster or cloud). Once the restore is complete, the VM will be available to use.

> **Note:** Copy Recovery option is the only option to recover VMs from VMware Cloud solutions.

> **Note:**
> - You can instantly recover vCloud Director VMs to their original location if all the vCloud Director VMs of the Protection Group belong to the same 'tag based placement rule' Storage profile.
> - VMs can also be backed up and recovered using the vCD plugin installed on the VMware vCloud Director web console. For more details on the installation and usage of the vCD plugin, see Plugin Installation.

10. **Existing VM Handling** options list (*Applies only to VMware and Hyper-V*)
    - **VMware**: From the **Existing VM Handling** options list, choose how you want to handle the original VM when recovering to the original location:
      - **None**: Recovers the VM as a new VM and retains the original VM. In the **Rename** field available in the **Recovery Options**, you can specify the name of the recovered VM by adding prefix and/or suffix strings to the name of the original VM. By default, the recovered VM is named as `copy-<original_VM_name>`.
      - **Overwrite Existing VM**: Recovers the VM by deleting the original VM. The recovered VM will have the original VM name. The original virtual machine is deleted prior to the recovery process. Therefore, a recovery failure or cancelation of recovery will also lead to the loss of the original VM.
        Once you select this option, a pop-up dialog box will be displayed. Review the message, type **YES**, and click **Confirm**.
      - **Attempt Differential Recovery**: Attempts to recover the VM by overwriting only the difference between the original VM and the snapshot selected for recovery. Any newly added data in the original VM is deleted.
        - This option is available only if you have selected **Overwrite Existing VM** and the **Recovery Type** option as **Copy Recovery**.
        - This option is disabled if you have selected **Leverage SAN Transport** under Recovery Options.

- You can choose this option if there are no hardware configuration changes involved in the original VM.
- If you want to reclaim free space for thin-provisioned disks, then Cohesity recommends not to attempt differential recovery and only perform **Overwrite Existing VM** recovery.
- Differential recovery reduces the amount of data transfer in a recovery process. In the pulse log, you can view the amount of data transfer saved by selecting differential recovery.
- If the original VM is not present or if the attempt to differential recovery fails, then Cohesity will perform **Overwrite Existing VM** recovery.
- In the original VM, if there are any newly added disks or any disks that are excluded during backup, then the recovered VM will not have these newly added disks and the disks excluded during backup. If you want to retain the newly added disks and the excluded disks in the original VM, contact Cohesity Support. However, Cohesity recommends you to choose the **Keep Existing VM** option if you want to retain the newly added disks and the excluded disks in the original VM while recovering.
- All the snapshots present on the original VM are consolidated and removed as part of differential recovery.
- **Keep Existing VM**: Recover the VM as a new VM with the original VM name. The original VM is retained powered off. The original VM will be renamed to `obsolete_<time_stamp><Orginal_VM_Name>`.

- **Hyper-V**: From the Existing VM Handling options list, choose how you want to handle the original VM when recovering to the original location:
  - **None**: Recovers the VM as a new VM and retains the original VM. In the Rename field available in the Recovery Options, you can specify the name of the recovered VM by adding prefix and/or suffix strings to the name of the original VM. By default, the recovered VM is named as copy-<original_VM_name>.
  - **Overwrite Existing VM**: Recovers the VM by deleting the original VM. The recovered VM will have the original VM name. The original virtual machine is deleted prior to the recovery process. Therefore, a recovery failure or cancellation of recovery will also lead to the loss of the original VM. Once you select this option, a pop-up dialog box will be displayed. Review the message, type YES, and click Confirm.

    The VM will initially be located on the Hyper-V host based on the original VM's UUID.

In highly available VMs that migrate to another node in the Hyper-V cluster after a backup, recovery will fail because deleting VMs from a non-original location is currently unsupported.

In the case of Hyper-V standalone clusters or clusters managed by SCVMM, restoring a VM will fail if a VM with the same UUID is present on multiple nodes. A VM can only be successfully restored if its original UUID is found on the original node.

If the VM exists on the host, it will be deleted first. If the VM is not present, the recovery process will proceed directly. Once it is confirmed that the VM is no longer on the host, it will be restored from the backup snapshot to its original location, using the same UUID. The recovery can be either instant or a copy recovery, depending on the options selected by the user.

VM recovery in SCVMM will fail if multiple VMs with the same original UUID are detected under SCVMM-managed hosts or clusters.

> **Note:** This feature is only available if the cluster and agents are on the required version.

When you choose to overwrite an existing VM, the current VM will be deleted before the recovery process begins. If the recovery fails or is canceled, the original VM will be permanently lost. To recover the VM, you must initiate a new restore from a specific point in time, which is determined by the backup snapshot you select.

11. Optional. Edit the default settings of the following **Recovery Options**:

Recovery Options	Description
Create Empty Disks for Excluded Disks	(Applicable only to AHV and Hyper-V Protection Groups) Enable this option if you want Cohesity to create blank disks for every disk you excluded from the backup. The metadata of the excluded disks will be used to create the blank disks. These blank disks are available post-recovery and only have the metadata of the original disk but no data. You can configure and run databases and applications on these disks, saving you from the effort of creating new disks. This feature is especially helpful if you have many VMs with excluded disks.

Recovery Options	Description
Exclude Disk Handling	(Applicable only to VMware) • **Create Excluded Disk as an Empty Disk**: Enable this option if you want Cohesity to create blank disks for every disk you excluded from the backup. The metadata of the excluded disks will be used to create the blank disks. These blank disks are available post-recovery and only contain the metadata of the original disk, but no data. You can configure and run databases and applications on these disks, saving you from the effort of creating new disks. This feature is especially helpful if you have many VMs with excluded disks. > **Note:** The Create Excluded Disk as an Empty Disk option is not supported with Differential Copy Recovery. • **Create Independent Disk as an Empty Disk**: By default, independent disks are not backed up. Enable this option if you want Cohesity to create blank disks for such independent disks. These blank disks are available post-recovery and only contain the metadata of the original disk, but no data. > **Note:** Excluded physical RDM disks cannot be created as blank disks, even when disk exclusion handling is enabled.

Recovery Options	Description
Network	By default, the VMs that are to be recovered do not have a virtual Network Interface Card (vNIC) attached. Enable the **Attach** option to attach a virtual Network Interface Card (vNIC) to each VM that is to be recovered. With the **Attach** option enabled, each VM will connect to its original network and the following option is displayed: • **Start Connected**– Enable this option to connect to the original network when the VMs reboots. If this option is disabled, the VMs are not connected to any network on reboot. While recovering VMs to the original location, there is no explicit control to preserve the MAC address. If the **Attach** option is enabled and the VM is configured to have a manual MAC address assigned at the time of backup, the same address will be recovered. **Note:** When recovering AHV VMs to the original location, the recovered VM will have the same number of NICs as the source VM. If the VM is configured to have an automatic MAC address at the time of backup, the same setting will be applied to the recovered VM. For information on preserving MAC address when recovering VMs to a new location, see Recover VMs to a New Location.
Rename	(*Applies for VM recovery*) Add Prefix and/or Suffix strings to the names of the new VMs created by this task. For example you could specify Prefix `Test_ and Suffix _QA` to the VM name WinOS and when the VM is recovered, the new VM that is created is called `Test_WinOS_QA`.
Rename vApp/vApp Template	(*Applies for vApp or vApp template recovery*) Add prefix and/or suffix strings to the names of the new vApp or vApp template created by this task. For example, you could specify prefix `Test_ and Suffix _QA` to the vApp template name WinOS and when the vApp template is recovered, the new vApp template that is created is called `Test_WinOS_QA`.
Rename VMs within vApp	(*Applies vApp or vApp template recovery*) Add prefix and/or suffix strings to the names of the new VMs within vApp created by this task. For example, you could specify prefix `Test_ and Suffix _QA` to the VM name WinOS and when the VM within the vApp is recovered, the new VM that is created is called `Test_WinOS_QA`.

Recovery Options	Description
Leverage SAN Transport for Copy Recovery	**Leverage SAN Transport** SAN transport will work only with the Copy Recovery option. You can turn on the Leverage SAN Transport toggle when you want to perform the copy recovery of VMware objects to vCenter target environments. You can now perform copy recovery of vCloud Director (vCD) objects, such as VMs and vApps, to vCD target environments, You can also leverage the SAN transport mode while you perform the copy recovery of the vCD objects. Once SAN Transport is enabled for copy recovery, the disk provisioning strategy selected during the Cohesity cluster setup will be reset to “Thick Provisioned Eager Zeroed” in adherence to the recommendation from VMware. For more details, see the KB article. Cohesity supports SAN transport for Fibre Channel (FC) and iSCSI-based storage arrays and datastores that contain such storage arrays. Turn on this option to enable the SAN transport mode over FC or iSCSI for backing up VMware VMs to Cohesity cluster. To use the SAN transport mode over FC, ensure the following pre-requirement: • Fibre channel is installed and zoned appropriately between the Cohesity cluster and the primary storage (Pure Flash Array and HPE Nimble Storage Array). To use the SAN transport mode over FC and iSCSI , ensure the following pre-requirement: • Volumes are mapped appropriately between the Cohesity cluster, ESXi hosts, and the primary storage.
	Allow NB DSSL Transport Fallback You can turn on the Allow NBDSSL Transport Fallback toggle if you do not want to enforce strict SAN transport mode for backing up VMware to the Cohesity cluster. With the toggle enabled, backup doesn't fail if the SAN transport is not available. If you disable the toggle, the backup fails if SAN transport mode is unavailable. NBDSSL encrypts all data passed over the TCP connection.
Power State	Disable **Power On** if you want the recovered VMs to remain powered off after they are created. If you recover VMs from a Storage Domain that has Cloud Tier enabled, Cohesity recommends leaving the VMs powered off. By default, the VMs are powered on after they are created.

Recovery Options	Description
Continue on Error	Enable **Continue recovery even if errors occur when recovering VMs** if you want the recovery task to continue even if errors occur when recovering the VMs. For example, if one of the VMs cannot be created, the Cohesity cluster will still attempt to create the other VMs. If this option is disabled, then the recovery task is discontinued if VM creation fails. However, if the VM creation succeeds, but VM storage migration fails, the task continues. By default this option is disabled.
Instant Recovery	(*Applies only to Hyper-V*) The **Instant Recovery** option allows you to access the recovered VMs almost instantly while the data is migrated to the VM's primary storage in the background. This is the default recovery type in the recovery workflow. **Note:** • You must turn off the toggle (from the **Recovery Options** list) to disable the Instant Recovery if you want to perform a Copy Recovery of the VM. • For Instant Recovery, the VM returns to its normal state once the storage migration is complete, as it no longer relies on the SMB view for storage. Prior to the storage migration, in SCVMM scenarios, the VM could be reported as being in an unsupported state.
Preserve VMs UUID	Select **Preserve VMs UUID** if you want to preserve the UUID for the recovered VMs. This is applicable only to Microsoft Hyper-V VMs. **Note:** If the UUID of the VM and the restored VM are same, a new UUID will be used by the restored VM.
Cluster Interface	By default, the **Auto Select** option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the **Interface Group** drop-down.
Task Name	Change the default name of the recovery task.

12. Click **Recover**. Review the Recovery Summary and click **Start Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Recover VMs to a New Location

You recover the data stored in the VMs and the configuration files of the VMs (for example, VMDK files which store the configuration of VMware VMs) to their original data stores and create new instances of the VMs in the original location in the original source. Before you can recover VMs to their original location, snapshots of those VMs must exist on the Cohesity cluster.

Before you can recover VMs to their new location, Snapshots of those volumes must exist on the Cohesity cluster. To create Snapshots, create and run a Protection Group.

To recover VMs to a new location:

1. Navigate to **Data Protection > Recoveries**.
2. Click on **Recover** located at the top right of the page and then select **Virtual Machines > VMs**.

   The Virtual Machines page appears.
3. Search for Protected Object (VM) or Protection Group that contains the snapshots to recover from by entering characters of the VM name, Protection Group name, or by specifying the wildcard character *.

   A list of VMs displays.

   You can optionally filter the search results by Source, Protection Group, Storage Domain, or Date.
4. From the list of search results, select one or more VMs or Protection Groups that contain the snapshots to recover.

   > **Note:**
   > - If you have selected a Protection Group, then all the VMs backed up in the latest protection run of this Protection Group will be selected for recovery and the option to select those VMs individually will be greyed out in the search result list.
   > - You can only select Protection Groups and VMs with snapshots stored in the same Storage Domain and belonging to the same source. Once you select a VM or Protection Group, the **Storage Domain** and **Source** filters will automatically get locked.
5. In the **VM Protection Group Selection** dialog box, review the list of Virtual Machines in the Protection Group and click **Confirm**. This pop-up is displayed for vCenter, Standalone ESXi Host, and vCloud Director.
6. By default, the latest snapshot of the VMs is selected for recovery. To recover from a different snapshot, perform the following steps depending on the object selected:

> **Note:** In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

To choose a different snapshot for a...	Then...
Protection Group	1. From the selected lists, mouse over the snapshot, and then click the **edit** icon. 2. From the Protection Run drop-down menu, select the snapshot from which you want to recover the VMs. By default the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. 3. Click **Select Recovery Point** and then go to step 6.

To choose a different snapshot for a...	Then...
VM	From the selected lists, mouse over the snapshot, and then click the edit icon. The Edit recovery point for <VM_name> page appears. By default, the option to select the snapshot is displayed in **Timeline** mode. You can also choose to view the option in **List** mode by clicking the List tab in the top-right corner of the page. • To select a snapshot from the Timeline mode: a. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar. b. Select the snapshot to be recovered by clicking the corresponding blue dot. For CDP, select the point-in-time restore. You can specify the exact point-in-time recovery by sliding the timeline bar. c. By default, the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. d. Click **Select Recovery Point** and then go to step 6. • To select a snapshot from the **List** mode: a. Select the List tab from the top-right corner of the Edit recovery point for <VM_name> page. By default, the page displays the snapshots available in the last one month. b. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range. c. Select the snapshots to be recovered. d. By default, the snapshot is recovered from the local Cohesity cluster. You can also select snapshots archived in the cloud by clicking the cloud (

To choose a different snapshot for a...	Then...
	) icon if available in the **Location** option. e. Click **Select Recovery Point** and then go to step 6.

7. Click **Next: Recover Options**.
8. From the **Recover To** options, select **New Location** to recover the VM files (such as the VMDK files) to an alternate datastore and create new instances of the VMs in a new location of a registered Source. For more information, see Recover to a New Location. For details about virtualization or cloud platform-specific options, see the respective section.
    - Acropolis
        a. **Source:** Select a registered Source to recover the VMs to.
        b. **Storage Container:** Select a storage container to store the recovered VMs.
    - AWS
        a. **Source:** Select a registered Source to recover the VMs to.
        b. **Region:** Select a region in the project to recover the VMs.
        c. **VPC:** Select an Amazon Virtual Private Cloud (VPC) to store the recovered VMs.
        d. **Subnet:** Select a subnet in the Amazon VPC to store the recovered VMs.
        e. **Key Pair:** Select an Amazon key pair that has permission to log in to the recovered VMs.
        f. **Network Security Group:** Select the associated network security group.
    - Azure
        a. **Source:** Select a registered Source to recover the VMs to.
        b. **Resource Group, Storage Account:** Select the corresponding Resource Group and Storage Account to which the recovery has to be done.
        c. **Storage Container:** Select the storage container in which page blobs will be created.
        d. **Compute:** Select the VM size type such as **Standard_D1** to use when recovering the VMs.

e. **Availability Set:** Optionally, select the availability set to which the VM has to be recovered. For more information, see Azure Availability Sets.
f. **Virtual Network:** Select the virtual network where the VM must be placed.
g. **Subnets:** Subnets in the virtual network where VMs must be placed.

- GCP
  a. **Source:** Select a registered Source to recover the VMs to.
  b. **Project:** Select a Google Cloud Platform (GCP) project to recover the VMs to.
  c. **Region:** Select a region in the project to recover the VMs to.
  d. **Availability Zone:** Select an availability zone in GCP to recover the VMs.
  e. **VPC:** Select a Virtual Private Cloud (VPC) to store the recovered VMs.
- Hyper-V
  a. **Source:** Select a registered Source to recover the VMs to.
  b. **Compute:** Select the compute host for the recovered VMs.
  c. **Volume:** Select a volume to store the recovered VMs.

  When recovering to a standalone Hyper-V host as a new location, SMB volumes are not supported locations.
- RHV
  a. **Source:** Select a registered Source to recover the VMs to.
  b. **Data Center:** Select a data center to store the recovered VMs.
  c. **Cluster:** Select an RHV to store the recovered VMs.
  d. **Storage Domain:** Select an RHV storage domain to store the recovered VMs.
- VMware
  a. **Source:** Select a registered Source to recover the VMs to.
  b. **Resource Pool:** Select a Resource Pool to store the recovered VMs.

> **Note:** When protecting a VMware Source, if you select a Resource Pool that is not part of the ESX cluster, all datastores in the vCenter are displayed. Ensure you select a datastore that is part of the selected Resource Pool. If you select the wrong datastore, storage migration fails, but the VM remains attached to the ESX Host and runs from the Cohesity datastore. You can manually migrate the VM to the desired datastore at a later time.

c. **Datastore:** Select one or more available target datastores. The VM files (such as VMDK files) extracted from the Snapshots are stored in the selected datastores. The number of target datastores you select must be equal to or less than the number of VMs selected for recovery.

   Cohesity also displays each datastore's amount of free space and total capacity. For more information about recovering VMs to multiple datastores, see Recover VMs to Multiple Datastores.

   > **Note:** Not applicable when recovering to a standalone ESX host. After recovery, VMs continue to run on the Cohesity datastore because Storage vMotion is not supported.

d. **VM Folder** Optionally select a logical VM folder in the data center in which to create the VMs.

   Cohesity recommends that you select the "VM" folder to recover to the root folder or select a folder from the displayed list of folders. If not, the Cohesity cluster recovers to a newly created folder named as follows:

   cohesity_vm_folder_<short_cluster_id>_<task_id>

   > **Note:** Not applicable when recovering to a standalone ESX host.

- vCloud Director

  a. **Source:** Select a registered vCloud Director source to which you plan to recover the VMs or vApp.

  b. **Organization VDC:** Select the target organization VDC.

  c. **vApp:** Optional. Select the target vApp. If not specified, VMs are recovered as standalone VMs inside the target organization VDC.

  d. **Storage Profile:** Select the target Storage Profile. The Cohesity cluster chooses any compliant datastore associated with the Storage Profile to store the VM files. If you are recovering multiple VMs, the Cohesity cluster chooses one or more datastores associated with the Storage Profile.

  e. **Catalog**: (*Appplies only for vApp template recovery*) Select the catalog for the vApp template recovery.

9. (*Applies only to VMware and Acropolis*) Select the **Recovery Type**:

   - **Instant Recovery**: The VMs will be instantly available after recovery in the target location. The data will be moved to the target storage later. The VM can be used in production during Instant Recovery when data is copied to the VM from the Cohesity cluster. In such scenarios the VM performance may be low as

the Storage vMotion is still in progress.

If you choose to keep the VM in a powered-off state when initiating instant recovery, wait for the Storage vMotion to complete before powering the VM on. Cohesity recommends that you choose Copy Recovery for powered-off VMs for better performance.

> **Note:** For instant recovery to Standalone ESXi, the VM(s) will be available immediately in the target environment and must be moved to the target storage manually.

- **Copy Recovery**: The VMs will be available in the target location only after all the data is copied to the target storage from the source location (Cohesity cluster or cloud). Once the restore is complete, the VM will be available to use.

  > **Note:**
  > - You can instantly recover vCloud Director VMs to their original location if all the vCloud Director VMs of the Protection Group belong to the same 'tag based placement rule' Storage profile.
  > - VMs can also be backed up and recovered using the vCD plugin installed on the VMware vCloud Director web console. For more details on the installation and usage of the vCD plugin, see Plugin Installation.

  > **Note:** Copy recovery is the only option to recover VMs from VMware Cloud solutions.

10. (*Applies only for vApp template recovery*) From the **Recover As** options, select how you want to recover the vApp template:
    - **vApp Template**: Select this option if you want to recover the vApp template as a vApp template itself.
    - **vApp**: Select this option if you want to recover the vApp template as a vApp.
11. Optional. Edit the default settings of the following **Recovery Options**:

Recovery Options	Description
Create Empty Disks for Excluded Disks	(Applicable only to AHV and Hyper-V Protection Groups) Enable this option if you want Cohesity to create blank disks for every disk you excluded from the backup. The metadata of the excluded disks will be used to create the blank disks. These blank disks are available post-recovery and only have the metadata of the original disk but no data. You can configure and run databases and applications on these disks, saving you from the effort of creating new disks. This feature is especially helpful if you have many VMs with excluded disks.
Exclude Disk Handling	(Applicable only to VMware) • **Create Excluded Disk as an Empty Disk**: Enable this option if you want Cohesity to create blank disks for every disk you excluded from the backup. The metadata of the excluded disks will be used to create the blank disks. These blank disks are available post-recovery and only contain the metadata of the original disk, but no data. You can configure and run databases and applications on these disks, saving you from the effort of creating new disks. This feature is especially helpful if you have many VMs with excluded disks. > **Note:** The Create Excluded Disk as an Empty Disk option is not supported with Differential Copy Recovery. • **Create Independent Disk as an Empty Disk**: By default, independent disks are not backed up. Enable this option if you want Cohesity to create blank disks for such independent disks. These blank disks are available post-recovery and only contain the metadata of the original disk, but no data. > **Note:** Excluded physical RDM disks cannot be created as blank disks, even when disk exclusion handling is enabled.

Recovery Options	Description

Network	By default, the VMs that are to be recovered do not have a virtual Network Interface Card (vNIC) attached. Enable the **Attach** option to attach a virtual Network Interface Card (vNIC) to each VM that is to be recovered.
	
	With the **Attach** option enabled, the following option is displayed:
	
	• **Network**: From the drop-down menu, select a network to attach the virtual Network Interface Card (vNIC) to a new network. The new network might be a standard port group or a distributed port group.
	  • When recovering VMware VMs, the selected Network port group will be attached to all the network interfaces of the VMs being recovered.
	  • When recovering the VMware VMs to vCloud Director, the Network drop-down menu displays the organization VDC networks attached to the Organization VDC on the vCloud Director.
	  • When recovering Hyper-V VMs, the selected virtual switch will be attached to all the network interfaces of the VMs being recovered.
	  • Recovering a network attached CentOS VM on VMware or Hyper-V, does not attach the VM to the network. Attach the VM to the network manually.
	  • If the VMware Resource Pool is not part of the ESX cluster, all networks available to the Datacenter are displayed. Ensure you select a network available to the selected Resource Pool. If you select the wrong network, VM creation and recovery will fail.
	
	  > **Note:** When recovering AHV VMs to the original location, the recovered VM will have the same number of NICs as the source VM.
	
	• **Start Connected**: Enable this option to connect to the new network when the VM reboots for each recovered VM. If this option is not selected, the VMs are not connected to any network on reboot.
	• **Preserve MAC Address**: Enable this option to preserve the MAC address when recovering to an alternate location.
	
	  > **Note:** If the VM is configured to have an automatic MAC address at the time of backup, a manual MAC address will be set on the recovered VM to preserve the MAC address.

Recovery Options	Description
	• **Network Override**: The option allows you to override the common network settings selected for the recovery job for VMware VMs. You can choose the VM for which the virtual Network Interface Card (vNIC) of the selected snapshot will be listed. For each vNIC, you can select the target network along with the "Start Connected" and "Preserve Mac Address" options. You can select the VM for which the virtual Network Interface Card (vNIC) of the chosen snapshot will be displayed.
Rename	(*Applies for VM recovery*) Add prefix and/or suffix strings to the names of the new VMs created by this task. For example, you could specify Prefix `Test_ and Suffix _QA` to the VM name WinOS and when the VM is recovered, the new VM that is created is called `Test_WinOS_QA`.
Rename vApp/vApp Template	(*Applies only when recovering vApp or vApp template*) Add prefix and/or suffix strings to the names of the new vApp or vApp template created by this task. For example, you could specify prefix `Test_ and Suffix _QA` to the vApp template name WinOS and when the vApp template is recovered, the new vApp template that is created is called `Test_WinOS_QA`.
Rename VMs within vApp	(*Applies only when recovering vApp or vApp template*) Add prefix and/or suffix strings to the names of the new VMs within vApp created by this task. For example, you could specify prefix `Test_ and Suffix _QA` to the VM name WinOS and when the VM within the vApp is recovered, the new VM that is created is called `Test_WinOS_QA`.
Power State	Disable **Power On** if you want the recovered VMs to remain powered off after they are created. If you recover VMs from a Storage Domain that has Cloud Tier enabled, Cohesity recommends leaving the VMs powered off. By default, the VMs are powered on after they are created.
Continue on Error	Enable **Continue recovery even if errors occur when recovering VMs** if you want the recovery task to continue even if errors occur when recovering the VMs. For example, if one of the VMs cannot be created, the Cohesity cluster will still attempt to create the other VMs. If this option is disabled, then the recovery task is discontinued if VM creation fails. However, if the VM creation succeeds, but VM storage migration fails, the task continues. By default this option is disabled.

Recovery Options	Description
Instant Recovery	(*Applies only to Hyper-V*) The **Instant Recovery** option allows you to access the recovered VMs almost instantly while the data is migrated to the VM's primary storage in the background. This is the default recovery type in the recovery workflow. **Note:** • You must turn off the toggle (from the **Recovery Options** list) to disable the Instant Recovery if you want to perform a Copy Recovery of the VM. • For Instant Recovery, the VM returns to its normal state once the storage migration is complete, as it no longer relies on the SMB view for storage. Prior to the storage migration, in SCVMM scenarios, the VM could be reported as being in an unsupported state.
Cluster Interface	By default, the **Auto Select** option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the **Interface Group** drop-down.
Task Name	Change the default name of the recovery task.

12. Click **Recover**. Review the Recovery Summary and click **Start Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Teardown of Failed VM Recovery Tasks

Cohesity supports the teardown of failed VM recovery tasks, allowing you to clean up residual resources left behind when these tasks do not complete successfully.

To teardown a failed VM recovery task that has left behind certain resources:

1. Navigate to **Data Protection > Recoveries**.
2. Locate the instant VM recovery task you wish to terminate.

   To teardown a recovery task, Click the **Actions** menu (⋮) of that task and select **Teardown**.

   > **Note:** The Teardown option is available only if there are objects to destroy.

3. When prompted to confirm the teardown, click **Teardown**.

A confirmation dialog appears with a warning stating that the restored VMs with data on the Cohesity mounted NFS datastore will be removed.

4. Click **Confirm**.

   The teardown process is initiated, and the Cohesity cluster performs the following steps:

   1. The VM running from the Cohesity datastore is removed.
   2. The NFS datastores are unmounted from the ESXi host.
   3. Cohesity cluster resources are released.
   4. The user interface for Cohesity will show the current status of the teardown task.
   5. The teardown status of each VM is displayed under the "Instant Recovery" column.
   6. "Destroyed" status indicates successful completion of the teardown process.

   > **Note:**
   > - The VMs that have been manually migrated to the target datastore will not be considered for teardown.
   > - The teardown task can be retried in case of any issues.

Recover Virtual Disks

You can recover VMware VM virtual disks to a point in time from a Snapshot created earlier by a Protection Group. You can recover a virtual disk to its original VM or a different VM in the same vCenter. If recovering to the original VM, you can overwrite the disk in its original datastore, or attach it as a new disk. If recovering to a different VM, the disk is attached as a new disk in the datastore you select. For more information, see:

- Recover Virtual Disks to the Original Location
- Recover Virtual Disks to a New Location

Prerequisite

VMware licensing is required for all VMware products to facilitate processes such as backup or recovery with Cohesity. For more information on the VMware license, see the following VMware articles:

- VMware vSphere Storage APIs
- Storage vMotion Requirements and Limitations

Process Overview

The recover task completes the following steps:

1. A new physical instance (VMDK) is extracted from the Snapshot and stored temporarily in the View (datastore) on the Cohesity cluster.
2. The new VMDK is migrated from the View to the specified datastore in the vCenter using Cohesity's implementation of vSphere Storage vMotion.
3. The temporary View (datastore) is deleted automatically once the Storage vMotion migration is completed.

After a successful recovery, the disks are attached to the VM. Depending on your environment, if the virtual disks were mapped to volumes, additional steps may be required to bring them online.

Note the following about recovering virtual disks:

- Support is currently limited to recovering VMware virtual disks.
- If the **Overwrite Original Disk** option is selected, the original disk is removed from the VM and deleted, and the backed-up Cohesity disk is attached. If the recovery fails during the overwrite, the original disk will not be available, but you can retry the recovery to restore the disks.
- If a virtual disk gets deleted after it is backed up, the disk must be recovered as a new disk.
- If one or more disks will be overwritten during recovery, the target VM will automatically be powered off prior to the recovery and can optionally be powered on automatically after the recovery. Cohesity recommends suspending activity on the VM prior to performing the disk recovery.
- If a Windows VM includes volumes created from a storage pool (Microsoft Storage spaces), VMDK recovery is not supported.

Recover Virtual Disks to the Original Location

If you are recovering the virtual disk to the original VM, you can overwrite the disk in its original datastore or attach it as a new disk.

To recover virtual disks to the original server:

1. Navigate to **Data Protection > Recoveries**.
2. Click on **Recover** located at the top right of the page and then select **Virtual Machines > Virtual Disks**.

   The Virtual Disks page appears.
3. Search for the VM whose virtual disks you want to recover by entering characters of the VM name, Protection Group name, or by specifying the wildcard character *.

   A list of VMs displays.

   You can optionally filter the search results by source, Protection Group, Storage Domain, server type, or date.
4. From the list of search results, select the VM whose virtual disks you want to recover.

By default, the latest snapshot is selected for recovery.

5. To recover from a different snapshot, mouse over the snapshot from the selected list, and then click the **edit** icon.

   The Edit recovery point for <VM_name> page appears.

   > **Note:** In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

   By default, the option to select the snapshot is displayed in the **Timeline** mode. You can also choose to view the option in List mode by clicking the **List** tab in the top-right corner of the page.

   - To select a snapshot from the **Timeline** mode:
     a. From the **Choose a date** drop-down, select a date.

        The snapshots available on the selected date are displayed in blue dots on the timeline bar.

     b. Select the snapshot to be recovered by clicking the corresponding blue dot.

        For CDP, select the point-in-time restore. You can specify the exact point-in-time recovery by sliding the timeline bar.

     c. By default, the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.

     d. Click **Select Recovery Point** and then go to step 6.
   - To select a snapshot from the **List** mode:
     a. Select the **List** tab from the top-right corner of the Edit recovery point for <VM_name> page.

        By default, the page displays the snapshots available in the last one month.

     b. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.

     c. Select the snapshots to be recovered.

     d. By default, the snapshot is recovered from the local Cohesity cluster. You can also select snapshots archived to the cloud by clicking the cloud (

) icon if available in the **Location** option.

e. Click **Select Recovery Point** and then go to step 6.

6. Click **Next: Recover Options**.
7. From the **Recover To** options, select **Original Location** to recover the virtual disks to the original location.
8. Provide the following information as required for **Disk Selection**:

Field	Description	Action to performed
Source Disks	List of virtual disks to recover	From the list, select the virtual disks to recover.
Mapped Volumes(s)	Indicates whether the virtual disks are mapped to the volumes.	None
Size	Indicates the size of the virtual disks.	None
Recovery Type	Option to recover the virtual disks.	Select one of the following options. • **Overwrite Original Disk**–Specify this option to recover the virtual disks to their original datastores using the same disk ID and controller information. The original disk is overwritten. The original virtual disk is deleted prior to the recovery process. Therefore, a recovery failure or cancelation of recovery will also lead to the loss of the original virtual disk. • **Recover as a New Disk**–Specify this option to recover the virtual disk as a new disk (without overwriting the original disk).
Datastore	The datastore to store the virtual disks extracted from the Snapshots.	Select a datastore to store the virtual disks extracted from the snapshots.

9. Optional. Edit the default settings of the following **Recovery options**:
   - **Power State**: Enable the **Power off VMs before restore** option to ensure that the VM is powered off before the virtual disks are recovered. Enable the

Power on VMs after restore option to power on the VM after the virtual disks are recovered.

- **Task Name**: Change the default name of the recovery task.

10. Click **Start Recovery**.

The recovery process is initiated. You can monitor the recovery task from the Recoveries page.

Recover Virtual Disks to a New Location

If recovering the virtual disk to a different VM, the disk is attached as a new disk in the datastore you select.

To recover virtual disks to a new server:

1. Navigate to **Data Protection > Recoveries**.
2. Click on **Recover** located at the top right of the page and then select **Virtual Machines > Virtual Disks**.

   The Virtual Disks page appears.
3. Search for the VM whose virtual disks you want to recover by entering characters of the VM name, Protection Group name, or by specifying the wildcard character *.

   A list of VMs displays.

   You can optionally filter the search results by source, Protection Group, Storage Domain, server type, or date.
4. From the list of search results, select the VM whose virtual disks you want to recover.

   By default, the latest snapshot is selected for recovery.
5. To recover from a different snapshot, mouse over the snapshot from the selected list, and then click the **edit** icon.

   The Edit recovery point for <VM_name> page appears.

   > **Note:** In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

   By default, the option to select the snapshot is displayed in the **Timeline** mode. You can also choose to view the option in List mode by clicking the **List** tab in the top-right corner of the page.

- To select a snapshot from the **Timeline** mode:
  a. From the **Choose a date** drop-down, select a date.

     The snapshots available on the selected date are displayed in blue dots on the timeline bar.

  b. Select the snapshot to be recovered by clicking the corresponding blue dot.

     For CDP, select the point-in-time restore. You can specify the exact point-in-time recovery by sliding the timeline bar.

  c. By default, the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.

  d. Click **Select Recovery Point** and then go to step 6.
- To select a snapshot from the **List** mode:
  a. Select the **List** tab from the top-right corner of the Edit recovery point for <VM_name> page.

     By default, the page displays the snapshots available in the last one month.

  b. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.

  c. Select the snapshots to be recovered.

  d. By default, the snapshot is recovered from the local Cohesity cluster. You can also select snapshots archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.

  e. Click **Select Recovery Point** and then go to step 6.

6. Click **Next: Recover Options**.
7. From the **Recover To** options, select **New Location** to recover the virtual disks to an alternate location.
8. From the **Source** drop-down menu, select a registered source having the VM on to which you want to recover the virtual disks. You can also register a new source by clicking **Register Source** from the **Source** drop-down menu.
9. From the **Target** drop-down menu, select a VM on which you want to recover the disk.
10. Provide the following information as required for **Disk Selection**:

Field	Description	Action to performed
Source Disks	List of virtual disks to recover	From the list, select the virtual disks to recover.
Mapped Volumes(s)	Indicates whether the virtual disks are mapped to the volumes.	None
Size	Indicates the size of the virtual disks.	None
Recovery Type	Option to recover the virtual disks.	Select **Recover as a New Disk** from the drop-down list and to recover the virtual disk as a new disk.
Datastore	The datastore to store the virtual disks extracted from the Snapshots.	Select a datastore to store the virtual disks extracted from the snapshots.

11. Optional. Edit the default settings of the following **Recovery options**:
    - **Power State**: Enable the **Power off VMs before restore** option to ensure that the VM is powered off before the virtual disks are recovered. Enable the **Power on VMs after restore** option to power on the VM after the virtual disks are recovered.
    - **Task Name**: Change the default name of the recovery task.
12. Click **Recover**.

The recovery process is initiated. You can monitor the recovery task from the Recoveries page.

Teardown of Failed VMDK Recovery Tasks

Cohesity supports the teardown of failed VMDK recovery tasks, allowing you to clean up residual resources left behind when these tasks do not complete successfully.

> **Note:** Tearing down a successful recovery is not allowed.

To teardown a failed VMDK recovery task that has left behind certain resources:

1. Navigate to **Data Protection > Recoveries**.
2. Locate the VMDK Recovery task you wish to terminate.

   To teardown a recovery task, Click the **Actions** menu (⋮) of that task and select **Teardown**.

   > **Note:** The Teardown option is available only if there are objects to destroy.

3. When prompted to confirm the teardown, click **Teardown**.

   A confirmation dialog appears with a warning stating that the restored VMs with data on the Cohesity mounted NFS datastore will be removed.

4. Click **Confirm**.

   The teardown process is initiated, and the Cohesity cluster performs the following steps:

   1. VMDKs hosted on Cohesity datastore are detached from the target VM.
   2. The Cohesity datastore is unmounted from the ESXi host.
   3. The underlying restore view is deleted.
   4. The user interface for Cohesity will show the current status of the teardown task.
   5. The teardown status of each VMDK is displayed under the "Instant Recovery" column.
   6. "Destroyed" status indicates successful completion of the teardown process.

   > **Note:**
   > - VMDKs that have been manually migrated to the target datastore will not be considered for teardown.
   > - The teardown task can be retried in case of any issues.

Instant Volume Mount

Instant volume mounting is supported for virtual and physical environments. This feature allows the selected backup volumes to be made available at the target location where you can then complete the desired operations. Instant Volume Mount is available for backed-up volumes, whether they are stored locally on the Cohesity cluster or archived to a registered external target. Use cases include granular recovery of Microsoft Exchange, SQL and SharePoint data.

You can mount the volume to its original location or to a new location. For more information, see:

- Instant Volume Mount to the Original Location
- Instant Volume Mount to a New Location

The following table lists the sources and the guest operating systems on which instant volume mounting is supported.

Source	Support for IVM on guest OS	
	Windows	Linux
AHV	No	No
VMware	Yes	Yes
HyperV	Yes	No
Physical*	Yes	Yes

*Supported only for block-based backups.

Prerequisites

- VMware licensing is required for all VMware products to facilitate processes such as backup or recovery with Cohesity. For more information on the VMware license, see the following VMware articles:
  - VMware vSphere Compute Virtualization
  - Storage vMotion Requirements and Limitations
- The default path of the recovered file or instantly mounted volume is *<Cluster_IP_address>/<Cloned view name>\<PATH>*.

  To access this location, both the target and the Cohesity cluster must be in the same AD domain.

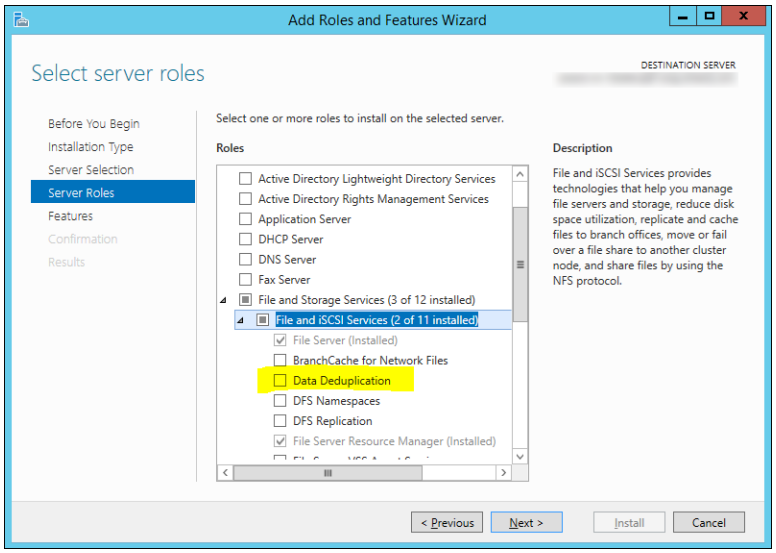
Considerations

- When recovering a file or instantly mounting a volume from a Windows VM or Physical Server Backup Source that has Windows deduplication installed and enabled for one or more volumes, you must choose a target machine that also has Windows deduplication installed (it does not have to be enabled for any volume). (However, this rule does not apply to Nutanix AHV VMs. If AHV VMs are enabled with Windows deduplication, the only supported recovery option is full VM recovery.)

  If the target does not have Windows deduplication installed:
  - File level recovery will fail with the error message: "Windows Data Deduplication role is not installed on the target machine. Retry recovery after installing the Windows Data Deduplication role on the target machine."
  - Instant volume mounting will fail with the error message: "Windows Data Deduplication role is not installed on the target machine. Retry recovery after installing the Windows Data Deduplication role on the target machine."

To determine if Windows deduplication is installed on the Source or target machine, follow the steps given below:

1. Open **Server Manager**.
2. Select **Roles and Features > File and Storage Services > File and iSCSI Services**.
3. Select the **Data Deduplication** check box, if necessary.
4. Click **Next** until the **Install** button is enabled and then click **Install**.



- Tearing down a cloned database or instant volume mount deletes the mounted volumes. Any new or modified data on these volumes will be deleted along with the volumes, so ensure you back up any important data before teardown.
- Review the following considerations when performing instant volume mount to Hyper-V VMs:
    - Only Windows VMs are supported.
    - Dynamic Disks (LDM and LVM) are not supported.
    - The Bring Disks Online option requires the following:
        - VM must be part of Active Directory, the VM and the Hyper-V host must be in the same AD.
        - Users must execute "winrm quickconfig" to enable winrm on the target VM and remote powershell must be enabled from Hyper-V host to VM.
    - Instant volume mount and file level recovery from Gen 1 to Gen 2 type VMs is not supported.
    - If SCVMM is unregistered from the Cohesity cluster, ensure you tear down all instant volume mounts. Not tearing them down can prevent the VM from being backed up when the source is registered with a different Cohesity cluster.

    - Instant volume mounting Hyper-V 2012 R2 VMs without a SCSI controller is not supported. This is because Hyper-V disallows dynamically adding a SCSI controller, which is required to add the virtual disks.
    - On 2012 R2 VMs, if an instant volume mount disk is attached during a Protection Group, that snapshot cannot be application-consistent. If this occurs, the event viewer may contain a VSS-catastrophic error or similar message.
- Instant Volume Mount for NetApp stub file is not supported.
- You cannot instantly mount a volume from a VM to a physical server, and vice-versa.
- Before you can instantly mount a volume, a Snapshot of the Object you want to recover must exist.
- Cohesity does not currently provide support for protecting the vSphere Clustering Service (vCLS) using temporary NFS datastores. For optimal results, we recommend configuring a VMware vSphere® Distributed Resource Scheduler (DRS) rule to ensure that vCLS is provisioned only on the datastores that you have added.
- If a Windows VM includes volumes created from a storage pool (Microsoft Storage spaces), Instant Volume Mount is not supported.

Troubleshooting

This section provides troubleshooting information for issues that might occur during IVM recovery.

Authentication Failures

Error Message

The IVM recovery fails due to an authentication failure and displays the following error:

"The specified network password is not correct".

Possible Root Cause

The cluster joined the AD but the Windows host has not joined the AD.

Solution

- Create a local user on the Cohesity cluster and use the local user to access the SMB share. To create a local user on the Cohesity cluster, contact Cohesity Support.

or

- Disable SMB Authentication on the Cohesity cluster. Perform the following steps to disable SMB Authentication:
    1. Log in to the Cohesity cluster.
    2. Select **SmartFiles** > **Views** and click the **Global Settings** tab.
    3. Toggle off the **SMB Authentication** setting.

Instant Volume Mount to the Original Location

To perform instant volume mounting to the original server:

1. Navigate to **Data Protection > Recoveries**.
2. Click on **Recover** located at the top right of the page and then select **Virtual Machines > Instant Volume Mount**.

   The Instant Volume Mount page appears.
3. Search for the server that contains the data you want to mount by entering characters of the server name or by specifying the wildcard character *.

   A list of servers displays.

   You can optionally filter the search results by source, Protection Group, Storage Domain, server type, or date.
4. From the list of search results, select the server that contains the data you want to mount.

   By default, the latest snapshot is selected for recovery.
5. To recover from a different snapshot, mouse over the snapshot from the selected list, and then click the **edit** icon.

   The Edit recovery point for <VM_name> page appears.

   > **Note:** In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

   By default, the option to select the snapshot is displayed in the **Timeline** mode. You can also choose to view the option in List mode by clicking the **List** tab in the top-right corner of the page.

   - To select a snapshot from the **Timeline** mode:
     a. From the **Choose a date** drop-down, select a date.

        The snapshots available on the selected date are displayed in blue dots on the timeline bar.

     b. Select the snapshot to be recovered by clicking the corresponding blue dot.

        For CDP, select the point-in-time restore. You can specify the exact point-in-time recovery by sliding the timeline bar.

     c. By default, the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.

     d. Click **Select Recovery Point** and then go to step 6.

- To select a snapshot from the **List** mode:
  a. Select the **List** tab from the top-right corner of the Edit recovery point for <VM_name> page.

     By default, the page displays the snapshots available in the last one month.
  b. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.
  c. Select the snapshots to be recovered.
  d. By default, the snapshot is recovered from the local Cohesity cluster. You can also select snapshots archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.
  e. Click **Select Recovery Point** and then go to step 6.

6. Click **Next: Recover Options**.
7. From the **Select Volume(s)** option, perform one of the following actions:
   - Enable **Select all Volumes** to recover all the volumes of the selected server
   - From the **Select one or more options** drop-down list, select the individual volumes you want to recover.

   After volumes are mounted, they may be displayed as volumes different from their source volume. For example, D: volume may be mounted as X: volume.
8. From the **Recover To** options, select **Original Location** to recover the volume to the original location.
9. (Applies only for VMs) With the **Ensure Disks are Online** option enabled, select one of the following options to deploy Cohesity Agent on the target VM.

   > **Note:** For Linux target VMs, you cannot disable this option. For Window target VMs, you can disable this option.

   - **Auto Deploy Cohesity Agent:** Select this option and provide the username and password of the target VM to automatically deploy the Cohesity Agent on the target VM.
   - **Use Existing Cohesity Agent**: Select this option to use the existing Cohesity Agent deployed on the target VM

     The following table provides information on how the volume is mounted when the **Ensure Disks are Online** option is enabled and disabled.

Environment	Ensure Disks are Online option is Turned On	Ensure Disks are Online option is Turned Off
VMware	After the VMDKs are attached to the VM, Cohesity cluster explicitly mounts the volume. To mount the volume to the VM, Cohesity cluster requires the built-in administrator credentials, such as the local system administrator of the VM. It uses the credentials provided in the **Mount Target Credentials** fields for mounting the volume. If the UAC property "Admin Approval mode" is disabled, then you can specify any user who is part of the system's Local Administrator group. • **Note:** VMware Tools are required to bring the disks online, but mounting is still supported without VMware Tools.	The VMDKs are just attached to the VM and the VM may bring the disks online. Cohesity cluster does not explicitly bring the volumes online within the VM. In this case, the Target Volume displays as "n/a" after mounting the volume succeeds.
Standalone Hyper-V host or cluster	You must add the guest VM to the reverse lookup zone in the DNS server to complete the recovery successfully.	Not Applicable

10. Optional. Edit the default settings of the following **Recovery Options**:
    - **Cluster Interface**: By default, the **Auto Select** option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the **Interface Group** drop-down.
    - **Task Name**: Change the default name of the recover task.
11. Click **Start Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

> **Note:** If a drive letter was provided as the file path for a file-based backup of NTFS volumes, the default attributes for drive letters were preserved, so hidden drives remain hidden. They are still recovered and can be accessed by providing the full path in the search bar.

Instant Volume Mount to a New Location

To perform instant volume mounting to a location:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click on **Recover** located at the top right of the page and then select **Virtual Machines > Instant Volume Mount**.

   The Instant Volume Mount page appears.
3. Search for the server that contains the data you want to mount by entering characters of the server name or by specifying the wildcard character *.

   A list of servers displays.

   You can optionally filter the search results by source, Protection Group, Storage Domain, server type, or date.
4. From the list of search results, select the server that contains the data you want to mount.

   By default, the latest snapshot is selected for recovery.
5. To recover from a different snapshot, mouse over the snapshot from the selected list, and then click the **edit** icon.

   The Edit recovery point for <VM_name> page appears.

   > **Note:** In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

   By default, the option to select the snapshot is displayed in the **Timeline** mode. You can also choose to view the option in List mode by clicking the **List** tab in the top-right corner of the page.

   - To select a snapshot from the **Timeline** mode:
     a. From the **Choose a date** drop-down, select a date.

        The snapshots available on the selected date are displayed in blue dots on the timeline bar.

     b. Select the snapshot to be recovered by clicking the corresponding blue dot.

        For CDP, select the point-in-time restore. You can specify the exact point-in-time recovery by sliding the timeline bar.

     c. By default, the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud (

) icon if available in the **Location** option.

d. Click **Select Recovery Point** and then go to step 6.

- To select a snapshot from the **List** mode:

a. Select the **List** tab from the top-right corner of the Edit recovery point for <VM_name> page.

By default, the page displays the snapshots available in the last one month.

b. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.

c. Select the snapshots to be recovered.

d. By default, the snapshot is recovered from the local Cohesity cluster. You can also select snapshots archived to the cloud by clicking the cloud (

) icon if available in the **Location** option.

e. Click **Select Recovery Point** and then go to step 6.

6. Click **Next: Recover Options**.
7. From the **Select Volume(s)** option, perform one of the following actions:
   - Enable **Select all Volumes** to recover all the volumes of the selected server
   - From the **Select one or more options** drop-down list, select the individual volumes you want to recover.

   After volumes are mounted, they may be displayed as volumes different from their source volume. For example, D: volume may be mounted as X: volume.
8. From the **Recover To** options, select **New Location** to recover the volume to a new location.
9. From the **Source** drop-down menu, select a registered source having the server to which you want to recover the volume. You can also register a new source by clicking **Register Source** from the **Registered Source** drop-down menu.
10. From the **Target** drop-down menu, select a physical server or VM to which the volume will be mounted.

> **Note:** To mount to a physical server, the server must already have the Cohesity agent installed and registered with the Cohesity cluster. If not, the server will not be available as a mount target.

11. (Applies only for VMs) With the **Ensure Disks are Online** option enabled, select one of the following options to deploy Cohesity Agent on the target VM.

> **Note:** For Linux target VMs, you cannot disable this option. For Window target VMs, you can disable this option.

- **Auto Deploy Cohesity Agent:** Select this option and provide the username and password of the target VM to automatically deploy the Cohesity Agent on the target VM.
- **Use Existing Cohesity Agent**: Select this option to use the existing Cohesity Agent deployed on the target VM

The following table provides information on how the volume is mounted when the **Ensure Disks are Online** option is enabled and disabled.

Environment	Ensure Disks are Online option is Turned On	Ensure Disks are Online option is Turned Off
VMware	After the VMDKs are attached to the VM, Cohesity cluster explicitly mounts the volume. To mount the volume to the VM, Cohesity cluster requires the built-in administrator credentials, such as the local system administrator of the VM. It uses the credentials provided in the **Mount Target Credentials** fields for mounting the volume. If the UAC property "Admin Approval mode" is disabled, then you can specify any user who is part of the system's Local Administrator group. • **Note:** VMware Tools are required to bring the disks online, but mounting is still supported without VMware Tools.	The VMDKs are just attached to the VM and the VM may bring the disks online. Cohesity cluster does not explicitly bring the volumes online within the VM. In this case, the Target Volume displays as "n/a" after mounting the volume succeeds.
Standalone Hyper-V host or cluster	You must add the guest VM to the reverse lookup zone in the DNS server to complete the recovery successfully.	Not Applicable

12. Optional. Edit the default settings of the following **Recovery Options**:

- **Cluster Interface**: By default, the **Auto Select** option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the **Interface Group** drop-down.
- **Task Name**: Change the default name of the recover task.

13. Click **Start Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

> **Note:** If a drive letter was provided as the file path for a file-based backup of NTFS volumes, the default attributes for drive letters were preserved, so hidden drives remain hidden. They are still recovered and can be accessed by providing the full path in the search bar.

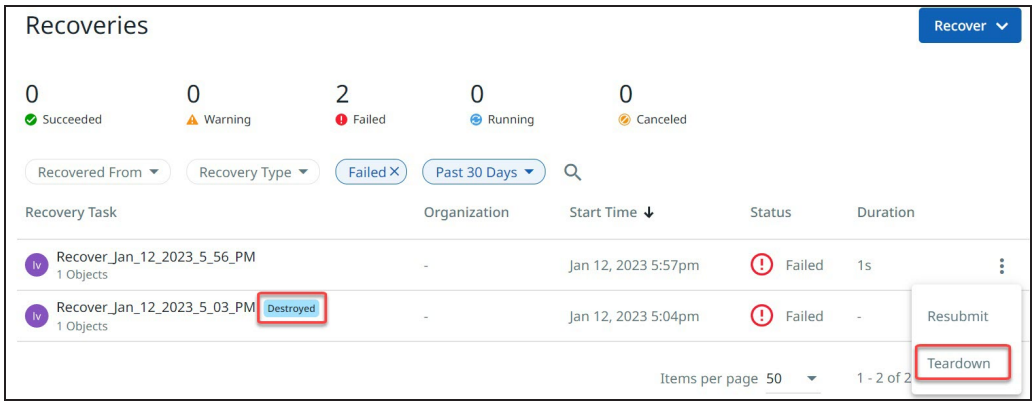
Teardown a Mounted Volume

Teardown a mounted volume when you are finished working with it.

To teardown a mounted volume:

1. Navigate to **Data Protection > Recoveries**.
2. To teardown a recovery task, click the Actions menu (⋮) of that task and select **Teardown**.

> **Note:** The Teardown option is available only if there are objects to destroy.



3. When prompted to confirm the teardown, click **Teardown**.

The teardown process is initiated, and the Cohesity cluster performs the following steps:

1. The virtual disk files (such as VMDK or VHD) are detached from the server.
2. The virtual disk files stored on the view are deleted.
3. The view is unmounted from the physical server or hypervisor host and then removed from the Cohesity cluster.

A "Destroyed" tag for a task on the Recoveries page indicates the completion of the teardown process.

Download a VMX File of a Virtual Machine

Cohesity supports the ability to download the VMX file of a Virtual Machine from the latest Snapshot of a Protection Group. A VMX file is the primary configuration file for a VMware Virtual Machine. Advanced VMware administrators may want to download and view the settings in a VMX file. In addition, they may want to download, modify and then upload a VMX file back to the original datastore to implement workarounds or global changes.

> **Warning:** Downloading a VMX file and uploading it directly back into your datastore without modifications can result in unusable and inaccessible VMs. This feature is for advanced VMware administrators who are experienced in directly editing VMX files and manually configuring VMs. Use at your own risk.

Before you download the VMX file of a Virtual Machine from the latest Snapshot of a Protection Group, you must create and run a Protection Group.

To download a VMX file:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover > Virtual Machines > VMs**.
3. Search for the Virtual Machine with the associated VMX file that you want to download. Enter characters of the VM name and a list of items displays. You can also optionally narrow the search results by specifying filter criteria, for example you can filter the search results by a specific Protection Group. You can optionally specify the wildcard character * in the search.
4. In the list, find the VM with the associated VMX file that you want to download, click the Actions Menu (⋮) and select **Download VMX file for MyVM**, where **MyVM** is the name of your VM.

If the Cohesity cluster locates the VMX file in the last Snapshot of the Protection Group, the VMX file is downloaded. (In some cases the VMX file may be unreachable when the Snapshot was originally created and therefore not saved and cannot be downloaded later. For example the Cohesity cluster cannot save a VMX file if the HTTPS port to the ESXi host was not open when the Snapshot was created.)

In addition, if the last Run of the Protection Group failed to back up the specified VM, the VMX file for that VM cannot be downloaded.

If you require downloading a VMX file from Snapshot besides the last Snapshot, contact Cohesity Support.

> **Warning:** Downloading a VMX file and uploading it directly back into your datastore without modifications can result in unusable and inaccessible VMs. This feature is for advanced VMware administrators who are experienced in directly editing VMX files and manually configuring VMs. Use at your own risk.

Azure VMware Solution (AVS)

Cohesity DataCloud makes it simple and affordable to back up, recover, and manage data in Azure VMware Solution (AVS). AVS combines VMware Software Defined Data Center (SDDC) with Microsoft Azure Cloud bare-metal infrastructure. For more information on AVS, see AVS documentation.

To protect your AVS SDDC using Cohesity DataCloud:

1. Ensure the requirements for AVS are met.
2. Register your AVS (SDDC) as a source in DataCloud.
3. Protect your AVS source.
4. Recover VMs, files and folders.

AVS Solution Requirements

Before registering your AVS source, ensure it meets user privileges and firewall port requirements.

User Privileges for VMware

To protect your AVS solution software-defined data center (SDDC), you need a user account with the vCenter Server Privileges.

Firewall Ports

Ensure the firewall ports are open to allow communication between the Cohesity clusters and the AVS environment.

Next> Register AVS Source.

Register AVS Source

To start protecting your vCenter in AVS, register it as a source on the Cohesity cluster.

Before you Begin

- Ensure that the requirements for the AVS source, such as user account role privileges and firewall ports, are met.

To begin with, register your AVS source with the Cohesity cluster.

To register AVS Solution with the Cohesity cluster:

1. Navigate to **Data Protection** > **Sources**.
2. Select **Register** > **Virtual Machines**.
3. Select a **Hypervisor Source Type** from the drop-down.
4. Enter the information for your source type.

   Click **Register**.

   The AVS source has been successfully registered and is now visible on the Sources page. For information on managing your AVS source, see Manage AVS Source.

   Next> you are now ready to protect your AVS.

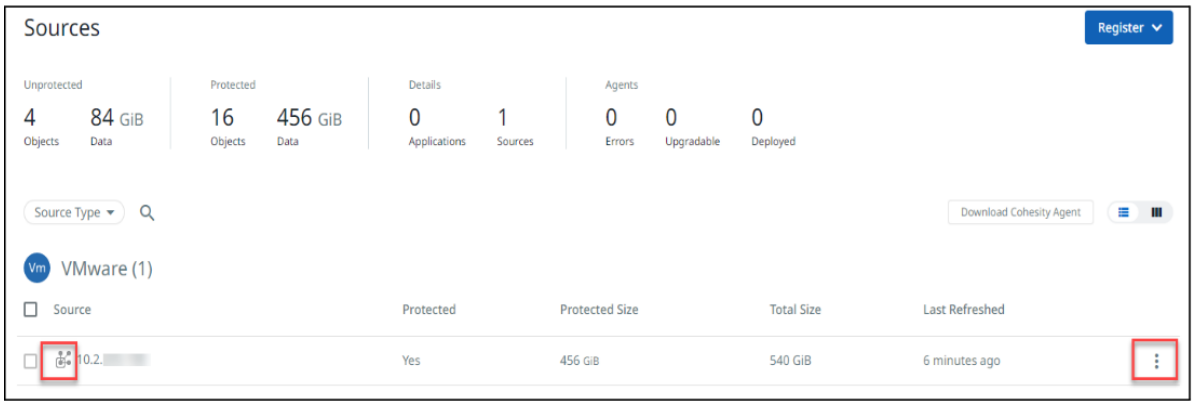
Manage AVS source

View the Registered AVS Source

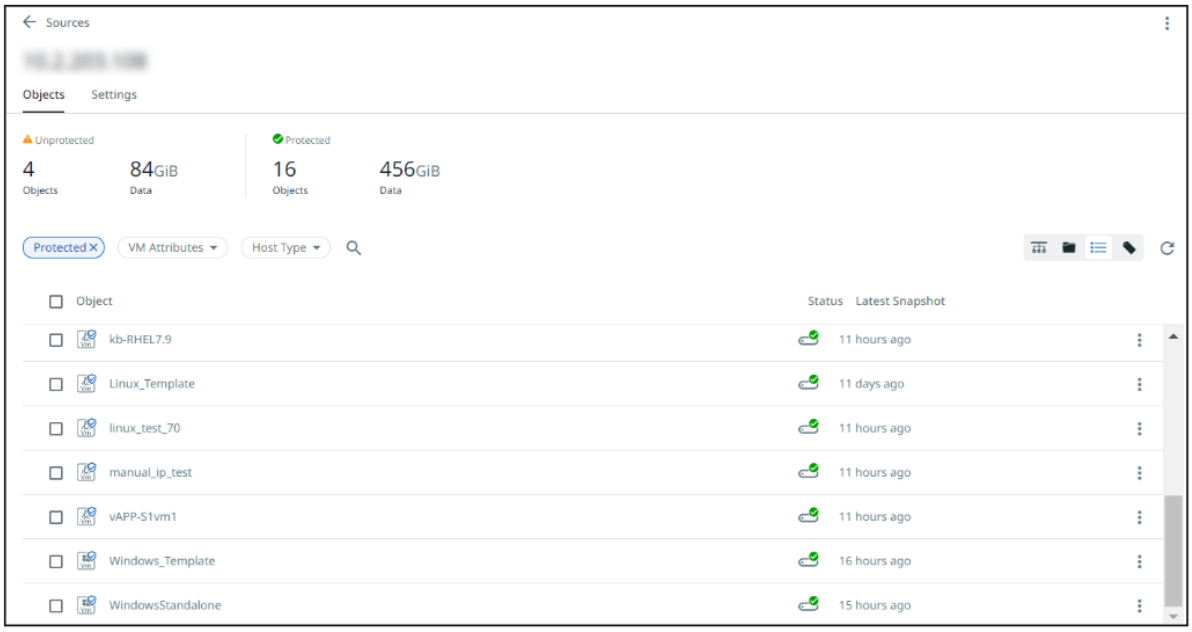
To view a registered AVS Source:

1. Navigate to **Data Protection** > **Source**.

   The Sources page displays all the sources registered with that Cohesity cluster. Click the Actions menu (⋮) of an AVS source to Edit, Refresh, or Unregister.



2. Click on a source to view the hierarchy of the data centers, clusters, ESXi hosts, folders, and VMs in that AVS source.



a. A selected check box ( ) indicates the object is selected to be backed up.

b. - Indicates a Linux VM.

c. - Indicates a Windows VM.

d. - Indicates a Windows or Linux template.

e. - Indicates a VM.

f. - A blue shield indicates a protected VM.

g. - Indicates an excluded object that is not protected. An ancestor of the object is auto-protected, but this object is excluded through inheritance (an ancestor is explicitly excluded).

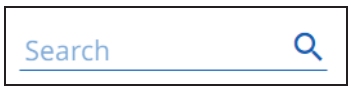
h. - Click to view the general information—type, server size, and version of the selected object.

3. Filters on the **Objects** tab help you display only the objects you want. The filtering options are:
   - **Protection Status**. Protected or Unprotected.
   - **VM Attributes**. VMware Tools Found, MS SQL Servers, vCenter Migrated.

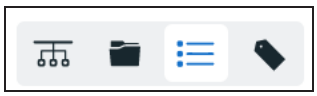
Cohesity Agent Installed or Cohesity Agent Not Installed.

Host Type. Linux or Windows.

4. Enter the name of an object in the **Search** box. You can even enter a partial name or an asterisk * wildcard. As you type, the objects that contain your search term appear.



Display modes can show the objects in a hierarchy or a flat list. The object hierarchy is automatically refreshed every four hours. To manually refresh the object hierarchy, select Data Protection > Sources, find the source in the list, and click the icon.



Update the AVS Source Configuration

You can update the AVS configuration you provided during the registration process with the latest configuration.

Refresh the AVS Source

You can refresh the AVS source configuration to fetch the latest changes. To refresh the AVS source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the AVS source and select **Refresh**.

Unregister AVS Source

To stop backing up your AVS source, unregister it from the Cohesity cluster. To unregister the AVS source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the AVS source and select **Unregister**.

Next > You are now ready to protect your AVS.

Protect AVS Source

After registering your AVS source, you can use Cohesity DataCloud to protect the VMs, files and folders in that source.

Backup AVS Source

Create a Protection Job for AVS objects. For more information, see Add or Edit a Protection Group for Virtual Servers.

Next > You are now ready to recover your AVS.

Recover AVS Source

After you protect your AVS source, you can recover VMs and files from your backups to their original or new location.

Recover AVS VMs to a New or Original Location

Recover AVS Files or Folders to a New or Original Location

Recover AVS VMs to a New or Original Location

You can recover the AVS VMs to the original (same location as the source) or a new location. After selecting the restore point, you can modify the storage domain and network. While recovering, you can either auto-deploy a Cohesity Agent, use an existing agent, or use VMware tools.

Recover AVS Files or Folders to a New or Original Location

Cohesity provides the ability to recover AVS files and folders from a snapshot created earlier by a Protection Group. Files and folders can be recovered to their original location (limitations apply to physical servers and specific operating systems) or to a newly specified location, which can be within the original source or a different one. You can choose to retain the recovered files' and folders' original (at the time of the backup) permissions and attributes. You can also download files and folders from selected snapshots that a Cohesity Protection Group created. For more information on recovering AVS files or folders to a new or original location, see Recover Files or Folders.

VMware vCloud Director (vCD)

VMware vCloud Director (vCD) allows Cloud Service providers to manage multiple tenants with data centers in different geographic locations and data stores that require different performance levels. Cloud Service Providers can use vCD to create organizations that are virtual administration units. Each organization can streamline services to multiple tenants.

Cohesity offers integration with vCD in two ways:

- Protect vCD resources from the Cohesity cluster
- Protect vCD resources from the vCD web console

Protect vCD resources from the Cohesity cluster

The Cohesity Data Cloud enables you to configure multi-tenant environments that can be securely isolated from each other. A single Cohesity cluster can service backups and workloads of multiple tenants with secure namespace isolation and per-tenant encryption.

For more information, see Protect vCD Resources from the Cohesity Cluster.

Protect vCD resources from the vCD web console

By installing the Cohesity vCD plugin, you can integrate Cohesity protection services with the vCD web console. When vCD is combined with Cohesity Data Cloud, you can provide backup and recovery for your vCD tenants.

Cohesity offers granular data protection by enabling you to protect the entire vCloud Director or just the organizations, VMs, and vApps within it. In addition to allowing cloud service providers or administrators to manage the organizations, Cohesity Data Cloud enables tenants to leverage data protection as self-service, lowering operating costs and strengthening tenant efficacy.

For more information, see Protect vCD resources using the Cohesity vCD Plugin.

Elastic Org VDC

Seamless use of Elastic Org VDCs with multiple resource pools is now supported for backup and recovery operations.

Key Concepts for vCD Protection

vCD

vCD allows Cloud Service providers to support multiple tenants with data centers across different geographic locations or data stores requiring different performance levels.

vCD Web Console

The vCD Web Console allows Service Providers to create organizations that are virtual administration units.

Organization

An organization is a collection of users, groups, and compute resources. System administrators create organizations while the organization administrations manage the users and groups in an organization. An organization is mapped to a vSphere data pool and can contain multiple data stores.

vApp

vApp is a deployment unit containing one or more VMs and their network configuration.

Protect vCD Resources from the Cohesity Cluster

Protecting the vCD resources from the Cohesity cluster involves the following steps:

1. Before protecting the vCD resources, ensure that you meet the requirements.
2. Setup vCD Protection for Tenants.
3. Backup the vCD objects
4. Recover the vCD sources
    - Recover VMs and vApps
    - Recover Files and Folders

Plan and Prepare for vCD Protection

Prerequisites

Cohesity cluster supports data protection and recovery of supported vCD resources. For supported versions of vCD, see the Support Matrix and Supported Software sections.

Minimum Permissions

Ensure that the vCD user account you use to manage and protect the vCD resources has adequate permissions. For details, see Minimum Permissions.

Considerations

- If a VMware vCloud Director (vCD) source sub-object is assigned to a tenant, the recovery of VMs and vApps to an alternate location will fail in the 6.2 release. When an entire vCD is registered within a tenant, then recovery to both the original location and alternate location is supported.
- If multiple VMs with different storage profiles are restored to the original location, the default storage policy of the organization VDC will be used for restoration purposes.
- Updating a vCD source to add a new vCenter instance requires entering credentials for all new and existing vCenter instances.

Backup and Recover Metadata for VMware vCD Objects

Cohesity supports backup and recovery of the metadata for VMware vCD objects such as vApps, VMs, and vApp templates. Metadata includes user-defined properties of the vCD objects whose values can be text, date, time, boolean, number, strings, badges, etc. You can recover metadata to the original location or a new location. The read-only metadata is not recovered while recovering vApps, VMs, and vApp templates. Cohesity also supports backup and recovery of metadata for Test & Dev clones.

Setup vCD Protection for Tenants

As a service provider, perform the following steps to set up data protection of vCD sources for your tenants:

1. **Register your vCD source**

   Register your vCD as a source with the Cohesity cluster. For details on how to do this, see Register and Manage a vCD Source.

2. **Enable Multi-Tenancy**

   Enable Organizations (Multitenancy) on Cluster by enabling the Organizations feature.

3. **Create and Map Organizations**

   To allow a vCD Organization user to protect their Organization's resources, create Cohesity Organizations.

   From the Cohesity cluster, you can also perform the following tasks to configure the organization:

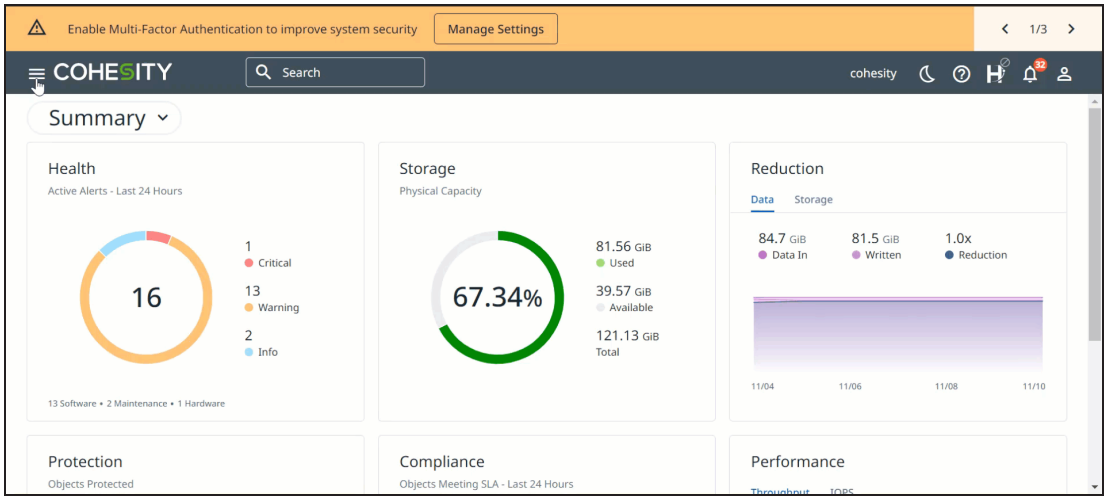
   a. Manage Access for Organizations
   b. Assign Users and Groups for Organizations
   c. Assign objects
   d. Impersonate an Organization

Register and Manage a vCD Source

Register vCD as a source

Once registered, its objects can be protected or backed up on the Cohesity cluster.

To register a source to back up:



1. On the **Dashboard** page in the Cohesity cluster, navigate to **Data Protection** > **Sources**.
2. Select **Register** > **Virtual Machines**.
3. From Source Type, select **VMware: vCloud Director**.

4. Enter the following vCD details:
   - **Hostname or IP Address**: Specify the hostname or IP address of the vCloud Director that contains the vCenters to protect.
   - **Password**: Enter the password for the specified user.
   - **Username**: Specify the local administrator user.
5. Click **Connect**.
6. Enter the following vCenter details:
   - **Username**: You must specify a VMware vCenter user with adequate privileges on the VMware vCenter server. The role assigned to the specified VMware vCenter user should include privileges to turn on Change Block Tracking (CBT) and other privileges required by the Cohesity cluster. For detailed information about the necessary privileges, see Create a Role with Necessary vCenter Server Privileges.

     When specifying a Windows Active Directory username, use the following format: *<domain>\<username>* or *<username>@domain*. For all other cases, just enter: *<username>*.
   - **Password**: Enter the password for the vCenter.
   - **Detect VM migration across vCenter to Preserve backup chain**: Toggle this option on if you want your Cohesity cluster to detect the VMs that are migrated from the current VMware vCenter to vCD.
7. Click **Register**.

After source registration finishes successfully, the new source is displayed on the **Sources** page.

View the Registered vCD Source

To view a registered vCD Source:

1. Navigate to **Data Protection** > **Source**.

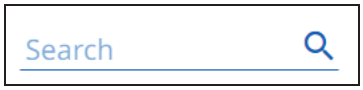
   The **Sources** page displays all the sources registered with that Cohesity cluster. The vCD ( ) icon indicates that the registered source is a vCD Source.

   Click the Actions menu (⋮) of that source to Edit, Refresh, or Unregister. From the Actions menu (⋮), you can also Deploy a Cohesity Agent and register Oracle, MS SQL, and Physical Servers.
2. Click on a source to view the hierarchy of the data centers, clusters, ESXi hosts, folders, VMs, vApps, and templates in that vCD source.
   - A selected check box ( ) indicates the object is selected to be backed up.
   - - Indicates a Linux VM.

- - Indicates a Windows VM.
- - Indicates a Windows or Linux template.
- - Indicates a vApp.
- - Indicates a VM
- - A blue shield indicates a protected VM.
- - Indicates an excluded object that is not protected. An ancestor of the object is auto-protected, but this object is excluded through inheritance (an ancestor is explicitly excluded).
- - Click to view the general information—type, server size, and version of the selected object.

3. Filters on the Objects tab help you display only the objects you want. The filtering options are:
   - **Protection Status**: Protected or Unprotected.
   - **VM Attributes**: VMware Tools Found, MS SQL Servers, vCenter Migrated, Cohesity Agent Installed or Cohesity Agent Not Installed.
   - **Host Type**: Linux or Windows.

4. Enter the name of an object in the **Search** box. You can even enter a partial name or an asterisk * wildcard. As you type, the objects that contain your search term appear.

5. Display modes can show the objects in a hierarchy or a flat list. The object hierarchy is automatically refreshed every four hours. To manually refresh the object hierarchy, select **Data Protection** > **Sources**, find the source in the list, and click the Refresh ( ) icon.

Update the vCD Source Configuration

You can update the vCD configuration you provided during the registration process with the latest configuration. To edit the vCD source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the **Actions** menu (⋮) next to the vCD source and select **Edit**.
3. In the **Edit Source** page, update the respective configurations.
4. Click **Save**.

Refresh the vCD Source

You can refresh the vCD source configuration to fetch the latest changes. To refresh the vCD source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the **Actions** menu (⋮) next to the vCD source and select **Refresh**.

Partial Refresh of the vCD Souce

You can perform a partial refresh of the vCD source using the API. A partial refresh is faster than a full source refresh. This enhancement allows you to selectively discover new VMs, vApps, Organizations, Org VDC, and vApp templates through the APIs into the vCD source, eliminating the need to wait for a full vCD refresh. You can refresh only the selected objects, such as specific VMs, vApps, Organizations, Org VDC, and vApp templates within the vCD source.

To do a partial refresh of the vCD source using the API:

Endpoint

```
PUT /v2/data-protect/sources/{sourceId}/objects
```

Parameters

Parameter	Type	Required	Description
sourceId	integer	Yes	The Entity ID of the data protection source

Finding the sourceId

You can find the sourceId from the UI by navigating to the Sources page and clicking your desired vCD source.

The URL will appear in the following format:

```
https://<Cluster IP>/protections/sources/details/{sourceId}/objects?environment=kVMware
```

The `{sourceId}` is the numeric ID you need for the API call. This value remains constant until the source is unregistered.

Headers

Header	Type	Required	Description
Content-Type	string	Yes	Must be `application/json`
Authorization	string	Yes	Bearer token for authentication

Request Body

The request body should include a JSON object with the following structure:

```
JSON
{
 "modificationRequests": [
 {
  "actionType": "Add",
  "vcdModifyParams": {
   "urn": "string"
 }
 }
 ]
 }
```

Request Body Schema

Field	Type	Required	Description
modificationRequests	array	Yes	Array of modification requests to process.
modificationRequests[].actionType	object	Yes	Action to perform. Valid values: `Add`.
modificationRequests []. vcdModifyParams	string	Yes	vCD-specific parameters for the modification.
modificationRequests []. vcdModifyParams.urn	string	Yes	The URN (Uniform Resource Name) of the VCD object to be discovered

vCD URN Format

VCD URNs follow the format:

```
`urn:vcloud:{type}:{uuid}`
```

Navigate to **Data Protection** > **Sources**.

The common VCD object types:

- `vapp` - Virtual Application
- `vm` - Virtual Machine
- `vapptemplate` - vApp Template
- `org` - Organization
- vdc` - Virtual Datacenter

To Perform a Partial Refresh:

1. **Authenticate**: Obtain Access Token using Authentication API:

```
POST /irisservices/api/v1/public/accessTokens
```

2. Get Source ID of the vCD source as described above.
3. Discovery request API .

```
PUT /v2/data-protect/sources/{sourceId}/objects
```

Example Requests

1. Discover a new VM.

```
curl --location --request PUT
'https://10.136.5.86/v2/data-protect/sources/1/objects' \
--header 'Content-Type: application/json' \

Response Status Code and Body

1. Success Response (207 Multi-Status).

```
JSON
{
 "results": [
 {
 "succeeded": true,
 "vcdResult": {
 "urn": "urn:vcloud:org:96228d49-a079-4b0e-a19f-c5e78acd65b1"
 }
 }
 ]
 }
```

2. Error Responses.
   a. 403 Forbidden

```
JSON
{
 "errorCode": "KInvalidRequest",
 "message": "Invalid inputs. Unknown input urn type"
 }
```

   a. 500 Internal Server Error

```
JSON
{
 "errorCode": "KInternalError",
 "message": "VM not found in VCD"
 }
```

Response Status Codes

Status Code	Description
207	Multi-Status - Request processed, check individual results,

Status Code	Description
403	Forbidden - Invalid request or unknown URN type.
500	Internal Server Error - vCD object not found or server error.

> **Note:**
> - You can include multiple objects in the **modificationRequests** array to process several modification requests in a single API call. The batch operations are not supported for vCD partial refresh.
> - **URN Validation**: The API verifies that the specified URN exists in the connected vCD environment before processing the request.
> - **Hierarchical Dependencies**: When you add a vApp, OrgVDC, or Organization, all descendant entities are automatically included.
> - **vCD Hierarchy**: The system adheres to the vCD organizational hierarchy (Organization → VDC → vApp/vAppTemplate → VM) when processing modifications.
> - Ensure that your authorization token has the required permissions to modify data protection sources and access vCD objects.

Authentication API

```
POST /irisservices/api/v1/public/accessTokens` - Obtain access token for authentication
```

Authentication API Documentation: Obtain Access Token

Endpoint: `POST /irisservices/api/v1/public/accessTokens`

Description: Authenticate with the system and obtain a bearer token for API access.

Headers

| Header | Type | Required | Description |

| Content-Type | string | Yes | Must be `application/json` |

Request Body

Field	Type	Required	Description
username	string	Yes	Username for authentication.
password	string	Yes	Password for authentication.
domain	string	No	Authentication domain (e.g., "LOCAL") .

Example Request

```
curl --location --request POST
 'https://10.136.5.86/irisservices/api/v1/public/accessTokens' \
 --header 'Content-Type: application/json' \
 --data '{
 "username": "admin",
 "password": "admin",
 "domain": "LOCAL"
 }'
```

Success Response (201 Created)

```
JSON
{
 "accessToken": "eyJhbGciOiJSUzI1NiIsInR5cCI6IkpXVCJ9...",
 "tokenType": "Bearer",
 "privileges": [
 "AD_LDAP_MODIFY"
 "AD_LDAP_VIEW",
 "AGENT_UPGRADE_MODIFY",
 "PROTECTION_MODIFY",
 "PROTECTION_VIEW",
 "..."
 ]
 }
```

Response Fields

Field	Type	Description
accessToken	string	JWT token to use in Authorization header.
tokenType	string	Type of token (Bearer).

Field	Type	Description
privileges	array	List of permissions granted to the authenticated user.

Usage

Use the returned `accessToken` in the Authorization header for subsequent API calls:

Authorization: Bearer <accessToken>.

This API allows you to perform a partial refresh to discover VMware vCloud Director (VCD) objects within a data protection source.

You can selectively refresh and add VCD entities such as vApps, VMs, VCD Orgs, and other VCD resources for backup and protection.

Unregister vCD Source

If you plan to stop taking the backup of your vCD source, you can unregister the vCD source from the Cohesity cluster. To unregister the vCD source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the **Actions** menu (⋮) next to the vCD source and select **Unregister**.

Access Management: Privileges for Service Providers and Tenants

A Service Provider can perform the following:

- Register a vCD protection source
- Enable multi-tenancy in the Cohesity cluster
- Create tenants
- Assign a vCD Organization to the tenant
- Create and assign Storage Domains to tenants
- Create and assign Protection Policy to tenants

A tenant can perform the following:

- Log in to the Cohesity cluster
- Change password
- Refresh the registered vCD protection source
- Create protection job for vCD sources
- Monitor the protection runs
- Recover vCD sources

For details on the privileges of the service provider admin and the organization administrator, see Privileges for Service Provider Admin and Organization Admin.

Create a Protection Group for vCD objects: Protect Organizations, vApps, and VMs

To add or edit a Protection Group:

1. If you are creating a Protection Group, click **Protect > Virtual Machines**.

   The New Protection page appears.

   When protecting vApp and vApp template, you must enable auto-protect. If you are not enabling auto-protect, then Cohesity cluster will only back up the underlying objects of the vApp and vApp template. When protecting vApp VMs, Cohesity recommends using one protection group exclusively for all VMs within a vApp and not mixing vApp VMs with other VMs.

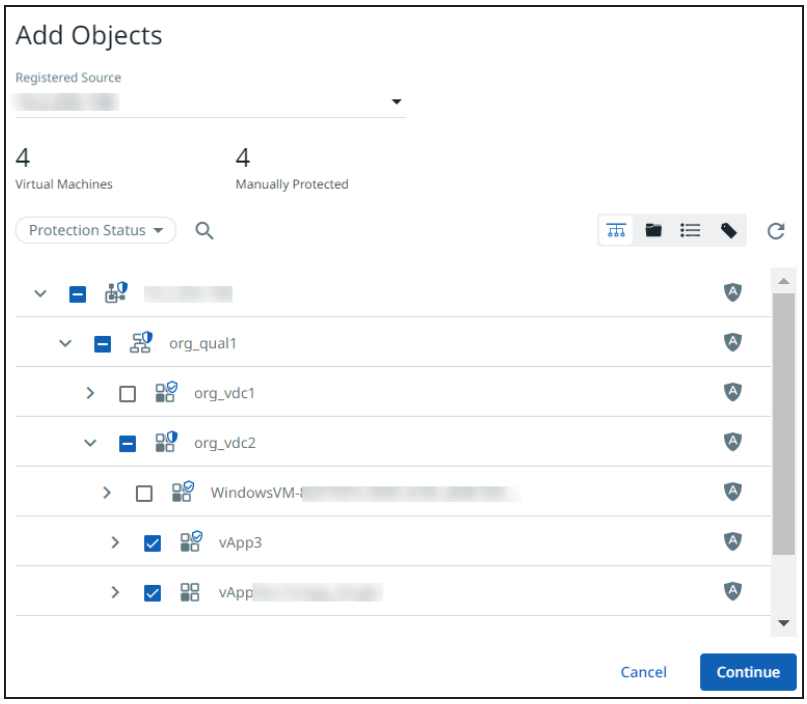
2. Navigate to **Data Protection** > **Protection** and do one of the following:

   - To create a Protection Group—Click **Protect** >**Virtual Machines**.

     The **New Protection** page appears.

     
   - To edit a Protection Group—Click the Actions menu (⋮) next to the displayed list of Protection Groups and select **Edit**.

3. Click **Add Objects**, and from the **Registered Source** drop-down list, select the Virtual server whose VMs you want to protect. You can also Register a new source with the Cohesity cluster by clicking the **Register Source** option.



> **Note:**
>
> - VMs that are on ESXi hosts which are not part of a cluster in vCenter are not supported.
> - Cohesity can exclude the backup of placeholder VMs in a VMware VMs Protection Group. This is an Early Access feature and you must contact Cohesity Support to enable this feature.

4. Click **Add Objects**, and from the **Registered Source** drop-down list, select the vCD source you want to protect. The hierarchy of the organizations, virtual data centers, VMs, vApps, and vApp templates in that vCD source are displayed. For more details, see View the Registered vCD Source. You can also Register a new source with the Cohesity cluster by clicking the **Register Source** option.
5. Click **Continue** to go back to the New Protection page.
6. Select **Protection Group** and in the **Name** field, enter a name from the Protection Group.
7. Select **Policy** and from the **Policy** drop-down list, select an existing protection policy or create a new one by selecting **New Policy**. For more information, see Create or Edit a Standard Policy.
8. Select **Storage Domain** and select an existing storage domain or create a new one by selecting **Add Storage Domain**.

9. Select one of the following options:
    - **Protect**: Select this option if you want to complete the Protection Group creation without changing or configuring any of the additional settings.
    - **More Options**: Select this option and go to step 12 if you want to change or configure any of the additional settings.
10. **Start Time:** Indicates when the Protection Group should run. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting.

    The default time zone is the browser's time zone. You can change the time zone by selecting a different time zone.
11. **SLA:** The service-level agreement (SLA) defines the expected time to complete either a full backup or incremental backup. The backup completion time depends on the Windows volume size on AD, objects changed between incremental backups, network speed, and other Protection Groups running on the Cohesity cluster.
    - **Incremental:** Enter the number of minutes you expect an incremental protection run to complete. An incremental backup captures only the differences (changed blocks) since the last protection run.
    - **Full:** Enter the number of minutes you expect a full backup protection run to complete. A full backup captures the entire object (all blocks).
12. **Pause Future Runs**: Enable this option to pause future protection runs for the Protection Group.
13. **End Date:** Optional. Toggle on and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
14. **QoS Policy:** Select an appropriate quality of service (QoS) policy.

    > **Note:** Cohesity recommends specifying **Backup HDD**, which is the default.

    - **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group.
    - **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups.
    - **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy.

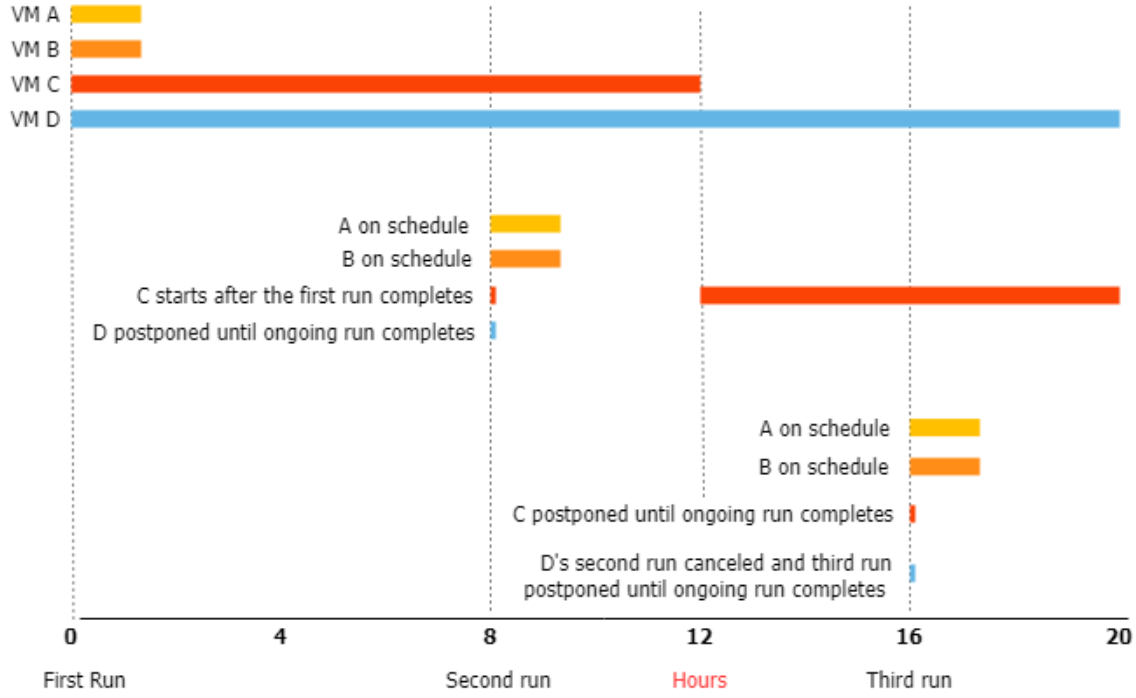
- **TestAndDev High:** The Cohesity cluster writes the data to an SSD drive for this Protection Group. The I/Os with this QoS policy are given higher priority compared to other QoS policies. Use this policy for workloads that require lower I/O latency.

15. **Defer Incomplete Objects in Concurrent Runs**: (Applies only to VMware VMs) A Protection Group can protect both small (for example, 1 GB VM) and large VMs (for example, 1 TB VM). While a short VM usually completes its protection runs within a few minutes, a large VM might take longer and still be running when it's time for the next run. By default, when it's time to start the next run, the Cohesity cluster checks for any in-progress protection run in that Protection Group. If there are in-progress protection runs (typically a large VM), the Cohesity cluster cancels the next run for that Protection Group, causing the small VMs to also miss that run and the SLA. When the **Defer Incomplete Objects in Concurrent Runs** option is enabled, if there is an in-progress protection run, the Cohesity cluster postpones the subsequent run only for that VM. The postponed run resumes as soon as the current run is completed. The protection runs of the remaining VMs (typically small VMs) in that Protection Group are not affected and run on schedule.

    For example, Protection Group PG1 runs every 8 hours to protect VMs A, B, and C. When the first protection run starts, A and B complete running in a few minutes. VM C, a large VM, needs 12 hours to complete running. If **Defer Incomplete Objects in Concurrent Runs** is disabled for PG1, when it's time for the second run, the Cohesity cluster cancels the second run in all three VMs because C is still in progress. However, the third run is completed in all three VMs. Because C is a large VM, A and B miss every alternate run.

    If **Defer Incomplete Objects in Concurrent Runs** is enabled for PG1, when it's time for the second run, the Cohesity cluster starts the second run in A and B but postpones the run in C. C's second run resumes when its first run completes. As a result, A, B, and C do not miss any scheduled runs.

If PG1 also protects VM D, another large VM, which needs 20 hours to complete, when it's time for the second run, the Cohesity cluster postpones D's second run. When it's time for the third run, because D's first run is still in progress, the Cohesity cluster cancels its second run but postpones its third run. D's next run will resume automatically when its ongoing run completes.



When the Cohesity cluster cancels the backup task of an object (such as D) in the Protection Group (such as PG1), the **Protection Group Details** page displays the following message at the corresponding protection run:

```
"Failed to back up some of the objects in the protection run as they are already backed in another protection run. ".
```

At the corresponding task (D's second backup task), the following message is displayed:

```
"cancelled the backup task of this object as it is already being backup up by another protection run."
```

Enabling the **Defer Incomplete Objects in Concurrent Runs** option helps you meet the defined SLAs, and improves the efficiency of the scheduled runs, thereby enhancing the backup performance.

> **Note: Defer Incomplete Objects in Concurrent Runs** can be enabled for runs with replication or archiving enabled.

16. **Leverage SAN Transport for Data Protection**: Cohesity supports SAN transport for Fibre Channel (FC) and iSCSI-based storage arrays and datastores that contain such storage arrays. Turn on this option to enable the SAN transport mode over FC or iSCSI for backing up VMware VMs to Cohesity cluster.

    > **Note:** Using the **Leverage SAN Transport for Data Protection** option with the **Leverage Storage Snapshots for Data Protection** option is not recommended.

    To use the SAN transport mode over FC, ensure the following pre-requirements:

    - Fibre channel is installed and zoned appropriately between the Cohesity cluster and the primary storage (Pure Flash Array and HPE Nimble Storage Array).
    - Volumes are mapped appropriately between the Cohesity cluster, ESXi hosts, and the primary storage.

    You can turn on the **Allow NBDSSL Transport Fallback** toggle if you do not want to enforce strict SAN transport mode for backing up VMware to the Cohesity cluster. With toggle enabled, the backup will not fail if the SAN transport is not available. If you disable this toggle, backup will fail if SAN transport mode is unavailable. NBDSSL encrypts all data passed over the TCP connection.

    > **Note:** Fallback to NBD is no longer supported if NBDSSL fails or is disabled.

    > **Note:** Ensure that the storage array connects to the primary environment (host) and the Cohesity node over the same protocol (FC on both ends or iSCSI on both ends). Cohesity does not support SAN transport for SAS (Serial Attached SCSI) based storage arrays.

17. **Exclude Disks**: (*Applies only to VMware VM*) By default, all the volumes on a selected server are protected. Toggle on to select disks to exclude for all VMs is this Protection Group. Provide the type of controller, bus number and unit number for each disk to exclude. Excluded disks are not backed up and are not recovered during VM recovery.

    > **Note:** If you exclude a disk that is part of a striped volume, the Cohesity cluster does not index the volume even if **Indexing** is toggled on for this Protection Group. You will not be able to search for or recover individual files in that volume.

18. **Exclude Physical RDM Volumes**: (*Applies only to VMware VM*) VMware vSphere Storage APIs cannot be used to snapshot physical compatibility RDM disks. Enable this option to allow the backup of VMs by excluding physical compatibility RDM disks. If you disable this option, the backup of VMs with physical compatibility RDM disks will fail. Excluded disks are not backed up and are not recovered during VM recovery. Cohesity recommends you to use agent-based backups to protect data on the physical RDM disks.

    > **Note:**
    > - VMware does not support taking the snapshot or backup of the VMs having RDM (physical and virtual) on Shared Bus.
    > - Backup of Virtual compatibility RDM disks is supported and does not depend on the **Exclude Physical RDM Volumes** toggle setting.

19. **App Consistent Backup**: Enable if you want the guest operating systems of all the VMs in the Protection Group to be quiesced before snapshots of these VMs are created. When this option is selected, the Cohesity cluster requests the VMware vSphere/AHV software to create a quiesced VM snapshot by invoking VMware Tools/Nutanix Guest Tools (installed on the guest operating systems of the VM). The VMware Tools/Nutanix Guest Tools requests that applications on the guest OS quiesce their state so that application-consistent snapshots can be created. Quiescing of VMs before capturing snapshots ensures the integrity of the data saved in the snapshots.

    If the Cohesity cluster fails to capture an app-consistent snapshot, you can use the **Take a Crash Consistent backup if unable to perform an App Consistent backup** option to capture a crash-consistent snapshot. The option is available only if the **App-Consistent backups option** is enabled.

    For example, the Cohesity cluster may fail to perform an app-consistent backup for the following reasons: when VMware Tools/Nutanix Guest Tools is not installed on the VM, the VM (VMware) is powered off, or if the VM cannot be quiesced. If the **Take a Crash Consistent backup if unable to perform an App Consistent backup** is enabled in that Cohesity cluster, a crash-consistent snapshot is captured.

    > **Note:** App-consistent backups apply to VMs only. For physical servers, Windows is app-consistent by default and Linux is crash-consistent. For more information, see Creating Application-Consistent Snapshots.

20. **Indexing:** Indexing is enabled by default and required for file recovery. The Cohesity cluster will scan all the files in the Protection Group and create an internal index that can be used later by a recover task to locate files by name.

    For information about customizing indexing, see Customize Indexing.

21. **Cloud Migration:** Enable this option to support the cloud migration of VMs between hypervisors (such as vCenter) servers and cloud services for failover and failback. Cohesity agents must be installed on the Windows VMs prior to backing up the snapshots on the on-premises Cohesity cluster. For more information, see Disaster Recovery of VMs Using AWS Cloud Edition.

    After enabling cloud migration, you can download the Cohesity Agent directly from the Cohesity Dashboard.
22. **Cancel Runs at Quiet Time Start**: Available only if the selected policy has at least one quiet time period. Toggle it on to specify that all currently executing protection runs should abort if a quiet time period specified for the Protection Group starts. By default this toggle is off, which means after a protection run starts, it continues to execute even when a quiet time period specified for this protection run starts. However, a new protection run will not start during a quiet time period.
23. **Alerts:** Optional. Select one or more of the following settings if you want alerts to be created for the following triggers:
    - **Success:** Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created.
    - **Failure:** Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created.
    - **SLA Violation:** Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created.

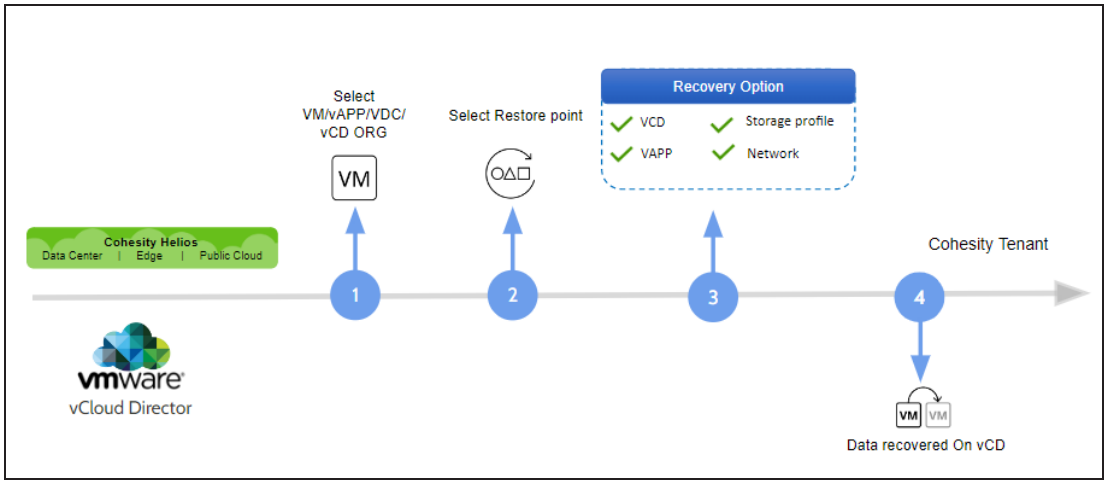
    For more information, see Alerts.
24. **Priority:** Select a priority for the Protection Group execution. Cohesity supports concurrent backups, but if the number of Protection Groups exceeds the ability to process them, those with **High** priority are given the highest priority to execute, **Medium** the second-highest priority, and **Low** the lowest priority.
25. **Email Recipients**: You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the Protection Group.

    > **Note:**
    > The connection to the SMTP Server must be enabled to send email notification. You can enable the SMTP Server connection in the configuration settings page (Cohesity UI > **Settings** > **Summary** > **Configure** > **Enable SMTP Server**).
26. **Description:** Optional. Click the plus sign and enter a description for the Protection Group.
27. Click **Protect**.

The Protection page is displayed and includes the new Protection Group.

> **Note:**
>
> - If a server is being backed up and files will also be recovered to that same server, the file recovery task starts after the backup is completed. The converse is also true; if files are being recovered to a server and that same server will be backed up, the backup starts after the file recovery is completed.
> - For a File-Based backup, the "Protected" and "Protected Size" fields on the source page for physical sources are updated after the source refresh.

Recover Organizations, vApps, and VMs to a New or Original Location

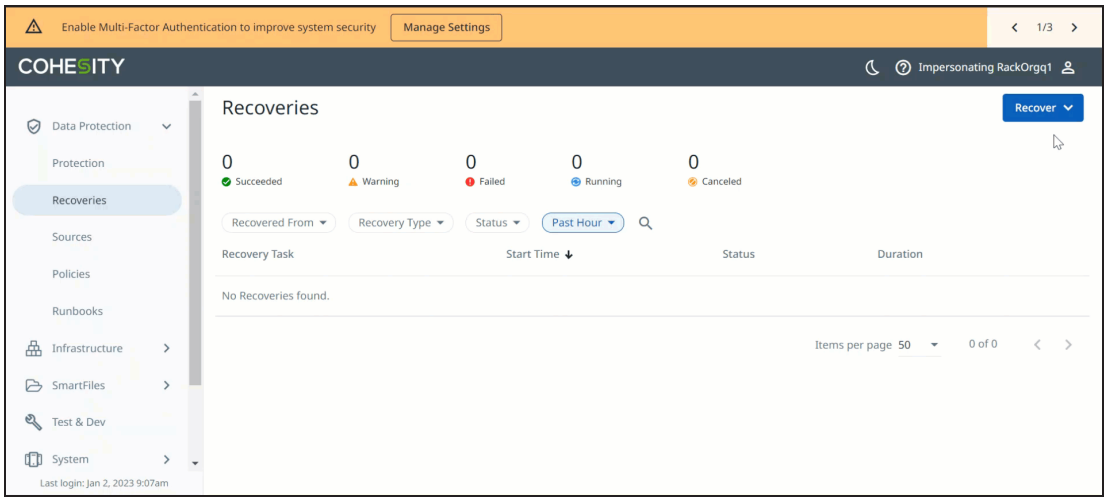


You can recover any object in vCD, such as an organization, data center, VM, vApp, and so on. You can recover the objects to the original (same location as the source) or a new location. After selecting the restore point, you can modify the storage domain and network. While recovering, you can either auto-deploy a Cohesity Agent, use an existing agent, or use VMware tools.

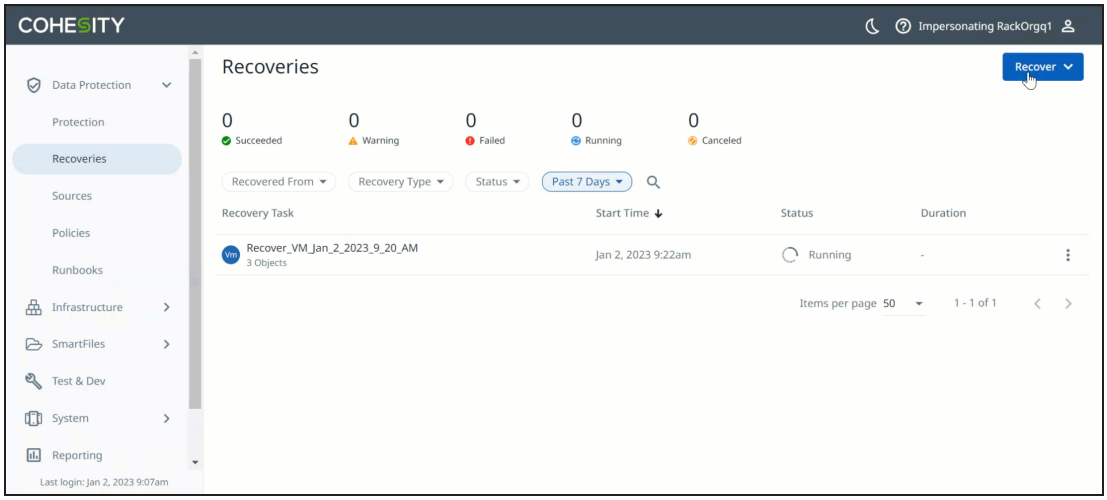
You recover the VM files (such as the VMDK files) to their original datastores and create new instances of the VMs in the original location in the original Source.

Before you can recover VMs to their original location, snapshots of those volumes must exist on the Cohesity cluster. To create Snapshots, create and run a Protection Group.

The following GIF illustrates the instant recovery of a Linux VM to a vApp in a new location:



The following GIF illustrates the copy recovery of a vAPP to the original location:



To recover VMs to its original location:

1. Navigate to **Data Protection > Recoveries**.
2. Click on **Recover** located at the top right of the page and then select **Virtual Machines > VMs**.

   The Virtual Machines page appears.
3. Search for a Protected Object (VM) or Protection Group that contains the snapshots to recover from by entering characters of the VM name, Protection Group name, or by specifying the wildcard character *.

   A list of VMs displays.

   You can optionally filter the search results by Source, Protection Group, Storage Domain, or Date.

4. From the list of search results, select one or more VMs or Protection Groups that contain the snapshots to recover.

   > **Note:**
   > - If you have selected a Protection Group, then all the VMs backed up in the latest protection run of this Protection Group will be selected for recovery and the option to select those VMs individually will be greyed out in the search result list.
   > - You can only select Protection Groups and VMs with snapshots stored in the same Storage Domain and belonging to the same source. Once you select a VM or Protection Group, the **Storage Domain** and **Source** filters will automatically get locked.

5. By default, the latest snapshot of the VMs is selected for recovery.

   > **Note:** In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

   To recover from a different snapshot, perform the following steps depending on the object selected:

   - From the **Selected** list, click the edit icon.
   - From the **Protection Run** drop-down, select the snapshot from which you want to recover the Organization. By default, the snapshot is recovered from the local Cohesity cluster.
   - Click **Select Recovery Point**.

6. Click **Next: Recover Options**.
7. On the **New Recovery** page, select **Original Location** to recover the VM to the original location or **New Location** to recover the organization or its entities to an alternate datastore and create new instances in the new location of a registered Source.
8. If you selected New Location in step 7, enter:
   - **Registered Source**: Select a registered vCloud Director source to which you plan to recover the VMs or vApp.
   - **Organization VDC**: Select the target organization VDC.

- **vApp**: Optional. Select the target vApp. If not specified, VMs are recovered as standalone VMs inside the target organization VDC.
- **Storage Profile**: Displays all the Storage Profiles assigned to that Organization. Select a target Storage Profile. The Cohesity cluster chooses any compliant datastore associated with the Storage Profile to store the VM files. If you are recovering multiple VMs, the Cohesity cluster chooses one or more datastores associated with the Storage Profile.
- **Catalog**: (Applies only for vApp template recovery) Select the catalog for the vApp template recovery.

9. If you selected, Original Location in Step 7 to recover the VMs, from the Existing VM Handling options list, choose how you want to handle the original VM when recovering to the original location:
    - **None**: Recovers the VM as a new VM and retains the original VM. In the Rename field available in the Recovery Options, you can specify the name of the recovered VM by adding prefix and/or suffix strings to the name of the original VM. By default, the recovered VM is named copy-<original_VM_name>.
    - **Overwrite Existing VM**: Recovers the VM by deleting the original VM. The recovered VM will have the original VM name. The original VM is deleted before the recovery. Therefore a recovery failure will also lead to the loss of the original VM.
    - **Attempt Differential Recovery**: Attempts to recover the VM by overwriting only the difference between the original VM and the snapshot selected for recovery. Any newly added data in the original VM is deleted.
        - This option is available only if you have selected **Overwrite Existing VM** and the **Recovery Type** option as **Copy Recovery**.
        - This option is disabled if you have selected **Leverage SAN Transport** under Recovery Options.
        - You can choose this option if there are no hardware configuration changes involved in the original VM.
        - If you want to reclaim free space for thin-provisioned disks, then Cohesity recommends not to attempt differential recovery and only perform **Overwrite Existing VM** recovery.
        - Differential recovery reduces the amount of data transfer in a recovery process. In the pulse log, you can view the amount of data transfer saved by selecting differential recovery.
        - If the original VM is not present or if the attempt to differential recovery fails, then Cohesity will perform **Overwrite Existing VM** recovery.

- In the original VM, if there are any newly added disks or any disks that are excluded during backup, then the recovered VM will not have these newly added disks and the disks excluded during backup. If you want to retain the newly added disks and the excluded disks in the original VM, contact Cohesity Support. However, Cohesity recommends you to choose the **Keep Existing VM** option if you want to retain the newly added disks and the excluded disks in the original VM while recovering.
- All the snapshots present on the original VM are consolidated and removed as part of differential recovery.

- **Keep Existing VM**: Recover the VM as a new VM with the original VM name. The original VM is retained and powered off. The original VM will be renamed to obsolete_<time_stamp><Orginal_VM_Name>.

10. Select the **Recovery Type**:

> **Note:**
> - You should have the `VirtualMachine.Config.Rename` permission on your user account to use this recovery option.
> - For VMware VMs, Virtual RDM disks are recovered as flat disks.

- **Instant Recovery**: The VMs will be instantly available after recovery in the target location. The data will be moved to the target storage later. The VM can be used in production during Instant Recovery when data is copied to the VM from the Cohesity cluster. In such scenarios the VM performance may be low as the Storage vMotion is still in progress.

  You can instantly recover vCloud Director VMs to their original location if all the vCloud Director VMs of the Protection Group belong to the same 'tag based placement rule' Storage profile.

  If you choose to keep the VM in a powered-off state when initiating instant recovery, wait for the Storage vMotion to complete before powering the VM on. Cohesity recommends that you choose Copy Recovery for powered-off VMs for better performance.

  > **Note:** For instant recovery to Standalone ESXi, the VM(s) will be available immediately in the target environment and will have to be moved to the target storage manually.

- **Copy Recovery**: The VMs will be available in the target location only after all the data is copied to the target storage from the source location. Once the

restore is complete, the VM will be available to use and the performance of the VM will be normal.

11. (Applies only for vApp template recovery) From the **Recover As** options, select how you want to recover the vApp template:
    - **vApp Template**: Select this option if you want to recover the vApp template as a vApp template itself.
    - **vApp**: Select this option if you want to recover the vApp template as a vApp.
12. Optional. Edit the default settings of the following **Recovery Options**:

Recovery Options	Description
Network	By default, the VMs that are to be recovered do not have a virtual Network Interface Card (vNIC) attached. Enable the **Attach** option to attach a virtual Network Interface Card (vNIC) to each VM that is to be recovered. With the **Attach** option enabled, each VM will connect to its original network and the following option is displayed: • **Start Connected**– Enable this option to connect to the original network when the VMs reboots. If this option is disabled, the VMs are not connected to any network on reboot. When recovering VMs to their original location, the original IP mode is restored to the respective NICs and the original IP address on each NIC is restored only if the original IP mode is set to “Static-Manual.” When recovering VMs to a new location, the original IP address and IP mode are not recovered to the NIC cards. By default, the IP mode is set to "none" and the IP address remains empty. Contact Cohesity support to recover the original IP addresses to a new location. While recovering VMs to the original location, there is no explicit control to preserve the MAC address. If the **Attach** option is enabled and the VM is configured to have a manual MAC address assigned at the time of backup, the same address will be recovered. If the VM is configured to have an automatic MAC address at the time of backup, the same setting will be applied to the recovered VM. For information on preserving MAC address when recovering VMs to a new location, see Recover VMs to a New Location.

Recovery Options	Description
Rename	(*Applies for VM recovery*) Add Prefix and/or Suffix strings to the names of the new VMs created by this task. For example you could specify Prefix `Test_ and Suffix _QA` to the VM name WinOS and when the VM is recovered, the new VM that is created is called `Test_WinOS_QA`.
Rename vApp/vApp Template	(*Applies for vApp or vApp template recovery*) Add prefix and/or suffix strings to the names of the new vApp or vApp template created by this task. For example, you could specify prefix `Test_ and Suffix _QA` to the vApp template name WinOS and when the vApp template is recovered, the new vApp template that is created is called `Test_WinOS_QA`.
Rename VMs within vApp	(*Applies vApp or vApp template recovery*) Add prefix and/or suffix strings to the names of the new VMs within vApp created by this task. For example, you could specify prefix `Test_ and Suffix _QA` to the VM name WinOS and when the VM within the vApp is recovered, the new VM that is created is called `Test_WinOS_QA`.
Power State	Disable **Power On** if you want the recovered VMs to remain powered off after they are created. If you recover VMs from a Storage Domain that has Cloud Tier enabled, Cohesity recommends leaving the VMs powered off. By default, the VMs are powered on after they are created.
Continue on Error	Enable **Continue recovery even if errors occur when recovering VMs** if you want the recovery task to continue even if errors occur when recovering the VMs. For example, if one of the VMs cannot be created, the Cohesity cluster will still attempt to create the other VMs. If this option is disabled, then the recovery task is discontinued if VM creation fails. However, if the VM creation succeeds, but VM storage migration fails, the task continues. By default this option is disabled.
Preserve VMs UUID	Select **Preserve VMs UUID** if you want to preserve the UUID for the recovered VMs. This is applicable only to Microsoft Hyper-V VMs.
Cluster Interface	By default, the **Auto Select** option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the **Interface Group** drop-down.
Task Name	Change the default name of the recovery task.

13. Click **Recover**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Recover Files or Folders in a vCD Source to a New or Original Location

To recover files and folders to the original server:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** located at the top right of the page and then select **Files or Folders**.

   The Recover Files or Folders page appears.
3. Select any one of the following options to search for the file or folder:
   - **Files and Folders**: Allows you to search and recover files using file or folder names from any backup available on the Cohesity cluster.
   - **Browse or Specify Path for Search**: Allows you to search and recover files using the name of the server or Protection Group from any backup available on the Cohesity cluster.

If you select...	Then...
Files and Folders	1. Enter characters of the file name, path, or by specifying the wildcard character *. A list of items displays. You can optionally filter the search results by object type, source, object, Protection Group, Storage Domain, files only, or folders only. > **Note:** When entering the path of a Windows VM, be sure to reformat as shown in the example: Instead of *C:\Windows\System32\winevt* use *C:/Windows/System32/winevt/*. 2. From the list of search results, select the required files or folders to recover. 3. By default, the latest snapshot is selected for recovery. To recover from a different snapshot: > **Note:** The option to change the recover point is not available if multiple items were selected for recovery. 1. From the selected list, mouse over the snapshot, and then click the **edit** icon.  The Edit recovery point page appears.  2. By default, only the snapshots that are indexed are displayed. To display all the available snapshots, toggle off the **Show Indexed Snapshots Only** option.

If you select...	Then...
	3. Select a date range and the snapshot point for recovery. 4. By default, the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud (icon) by clicking this icon if available in the **Location** option. 5. When recovering from an archive, consider the following points: • The archive (external target) must be currently registered for the task to succeed. • (*Applies only for cloud archive incremental with periodic full*) Provisioned Capacity Units (PCU) are required for all file-level recoveries. Provisioned capacity ensures that your retrieval capacity for expedited retrievals is available when needed. Each unit of capacity guarantees that at least three expedited retrievals can be performed every five minutes and provides up to 150 MB/s of retrieval throughput. 4. Click **Select Recovery Point** and go to step 4.

If you select...	Then...
Browse	1. Enter the full or partial server or Protection Group name. You can by specify the wildcard character *. You can also optionally filter the search results by object type, source, object, Protection Group, Storage Domain. 2. From the list of search results, select the object whose files or folders are to be recovered. 3. By default, the latest snapshot is selected for recovery. To recover from a different snapshot, click the snapshots drop-down in the top-left corner and select the snapshot you need. 4. **Browse on Indexed Data**: Toggle on this setting to browse the indexed data. It helps to speed up browsing of recovery data. By default, it only displays the files and folders that are indexed. Hidden files, folders, paths such as /usr, /var, /sys , /Windows, /ProgramData etc. are excluded from indexing. To display all the available files and folders, including hidden files and folders toggle off the **Browse on Indexed Data** setting. **Note:** • Changing the snapshot after selecting the items (files or folder) removes the selected items from the cart. • Enabling or disabling the **Browse on Indexed Data** option after selecting the items (files or folder) removes the selected items from the cart. • Deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process. 5. Browse to the file or folder that you want to recover by clicking a folder and subfolders. 6. Click **Save**. 7. After saving the selection, if you want to recover from a different snapshot or change the location from where the snapshot is recovered, perform the following steps: 1. From the selected list, mouse over the snapshot, and click the edit icon. 2. The Edit recovery point page appears. 3. By default, only the snapshots that are indexed are displayed. To display

If you select...	Then...
	all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. 4. Select a date range and the snapshot point for recovery. 5. By default, the snapshot is recovered from the local Cohesity cluster. You can also select a snapshot archived to the cloud (icon) by clicking this icon if available in the **Location** option. When recovering from an archive, consider the following points: • The archive (external target) must be currently registered for the task to succeed. • (*Applies only for cloud archive incremental with periodic full*) Provisioned Capacity Units (PCU) are required for all file-level recoveries. Provisioned capacity ensures that your retrieval capacity for expedited retrievals is available when needed. Each unit of capacity guarantees that at least three expedited retrievals can be performed every five minutes and provides up to 150 MB/s of retrieval throughput. 8. Click **Select Recovery Point** and go to step 4.

The Cohesity cluster attempts to index all files and folders to a drive on both Windows and Linux systems. If the Cohesity cluster is unable to find mount point information about files or directories, it indexes and displays these files and directories in the `lvol_N` directory, where `N` is a unique number such as `1`.

On Windows systems, if the Cohesity cluster finds the mount point information about files and directories, it indexes and displays these files and directories with a drive letter such as `C:`.

Linux LVM indexing supports the following LVM types only: Linear, Striped, Mirrored, Mirrored + Striped, Thin. On Linux systems, how files and directories are indexed and displayed is dependent on the conditions specified in the following table.

Server Type	Volume Type	

Linux Virtual Machine	Simple Volume	The Cohesity cluster detects mount points for entries in the `/etc/fstab` file with the following formats:
		`UUID=ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc /mnt ext4 auto 0`
		`UUID="ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc" /mnt ext4 auto 0`
		If the Cohesity cluster can detect a mount point, it indexes and displays files and directories in the volume with the mount point that was specified in the `/etc/fstab` file. For these example entries, files and directories are indexed with the `/mnt` mount path, such as `/mnt/example/test.txt`.
		If the Cohesity cluster cannot detect a mount point, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

Linux Virtual Machine	LVM Volume	The Cohesity cluster detects mount points for entries in the `/etc/fstab` file with the following formats:
		`UUID=ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc /mnt ext4 auto 0`
		`/dev/mapper/VG1-root /mnt ext4 defaults 1 1`
		`/dev/VG1/root /mnt ext4 defaults 1 1`
		If the Cohesity cluster can detect a mount point, it indexes and displays files and directories in the volume with the mount point specified in the `/etc/fstab` file. For these example entries, files and directories are indexed with the `/mnt` mount path, such as `/mnt/example/test.txt`.
		If the Cohesity cluster cannot detect a mount point, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

Linux Physical	LVM Volume	The Cohesity agent can only return mount data when the volume is mounted on the Linux physical Server. If the volume is mounted, the Cohesity cluster indexes and displays files and directories in the volume with the mount point such as `/mnt/example/test.txt`. If the volume is not mounted, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

4. From the **Recover To** drop-down:

- Select **Original Server** to recover the files or folders to the original server.
- Select **New Server** to recover the files or folders to a new location.

5. If you selected **New Server**, in the previous step, enter:
   - From the **Source** drop-down, select a registered server to which you want to recover the files and folders. You can also register a new source by clicking Register Source from the Source drop-down.
   - From the **Target** drop-down, select a VM to which the files and files are to be recovered.

     For recovering files and folders of a VMware VM, ensure that VMware Tools are installed and running on the target VM. The target list displayed includes only VMs with VMware Tools installed and running.
6. Once you select the files and folder to recover, select one of the following options:
   - **Next Recover Option**: If you select this option, then continue with the step 5 to configure the file recovery options.
   - **Download Files**: If you are recovering a single file, this option downloads the file to your browser's download folder. For all other selections, this creates a recover task. When the task is completed, from the Recoveries page, click the task name and then click **Download Files** to download the generated zip file.

     Character replacement explanation for : and \ in file and directory names in zip files

     If the original file or directory name contains a ':' , it is replaced with '_COLON_' in the archive.
     Example:
     - The original name is "a:b" then the archived name is "a_COLON_b"
     - The original name is "a:b:c" then the archived name is "a_COLON_b_COLON_c"

     If the original file or directory name contains a '\', it is replaced with '_BACK_SLASH_' in the archive.
     Example:
     - The original name is "x\y" then the archived name is "x_BACK_SLASH_y"
     - The original name is "x\y\z" then the archived name is "x_BACK_SLASH_y_BACK_SLASH_z"
7. Select one of the following **Restore Method** options and provide the required information:
   - **Auto Deploy Cohesity Agent**: Select this option to automatically deploy the Cohesity Agent on the target VM. This allows you to use domain credentials to access the target VM. If you are using domain credentials, then you should provide the username in the format <username@domain.com> and the user

should be either a domain administrator or a member of the local administrators group on the server.

- **Use Existing Cohesity Agent**: Select this option to use the existing Cohesity Agent deployed on the target VM.

  > **Note:** To recover files and folders of VMware VMs using Cohesity Agent, VMware tools must be installed and running on the target VM.

- **Use VMware Tools**: Select this option to use the VMware Tools for recovery. You have to enter the credentials required to access the target VM. If you are using domain credentials to access a target VM, then you should provide the username in the format <username@domain.com>. Ensure to install the VMware Tools on the target VM.

8. Optional. Edit the default settings of the following **Recovery options**:

   - **Overwrite Existing File/Folder**: By default, this option is enabled to overwrite the existing files and folders. Disable this option to create the files and folders in the specified location. Any duplicate files are skipped.

     Example for a Windows alternate location with **Overwrite Existing File/Folder** enabled and the target already exists:

     Files to be recovered: "C:\foo\1.txt", "C:\foo\test\1.txt", "C:\bar", "C:\foo\bar". Specified alternate location: "C:\restore". At the end of the copy, the target folder looks like this:

     - C:\restore\1.txt
     - C:\restore\cohesity<taskid>_0\1.txt
     - C:\restore\bar
     - C:\restore\cohesity<taskid>_1\bar

     If **Overwrite Existing File/Folder** is enabled, recovering a file to source when the file is in use may cause the open file to be overwritten. Whether overwriting occurs depends on the application using the file.

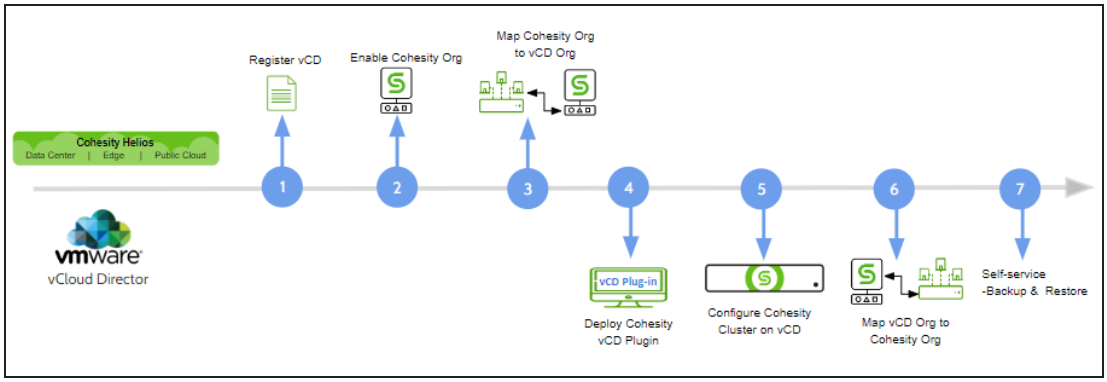
   - **Preserve File/Folder Attributes**: By default, this option is enabled and the ACLs, permissions, and timestamps are preserved for all files and folders. If you disable this option, then ACLs and permissions are not preserved. If recovering both folders and files, then folders will receive the new timestamps, but files retain their original timestamps. If recovering only, files, then files will receive the new timestamps.
   - **Continue on Error**: Enable this option if you want to continue the recovery even if one of the objects encounters an error. By default, this option is disabled and the recovery operation will fail if one of the objects encounters an error.

- **Cluster Interface**: By default, the Auto Select option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the Interface Group drop-down.
- **Task Name**: Change the default name of the recovery task.
- **Save Success Files**: Enable this option to download the success logs for a recovery run.

9. Click **Recover**.

Protect vCD resources using the Cohesity vCD Plugin

Cohesity Plugin for VMware vCloud Director enables cloud providers to offer data protection as a service in multi-tenant environments. The vCD Plugin provides a seamless experience by facilitating backup and recovery operations in the same vCD console. It delivers self-service securely through role-based access control. The vCD Plugin's integrated data protection service streamlines operations and provides a rich tenant experience.



Data Protection using the Cohesity vCD plugin involves the following steps:

1. Ensure that you meet the requirements.
2. Manage access to the tenants and providers.
3. Setup the Cohesity vCD Plugin
   a. Register vCD as a source with the Cohesity cluster
   b. Enable Multi-tenancy on Cohesity cluster
   c. Create Organizations and Map to vCD Source
   d. Install the Cohesity vCD plugin
   e. Configure the Cluster and Map Tenants
4. Backup vCD Objects

   For details on how to protect, a single vCD object or multiple objects as a tenant, see Backup VMs, vApps, or vApp Templates.
5. Recover vCD Objects

- Restore VMs
- Restore vApps
- Restore Files or Folders

Prerequisites for Cohesity vCD Plugin

The prerequisites are as follows:

- Signed and trusted certificate must be installed on the Cohesity cluster.
- Cohesity cluster must be accessible through port 443.

Supported Software

Software	Version
vCloud Director	See the Compatibility Matrix.
Cohesity Data Platform	See the Compatibility Matrix.
Web browsers	Google Chrome, Firefox, Safari

Compatibility Matrix

Plugin Version	vCD Version	Cohesity Cluster Version	Notes
2.5.x	10.5.x, 10.4.x	7.0.x, 7.1.1, 7.1.2	vCD 10.5 and 10.4.2 are supported in 7.0.1 and above versions.
	10.3.x	6.6.x, 6.8.x, 7.0.x, 7.1.1, 7.1.2	
2.4.x	10.4.2	7.0.1	
	10.4, 10.4.1	7.0	vCD 10.4 and 10.4.1 are supported in 7.0 and above versions.
	10.1.x, 10.2.x, 10.3.x	6.6.x, 6.8.x, 7.0	

Plugin Version	vCD Version	Cohesity Cluster Version	Notes
2.3.6	10.0.x, 10.1.x, 10.2.x, 10.3.x	6.5.1b (CPD), 6.5.1d (CPD), 6.6.x, 6.8.x	• vCD 10.3 is supported in 6.6.0d_cpd and above versions. • vCD 10.3.1 and 10.3.2 are supported in 6.6.0d-p6. You must contact Cohesity Support to enable the backup and recovery support for vCD 10.3.1 and 10.3.2. • vCD 10.3.3 is supported in 6.6.0d_u5 and above versions. • Cohesity cluster version 6.8 is supported with an additional patch. Contact Cohesity Support for the patch binaries.
2.3.5	10.0.x, 10.1.x, 10.2.x, 10.3.x	6.5.1b (CPD), 6.5.1d (CPD), 6.6.x, 6.8.x	• vCD 10.3 is supported in 6.6.0d_cpd and above versions. • vCD 10.3.1 and 10.3.2 are supported in 6.6.0d-p6. You must contact Cohesity Support to enable the backup and recovery support for vCD 10.3.1 and 10.3.2. • vCD 10.3.3 is supported in 6.6.0d_u5 and above versions. • Cohesity cluster version 6.8 is supported with an additional patch. Contact Cohesity Support for the patch binaries.
2.3.4	10.0.x, 10.1.x, 10.2.x, 10.3.x	6.5.1b (CPD), 6.5.1d (CPD), 6.6.x, 6.8.x	• vCD 10.3 is supported in 6.6.0d_cpd and above versions. • vCD 10.3.1 and 10.3.2 are supported in 6.6.0d-p6. You must contact Cohesity Support to enable the backup and recovery support for vCD 10.3.1 and 10.3.2. • vCD 10.3.3 is supported in 6.6.0d_u5 and above versions. • Cohesity cluster version 6.8 is supported with an additional patch. Contact Cohesity Support for the patch binaries.

2.0.3	9.5, 9.7, 10.0, 10.1	6.3.1, 6.4.1, 6.5.1, 6.6.x	

Access Management: Privileges for Service Providers and Tenants

A Service Provider can perform the following:

- Register vCD as a source with the Cohesity cluster
- Enable Multi-tenancy on Cohesity cluster
- Create Organizations and Map to vCD Source
- Install the vCD plugin
- Configure the Cluster and Map Tenants
- Edit or remove the Cohesity cluster configuration in the vCD Web Console.

A tenant can perform the following:

- Discover VMs
- Backup VMs, vApps, or vApp Templates
- Auto-protect vApps and vApp Templates
- Exclude VMs from an auto-protect job
- Unprotect a protected VM
- Edit Protection Group
- Delete Protection Group (including or excluding snapshots)
- On-demand Protection Runs
- Restore VMs
- Restore vApps
- Restore Files or Folders
- Monitor vCD Backup and Restore Tasks
- Access Cohesity Cluster from the Cohesity vCD Plugin

For more details, see Privileges for Service Provider Admin and Organization Admin.

Setup the Cohesity vCD Plugin

Setting up the Cohesity vCD Plugin involves the following steps:

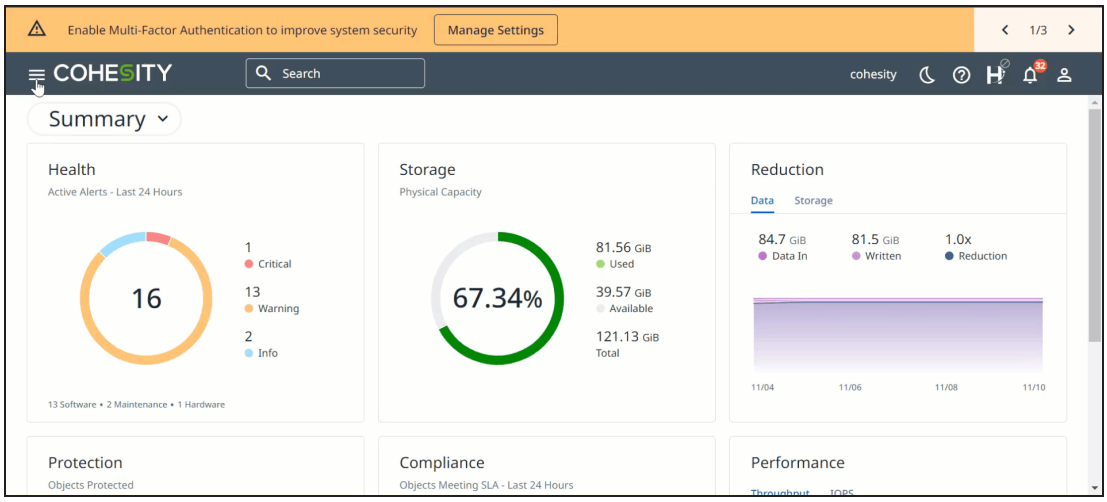
1. Register vCD as a source with the Cohesity cluster
2. Enable Multitenancy on Cohesity cluster
3. Create Organizations and Map to vCD Source
4. Install the Cohesity vCD plugin
5. Configure the Cluster and Map Tenants

Register and Manage a vCD Source

Register vCD as a source

Once registered, its objects can be protected or backed up on the Cohesity cluster.

To register a source to back up:



1. On the **Dashboard** page in the Cohesity cluster, navigate to **Data Protection** > **Sources**.
2. Select **Register** > **Virtual Machines**.
3. From Source Type, select **VMware: vCloud Director**.
4. Enter the following vCD details:
   - **Hostname or IP Address**: Specify the hostname or IP address of the vCloud Director that contains the vCenters to protect.
   - **Password**: Enter the password for the specified user.
   - **Username**: Specify the local administrator user.
5. Click **Connect**.
6. Enter the following vCenter details:
   - **Username**: You must specify a VMware vCenter user with adequate privileges on the VMware vCenter server. The role assigned to the specified VMware vCenter user should include privileges to turn on Change Block Tracking (CBT) and other privileges required by the Cohesity cluster. For detailed information about the necessary privileges, see Create a Role with Necessary vCenter Server Privileges.

     When specifying a Windows Active Directory username, use the following format: *<domain>\<username>* or *<username>@domain*. For all other cases, just enter: *<username>*.
   - **Password**: Enter the password for the vCenter.
   - **Detect VM migration across vCenter to Preserve backup chain**: Toggle this option on if you want your Cohesity cluster to detect the VMs that are migrated from the current VMware vCenter to vCD.
7. Click **Register**.

After source registration finishes successfully, the new source is displayed on the **Sources** page.

View the Registered vCD Source

To view a registered vCD Source:

1. Navigate to **Data Protection** > **Source**.

   The **Sources** page displays all the sources registered with that Cohesity cluster. The vCD ( ) icon indicates that the registered source is a vCD Source.

   Click the Actions menu (⋮) of that source to Edit, Refresh, or Unregister. From the Actions menu (⋮), you can also Deploy a Cohesity Agent and register Oracle, MS SQL, and Physical Servers.

2. Click on a source to view the hierarchy of the data centers, clusters, ESXi hosts, folders, VMs, vApps, and templates in that vCD source.

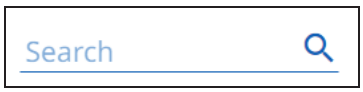
   - A selected check box ( ) indicates the object is selected to be backed up.
   - - Indicates a Linux VM.
   - - Indicates a Windows VM.
   - - Indicates a Windows or Linux template.
   - - Indicates a vApp.
   - - Indicates a VM
   - - A blue shield indicates a protected VM.
   - - Indicates an excluded object that is not protected. An ancestor of the object is auto-protected, but this object is excluded through inheritance (an ancestor is explicitly excluded).
   - - Click to view the general information—type, server size, and version of the selected object.

3. Filters on the Objects tab help you display only the objects you want. The filtering options are:

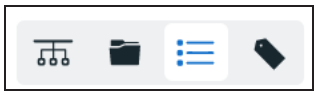
   - **Protection Status**: Protected or Unprotected.
   - **VM Attributes**: VMware Tools Found, MS SQL Servers, vCenter Migrated, Cohesity Agent Installed or Cohesity Agent Not Installed.

- **Host Type**: Linux or Windows.

4. Enter the name of an object in the **Search** box. You can even enter a partial name or an asterisk * wildcard. As you type, the objects that contain your search term appear.



5. Display modes can show the objects in a hierarchy or a flat list. The object hierarchy is automatically refreshed every four hours. To manually refresh the object hierarchy, select **Data Protection** > **Sources**, find the source in the list, and click the Refresh ( ) icon.



Update the vCD Source Configuration

You can update the vCD configuration you provided during the registration process with the latest configuration. To edit the vCD source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the **Actions** menu (⋮) next to the vCD source and select **Edit**.
3. In the **Edit Source** page, update the respective configurations.
4. Click **Save**.

Refresh the vCD Source

You can refresh the vCD source configuration to fetch the latest changes. To refresh the vCD source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the **Actions** menu (⋮) next to the vCD source and select **Refresh**.

Partial Refresh of the vCD Souce

You can perform a partial refresh of the vCD source using the API. A partial refresh is faster than a full source refresh. This enhancement allows you to selectively discover new VMs, vApps, Organizations, Org VDC, and vApp templates through the APIs into the vCD source, eliminating the need to wait for a full vCD refresh. You can refresh only the selected objects, such as specific VMs, vApps, Organizations, Org VDC, and vApp templates within the vCD source.

To do a partial refresh of the vCD source using the API:

Endpoint

```
PUT /v2/data-protect/sources/{sourceId}/objects
```

Parameters

Parameter	Type	Required	Description
sourceId	integer	Yes	The Entity ID of the data protection source

Finding the sourceId

You can find the sourceId from the UI by navigating to the Sources page and clicking your desired vCD source.

The URL will appear in the following format:

```
https://<Cluster IP>/protections/sources/details/{sourceId}/objects?environment=kVMware
```

The `{sourceId}` is the numeric ID you need for the API call. This value remains constant until the source is unregistered.

Headers

Header	Type	Required	Description
Content-Type	string	Yes	Must be `application/json`
Authorization	string	Yes	Bearer token for authentication

Request Body

The request body should include a JSON object with the following structure:

```
JSON
{
 "modificationRequests": [
 {
  "actionType": "Add",
  "vcdModifyParams": {
   "urn": "string"
```

```
}
}
]
}
```

Request Body Schema

Field	Type	Required	Description
modificationRequests	array	Yes	Array of modification requests to process.
modificationRequests[].actionType	object	Yes	Action to perform. Valid values: `Add`.
modificationRequests []. vcdModifyParams	string	Yes	vCD-specific parameters for the modification.
modificationRequests []. vcdModifyParams.urn	string	Yes	The URN (Uniform Resource Name) of the VCD object to be discovered

vCD URN Format

VCD URNs follow the format:

```
`urn:vcloud:{type}:{uuid}`
```

Navigate to **Data Protection** > **Sources**.

The common VCD object types:

- `vapp` - Virtual Application
- `vm` - Virtual Machine
- `vapptemplate` - vApp Template
- `org` - Organization
- vdc` - Virtual Datacenter

To Perform a Partial Refresh:

1. **Authenticate**: Obtain Access Token using Authentication API:

   ```
   POST /irisservices/api/v1/public/accessTokens
   ```

2. Get Source ID of the vCD source as described above.
3. Discovery request API .

   ```
   PUT /v2/data-protect/sources/{sourceId}/objects
   ```

Example Requests

1. Discover a new VM.

```
curl --location --request PUT
'https://10.136.5.86/v2/data-protect/sources/1/objects' \
--header 'Content-Type: application/json' \
--header 'Authorization: Bearer YOUR_TOKEN_HERE' \
--data '{
 "modificationRequests": [
 {
 "actionType": "Add",
 "vcdModifyParams": {
 "urn": "urn:vcloud:vm:96228d49-a079-4b0e-a19f-c5e78acd65b1"
 }
 }
 ]
 }'
```

2. Discover a new VCD org.

```
JSON
{
 curl --location --request PUT
 'https://10.136.5.86/v2/data-protect/sources/1/objects' \
 --header 'Content-Type: application/json' \
 --header 'Authorization: Bearer YOUR_TOKEN_HERE' \
 --data '{
 "modificationRequests": [
 {
 "actionType": "Add",
 "vcdModifyParams": {
 urn": "urn:vcloud:org:96228d48-a079-4b0e-a19f-f5e78acd65b1"
 }
 }
 ]
 }
```

Response Status Code and Body

1. Success Response (207 Multi-Status).

```
JSON
{
 "results": [
 {
```

```
"succeeded": true,
"vcdResult": {
"urn": "urn:vcloud:org:96228d49-a079-4b0e-a19f-c5e78acd65b1"
}
}
]
}
```

2. Error Responses.
   a. 403 Forbidden

```
JSON
{
 "errorCode": "KInvalidRequest",
 "message": "Invalid inputs. Unknown input urn type"
 }
```

   a. 500 Internal Server Error

```
JSON
{
 "errorCode": "KInternalError",
 "message": "VM not found in VCD"
 }
```

Response Status Codes

Status Code	Description
207	Multi-Status - Request processed, check individual results,
403	Forbidden - Invalid request or unknown URN type.
500	Internal Server Error - vCD object not found or server error.

> **Note:**
> - You can include multiple objects in the **modificationRequests** array to process several modification requests in a single API call. The batch operations are not supported for vCD partial refresh.
> - **URN Validation**: The API verifies that the specified URN exists in the connected vCD environment before processing the request.
> - **Hierarchical Dependencies**: When you add a vApp, OrgVDC, or Organization, all descendant entities are automatically included.
> - **vCD Hierarchy**: The system adheres to the vCD organizational hierarchy (Organization → VDC → vApp/vAppTemplate → VM) when processing modifications.
> - Ensure that your authorization token has the required permissions to modify data protection sources and access vCD objects.

Related Endpoints

Authentication API

```
POST /irisservices/api/v1/public/accessTokens` - Obtain access token for authentication
```

Authentication API Documentation: Obtain Access Token

Endpoint: `POST /irisservices/api/v1/public/accessTokens`

Description: Authenticate with the system and obtain a bearer token for API access.

Headers

| Header | Type | Required | Description |

| Content-Type | string | Yes | Must be `application/json` |

Request Body

Field	Type	Required	Description
username	string	Yes	Username for authentication.
password	string	Yes	Password for authentication.
domain	string	No	Authentication domain (e.g., "LOCAL") .

Example Request

```
curl --location --request POST
 'https://10.136.5.86/irisservices/api/v1/public/accessTokens' \
 --header 'Content-Type: application/json' \
 --data '{
 "username": "admin",
 "password": "admin",
 "domain": "LOCAL"
 }'
```

Success Response (201 Created)

```
JSON
{
 "accessToken": "eyJhbGciOiJSUzI1NiIsInR5cCI6IkpXVCJ9...",
 "tokenType": "Bearer",
 "privileges": [
 "AD_LDAP_MODIFY"
 "AD_LDAP_VIEW",
 "AGENT_UPGRADE_MODIFY",
 "PROTECTION_MODIFY",
 "PROTECTION_VIEW",
 "..."
 ]
 }
```

Response Fields

Field	Type	Description
accessToken	string	JWT token to use in Authorization header.
tokenType	string	Type of token (Bearer).
privileges	array	List of permissions granted to the authenticated user.

Usage

Use the returned `accessToken` in the Authorization header for subsequent API calls:

Authorization: Bearer <accessToken>.

This API allows you to perform a partial refresh to discover VMware vCloud Director (VCD) objects within a data protection source.

You can selectively refresh and add VCD entities such as vApps, VMs, VCD Orgs, and other VCD resources for backup and protection.

Unregister vCD Source

If you plan to stop taking the backup of your vCD source, you can unregister the vCD source from the Cohesity cluster. To unregister the vCD source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the **Actions** menu (⋮) next to the vCD source and select **Unregister**.

Configure the Organizations on Cohesity Cluster

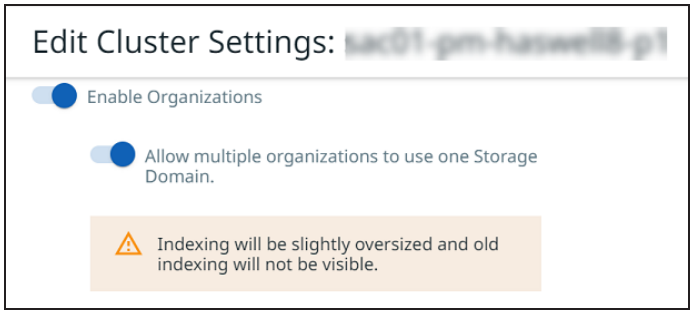
Enable Multitenancy on Cohesity Cluster

To create a tenant or organization on a Cohesity cluster, you must first enable organizations on your cluster and then create a new organization.

> **Note:** The term tenant also refers to an organization, and these terms have been used interchangeably throughout these sections.

To enable the Multitenancy in a Cohesity cluster:

1. In the Cohesity cluster, navigate to **Settings** > **Summary** and click **Configure**.
2. Turn on the **Enable Organizations** toggle.



3. *(Optional)* Turn on the **Allow multiple Organizations to use one Storage Domain** toggle.

   When you select this option, the storage consumption on the cluster reduces by providing Cohesity deduplication across all the Organizations using the storage domain. Organizations will be isolated from other Organizations whether this option is on or off.

4. Click **Save**.

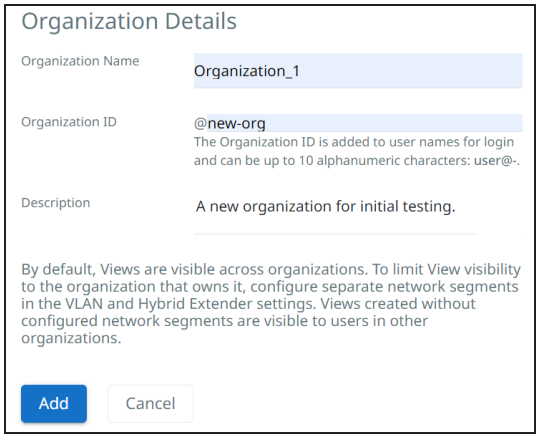
Create Organizations and Map to vCD Source

Before you Begin

When creating a new organization or tenant, vCD must be registered as a source.

To create a new organization in the Cohesity cluster:

1. On your Cohesity cluster, navigate to **Settings** > **Organizations**.
   a. Click **Add Organization**.
   b. Enter the Organization Name, ID, and Description.
   c. Click **Add**.

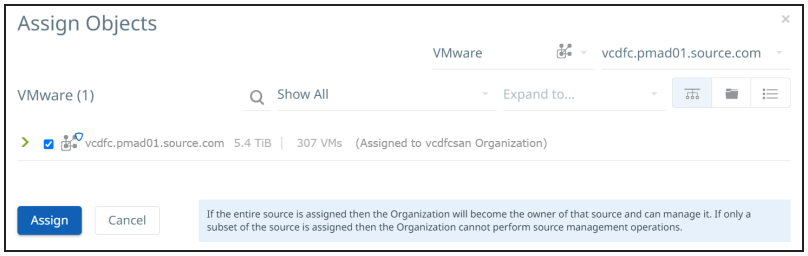


2. Select Storage Domain for the organization from the drop-down list. You can either select an existing domain or add a new Storage Domain.

   For more details on creating Storage Domains, see Create or Edit Storage Domains.
3. *(Optional)* Select **Views** from the drop-down list.
4. In the **Edit Organizations** page, click **Assign Users/Groups**.
5. In the **Assign Users/Groups** dialog, select an existing user and assign as an Administrator or create a new user. To create and assign a new user:
   a. Click **Add User**.
   b. Enter the user details and click **Add**.
   c. Select the newly created user and click **Assign**.

   For more details on adding users or groups, see Users and Groups for Organizations.
6. Under **Sources**, select **Assign Objects** to assign a source to this organization.
   a. Click on a vCD source to view the hierarchy of the data centers, clusters, ESXi hosts, folders, VMs, vApps, and templates in that vCD source.

b. Select the objects that are to be assigned to the newly created Cohesity tenant and select **Assign**. For more details, see Register and Manage a vCD Source.



7. Click **Assign Policies and Protection Groups** to assign policies to the organization and select **Assign**. For more details, see Data Protection for Organizations.
8. Click **Save**.

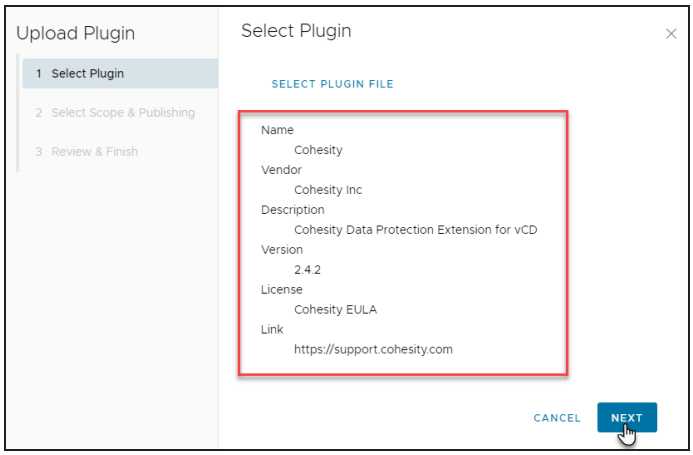
   An organization or tenant is successfully created.

Install the Cohesity vCD Plugin

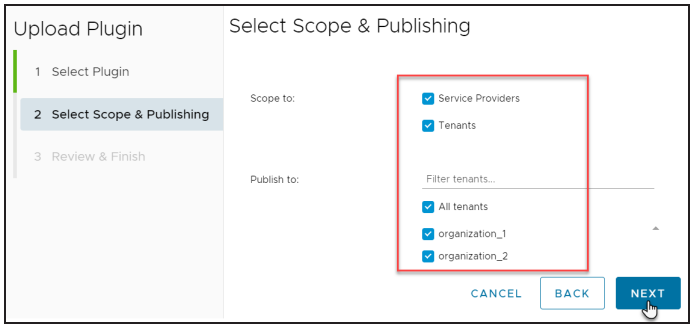
To install the vCD plugin, follow these steps:

1. Log into Github.
2. Under the **Release** tab, find your vCD plugin version.
3. Under **Assests**, click on *cohesity_vcd_extension.zip* to download the file.

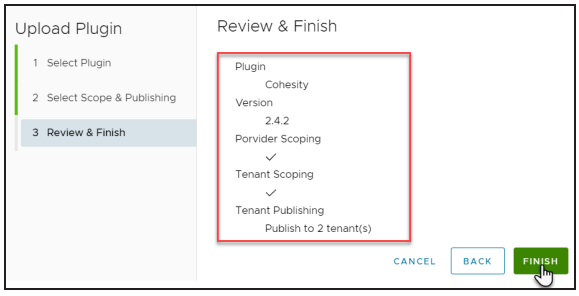
4. Login to vCD as the provider.
5. Select **More** > **Customize Portal**.
6. Click **Upload**.
7. Click **Select plugin** file, select the **cohesity_vcd_extension.zip** file, and click **Open**. The plugin is uploaded and details of the plugin are displayed.



8. Click **Next**.
9. Select the scope for this plug-in:
    - **Service Providers**: The plug-in function becomes available for all in the VMware Cloud Director Service Provider Admin Portal.
    - **Tenants**: The plug-in function becomes available in the VMware Cloud Director Service Provider Admin Portal of the organizations that you select.



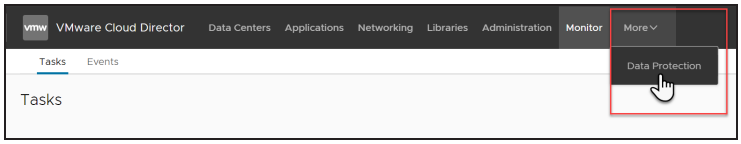
10. *(Optional)* Select the organizations to which you want to publish this plug-in. You can choose between all tenants or specific tenants.
11. Click **Next**.
12. Review the information and click **Finish**.



Verify the Cohesity extension is successfully installed

Log in to vCD, and select **More**.

The **Data Protection** option is displayed in the menu.



Upgrade the Plugin

> **Note:** Before you upgrade the plugin, delete the existing plugin.

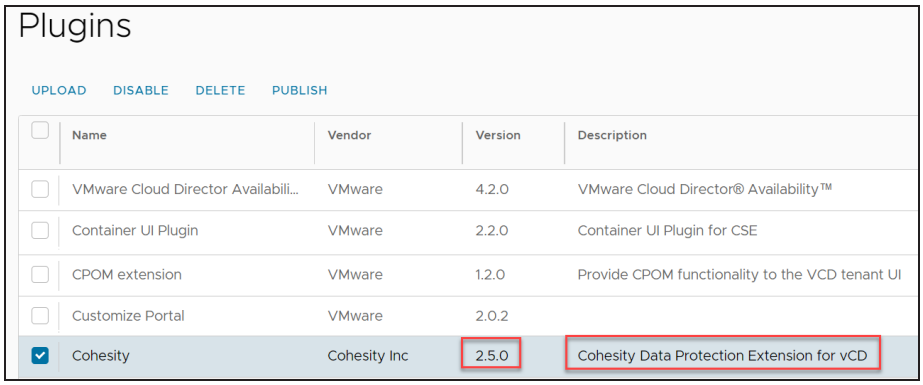
The procedure for upgrading the vCD plugin is similar to installing the plugin. To upgrade the plugin, simply repeat the steps in the Install the Cohesity vCD Plugin section.

> **Note:** After upgrading the vCD plugin, you must manually refresh the vCD source before you start protecting your vCD objects.

Verify the Plugin Version

1. Log into vCD as a provider.
2. Select **More** > **Customize Portal**.

Among the list of plugins, the Cohesity vCD plugin version is displayed as shown in the below image.



Configure the Cluster and Map Tenants

Before you Begin

The Cohesity vCD plugin makes cross-origin API requests to the Cohesity cluster. To enable support for Cross Origin Resource Sharing (CORS) headers on the Cohesity cluster, contact your Cohesity account team.

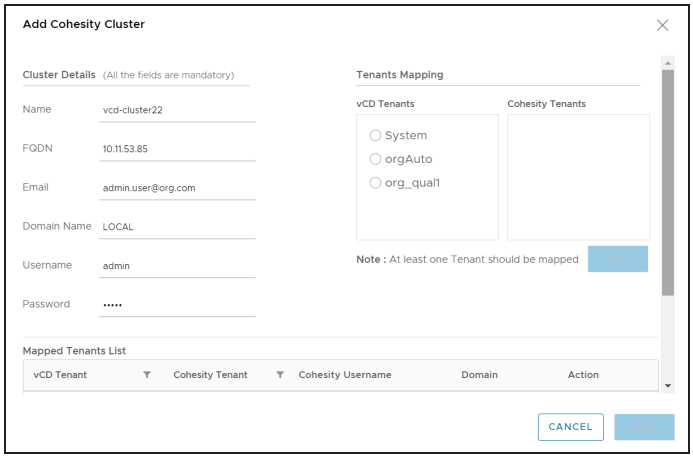
Configure the Cohesity Cluster in vCD Console and Map Tentants

After the Cohesity vCD Plugin is successfully deployed in vCD, you must configure the Cohesity cluster in the vCD Console and map the tenants or organizations created in the Cohesity cluster with a vCD organization.

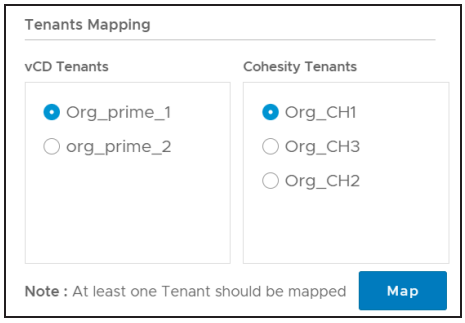
> **Note:** At least one tenant must be mapped before you start protecting your vCD objects.

To map the organizations in a Cohesity cluster with a vCD organization, follow these steps:

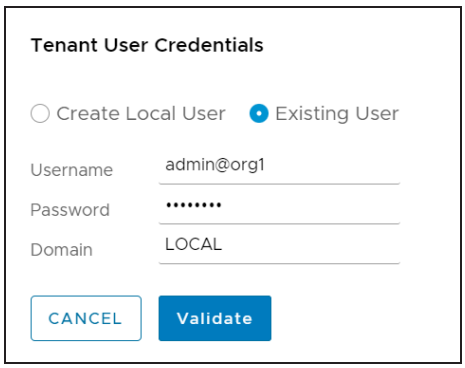
1. Log into the vCD console as a provider with admin credentials.
2. Select **More** > **Data Protection**. The **Configuration** page displays.
3. Click **Add**. The **Add Cohesity Cluster** page displays.



4. Enter the Cohesity cluster details such as IP address or hostname of the cluster along with the Service Provider credentials. These credentials are used to fetch the Cohesity tenants.
5. Once the credentials are validated, the Cohesity tenants are listed in the **Tenants Mapping** section.
6. Select the **vCD Tenant** and the **Cohesity Tenant** and click **Map**.



7. In the **Tenant User Credentials** prompt, you can either **Create New Local User** or select an **Existing User**. The tenant user credentials are used to execute all workflows for the tenant.



> **Note:**
> - If you create a new user, the Service Provider user must have privileges listed in the Access Management: Privileges for Service Providers and Tenants section.
> - If you are an existing vCD plugin user and upgrading your Cohesity cluster to 6.6.0c or later version, then you need to change the passwords of all mapped Cohesity Tenant Users to access Cohesity workflows.

8. Click **Save**.

   The Cohesity tenant is mapped successfully to the vCD tenant. The Cohesity cluster has been added and the vCD tenant user can now access Cohesity protection workflows through the tenant portal.

Backup VMs, vApps, or vApp Templates

Before you Begin

Discover VMs

The first step before we execute the vCD workflows is to make sure that VMs are discovered by Cohesity. You can check the status based on the **Protection Status** field.

1. Log into the vCD Console as a tenant user.
2. Navigate to **Data Protection** > **vApps** or **VMs**.
3. Check the status of all the VMs in the **Protection Status** field.
4. If the status is **Undiscovered** for any VM, click **Discover**. This initiates a refresh operation on the vCD source.

> **Note:** After upgrading the vCD plugin, you must manually refresh the vCD source before you start protecting your vCD objects.

Backup vCD Resources

There are two workflows for protecting and backing up your VMs, vApps, and vApp Templates as a tenant:

- Protect Individual VMs, vApps, and vApp Templates
- Protect Multiple Objects in a Single vCD Protection Group

Protect Individual VMs, vApps, and vApp Templates

To protect a specific vCD object, you must first create a Protection Group following the process below.

To protect individual VMs, vApps, and vApp Templates:

1. Log into the vCD Console as a tenant user.
2. Navigate to **Data Protection** > **vApps** or **VMs**.
3. Use the **Org vDC** and **Object Type** filter on the top to list to filter the objects based on the selected vDC or choose from the listed VMs, vApps, and vApp Templates.

   Verify the status of the object in the **Protection Status** column. If any of the objects that you want to back up are in an **Undiscovered** state, then you must first discover that object. See Backup VMs, vApps, or vApp Templates.

   Once the status of the object changes to **Unprotected**, click on the ellipsis (⋮) on the row for the unprotected object and select **Protect VM** (or **vApp** or **vApp Template**). If you choose **AutoProtect Object** (for a vApp or vApp Template), any VM that belongs to that object or any new VM created in that object will be protected automatically.
4. Click **Create New Group** in the **Protect Object** window.
   If you already have one, you can select an existing Protection Group instead.
5. Configure the Protection Group details and click **Save**.

   > **Note:** For more information on Leverage SAN Transport, see SAN Transport.
6. The Protection Status is updated as **Protected**.

   > **Note:** You can also log in to the Cohesity cluster at this point to verify that the Protection Group was successfully created.

7. Click the ellipsis (⋮) and either **Backup VM** (or **vApp** or **vApp Template**) **Now** or **Unprotect VM** (or **vApp** or **vApp Template**).
   If you enabled **Allow Archival** or **Replication Target Selection**when you configured vCD above, specify the **Archive to** and **Replicate to** targets. After that, click **Backup Now**.

Protect Multiple Objects in a Single vCD Protection Group

Another way of protecting vCD resources is by creating a Protection Group in vCD. This method allows you to select multiple resources to be protected in a single vCD Protection Group.

To protect multiple vCD resources in the same vCD Protection Group:

1. Log into the vCD Console as a tenant user.
2. Navigate to **Data Protection** > **Protection Group**> **New**.
3. In the **New Protection** dialog, enter the relevant information according to your requirement and click **Next** to select the objects to be protected.
   You can use options like setting **Email Recipients** to receive alerts for Protection Group **Success** and **Failure** runs.

   > **Note:** For more information on Leverage SAN Transport, see SAN Transport.

4. In the **Objects** page, click **Add Objects** to protect the vApp, vApp Template, or VM. There is also an option to specify **Auto Protection** for a vApp or vApp template. If you choose **AutoProtect Object** (for a **vApp** or **vApp Template**), any VM that belongs to that object or any new VM created in that object will be protected automatically.
5. Select the objects to be protected and click **Save Selection**.
6. Review the objects that are protected and click **Finish** to create the vCD Protection Group.
7. Run the Group by clicking the ellipsis (⋮) and selecting **Run Now**.
   You can also edit the Protection Group to add or remove protection objects or change the configured parameters.

   If you enabled **Allow Archival** or **Replication Target Selection** when you configured vCD above, specify the **Archive to** and **Replicate to** targets. After that, click **Backup Now**.

SAN Transport

Leverage SAN Transport for Data Protection: Cohesity supports SAN transport for Fibre Channel (FC) and iSCSI-based storage arrays and datastores that contain such storage arrays. Turn on this option to enable the SAN transport mode over FC or iSCSI for backing up VMware VMs to the Cohesity cluster.

> **Note:** Using the Leverage SAN Transport for Data Protection option with the Leverage Storage Snapshots for Data Protection option is not recommended.

To use the SAN transport mode over FC, ensure the following pre-requirement:

- Fibre channel is installed and zoned appropriately between the Cohesity cluster and the primary storage (Pure Flash Array and HPE Nimble Storage Array).

To use the SAN transport mode over FC, ensure the following pre-requirement:

- Volumes are mapped appropriately between the Cohesity cluster, ESXi hosts, and the primary storage.

  You can turn on the Allow NBDSSL Transport Fallback toggle if you do not want to enforce strict SAN transport mode for backing up VMware to the Cohesity cluster. With toggle enabled, backup will not fail if SAN transport is not available. If you disable this toggle, the backup will fail if the SAN transport mode is unavailable.

> **Note:**
> - Fallback to NBD is no longer supported if NBDSSL fails or is disabled.
> - Ensure that the storage array connects to the primary environment (host) and the Cohesity node over the same protocol (FC on both ends or iSCSI on both ends). Cohesity does not support SAN transport for SAS (Serial Attached SCSI) based storage arrays.
> - VMware SAN transport mode is not supported with Cohesity virtual nodes. To use SAN transport mode for backing up VMware VMs, zoning and granting datastores access to the Cohesity nodes has to be done manually. VMware SAN transport mode is not supported with Cohesity virtual nodes.

Recover VMs from a VCD Source

To restore a VM:

1. Log into the vCD Console.
2. Navigate to **Data Protection** > **Recovery**.
3. Click **VM**.
4. Search for a VM to restore.
5. Select the VM and click **Continue**.
6. In the **Restore VM** page, select the snapshot and provide a prefix and suffix.

> **Note:**
> - Prefix or suffix is required to ensure that the VM name is unique. By default, the VM is restored back to the original location. However, you can choose to recover to a new location by toggling on the option.
> - Restore to an alternate location is only supported for the Cohesity cluster running version 6.4.1c, 6.5.1 and later.
> - Using the Leverage SAN Transport for Data Protection option with the Leverage Storage Snapshots for Data Protection option is not recommended.
> - The placement and sizing policy for the VMs is restored during recovery to its original location.

To use the SAN transport mode over FC, ensure the following pre-requirements:

- Fibre channel is installed and zoned appropriately between the Cohesity cluster and the primary storage (Pure Flash Array and HPE Nimble Storage Array).
- Volumes are mapped appropriately between the Cohesity cluster, ESXi hosts, and the primary storage.
- You can turn on the Allow NBDSSL Transport Fallback toggle if you do not want to enforce strict SAN transport mode for backing up VMware to Cohesity cluster. With toggle enabled, backup will not fail if SAN transport is not available. If you disable this toggle, backup will fail if SAN transport mode is unavailable. NBDSSL encrypts all data passed over the TCP connection.

> **Note:**
> - Fallback to NBD is no longer supported if NBDSSL fails or is disabled.
> - Ensure that the storage array connects to the primary environment (host) and the Cohesity node over the same protocol (FC on both ends or iSCSI on both ends). Cohesity does not support SAN transport for SAS (Serial Attached SCSI) based storage arrays.

7. Click **Restore**.
8. To check the status, navigate to **Recovery** to check for the recovery task as described in Monitor vCD Backup and Restore Tasks.

Recover vApps from a vCD Source

To restore a vApp:

1. Log into the vCD Console.
2. Navigate to **Data Protection** > **Recovery**.
3. Click **vApp**.
4. You can search for a specific vApp name or use wildcard characters such as * to list all the VMs in the vApp.
5. Select a specific vApp, and click **Continue**.
6. Configure the details:
    1. Under **vApp Details**, enter a prefix and suffix that will help you identify the vApp being restored.
    2. Under **VM Details**, enter a similar prefix.
7. Under **Restore Properties**, select the snapshot that you want to recover.

    > **Note:** Using the Leverage SAN Transport for Data Protection option with the Leverage Storage Snapshots for Data Protection option is not recommended.

    To use the SAN transport mode over FC, ensure the following pre-requirements:

    - Fibre channel is installed and zoned appropriately between the Cohesity cluster and the primary storage (Pure Flash Array and HPE Nimble Storage Array).
    - Volumes are mapped appropriately between the Cohesity cluster, ESXi hosts, and the primary storage.
    - You can turn on the Allow NBDSSL Transport Fallback toggle if you do not want to enforce strict SAN transport mode for backing up VMware to the Cohesity cluster. With toggle enabled, backup will not fail if SAN transport is not available. If you disable this toggle, the backup will fail if the SAN transport mode is unavailable. NBDSSL encrypts all data passed over the TCP connection.

    > **Note:**
    > - Fallback to NBD is no longer supported if NBDSSL fails or is disabled.
    > - Ensure that the storage array connects to the primary environment (host) and the Cohesity node over the same protocol (FC on both ends or iSCSI on both ends). Cohesity does not support SAN transport for SAS (Serial Attached SCSI) based storage arrays.

8. Click **Restore**.
9. To check the status, navigate to **Recovery** to check for the recovery task as described in Monitor vCD Backup and Restore Tasks.

Recover Files or Folders from a vCD Source

To recover a file or folder:

1. Log into the vCD Console.
2. Navigate to **Data Protection** > **Recovery**.
3. Click **Files and Folders**.
4. Click **Files and Folders** to search for a specific indexed file. You can search for a partial name or use a wildcard expression such as * to search.

   The search output is displayed in the table.
5. Select the file from the table and click **Add to Cart**.
6. From the list of snapshots, select the recovery point which will be applied to all files or folders recovered in the task.

   To restore multiple files in the same task, follow these additional steps:

   a. Click **Add More**.

   b. Select the files from the filtered list and click **Add to Cart**.

   > **Note:** Cohesity allows you to recover multiple files for recovery only when the selected files belong to the same Server, Protection Group, Cluster, and Snapshot.
7. Enter the user credentials for the VM. You can also choose to recover to a new location, in which case the recovery path should be mentioned.
8. Click **Restore**.

   To check the status, navigate to **Recovery** and click **Refresh** to check for the recovery task as described in Monitor vCD Backup and Restore Tasks.

If you have chosen **Browse or Specify Path**, you can search for non-indexed files. Enter the VM name to search, select the VM, click **Continue**. From the tree structure, browse and check the box of the file(s) that you want to recover, select the snapshot version from the drop-down menu on the top left corner, and click **Continue**.Fill in the configuration details and click **Restore**.

Download files or folders

You can also download files locally. Search for the file, click **Continue**, select the snapshot and click **Download Now.** To download the file, navigate to **Recovery**, select the job, right click and select **Show Details** and click **Download Files**.

Monitor vCD Backup and Restore Tasks

You can check the status of the backup and recovery tasks under the **Recovery** tab. The following can be monitored:

- Scheduled or on-demand backup
- VM or vApp recovery
- File or Folder recovery
- File or Folder download

Monitor Backup

To monitor backup and restore tasks, follow these steps:

1. Log into the vCD Console as a tenant user.
2. Navigate to **Data Protection** > **Protection Group**. All the protection groups that are present in the cluster are listed.
3. Select the protection group whose runs you need to monitor.
4. Click on the **Protection Runs** tab.

   All the backup runs (scheduled or on-demand) which were triggered in the last 7 days are listed.
5. You can use the **Date** filter to filter the protection runs.

Monitor Recoveries

You can monitor the status of all recovery tasks which were triggered through the vCD plugin.

To monitor the status, follow these steps:

1. Log into the vCD Console as a tenant user.
2. Click **Recoveries**. All the recovery requests made in the last 30 minutes.
3. Click on the task name to get the status of the recovery task.

   You can use the **Filter By** option to filter recovery tasks based on their type. Use the **Duration** filter to fetch requests based on time.

   > **Note:** You can only monitor the status of recovery tasks which were triggered in the last 7 days through the plugin.

Access Cohesity Cluster from the Cohesity vCD Plugin

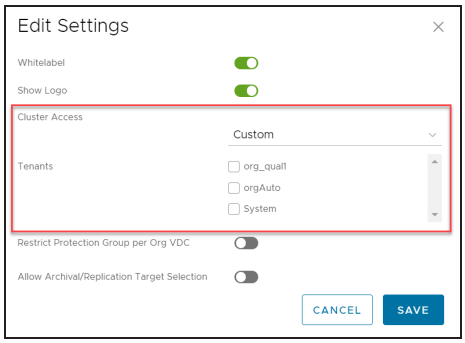
vCD tenants can launch Cohesity UI from the vCD extension and access advanced workflows that are currently not available in the vCD extension.

> **Note:** This feature is disabled by default. Contact your Cohesity account team to enable this feature.

Enable Access to the Cohesity Cluster

To enable access to the Cohesity cluster:

1. Log into the vCD Console as a provider with admin credentials.
2. Navigate to **More** > **Data Protection.** The **Configuration** page is displayed.
3. Select **Settings** from the navigation pane on the left.
4. Click **Edit**. The **Edit Settings** dialog is displayed.



5. The **Cluster Access** field is disabled by default. Turn the **Cluster Access** toggle ON to enable Cohesity cluster access. You can select **All Tenants** to enable this feature for all your vCD tenants or select **Custom** to enable it for selective tenants.
6. Click **Save**.

Access the Cohesity cluster

To access the Cohesity cluster:

1. Login to vCD as a tenant user.
2. Navigate to **More** > **Data Protection**. The **Dashboard** page displays.
3. From the navigation pane on the left, expand the **Advanced** option to see the Cohesity clusters to which the tenants have access to.
4. Click on any cluster to launch the Cohesity cluster.

Chapter 12: Databases

Cohesity supports the backup and recovery of the following databases:

- Amazon RDS and Amazon Aurora 2544
- Cassandra 2553
- Couchbase Using Connector Agent 2593
- MongoDB 2607
- MongoDB via Ops Manager 2628
- Microsoft SQL Server 2644
- Oracle Database 2755
- CockroachDB 2879
- Epic Database Protection using Cohesity Physical Agents 2897
- IBM DB2 2901
- MySQL EE 2928
- Percona MySQL on Linux 2946
- SAP HANA 2965
- SAP Sybase IQ 3004
- SAP MaxDB on Linux 3026
- SAP MaxDB on Windows 3049
- SAP Sybase ASE on Linux 3071
- SAP Sybase ASE on Microsoft Windows 3092
- SAP on Oracle for Linux 3112
- SAP on Oracle for Microsoft Windows 3138
- PostgreSQL 3158

Amazon RDS and Amazon Aurora

You can use a Protection Group to back up Amazon Relational Database Service (Amazon RDS) database instances and Amazon Aurora. Supported database engines include PostgreSQL, MySQL, MariaDB, Oracle Database, and SQL Server. Cohesity protects the data at the database level using RDS snapshots (no data is stored on the cluster).

Prerequisite

For replicating encrypted RDS snapshots from one location to another:

- The KMS key Aliases used to encrypt the RDS snapshots in the source location must be available in the target location.
- The IAM user/role used to register the target source must have access to the KMS key at the target location.

Considerations

- Backup and recovery of Amazon RDS and Amazon Aurora are not supported on Physical clusters or Virtual Edition clusters. To back up and recover Amazon RDS and Amazon Aurora, the cluster must be either a Cloud Edition cluster or a Next-Gen Cloud Edition (NGCE) cluster.
- You can perform the backup and recovery of Amazon RDS for MySQL and Amazon Aurora MySQL at database level (ingest-based protection) on AWS NGCE clusters. For more information, see Amazon Relational Database Service for MySQL and Amazon Aurora MySQL.
- Cohesity uses the Amazon RDS API to take snapshots according to the scheduled protection policy.
- Cohesity supports automated and manual RDS snapshots.
- You can restore the backups to the original location or a new location.
- Cohesity does not support recovery to different accounts with different regions but recovery to different accounts with the same region, the same account with the same region, and the same account with different regions are supported.
- Point in time recovery is supported only if you enable automated backups on the RDS instance. You can select a time and restore the database instance to the time selected. Automated backups occur once daily at the time selected. You can restore to any point in time within your backup retention period.
- Amazon Aurora Serverless backups are not supported.
- Recovery of an RDS instance encrypted with the default CMK (Customer Managed Key) to a different account is not supported as AWS does not support sharing a snapshot that is encrypted using the default KMS key of the AWS account.

- You cannot recover an Amazon RDS database to the same or alternate location if the name of the database you are restoring and at the target location are the same. AWS does not allow creating more than one RDS database instance with the same name.

  Workaround: Specify a unique name for the RDS database instance and then perform a recovery.

- The following table lists the service endpoints required for the backup and recovery of AWS RDS databases:

AWS Resource Type	Service Endpoints
IAM	iam.amazonaws.com
KMS	kms.<region>.amazonaws.com
RDS	rds.<region>.amazonaws.com

- If you are protecting Amazon RDS and Aurora instances within a private VPC, then you must:
  - Register the AWS cloud source using an IAM role. For more information, see To register an AWS C2S source using IAM Role.
  - Ensure the following endpoints are open.
    -

AWS Resource Type	Service Endpoints
STS	sts.<region>.amazonaws.com
RDS	rds.<region>.amazonaws.com
KMS	kms.<region>.amazonaws.com

  - Enable AWS Security Token Service (STS) in the default region where the Cohesity cluster is deployed.

To learn more, see the following topics:

- Manage Protection Policy
- Add or Edit a Protection Group for Amazon RDS or Amazon Aurora

Add or Edit a Protection Group for Amazon RDS or Amazon Aurora

Cohesity supports backing up Amazon Relational Database Service (RDS) databases and Amazon Aurora.

For information about required permissions, see AWS and AWS GovCloud Permissions.

Before you begin

When you create a Protection Group, you can select an existing source, policy, or storage domain. You can also create them while creating the Protection Group. However, you might find it easier to create them prior to creating the Protection Group, as described in the following topics.

- Register or Edit a Hypervisor Source
- Create or Edit a Standard Policy
- Create or Edit Storage Domains

To create a Protection Group for Amazon RDS:

1. Navigate to **Data Protection > Protection** and do one of the following:
   - To create a Protection Group—Click **Protect** on the top-right of the page and then select the type of Protection Group.
   - To edit a Protection Group—Click the action icon ( ) next to the Protection Group and select **Edit**.

   If creating a Protection Group for Amazon RDS, select **Databases > Amazon RDS**.

   If creating a Protection Group for Amazon Aurora, select **Databases > Amazon Aurora**.
2. **Name:** Enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.
3. **Source:** Select the database you want to protect. You can also register a new source with the Cohesity cluster so you can protect it.
1. Select the source objects to back up or exclude. By default, all objects in the source are excluded as indicated by the unselected check box. Expand the source objects and select the objects you want to include in the Protection Group. A selected check box ( ) indicates the object is selected to be backed up.
2. Use the filtering options to tailor the list of servers. You can also filter the objects based on the tags by clicking the **Tags** icon and selecting the required tag from the **Tags** drop-down list.
3. Click the arrow adjacent to the Object (**Expand All**) to expand the entire Object hierarchy. Click the arrow again (**Collapse All**) to collapse the entire Object hierarchy.
4. The graphical representations in the table are described below.

   When creating a new Protection Group, a shield next to the Object name indicates the Object is already been protected by another Protection Group.

Click the icon to see details about the object.

If the object name is in red, it is inaccessible, invalid, or orphaned. If the object is in one of the specified states when the Protection Group runs, no snapshot is created. If the object becomes accessible, a snapshot is created the next time the Protection Group runs.

5. Click **Save Selection**.
6. **Policy:** Select an existing protection policy or create a new one by selecting **New Policy**.

   The selected Storage Domain will contain the new View where the script results are stored.
7. **Start Time:** Indicates when the Protection Group should run. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting.

   The default time zone is the browser's time zone. You can change the time zone by selecting a different time zone.
8. **End Date:** Optional. Toggle on and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
9. **Cancel Runs at Quiet Time Start:** Available only if the selected policy has at least one quiet time period. Toggle it on to specify that all currently executing protection runs should abort if a quiet time period specified for the Protection Group starts. By default this toggle is off, which means after a protection run starts, it continues to execute even when a quiet time period specified for this protection run starts. However, a new protection run will not start during a quiet time period.
10. **Alerts:** Optional. Select one or more of the following settings if you want alerts to be created for the following triggers:

    - **Success:** Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created.
    - **Failure:** Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created.
    - **SLA Violation:** Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created.

    For more information, see Alerts.
11. **Priority:** Select a priority for the Protection Group execution. Cohesity supports concurrent backups, but if the number of Protection Groups exceeds the ability to process them, those with **High** priority are given the highest priority to execute, **Medium** the second-highest priority, and **Low** the lowest priority.

12. **Email Recipients**: You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the Protection Group.

    > **Note:**
    > The connection to the SMTP Server must be enabled to send email notification. You can enable the SMTP Server connection in the configuration settings page (Cohesity UI > **Settings** > **Summary** > **Configure** > **Enable SMTP Server**).

13. **SLA:** The service-level agreement (SLA) defines the expected time to complete either a full backup or incremental backup. The backup completion time depends on the Windows volume size on AD, objects changed between incremental backups, network speed, and other Protection Groups running on the Cohesity cluster.
    - **Incremental:** Enter the number of minutes you expect an incremental protection run to complete. An incremental backup captures only the differences (changed blocks) since the last protection run.
    - **Full:** Enter the number of minutes you expect a full backup protection run to complete. A full backup captures the entire object (all blocks).
14. **Description:** Optional. Click the plus sign and enter a description for the Protection Group.
15. Click **Protect**.

    The Protection page is displayed and includes the new Protection Group.

Recover Amazon RDS or Amazon Aurora

Cohesity provides the ability to recover the Amazon RDS database or Amazon Aurora to its original location or an alternate location. For more information, see:

- Recover Amazon RDS or Amazon Aurora to the Original location
- Recover Amazon RDS or Amazon Aurora to an Alternate Location

Recover Amazon RDS or Amazon Aurora to the Original location

To recover the Amazon RDS or Amazon Aurora to the original location:

1. In the Cohesity Dashboard, select **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **Databases > Amazon RDS**.

   The Amazon RDS page appears.
3. Search for the database you want to recover by entering the characters of the database name or by specifying the wildcard character *.

A list of VMs displays.

You can optionally filter the search results by Source, Protection Group, Storage Domain, or Date.

4. From the list of search results, select the database you want to recover.

   By default, the latest snapshot is selected for recovery.

5. To recover from a different snapshot, mouse over the snapshot from the selected list, and then click the **edit** icon.

   The Edit recovery point for <VM_name> page appears.

   By default, the option to select the snapshot is displayed in **Timeline** mode. You can also choose to view the option in **List** mode by clicking the **List** tab in the top-right corner of the page.

   - To select a snapshot from the **Timeline** mode:
     a. From the **Choose a date** drop-down, select a date for the recovery point.
     b. The snapshots available on the selected date are displayed in blue dots on the timeline bar.
     c. Select the snapshot to be recovered by clicking the corresponding blue dot on the timeline bar.

        If multiple snapshots are available, then you can choose any point in timeline (Point-in-Time snapshot) between the two snapshots either by adjusting the timeline bar or by selecting the time from the timer field. If you have selected an invalid time, then the nearest valid snapshot will be selected for recovery.
     d. Click **Select Recovery Point** and then go to step 6.
   - To select a snapshot from the List mode:
     a. Select the **List** tab from the top-right corner of the Edit recovery point for <VM_name> page.
     b. By default, the page displays the snapshots available in the last one month.
     c. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.
     d. Select the snapshot to be recovered.
     e. Click **Select Recovery Point** and then go to step 6.

6. Click **Next: Recover Options**.
7. From the **Recover To** options, select **Original Location** to recover the Amazon RDS to the original location.

8. Provide the following **Network Settings** information:
    1. **VPC**: Select an Amazon Virtual Private Cloud (VPC) to store the recovered RDS.
    2. **Subnet**: From the drop-down list, select a subnet in the Amazon VPC to store the recovered Amazon RDS.
    3. **Availability Zone**: From the drop-down list, select an availability zone in AWS to recover the RDS.
9. Configure the following **Additional Settings**:

    The **Database Engine** field auto-populates the database engine name used for this instance.
    1. **Database Instance Identifier**: Specify the unique key that identifies the database instance that will be recovered.
    2. **DB Port**: Specify the TCP/IP port that the DB instance will use for application connections. The connection string of any application connecting to the DB instance must specify the port number of the DB instance. Both the security group applied to the instance and your company's firewalls must allow connections to this port.
    3. **DB Option Group**: Select an option group that contains the option you want to attach to the DB instance that will be recovered. If there are not any option groups compatible with the selected engine, a default group will be created at launch.
    4. **DB Parameter Group**: Select the database parameter group to associate with the DB instance.
    5. **Multi A-Z Deployment**: Enable this option if you want the DB instance to be recovered to have a standby instance deployed in another availability zone. This option is disabled by default.
    6. **IAM DB Authentication**: Enable this option if you want to manage your database user credentials through AWS IAM users and roles. This option is disabled by default.
    7. **Public Accessibility**: Enable this option if you want the DB instance to also have a public IP address in addition to the private IP address. This option is disabled by default.
    8. **Copy Tags To Snapshots**: Enable this option for copying tags to snapshots. This option is disabled by default.
    9. **Auto Minor Version Upgrade**: Enable this option if you want the DB instance to automatically upgrade when a new minor database engine version is available. This option is disabled by default.
10. Optional. Change the default name of the recovery task in the **Task Name** field.
11. Click **Start Recovery**.

The recovery process is initiated. You can monitor the recovery task from the Recoveries page.

Recover Amazon RDS or Amazon Aurora to an Alternate Location

To recover the Amazon RDS or Amazon Aurora to an alternate location:

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Click on **Recover** located at the top right of the page and then select **Databases > Amazon RDS**.

   The Amazon RDS page appears.
3. Search for the database you want to recover by entering the characters of the database name or by specifying the wildcard character *.

   A list of VMs displays.

   You can optionally filter the search results by Source, Protection Group, Storage Domain, or Date.
4. From the list of search results, select the database you want to recover.

   By default, the latest snapshot is selected for recovery.
5. To recover from a different snapshot, mouse over the snapshot from the selected list, and then click the **edit** icon.

   The Edit recovery point for <VM_name> page appears.

   By default, the option to select the snapshot is displayed in **Timeline** mode. You can also choose to view the option in **List** mode by clicking the **List** tab in the top-right corner of the page.

   - To select a snapshot from the **Timeline** mode:
     a. From the **Choose a date** drop-down, select a date for the recovery point.
     b. The snapshots available on the selected date are displayed in blue dots on the timeline bar.
     c. Select the snapshot to be recovered by clicking the corresponding blue dot on the timeline bar.

        If multiple snapshots are available, then you can choose any point in timeline (Point-in-Time snapshot) between the two snapshots either by adjusting the timeline bar or by selecting the time from the timer field. If you have selected an invalid time, then the nearest valid snapshot will be selected for recovery.
     d. Click **Select Recovery Point** and then go to step 6.
   - To select a snapshot from the List mode:

a. Select the **List** tab from the top-right corner of the Edit recovery point for <VM_name> page.
b. By default, the page displays the snapshots available in the last one month.
c. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.
d. Select the snapshot to be recovered.
e. Click **Select Recovery Point** and then go to step 6.

6. Click **Next: Recover Options**.
7. From the **Recover To** options, select **New Location** to recover the Amazon RDS to an alternate Amazon RDS instance
8. From the **Source** drop-down menu, select a registered RDS instance to which you want to restore the Amazon RDS . You can also register a new source by clicking **Register Source** from the **Source** drop-down menu.
9. From the **Region** drop-down menu, select a region to restore the Amazon RDS.
10. Provide the following **Network Settings** information:
    1. **VPC**: Select an Amazon Virtual Private Cloud (VPC) to store the recovered RDS.
    2. **Subnet**: From the drop-down list, select a subnet in the Amazon VPC to store the recovered Amazon RDS.
    3. **Availability Zone**: From the drop-down list, select an availability zone in AWS to recover the RDS.
11. Configure the following **Additional Settings**:

    The **Database Engine** field auto-populates the database engine name used for this instance.

    1. **Database Instance Identifier**: Specify the unique key that identifies the database instance that will be recovered.
    2. **DB Port**: Specify the TCP/IP port that the DB instance will use for application connections. The connection string of any application connecting to the DB instance must specify the port number of the DB instance. Both the security group applied to the instance and your company's firewalls must allow connections to this port.
    3. **DB Option Group**: Select an option group that contains the option you want to attach to the DB instance that will be recovered. If there are not any option groups compatible with the selected engine, a default group will be created at launch.

4. **DB Parameter Group**: Select the database parameter group to associate with the DB instance.
5. **Multi A-Z Deployment**: Enable this option if you want the DB instance to be recovered to have a standby instance deployed in another availability zone. This option is disabled by default.
6. **IAM DB Authentication**: Enable this option if you want to manage your database user credentials through AWS IAM users and roles. This option is disabled by default.
7. **Public Accessibility**: Enable this option if you want the DB instance to also have a public IP address in addition to the private IP address. This option is disabled by default.
8. **Copy Tags To Snapshots**: Enable this option for copying tags to snapshots. This option is disabled by default.
9. **Auto Minor Version Upgrade**: Enable this option if you want the DB instance to automatically upgrade when a new minor database engine version is available. This option is disabled by default.

12. Optional. Change the default name of the recovery task in the **Task Name** field.
13. Click **Start Recovery**.

The recovery process is initiated. You can monitor the recovery task from the Recoveries page.

Cassandra

9 January 2026

The Cohesity Cassandra DataProtect solution natively integrates with Apache Cassandra and Datastax Enterprise to provide consistent backup and recovery for clustered Cassandra deployments. See the following topics for details:

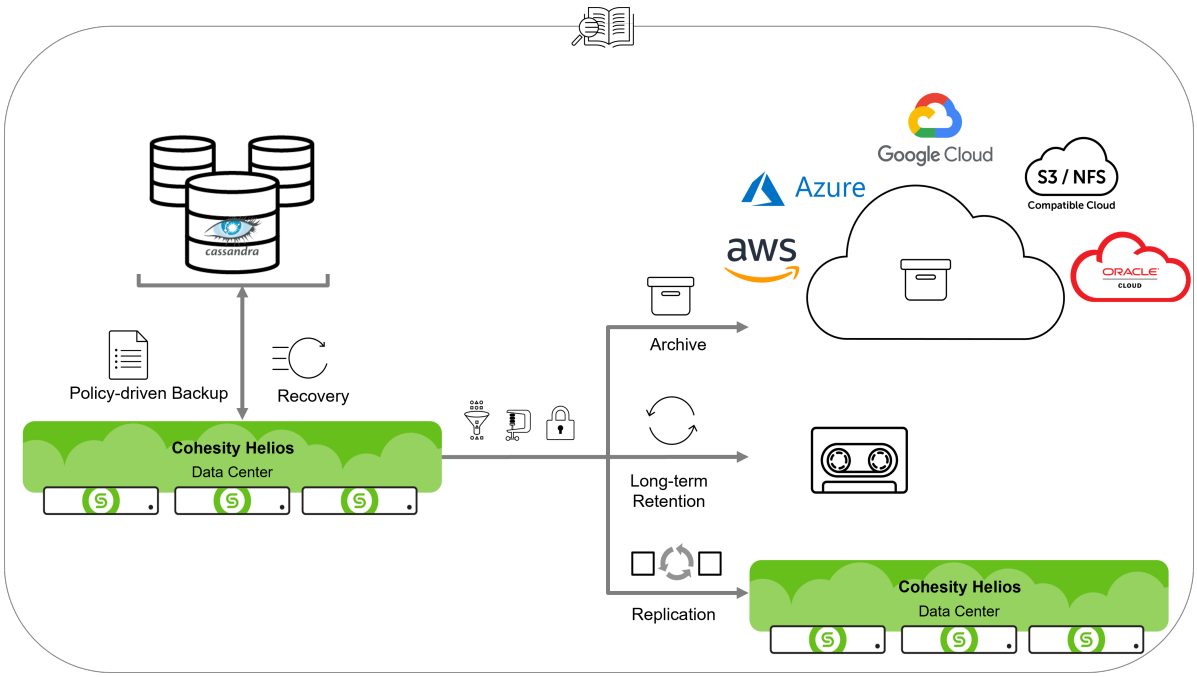
Based on the policy settings, the Cohesity NoSQL and Hadoop Service initiates a backup of the Cassandra Database. The initial protection run/first backup is a full-backup and everything after that is an incremental backup only. The service automatically determines the number of backup channels, based on the compute resources on Cohesity and the topology of the Cassandra cluster. The necessary Cohesity Views are automatically generated where the backups are going to be written. Communication between Cohesity and the Cassandra Databases is managed by the NoSQL and Hadoop Service as described in the section below.

Core components

The following lists the core components of the Cohesity Cassandra solution:

- Physical or virtual Cassandra instance.
- Cohesity Data Cloud.
- Cohesity Compute Nodes.
- Cohesity NoSQL and Hadoop Service running on Cohesity Compute Nodes.
- Optional. Archive or tiering target at your data center or cloud provider of choice.

As illustrated in the figure below, you can integrate Cohesity with an existing Cassandra infrastructure by installing the Cohesity NoSQL and Hadoop Service on Compute Nodes. Once the service is installed and running, you can create protection policies, and Protection Groups for the Cassandra database. Once the database is protected, it can be archived, sent to tape, and or replicated to another instance running in the cloud or on-premises as shown in the image below.



Cassandra Features

Following are the key Cassandra-specific features of the solution:

- Incremental-forever backups - after the first full backup, all subsequent backups are incremental only forever
- Granular backup and recovery - backup and recover tables or keyspaces
- Schema & data backed up and restored
- Multi-DC aware - option to back up data from a local data center
- Optimized restore - much faster recovery if Cassandra cluster topology is unchanged
- Backup & Recover DSE Solr indexes

- Handle topology changes seamlessly (node addition, removal, IP changes, etc.)
- Support Kerberos and LDAP authenticated clusters
- Support SSL-enabled clusters
- Change schema on restore

Plan and Prepare for Cassandra Protection

9 January 2026

The following topics provide guidance that helps you get ready to implement the Cassandra DataProtect Solution:

Supported Versions

For more information, see NoSQL and Hadoop Platforms.

> **Note:**
>
> Users whose existing Cassandra setups match any of the following criteria must edit their Cassandra source and go through the registration process.
>
> - Cassandra cluster set up with different public and private IP addresses(rpc_address/broadcast_rpc_address and different listen_address)
> - Cassandra setup with different listen_address and broadcast_rpc_address (listen_address = address1, rpc_address = 0.0.0.0, broadcast_rpc_address = address2)

Prerequisites

Make sure the following prerequisites are met before backing up Cassandra databases:

- The NoSQL and Hadoop Service is in Running status. See NoSQL and Hadoop Service for details.
- Refer to the NoSQL and Hadoop Service - Post Installation Procedures to get a general idea about the following operations:
  - Manage SSL enabled NoSQL primary clusters
  - Work with Kerberos Security enabled primaries for data protection
- Linux User on Cassandra Primary
- SSL Enabled Cassandra Clusters

    - Steps Required to Support SSL Enabled Cassandra Clusters
    - Obtain SSL Certificates in Cassandra Nodes and Import them on the Cohesity cluster that are Running the NoSQL and Hadoop Services
    - Import NoSQL and Hadoop Services Certificates
- Setting the Number of Open Files Limit for Cassandra
- Enabling JMX

Linux User on Cassandra Primary

For adding a Cassandra data source, either an SSH username and password or a private key is needed. SSH keys can be used to establish a secure connection. For more details on the minimum permissions needed for the user, see Minimum Permissions.

> **Note:** You need to use the same Linux user & password or SSH key on all Cassandra nodes that belong to the same source/cluster.

SSL Enabled Cassandra Clusters

Steps Required to Support SSL Enabled Cassandra Clusters

The `cassandra.yaml` file is the main configuration file for Cassandra. Check the following SSL options in the cassandra yaml file:

- `client_encryption_options` (Client-to-node encryption)
    - `enabled`: By default, the enabled option is set to `False`. If the enabled option is set to True, then you must Setting up truststore:.
    - `require_client_auth`: By default, the require_client_auth is set to `False`. If the `require_client_auth` is set to True, then you must Setting up keystore and import them in all Cassandra nodes, and restart Cassandra services for the changes to take effect
- server_encryption_options (Node-to-node encryption)
    - `internode_encryption`: If this option is set to `all`, dc or rack, then you must copy Cassandra certificates into NoSQL and Hadoop Services TrustStore using `imanis_cli.sh -c ssl`.
    - `require_client_auth`: By default, the `require_client_auth` is set to False. If set to true, then you must copy NoSQL and Hadoop Services SSL certificates into every Cassandra nodes TrustStore and restart Cassandra node for the changes to take effect.

Obtain SSL Certificates in Cassandra Nodes and Import them on the Cohesity cluster that are Running the NoSQL and Hadoop Services

This section describes the procedure of creating SSL certificates in Cassandra nodes and importing them in NoSQL and Hadoop Services cluster. However, if you already have SSL

certificate (*.cer) files, you can start from Step #4.

1. Check the location of Truststore and password in Cassandra Primary. You must execute the following command from the directory which contains the cassandra.yaml file.

```
[root@nosql13 conf]# grep "truststore:" cassandra.yaml
truststore:  <trustore location1>/cassandra.truststore
truststore: <trustore location2>/cassandra.truststore
[root@nosql13 conf]#
[root@ nosql13 certs]# grep password <configuration file location>/cassandra.yaml
# - PasswordAuthenticator relies on username/password pairs to authenticate users. It keeps usernames and hashed passwords in system_auth.credentials table.

# The passwords used in these options must match the passwords used when generating
keystore_password: nosql2016
truststore_password: nosql2016
keystore_password: nosql2016

# Set trustore and truststore_password if require_client_auth is true
truststore_password: nosql2016
```

2. Go to truststore location from the grep command (e.g.: /home/cassandra/certs/) and create SSL certificates for both the client and server encryption options using the password from the grep command (e.g.: nosql2016). The "/root/jdk1.7.0_45" is the Java home directory in Cassandra nodes.

```
[root@nosql13 certs]# /root/jdk1.7.0_45/jre/bin/keytool -export -alias nosql13 -file nosql13new.cer -keystore cassandra.keystore

Enter keystore password:

Certificate stored in file <nosql13new.cer>
```

3. Repeat Step #2 in all the Cassandra nodes:

```
[root@nosql14 certs]# /root/jdk1.7.0_45/jre/bin/keytool -export -alias
nosql14 -file nosql14new.cer -keystore cassandra.keystore

Enter keystore password:

Certificate stored in file <nosql14new.cer>

[root@nosql14 certs]#
```

Where /root/jdk1.7.0_45 is the Java home directory in Cassandra nodes.

4. Import all the SSL certificates. For more details, refer Setting up truststore:.

Import NoSQL and Hadoop Services Certificates

1. For more information on creating the SSL certificates, refer Setting up keystore.
2. Import NoSQL and Hadoop Services certificates on each of the Cassandra nodes. Ensure that this step is repeated for all the remaining Cassandra nodes.

```
[root@nosql13 certs]# keytool -import -v -trustcacerts -alias nosql1 -
file nosql1.cer -keystore .truststore

Enter keystore password:

```

> **Note:** Ensure that permissions of Cassandra's truststore file are given to the Cassandra user.

Setting the Number of Open Files Limit for Cassandra

The default setting for the number of open files in Cassandra primary is 1024. Please set the number of open files to 100,000 by running the following command on the Cassandra primary.

```
ulimit -n 100000
```

> **Note:** Without this step you may face an error on the Primary cluster while executing Cassandra restore.

Enabling JMX

Enable remote JMX connection on all the Cassandra nodes before you add Cassandra as a source. Cassandra DataProtect Solution connects to the primary using the remote JMX connection so a local JMX cannot be used in this case.

> **Note:** You need to use the same JMX credentials on all Cassandra nodes that belong to the same source/cluster.

To enable JMX:

1. Enable the Remote JMX connection: For Cassandra 2.0.14 (2.0 branch) and Cassandra 2.1.4 (2.1 branch) onwards.
2. Access the cassandra-env.sh from the Cassandra configuration directory on all the Cassandra nodes and set ["$LOCAL_JMX" = "yes"] entry to "no".
3. For the default DSE installation, the preceding file is available in /etc/dse/cassandra.
4. For a successful data source discovery in DSE 6.7.x, the following parameter must be set in /etc/dse/cassandra/cassandra-env.sh.

   "JVM_OPTS"="JVM_OPTS -Djava.rmi.server.hostname=<ip>"
5. Restart Cassandra services.

Considerations

- For users who have their Cassandra cluster set up with **public address = rpc_address/broadcast_rpc_address** and **private address = listen_address**, for DSE below 6.x (5.x and below), a bulk restore will not work if the private IPs for the

Cassandra nodes are not accessible by the Cohesity cluster (SCP restore will work as expected).

- Users must refresh a data source when configuration settings of the data source are modified. For example, if changes are made to cassandra.yaml, cassandra-env.sh, or dse.yaml file of a data source, then the data source must be re-discovered and re-verified.
- Backup is not supported for the following system keyspaces:
  - system
  - system_auth
  - system_distributed
  - system_schema
  - system_traces
  - dse_leases
  - dse_perf
  - dse_security
  - dse_system
  - solr_admin
  - dse_insights_local
  - dse_insights
  - dse_system_local
  - system_virtual_schema
  - system_views
  - system_backups
- Restore of system keyspaces such as OpsCenter is only supported for the same cluster from which it was backed up.
- Backup and recovery of tables containing semicolon (';') in the column name is not supported.
- Data recovery from Cassandra 2.x to 3.x is not supported if the backed-up tables contain dropped columns.
- For Cassandra 2.x or DSE 4.x, backup recovery is not supported for tables where all columns are part of the Primary Key.
- Appending suffix is not supported while restoring graph objects. This is because individual graph keyspaces cannot be renamed. This issue occurs during the jobtag recovery process when the global suffix is applied to all keyspaces thus wrongly renaming the '_system' keyspace for a graph. For example, we need to back up two

types of keyspaces for a graph. If the name of the graph is ‘exampleGraph’, then we should back up ‘exampleGraph’ and ‘exampleGraph_system’. However, during jobtag recovery, if global suffix is applied to all keyspaces it wrongly renames the keyspaces 'exampleGraph_suffix' and 'exampleGraph_system_suffix' for a graph.

- Support for non-default store_type, algorithm, and protocol in cassandra.yaml is not available in this release.
- **For DataStax Enterprise 6.x, the following considerations are applicable:
    a. To restore DSE 5.x backups to DSE 6.x cluster, the minimum version must be DSE 6.0.6.
    b. If a protection run gets killed or the primary Cassandra node goes down during a restore, the temporary directories on the primary nodes are not deleted. In such cases, the user has to manually delete the temporary directories on the primary Cassandra nodes.

       The directories are created in each of the storage directories on the primary nodes and are named by the restore protection run's UUID.
- In DSE 6.x, restoring a Cassandra table where the primary key contains UDT would fail if the corresponding keyspace object had been renamed.
- Apache Cassandra 4.0 does not support the experimental features.
- Data restore from Cassandra 3.x to 4.0 is not supported.
- Review and understand the following considerations of **Restrict access to specific Objects**:
    - For Log backups, **Restricted access to specific Objects** must be provided at the source level. Log backups are necessary for Cassandra PITR.
    - For recovery, to select the specific data centers, **Restricted access to specific Objects** must be provided at the source level. If access is not provided or if the user does not select the data center for recovery the data is bulk loaded to all data centers.
    - **Restricted access to specific Objects** on replicated clusters is not supported.

    > **Note: Restrict access to specific Objects** for NoSQL and Hadoop Service is an Early Access feature. Contact your Cohesity account team to enable the feature.
- Supports IPv6 on DataStax Enterprise 6.x only.
- Cohesity does not support registering a Cassandra cluster using a mix of IPv4 and IPv6 addresses.
- For IPv6, Kerberos authentication is not supported.

- During the recovery, roles are not deleted or updated.
- Backup and restore of role passwords are not supported.
- During the recovery, If there is already a role with the same name on the target, even if it has different properties, the permissions will still be applied to that role.

Firewall Ports

The following table lists the required firewall ports that are to be open to enable communication between Cohesity and Cassandra DataProtect Solution.

Port	Source	Target	Direction (From Node)	Network Protocol	Usage Notes	Type of Traffic
22	Cohesity cluster	Cassandra nodes	Outgoing	TCP	Cassandra backup Cassandra optimized restore/DSE 6.x restore	Backup and restore
7000	Cohesity cluster	Cassandra nodes	Outgoing	TCP	Cassandra bulk restore	Restore
7001	Cohesity cluster	Cassandra nodes	Outgoing	TCP	Cassandra bulk restore incase of ssl enabled cluster	Restore
7199	Cohesity cluster	Cassandra nodes	Outgoing	TCP	Cassandra repository registration Cassandra backup (snapshot operation) Fetching Cassandra configurations (list of nodes, token map etc)	Management

Minimum Permissions

Authentication Enabled Cassandra Cluster

In case of authentication enabled Cassandra cluster, the specified cassandra user must be a super user.

Discovery:

ssh user should have read/execute access to Cassandra config directory.

Backup:

ssh user should have read/execute access to Cassandra data directories.

Restore:

For optimized recovery:

- The ssh user must have read/write/execute access to Cassandra data directories.
- The ssh user must have privileges to change the file ownership to Cassandra user.

Additionally, for DSE 6.x and restore with staging dir option selection, ssh user should have permission to execute sstableloader cmd on the Cassandra nodes. This means that sstableloader cmd should be in the PATH of ssh user, and the ssh user should have write access to the following directories:

- commitlog directory
- cdc_raw directory (if this dir is missing, need to create an empty dir)
- data directory
- saved_caches directory

Write-access to these directories are DSE requirements since the sstableloader tool checks for the same.

Additionally, if password encryption is enabled through client_encryption_options and server_encryption_options in cassandra.yaml, the SSH user must have read access to the system_key file (defined by the config_encryption_key_name setting in dse.yaml), as it contains the encryption key.

Register a Cassandra Source

9 January 2026

Register Cassandra as a Source

To configure Cassandra for data protection on Cohesity, you need to register it as a source.

Before you register Cassandra as a source, ensure that you have reviewed and completed the instructions provided in the Plan and Prepare for Cassandra Protection topic.

To register Cassandra as a source:

1. Navigate to **Data Protection > Sources**.
2. Click **Register** on the top-right of the page and then select **Databases > Cassandra**. The **Register Cassandra** dialog is displayed.
3. **Primary Host**: Specify any one seed node of the Cassandra cluster.
4. **customName**: Specify a generic source name of the Cassandra cluster.

> **Note:** You can register two sources with the same IP address on the Cohesity cluster by adding a different custom name.

> **Note:** This is an Early Access feature. Contact your Cohesity account team

> to enable the feature.

5. **Cassandra Configuration Directory**: Specify the directory path for the Cassandra configuration YAML file.
6. **Password**: Select **Password** if you want it as the authentication type.
    1. **Username**: Specify the username.
    2. **Password**: Specify the password.
7. **Private Keys**: Select **Private Keys** if you want it as the authentication type.
    1. **Login**: Specify the username.
    2. **SSH Private Key**: Specify the private key.
    3. **Passphrase (Optional)**: Specify the password.
8. **Cassandra Distribution**: Select the required Cassandra distribution:
    - **DSE**: Select **DSE** to use DataStax Enterprise as the Cassandra distribution.
        a. **DSE Configuration Directory**: Specify the directory path for DSE specific configuration.
        b. **DSE Tired Storage**: Select this check box if the cluster has DSE tiered storage.
        c. **DSE Authenticator**: Select this check box if the cluster has a DSE Authenticator.
        d. **DSE Solr**: Select this check box if the cluster has DSE Solr.
            i. **Solr Nodes**: Enter all the Solr node IP Addresses
            ii. **Solr Ports**: Enter the Solr node Port.
    - **Apache Cassandra**: Select **Apache Cassandra** to use Apache Cassandra as the Cassandra distribution.
9. Click **Register**.
10. Enter the details for the additional authentication and configurations as needed.

> **Note:** For users who have their Cassandra cluster set up with different public and private IP addresses(different listen_address and rpc_address/broadcast_rpc_address), when registering/updating a Cassandra source, the full list of seeds may not be displayed on the verification screen. Instead, the public address of the node supplied in the registration screen is displayed in the seeds list. After verification is complete and the cluster is fully registered, the settings page for the Cassandra cluster displays the full correct seed list.

Field	Description
JMX Authentication	JMX Credentials for this cluster. This should be the same for all the nodes.
Cassandra Authentication	Cassandra Credentials for this cluster.
Kerberos Principal	Specify the Kerberos principal to access the Cassandra primary.
Data Centers (optional)	Data centers for this cluster.
Commit Log Archive Location (optional)	Specify the commit log archive location. You must specify the commit log archive location when registering the Cassandra cluster as a source for point-in-time recovery.
Cassandra Configuration Details	Displays the information from the Cassandra configuration directory. If DSE Cassandra is selected, DSE specific configuration is also displayed.

11. Click **Register**.

If the registration is successful, the registered cluster appears in the list of the **Sources** page.

> **Note:**
> - Registering a faulty source triggers an error. Users must Update Cassandra Configuration to correct the information and save it to resolve the errors.

Update Cassandra Configuration

You can update the Cassandra details that you provided during the registration process with the latest Cassandra configuration.

To edit the Cassandra Source Configuration:

1. Navigate to **Data Protection > Sources**.
2. Browse to the required Cassandra source you want to edit, click ⋮ and select **Edit**. The **Edit Cassandra Registration** dialog is displayed.
3. Edit the authentication details and other configurations as required.
    1. If the entire Cassandra configuration has changed and new nodes are to be added, click ✎ adjacent to **Host Details**.

    > **Note:** Performing step 4 leads to rediscovering the Cassandra source. The source ID, protection runs and Protection Groups that are already created are retained.

    2. Edit the required details and click **Update**.
    3. Enter the Cassandra authentication details.
4. To update the details, click **Update**.

Refresh the Cassandra Source

You can manually refresh the Cassandra source configuration and fetch the latest changes on the source.

To refresh the Cassandra Source Configuration:

1. Navigate to **Data Protection > Sources**.
2. Click ⋮ next to the Cassandra source and select **Refresh**.

When you refresh the Cassandra source, Cohesity auto-updates the Cassandra version and seed nodes. During the refresh, seed nodes are retrieved using the nodetool getseeds API.

> **Note:** This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

Consideration

The output of the nodetool getseeds API should be consistent across all nodes in the registered data centers of the cluster.

Unregister the Cassandra Source

If you want to stop taking backups of the Cassandra source, you can unregister the source from Cohesity.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the Cassandra source.

To unregister the Cassandra Source:

1. Navigate to **Data Protection > Sources**.
2. Click ⋮ next to the Cassandra source and select **Unregister**.

Backup Cassandra

9 January 2026

Cohesity provides a simple sequence of tasks that constitute the procedure for backing up your Cassandra source. Once Cassandra is registered as a source on Cohesity, you can start configuring your backups.

> **Note:** If the regular backup run for the Cassandra Primary is canceled, Cohesity will automatically delete the snapshots of the keyspaces that were created on Cassandra during the backup process.

Protect Cassandra Objects

Cassandra Objects are protected using a Protection Group and a Protection Policy. A Protection Group enables you to select the objects that you want to back up. It uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured, retained, archived, and replicated.

A Protection Policy is a reusable list of settings that define the type of backup, backup schedule, and backup snapshot retention. Also, for disaster recovery, you can add replication for the Protection Group using the Protection Policy. For detailed instructions on how to create a Protection Policy, see Create or Edit a Standard Policy.

To protect a Cassandra object:

1. **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then select **Databases > Cassandra**. The **New Protection** page is displayed.
3. **Source**: Select the required Data Source from the drop-down menu.

> **Note:** For commit log backup, select the Cassandra source that has the **Commit Log Archive Location (optional)** specified.

4. **Data Centers**: Select the required **Data Center** from the drop-down menu.
5. **Log Backup Selection**: Toggle on the **Log Backup** setting to schedule a backup of the log archives of the Cassandra source.

> **Note:**
> - Once **Log Backup** is enabled you cannot select any objects.
> - You can only create one Log Backup Protection Group for a Cassandra source.

6. Select the required objects to protect.

> **Note:** This option is available only if the **Log Backup Selection** toggle setting is off.

7. To auto-protect an object, click adjacent to it. For more information, see Enable or Disable Auto Protect.
8. Click **Save Selection**.
9. Under **Protection Group**, enter a Protection Group name. Existing Protection Groups cannot be used while creating a new Cassandra protection.
10. Under **Policy**, select an existing protection policy or create a New Policy if the available policies do not meet your schedule and retention needs.

> **Note:** For commit log backup, only policies with Log Backup are made available to select.

11. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains.
12. After selecting a Storage Domain, if you need to change any of the additional settings on the Cassandra Protection page, scroll down and click **Edit** on the right. For more information, see Additional Settings.
13. Click **Protect**.

Your new Protection Group is now active and running.

Additional Settings

Field	Description
Start Time	The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection group by selecting a different time zone.
End Date	Optional. Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts prior to this date runs until completion even if it completes after this date.
QoS Policy	Select an appropriate quality of service (QoS) policy. **Note:** Cohesity recommends specifying **Backup HDD**, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Concurrency	Maximum number of backup streams that will be created to exchange data with the cluster. By default, the maximum scaling is set to 16.
Bandwidth Throttling	Maximum network bandwidth that each backup stream can use for exchanging data with the cluster.

Field	Description
Alerts	Optional. Select one or more of the following settings if you want alerts to be created for the following triggers: • Success: Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • Failure: Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • SLA Violation: Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection groups exceeds the ability to process protection groups, this will be the priority of implementation of the protection groups: • High-priority protection groups • Medium-priority protection groups • Low-priority protection groups.
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks). • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run.
Description	Optional. Enter a brief description about the Protection Group.
Pause Future Runs	Toggle on this setting to stop new runs of this Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current protection run continues to execute and only future protection runs of this protection group are paused. > **Note:** Once the **Pause Future Runs** option is enabled, protection runs are not scheduled.

Manage the Cassandra Backup Configuration

A backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Objects to an Existing Protection Group

You can add new objects to the Protection Group created for Cassandra protection. The newly added objects are backed up from the next protection run.

To add objects to the Protection Group:

1. **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Cassandra.
3. Click ⋮ next to the Protection Group and select **Edit**.
4. In the Edit Protection page, Click ✎ next to **Objects**.
5. Make the required changes. For more information, see Protect Cassandra Objects.
6. Click **Protect**.

Enable or Disable Auto Protect

The Auto Protect option enables you to automatically protect the objects that are added to the Cassandra source. You can auto protect either the entire cluster or a Keyspace.

When the Auto Protect option is enabled:

- All the objects that are added to the Cassandra source in the future are automatically added to the Protection Group and are protected from the next protection run.
- All the objects that are removed from the Cassandra source in the future are automatically removed from the Protection Group and are not protected from the next protection run. The existing backups are preserved until the snapshot expires.

When the Auto Protect option is disabled, you need to manually:

- Add newly added objects in the Cassandra source to the Protection Group.
- Remove existing objects that are removed from the Cassandra source. The existing backups are preserved until the snapshot expires.

To enable or disable Auto Protect:

1. **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Cassandra. For more information, see Protect Cassandra Objects.
3. Click ⋮ next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** area, click **Edit**.

5. In the pop-up window , toggle the to enable or disable Auto Protect.
6. Click **Protect**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group in the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Cassandra. For more information, see Protect Cassandra Objects.
3. Click ⋮ next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Protect**.

Start an On-demand Protection Run

You can manually start a run for the Protection Group that you have created to backup Cassandra objects. It provides you options to:

- Back up all the objects in the Protection Group.
- Select an incremental or full backup.
- Add replication and archive.

To start a protection run:

1. **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Cassandra.
3. Click ⋮ next to the Protection Group and select **Run Now**.
4. In the pop-up window, perform the following:
    1. The **Backup** drop-down list is defaulted to **Backup all Objects in the Protection Group**.
    2. In the **Backup Type** drop-down list, select the backup type.
    3. If required add details for Replication and Archival.
5. Click **Backup Now**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group. However, if a protection run is in progress, it continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Cassandra.
3. Click ⋮ next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired then a full backup is triggered.

To resume future protection run:

1. **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click ⋮ next to the Protection Group and select **Resume**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the snapshots (local, archived, and replicated) that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete the Protection Group

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived snapshots generated by the Protection Group and reclaim the space utilized by the Protection Group.

> **Note:** The storage space reclaimed by deleting the Protection Group takes some time to reflect.

To delete the Protection Group:

1. **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Cassandra.
3. Click ⋮ next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Delete Protection Group Only
    - Delete Protection Group and Snapshots

Enable/Disable Megafile support

Megafile feature improves Cassandra backup/restore task performance by copying mega files (greater 32 GB in size) by splitting them into subfiles and copying the subfiles in parallel. It requires a modified version of SCP binary on the primary nodes to achieve this. By enabling this feature, you allow the NoSQL and Hadoop Service to copy this binary to primary cluster nodes on demand and execute them as needed.

> **Note:** The directory to copy the binary should be accessible by the user to allow the backup/restore functionality to work. You may also need to explicitly allow this executable in puppet/chef tools (if required).

Run imanis_cli tool from any Cohesity node where the NoSQL and Hadoop Service is running.

```
$ imanis_cli.sh -c megafile --help
INFO : Checking reachability of pod imanis-nodemanager-0
-----------------------------------------------------------------------
imanis_cli.sh -c megafile --connector <cname> [--workdir <dirpath>] --enable
true|false
--connector value can be cassandra-backup or cassandra-restore
--workdir value will be the directory path on primary cluster where
talena-scp will be copied
NOTE: --workdir is not needed in case of '--enable false'
--workdir is optional in case of cassandra-restore
-----------------------------------------------------------------------
```

Enable Megafile support

Run the following commands to enable megafile support:

```
$ imanis_cli.sh -c megafile  --connector cassandra-backup  --workdir
/data/binaries/talenascp --enable true

INFO : Checking reachability of pod imanis-nodemanager-0

NOTE:

Megafile feature improves the performance of Cassandra backup/restore tasks
by

copying mega files ( > 32GB in size) by splitting them into subfiles and
copying the

subfiles in parallel. It requires a modified version of scp binary on the
primary

nodes to achieve this.

By enabling this feature, you are allowing the NoSQL app to copy this

binary to primary cluster nodes on demand and execute them as needed. Please

note that the directory to copy the binary should be accessible by the user
with

which you are allowing the backup/restore functionality to work. You may
also need to

allowlist this executable in puppet/chef tools, if needed

Enable megafile for cassandra-backup connector :  (yes/no) yes ? yes

INFO : Updating value for cassandra.backup.megafile.enable

INFO : Updating value for cassandra.backup.megafile.workdir

INFO : core-site.xml updated successfully.
```

Disable Megafile support

Run the following commands to disable megafile support:

```
$ imanis_cli.sh -c megafile  --connector cassandra-backup   --enable false

INFO : Checking reachability of pod imanis-nodemanager-0

INFO : Updating value for cassandra.backup.megafile.enable

INFO : core-site.xml updated successfully.
```

Recover Cassandra

9 January 2026

You can recover the protected Cassandra Objects using Cohesity. You can recover to the same location or an alternate location.

Considerations

- Recovering at the protection group level is supported for Cassandra.
- Recovering with a suffix at the protection group level applies the suffix to the leaf-level objects in the selected protection group.
- Recovering multiple protection groups in a single recovery task is not supported.
- Recovering items in the same protection group but from different recovery points is not supported in the same recovery task. You need to create different recovery tasks for different recovery points.
- Recovering objects from more than one protection group in a single recovery task is not supported.

Recover Cassandra Objects

To recover Cassandra objects you can search through the backups using the protection group, keyspaces or table name for the objects you plan to recover, and then start the recovery.

To recover Cassandra objects:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** on the top-right of the page and then select **Databases > Cassandra**. The **Databases | Cassandra** page appears.
3. Enter characters of the object name or Protection Group name or source name, or Use Wildcard * in Search for Recovery. A list of protected items appears.

   You can optionally filter the search results by Source, Protection Group, or Storage Domain.
4. By default, the latest snapshot is selected for recovery.

   Perform the following steps to recover from a different snapshot:

   1. From the selected list, hover the mouse pointer over the highlighted snapshot, and then click .

      The **Edit recovery point** page appears.
   2. From the built-in calendar, select a date range.
   3. Select the snapshot point for recovery.
   4. Click **Select Recovery Point**.

   Perform the following steps to recover to a point in time:

   1. From the selected list, hover the mouse pointer over the highlighted snapshot, and then click .

      The **Edit recovery point** page appears.

2. Select **Timeline** view.
3. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar.
4. For snapshot recovery, select the snapshot to be recovered by clicking the corresponding blue dot. You can also select any point from the green solid line on the slider if you want to restore to a specific point in time.
5. Click **Select Recovery Point**.

5. Click **Next: Recover Options**. The recovery details are displayed.
6. Under **Recover As** select **Replace Original**, **Modify Original**, or **New Object**.
   - **Replace Original** - Select the **Data Center** to replace the object(s) back to the source from where it was backed up.
   - **Modify Original** - Choose this option and select the Data Centers to perform the object(s) restore on live Cassandra tables. This option allows you to skip truncate and retain the current Cassandra data while recovering objects.

     > **Warning:** The live Cassandra table restore operation may result in undesirable outcomes, ensure that you review and understand the recommendations and limitations before performing live table restore. For more information, see Considerations for Live Cassandra Table Restore.

   - **New Object**:
     a. **Target** - Specify the target for the recovered object.
     b. **Overwrite existing objects with the same name** - Toggle this setting on if you want to overwrite existing objects with the same name. A warning is displayed, type **YES** to proceed.
7. **Log Restore Directory**: Specify the path of the directory on the Cassandra cluster to which you want to recover the commit logs. You must specify the same path for all Cassandra nodes.

   > **Note:**
   > - The SSH user must have read and write permissions to the archive directory.
   > - The user running the Cassandra process must have read permissions to the archive directory.

8. **Staging Directory List**: Specify the staging directory path to which you want to recover the files. You can specify one or more directories separated by comma.

   > **Note:** Applicable only when restoring DSE 6.x.

9. **Restart Cassandra Cluster**: Toggle the **Restart Using Cohesity** setting on if you want Cohesity to restart the Cassandra cluster.
   a. **Command**: In the **Command** field, specify the command or script that can be used to restart the Cassandra cluster.
      - If the command is provided, Cohesity runs the command as the SSH user specified during the registration process. You must create a script or command so that the Cassandra services can be either stopped or started with the appropriate credentials and permissions.
      - If the command is not provided:
        - For DSE, Cohesity uses nodetool stopdaemon API using remote JMX connection to Cassandra nodes to stop the Cassandra services.

          Cohesity runs the `service dse start` command as the SSH user to start the Cassandra services.
        - For Apache, Cohesity uses nodetool stopdaemon API using remote JMX connection to Cassandra nodes to stop the Cassandra services.

          Cohesity runs the `<Config_Dir>/../bin/cassandra -R` command as the SSH user to start the Cassandra services.

   b. **Restart Immediately**: Select this option to restart the Cassandra cluster immediately after recovery is complete.
   c. **Restart On**: Select this option if you want to schedule the restart of the Cassandra cluster on a specific date and time after recovery is complete.
      i. **Date**: From the built-in calendar specify a date.
      ii. **Time**: From the time picker, select the time.

   > **Note:** If you do not want Cohesity to restart the Cassandra cluster, perform the procedure mentioned in Configure Log Replay.

10. Under **Recovery Options**, select the required options for the recovery and complete the following:

Option	Description
Roles and Permissions	Restores the roles and permissions associated with the objects. The option is enabled by default.
Rename	Rename objects. Choose **Bulk Rename** to append a suffix to all the selected objects, or choose **Rename Individual Objects**. This option is displayed only if you select **New Object** in the **Recover As** option.
Object Properties	The following property overrides are supported: • Keyspace property override: This option is only available when the user chooses keyspace objects to be restored. The only available property that can be overridden is **replication**. Replication property example : Simple strategy - {'class': 'SimpleStrategy', 'replication_factor': '2'} Network strategy - {'class': 'NetworkTopologyStrategy', 'dc1': '3'} • Table property override: This option is only available when the user chooses table objects to be restored. The only available properties that can be overridden are **compression** and **compaction**. Compression example - {'chunk_length_in_kb': '64', 'class': 'org.apache.cassandra.io.compress.LZ4Compressor'} Compaction example - {'class': 'org.apache.cassandra.db.compaction.SizeTieredCompactionStrategy', 'max_threshold': '32', 'min_threshold': '4'}
Concurrency	Maximum number of recovery streams that will be created to exchange data with the cluster.
Bandwidth Throttling	Maximum network bandwidth that each recovery stream can use for exchanging data with the cluster.
Task Name	Recovery task name.

11. Click **Start Recovery** to start the recovery operation.

Considerations for Live Cassandra Table Restore

Review and understand the following recommendations and limitations before performing live table restore:

- Live Cassandra table restore can only be performed if you restore the objects on the same Cassandra cluster.

- Ensure you run Imanis Apps on all data centers where the Cassandra cluster will be deployed.
- During live Cassandra table restore operation, renaming or changing object properties is prohibited.
- Point-in-time recovery (PITR) recovery is not supported.
- Sequentially perform the restore operations. Only start live table restore on other data centers once the expected restoration of one data center is successfully finished.
- Live-table restore only applies to objects with a "**NetworkTopologyStrategy**" as the replication strategy.
- Live Cassandra table restore is only possible if the objects being restored exist in the target Cassandra database.
- Live table restore can only be performed if the schema of the objects to be restored is the same as that of the backed-up objects.
- To ensure efficient data restoration, Cohesity recommends taking backup snapshots of different data centers, including the data center from which regular restores will be performed and the data centers from which live-table restores will be performed. These snapshots should be taken almost simultaneously and should contain similar objects.
- If different snapshots have different objects, then live-table restore is only possible for those common objects present in all the snapshots.
- Cohesity recommends replicating snapshots using a replication policy between clusters for both restore types (regular and live-table).
- Live Cassandra table restore only applies if table properties (**compaction** & **compression**) match their backup properties.
- Avoid using any **mutation operation** (**insert**/**update**/**delete**) on any objects (backed up by the same snapshot) after starting a regular restore on one data center and before completing the live-table restore on any other data center.
- When performing a live-table restore, it is crucial to carefully choose the source cluster or data center from where the data will be restored. This will help ensure a successful restoration process.

Cassandra Point-in-time Recovery (PITR)

Point in Time Recovery (PITR) enables you to have aggressive Recovery Point Objectives (RPO) for Cassandra source. PITR provides more granular recovery to scenarios of accidental data error or corruption. For PITR, commit logs on the Cassandra cluster are backed up which helps you to select a recovery point on a time scale.

Prerequisites

- On the Cassandra cluster:
  - You must enable commit log backup for successful point-in-time recovery.
  - You must ensure that the location to which the commit logs are restored must have sufficient disk space for new logs.
  - Cassandra service must be restarted on all nodes after enabling Commit Log Archival for backup to copy the commit logs.
  - You must run one full backup after enabling point in time on the Cassandra cluster.
  - The SSH user must have read and write access to the backup location.
  - The backup location must be the same for all nodes on the Cassandra cluster where PITR is enabled.
- For PITR, the Cassandra cluster must be registered on one Cohesity cluster only.

Configure Commit Log Archival

For PITR, the archival of commit logs must be enabled on the Cassandra cluster.

You need to configure the commit log archival on the Cassandra cluster in the `commitlog_archiving.properties` configuration file. The commit log is put to the archive location at node startup and when a commit log is written onto disk, or at a specific point-in-time.

The command `archive_command` expects only a single command with arguments. The parameters must be entered verbatim. `STDOUT` and `STDIN` or multiple commands cannot be executed. To execute multiple commands you need to create a script with multiple commands and then call the script from the configuration file.

Enable Commit Log Archival

You must specify the parameters in the `archive_command` to enable commit log archival.

The following is a sample command:

`archive_command=/bin/ln %path /backup/%name` where

- `%path` is the fully qualified path of the segment to archive.
- `/backup` is the location where you want to archive the commit log.
- `%name` is the name of the commit log.

> **Note:**
> - The SSH user must have read and write access to the `/backup` location.
> - The backup location must be the same for all nodes on the Cassandra cluster where PITR is enabled.

Disable Commit Log Archival

To disable commit log archival, you must reset the `archive_command` as `archive_command=` (must be set to empty).

Points to Note

- The modification on the `commitlog_archiving.properties` configuration file must be done on all the Cassandra nodes.
- The Cassandra process must be restarted after editing the configuration file.
- Commit logs are archived frequently because all writes to Cassandra are part of commit logs and this may consume more disk space. The disk on which the archive location is mounted must have adequate disk space.
- For improved performance, it is recommended to have the Cassandra directory and commit log directory on separate disks.

Configure Log Replay

> **Note:** By default, Cohesity configures the log replay. Optionally, if you do not want Cohesity to make any changes on the Cassandra cluster you can manually configure log replay by following the procedure given below. Before you start with the procedure, contact Cohesity Support to update a setting on the Cohesity cluster thus allowing you to manually configure the log replay.

You need to configure the `restore_command`, `restore_directories`, and `restore_point_in_time` commands on the Cassandra cluster.

The command `restore_command` expects only a single command with arguments. The parameters must be entered verbatim. `STDOUT` and `STDIN` or multiple commands cannot be executed. To execute multiple commands you need to create a script with multiple commands and then call the script from the configuration file.

Enable Restore of Archived Commit Log

You must specify the parameters in the `restore_command` to enable the restoration of the archived commit log.

The following is a sample command:

`restore_command=/bin/cp -f %from %to` where

- `%from` is the fully qualified path of the archived commit log segment from the `restore_directories`.
- `%to` is the name of the live commit log directory.

You must also specify the parameters in the `restore_directories` command.

The following is a sample command:

```
restore_directories=/restore_directory
```

You must also specify the parameters in the `restore_point_in_time` command to restore to a point-in-time. Cassandra replays all the logs in the restore directory till the specified time.

The command accepts the time in the following format represented in GMT:

```
YYYY::MM::DD HH:MM:SS
```

The following is a sample command:

```
restore_point_in_time=2013:12:11 17:00:00
```

Disable Restore of Archived Commit Log

To disable the restore of commit log archival, the `restore_command`, `restore_directories`, and `restore_point_in_time` commands must be set to empty.

Register

To configure Cassandra for data protection on Cohesity, you need to register it as a source.

For more information, see Register a Cassandra Source.

Backup

A point-in-time backup is achieved by backing up the data and the commit logs of the Cassandra cluster. Data can be backed up at a lesser frequency than the logs. In Cassandra, commit logs are generated for the entire node and cannot be filtered based on keyspaces or tables. Therefore, the commit log backup and data backups cannot be tied together based on keyspace or table. You need to create two Protection Groups, one for data backup (keyspace and table) and the other for commit log backup. For more information, see Backup Cassandra.

Perform the following steps to create a Cassandra commit log backup:

- Configure the commit log archival in the Cassandra cluster. For more information, see Configure Commit Log Archival.

  > **Note:** The SSH user must have read and write permissions to the archive directory.

- Specify the archive log location while registering the Cassandra cluster as a source. For more information, see Register a Cassandra Source.
- Create a protection policy that has the commit log backup details. You can also use an existing policy that has the commit log backup details. For more information, see Create or Edit a Standard Policy.
- Create a Protection Group to backup the commit log. For more information, see Backup Cassandra.

> **Note:** Cohesity removes the backed-up commit logs from the `/backup` location.

Recover

Point-in-time recovery is achieved by copying both the data and commit logs on the Cassandra primary. Data restore is a copy of the `ss` tables from Cohesity. Commit log restore included both copying and replaying the logs.

For more information, see Recover Cassandra.

Considerations

- Commit logs can be replayed only to the original Cassandra cluster and with the same schema.
- Archival of Log Backups is not supported.
- For PITR, object renaming is not supported.
- DDL changes are not restored during log replay.
- You cannot back up specific keyspace or table commit logs for point-in-time recovery. The commit log backup is for the entire Cassandra cluster.
- You must have performed at least one protection run after the first commit log backup for successful point-in-time recovery.
- For recovery from a remote cluster (archival or replication), you must specify the target cluster in the protection run policy, data backup, and commit log backup.
- Cohesity allows only one backup of the commit logs per source.
- You cannot recover objects using a Log Backup Protection Group. For recovery of objects you must create a regular backup Protection Group.
- If a backup job is edited to add objects, the recovery timeline may display those objects even before their first backup run. A PITR recovery attempt for such objects within this time range will fail.
- If a backup job is edited to remove objects, the recovery timeline may continue to display those objects even after they are removed. A PITR recovery attempt for such objects within this time range will also fail.

- For PITR:
  - Do not register Cassandra on multiple Cohesity clusters.
  - Do not register the same Cassandra cluster with different names or IPs on a Cohesity cluster.
  - If registering the same source on multiple Cohesity clusters, do not set the retention for Cassandra Log (PITR) Backups on a replicated Cohesity cluster higher than the retention on the Primary Cohesity cluster to avoid data loss.

Cassandra Hot Standby

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

Cassandra Hot Standby allows you to recover the latest snapshots from a full or incremental backup. You can recover the incremental changes of the protected Cassandra objects using Cohesity Platform. The latest snapshots are recovered from the source cluster to a target cluster. You can create an incremental recovery of a protected Cassandra object and if there is an incremental change in the backup, the Cohesity Platform initiates an incremental recovery. This ensures that the source cluster and the target cluster are always in sync.

The first recovery is a full recovery and all subsequent recoveries are incremental.

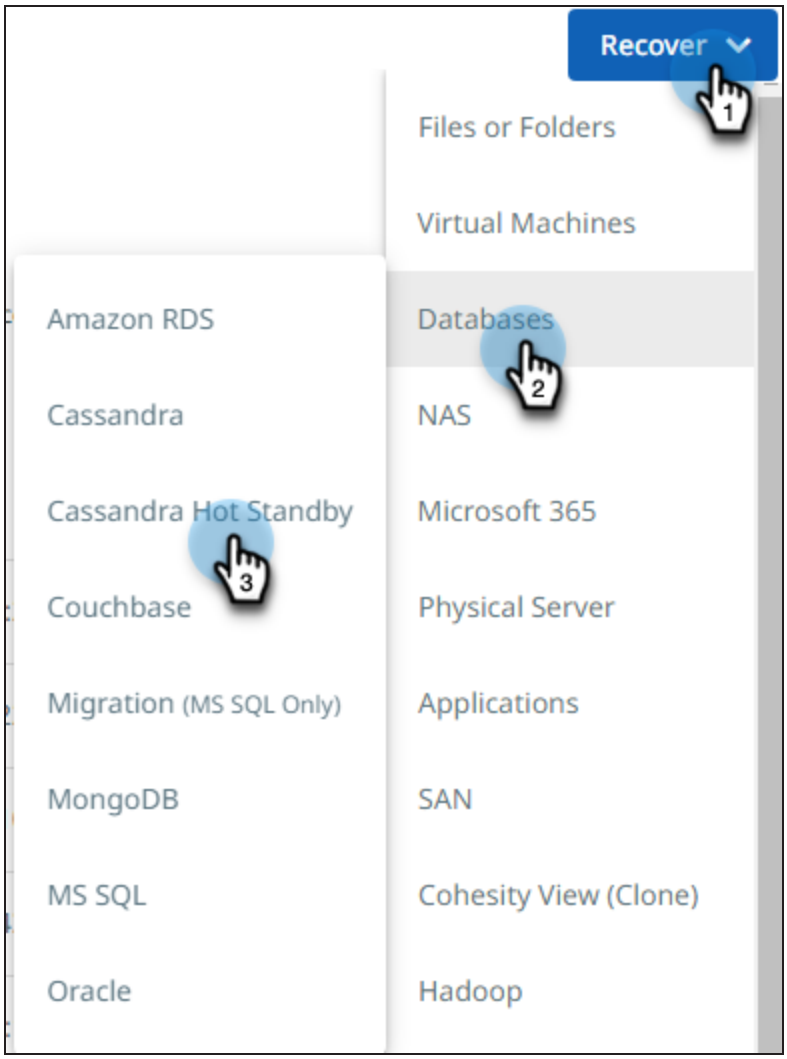
Incremental Recovery of Cassandra Objects

You can search through the backups using the protection group, keyspaces, or table name for the objects you plan to recover.

Perform the following steps to initiate incremental recovery of Cassandra objects:

1. In the Cohesity Platform, select **Data Protection > Recoveries**.

2. Click **Recover** at the upper right and navigate to **Databases** > **Cassandra Hot Standby**. The **New Recovery** page appears.



3. Search for the Cassandra database. Enter characters of the name and a list of item displays. You can optionally Use Wildcard * in Search for Recovery. You can also optionally narrow the search results by specifying filter criteria, for example, you can filter the search results by a specific **Protection Group** or **Source** or **Storage Domain.**
4. Select the object(s) or Protection Group and click **Cassandra Hot Standby**. The Cassandra Hot Standby page appears.

   If you need to select another Cassandra object, click the edit icon and select the required object and then click **Cassandra Hot Standby**.
5. In the **Hot Standby** section, do the following:
   a. **Target** - Specify the IP address of the target cluster to which you want to migrate the object.

b. **Overwrite existing objects with the same name** - Toggle this setting on if you want to overwrite existing objects with the same name. A warning is displayed, type **YES** to proceed.

c. **Data Centers** - Select the data center.

> **Note:** This field appears when the source and target Cassandra clusters are the same.

d. **Staging Directory List** - Specify the staging directory path to which you want to recover the files. You can specify one or more directories separated by a comma.

> **Note:** This field appears when the selected target is Cassandra DSE 6.x.

6. In the **Recovery Options** section, do the following:

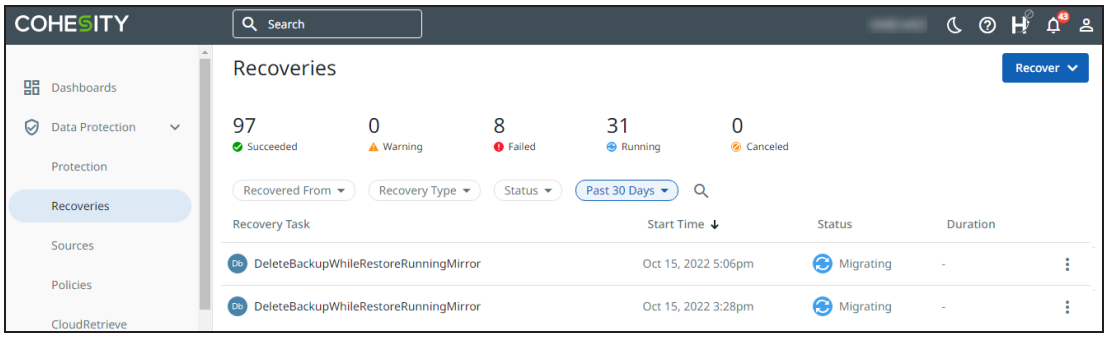
   a. **Concurrency** - Maximum number of recovery streams that will be created to exchange data with the cluster.

   b. **Bandwidth Throttling** - Maximum network bandwidth that each recovery stream can use for exchanging data with the cluster. Turn on the **Enabling this will allow you to set bandwidth throttling for each worker** toggle to specify the bandwidth throttling. In the **MB/s per Recovery Stream** field, specify the value.

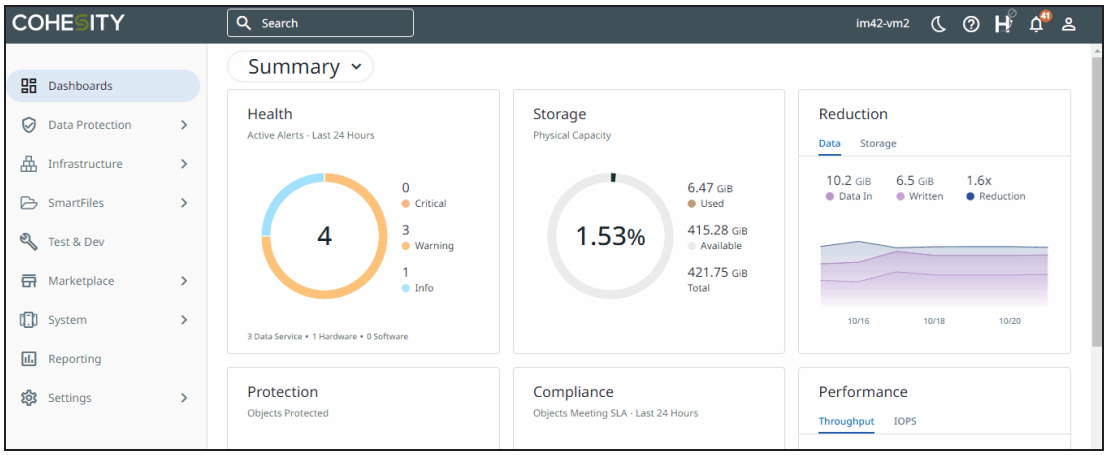
   c. **Task Name** - Enter the recovery task name.

7. Click **Start Hot Standby**.

The incremental recovery workflow appears on the **Recoveries** page and the status shows as **Migrating**.



The following animated image shows an example of Cassandra incremental recovery workflow.



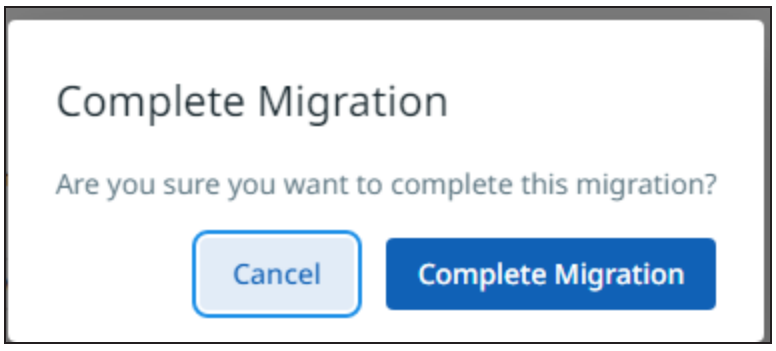
Finalize Migration

You can finalize an in-progress incremental recovery workflow. Finalizing an incremental recovery does not stop the current running recovery but new incremental recoveries are not initiated.

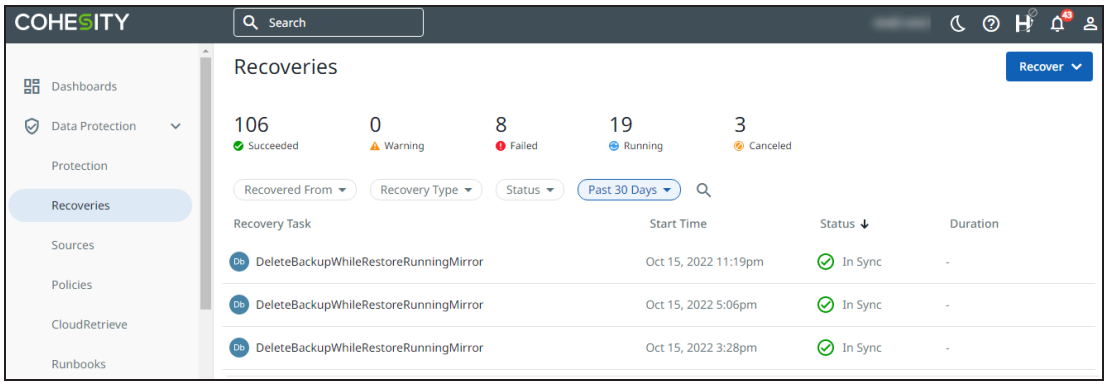
Perform the following steps to finalize an in-progress incremental recovery workflow:

1. Navigate to **Data Protection > Recoveries**. The Recoveries page appears.
2. Find the incremental recovery in the list and do any one of the following:
   - Click the task name to display its detail page, click ⋮ and select **Finalize Migration**.
   - Click ⋮ for the incremental recovery that you want to finalize and click **Finalize Migration**.

     The **Complete Migration** page appears.
3. Click **Complete Migration** if you want to finalize the incremental recovery or click **Cancel** to continue the incremental recovery.



Once you finalize the incremental recovery the status changes from **Migrating** to **In Sync** on the **Recoveries** page.

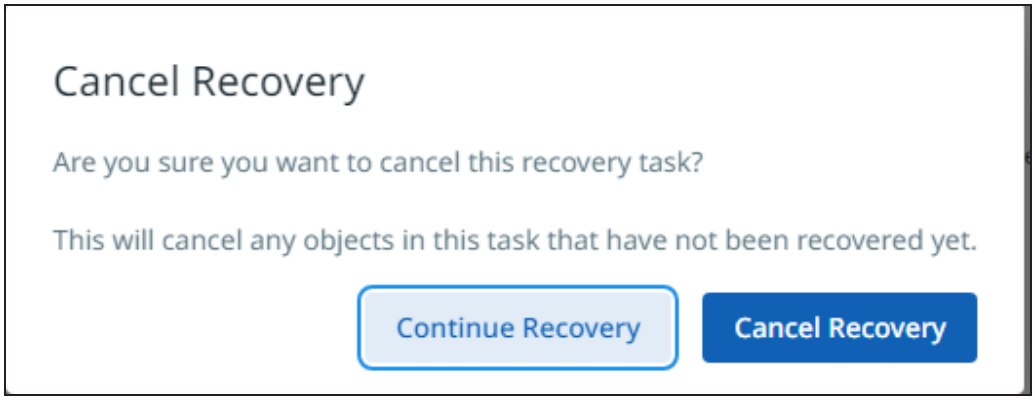


Cancel

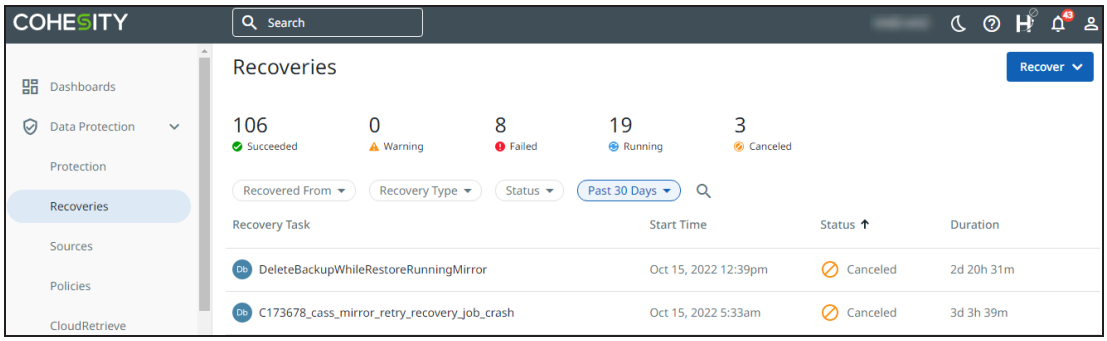
You can cancel an in-progress incremental recovery workflow.

Perform the following steps to cancel the incremental recovery workflow:

1. Navigate to **Data Protection > Recoveries**. The Recoveries page appears.
2. Find the incremental recovery in the list and do any one of the following:
   - Click the task name to display its details page and click **Cancel**.
   - Click for the incremental recovery that you want to stop and click **Cancel**. The **Cancel Recovery** page appears.
3. Click **Cancel Recovery** if you want to cancel the incremental recovery or click **Continue Recovery** to continue the incremental recovery.



Once you cancel the incremental recovery the status changes from **Migrating** to **Canceled** on the **Recoveries** page.



Considerations

- The Cassandra version on the source cluster and the target cluster must be the same.
- Two consecutive protection runs of the Cassandra objects must be less than the gc_grace_seconds of a table.
- Table truncation is not supported.
- Multiple schema alteration queries executed on the single column on the source Cassandra cluster between two backups is not restored to the target Cassandra cluster during a single invocation of incremental data recovery and results in an error.

  For example, if the following schema alteration commands are used on a table:

  - ALTER TABLE newyork.transit_map DROP events [where events column is dropped]
  - ALTER TABLE newyork.transit_map ADD events text [where events column of type text is added again to the schema]

  The preceding commands are performed on the Cassandra cluster and then the incremental data recovery workflow is executed which moves data objects to the destination Cassandra cluster.

  This results in an error with the incremental data recovery workflow as schema alteration queries executed on the source Cassandra cluster will not be propagated to the destination Cassandra cluster during a single invocation of data recovery workflow.

Couchbase Using Connector Agent

Cohesity natively integrates with Couchbase to provide backup and recovery for Couchbase deployments on Linux x86_64 platform.

Cohesity provides a connector agent that enables you to perform a full backup, incremental backup, and restore at the bucket level.

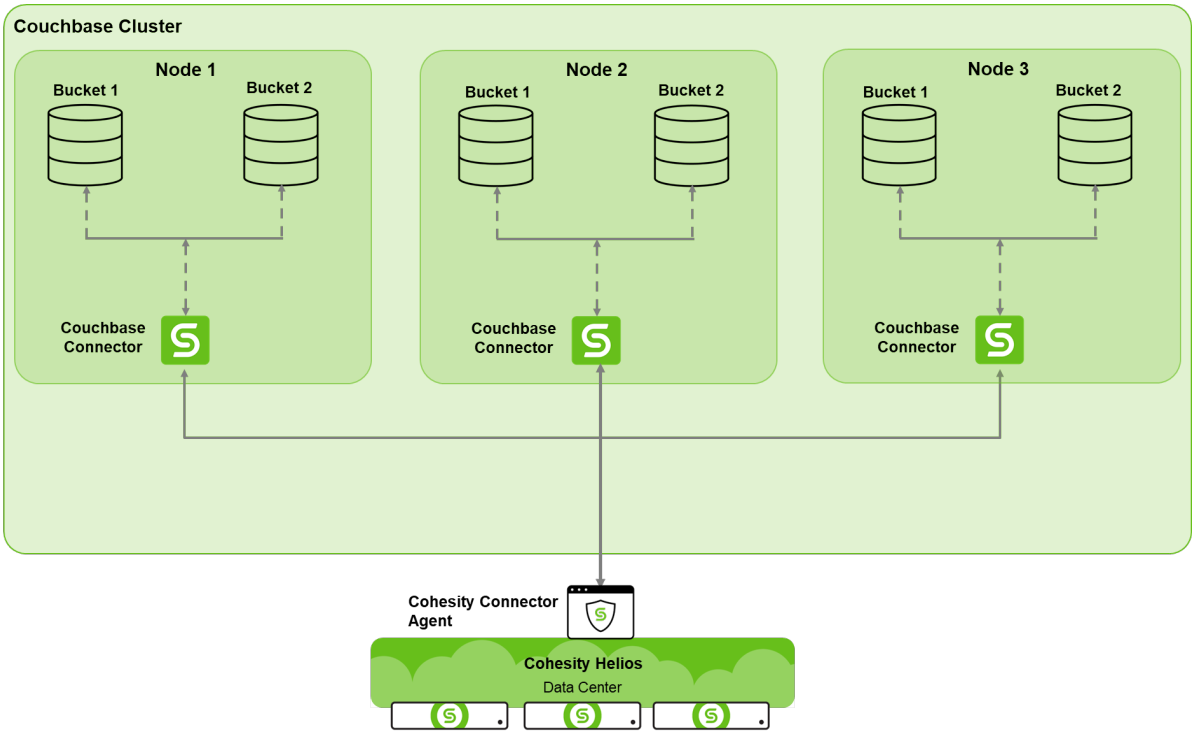
> **Note:** With Cohesity Connector Agent, you can now backup and restore Couchbase buckets and Ephemeral buckets.

Core Components

The following are the core components for protecting Couchbase buckets:

- Couchbase cluster
- Cohesity Couchbase Connector Agent

As illustrated, you can integrate Cohesity with your Couchbase deployments using the Cohesity Connector Agent.



Plan and Prepare for Couchbase Protection Using Connector Agent

Before you register your Couchbase deployment as a source with Cohesity, ensure the following prerequisites:

- The user account of the instance must have bucket admin privileges.
- Download and install the Cohesity Linux Agent on the Couchbase nodes. A minimum of 3 nodes are recommended during registration.
- Download and install the Couchbase connector plug-in.
- Review and understand the prerequisites.

Supported Couchbase Versions

For more information, see NoSQL and Hadoop Platforms.

Port Requirements

You must open certain ports in the firewall to allow the Cohesity cluster to transmit and receive data. Ensure that you open the following ports in the firewall to allow data transfer between Couchbase and the Cohesity cluster:

Port	Source	Target	Direction	Network Protocol
50051	Cohesity cluster	Couchbase	Unidirectional	TCP/IP
59999	Cohesity cluster	Couchbase	Unidirectional	TCP/IP
8091	Couchbase	Couchbase	Bidirectional	TCP/IP
18091	Couchbase	Couchbase	Bidirectional	TCP/IP
3000	Couchbase	Cohesity cluster	Unidirectional	TCP/IP

*Couchbase nodes must be able to communicate with each other on ports 8091 and 18091.

Minimum Permissions

Cohesity requires the following privileges enabled for the Couchbase user used during source registration for successful backup and recovery:

Permission	Description
Data Backup & Restore	Required to: • Run backup • Run DDL restore • Restore documents to existing bucket
Cluster Admin	Required to create or re-create a bucket during recovery.
Backup Full Admin	Required to: • Perform the backup-related task. • Access to the Couchbase Web Console.

Considerations

Review and understand the following before you protect your Couchbase cluster:

- Cohesity now supports bucket-level, scope-level, and collection-level of backup.
- Once a bucket or its objects such as scopes and collections are configured to be backed up using Cohesity, users should not initiate a manual backup on the same bucket outside of the Cohesity cluster.
- The same objects should not be part of multiple Protection Groups.
- Configure a protection policy to perform a periodic full backup at intervals less than the retention period.
- When restoring to the Couchbase 6.6 version, indexes won't be restored if the rename option is used. Index rebuild will be required after the restore operation, if the indexes get restored to a separate node from where they were backed up. For more information, see the description section on "cbbackupmgr restore" here.
- Cohesity recommends performing functional testing where the bucket size is not more than 250GB.
- Couchbase compaction is a resource intensive operation and can substantially increase the backup or recovery SLAs when run in parallel. It is recommended that the Cohesity workflows and Couchbase compaction are scheduled to run at different time periods.

Prerequisites

Ensure that:

- You use a root user or non-root user to install the Cohesity Linux agent and Couchbase Connector. If you choose to use a non-root user, you must add the `sudo` privileges for the non-root user using the syntax given below:

  ```
  <user_name> ALL=(ALL) NOPASSWD:SETENV: /path/to/command1,
  /path/to/command2, /path/to/command3
  ```

  The following is the `sudo` commands for Couchbase Connector:

  ```
  cohesityagent ALL=NOPASSWD:SETENV: /usr/bin/find,
  /usr/bin/stat,/usr/bin/test, /usr/bin/mv, /usr/bin/cat, /bin/mkdir,
  /bin/rm, /bin/cp, /bin/chown, /bin/chmod, /bin/java
  ```

  Where, `/opt/cohesity/couchbase` is the Couchbase connector installation directory.

  > **Note:**
  > - If the **cohesityagent** user entry is already present in **/etc/sudoers**, append the list of commands to the existing entry.
  > - The actual paths for each command might vary depending on the Platform and OS distribution. For detailed instructions, see Download and Install the Linux Agent.

- While you Register and Manage the Couchbase Source Using Connector Agent, provide the path of the certificate config file in the **Couchbase SSL Settings** field.

  > **Note:**
  > Cohesity Agent uses VIPs or FQDN for transmitting data while using S3 protocol. For Cohesity Connector Agents that use S3, the client fails with SSL errors, if x509_extensions is not present in the Cohesity SSL certificates. Ensure that you edit the sample file (**cert_req.conf**) to include the following x509_extensions and add all the VIPs to the `alt_names` list. For more information, see the Update SSL Certificates Using Cohesity CA or Customer CA certificate.

  ```
  #REQ FILE: cert_req.conf
  #--------------------------
  [ req ]
  default_bits    = 2048
  default_md      = sha384 (or sha256)
  prompt          = no
  encrypt_key     = no
  distinguished_name = req_distinguished_name
  req_extensions     = req_ext
  x509_extensions = req_ext
  ```

- Java 1.8 or higher version is installed on the Couchbase nodes.
- Java binary is available in the `$PATH` environment variable.
- The staging directory path must have a free space which is equal to 10% of the bucket size. For more information, see Couchbase documentation.

Download and Install the Cohesity Linux Agent

The Cohesity Linux Agent is available as an RPM-based installer. Based on your requirements, download the installer and install it accordingly on the node(s) of the Couchbase cluster. For detailed instructions, see Download and Install the Linux Agent.

Download and Install the Couchbase Connector

Cohesity provides Couchbase connector RPM for backup and restore of Couchbase deployments.

Download the Couchbase Connector

Cohesity provides a Couchbase Connector to backup and restore Couchbase buckets. The Couchbase Connector is available as a data source agent on the Cohesity Download portal.

Log in to the Cohesity Download portal, download the respective data source agent for Couchbase Connector, and copy the data source agent to the Couchbase host.

> **Note:** With Cohesity Connector Agent, you can now backup and restore Couchbase buckets and Ephemeral buckets.

Install the Cohesity Couchbase Connector RPM

Before you install the Cohesity Couchbase connector, ensure that you have `sudo` privileges.

To install the Cohesity Couchbase connector:

1. Log in to the Couchbase node where you have copied the Cohesity Couchbase connector RPM-based installer, `cohesity-couchbase-connector-<version>.x86_64.rpm`.
2. Run the following command to install the Cohesity Couchbase connector:

   Using `yum`:

   ```
   sudo sh -c 'yum localinstall /tmp/cohesity/cohesity-couchbase-connector-<version>.x86_64.rpm'
   ```

   Using `rpm -ivh`:

   ```
   sudo rpm -ivh cohesity-couchbase-connector-<version>.x86_64.rpm
   ```

Upgrade the Cohesity Couchbase Connector

To upgrade the Cohesity Couchbase connector, run the following command on Couchbase host:

```
sudo rpm -U cohesity-couchbase-connector-<version>.x86_64.rpm
```

Uninstall the Cohesity Couchbase Connector

To uninstall the Cohesity Couchbase connector, log in to the Couchbase node where you have installed the Cohesity Couchbase connector and run the following command:

Using `yum`:

```
rpm U --force <rpm-file name>
```

> **Note:** Once the connector is upgraded, edit and save the source to reflect the newly added groups, scopes, and collections. For more information, see Update the Couchbase Source Configuration.

Using `rpm`:

```
sudo rpm -e cohesity-couchbase-connector-<version>.x86_64.rpm
```

Register and Manage the Couchbase Source Using Connector Agent

To protect your Couchbase buckets, you need to register your Couchbase deployment as a source on the Cohesity cluster. After registering your Couchbase deployment as a source, you can:

- Update the Couchbase source configuration.
- Unregister the Couchbase source from the Cohesity cluster.

> **Note:** With Cohesity Connector Agent, you can now backup and restore Couchbase buckets and Ephemeral buckets.

Register Couchbase as a Source

Before you register Couchbase as a source, ensure that you:

- Review the considerations.
- Perform the prerequisite tasks.

For more information, see Plan and Prepare for Couchbase Protection Using Connector Agent.

To register Couchbase as a source:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Register** on the top-right of the page and then select **Universal Data Adapter**.
3. In the **Register Universal Data Adapter** page, perform the following:
    a. From the **Source Type** drop-down menu, select **Couchbase**.
    b. From the **Host OS Type** drop-down menu, select **Linux**.
    c. In the **Hostnames/IP Addresses** field, enter the hostname or IP address of the node(s) that you have identified to run the Cohesity Couchbase connector. For more information, see Plan and Prepare for Couchbase Protection Using Connector Agent.
    d. In the **Datasource Agent Installation Path** field, enter the directory path on the Couchbase Linux machine, where you have installed the Cohesity Couchbase connector. For more information, see Install the Cohesity Couchbase Connector RPM section in Plan and Prepare for Couchbase Protection Using Connector Agent.
    e. Optional. In the **App Authentication** field, enter the username and password.
    f. Enable **Couchbase SSL Settings** to enable secure connection to the Couchbase cluster while reading or writing data. In the **SSL Certificate Path** field, enter the path to the SSL certificate on the Couchbase node which is used

to securely connect to the Couchbase cluster.

> **Note:**
> Cohesity Agent uses VIPs or FQDN for transmitting data while using S3 protocol. For Cohesity Connector Agents that use S3, the client fails with SSL errors, if x509_extensions is not present in the Cohesity SSL certificates. Ensure that you edit the sample file (**cert_req.conf**) to include the following x509_extensions and add all the VIPs to the `alt_names` list. For more information, see the Update SSL Certificates Using Cohesity CA or Customer CA certificate.
>
> ```
> #REQ FILE: cert_req.conf
> #--------------------------
> [ req ]
> default_bits    = 2048
> default_md      = sha384 (or sha256)
> prompt          = no
> encrypt_key     = no
> distinguished_name = req_distinguished_name
> req_extensions     = req_ext
> x509_extensions = req_ext
> ```

g. Under **Source Settings**, enter the details of the Couchbase source:

Field	Mandatory?	Description
Staging Directory Path	Yes	Path to the staging directory. Spaces are not supported in the staging directory path.
Couchbase Installation Directory	Yes	Path to the Couchbase installation directory. Spaces are not supported in the Couchbase installation directory path.
Couchbase Administration Port or Secured Administration Port	No	Port for Couchbase administration

h. Click **Register**.

Update the Couchbase Source Configuration

After registering Couchbase as a source on the Cohesity cluster, you can update the Couchbase source configuration.

> **Note:**
> - Ensure that the Cohesity connector is installed on all the node(s) in the Couchbase cluster.
> - You cannot modify the source name.

To update the Couchbase source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Couchbase source and select **Edit**.
3. In the **Update Universal Data Adapter** page, update the required configurations.
4. Click **Update**.

Unregister the Couchbase Source

If you plan to stop protecting your Couchbase buckets, you can unregister the Couchbase source from the Cohesity cluster.

To unregister the Couchbase source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Couchbase source and select **Unregister**.

Backup Couchbase Using Connector Agent

Cohesity provides a simple workflow to back up your Couchbase buckets. After registering Couchbase as a source on Cohesity, you can start configuring your backups.

> **Note:** With Cohesity Connector Agent, you can now backup and restore Couchbase buckets and Ephemeral buckets.

Backup Process

Cohesity provides a Couchbase Connector for backup and restore of Couchbase deployments. The Couchbase Connector leverages the native backup capabilities provided by Couchbase.

After registering the Couchbase source on Cohesity, you can create a Protection Group and specify the objects you want to backup.

Protect Couchbase Deployments Using Connector Agent

Couchbase deployments are protected using a Protection Group and a Protection Policy. A Protection Group enables you to specify the objects such as buckets, scopes, and collections that you want to back up.

The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select which standard or custom policy to use when creating a Protection GroupFor more information, see Manage Protection Policy.

To protect Couchbase deployments:

1. Do one of the following:
   - Select **Data Protection > Protection**. Click **Protect** on the top-right of the page and then select **Universal Data Adapter**.
   - Select **Data Protection > Sources**. Click the actions menu (⋮) next to the Couchbase source and then select **Protect**.
2. From the **Source** drop-down list, select the registered Couchbase source or click **Register Source** to register a Couchbase source. For more information, see Register Couchbase as a Source.
3. In the **Objects** section, select the object(s) that you plan to protect.

   > **Note:** You can select the objects using checkboxes or auto-protect. If you select the checkbox, all the collections inside the selected object will be backed up. If you select auto-protect, all the collections inside the selected object and any newly added collections will also be backed up.
   > For recovering buckets, the auto-protect has to be enabled at the bucket level and for scopes, the auto-protect has to be enabled at either scope or bucket level. The manual selection of scopes and buckets using the checkbox will only allow recovery at the scope level.
4. In the **Protection Group** section, enter a name for the Protection Group in the **Name** field.
5. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy.
6. In the **Settings** section, enter the following details:

Field	Mandatory?	Description
Storage Domain	Yes	Select the appropriate storage domain. For more information, see Manage Storage Domains.
Start Time	No	Define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
Mounts/VIPs	No	N/A for Couchbase data protection.

7. In the **Additional Settings** section, enter the maximum backup streams in the **Concurrency** field. It defines the maximum number of backup streams that will be created to exchange data with the cluster. Couchbase servers do not efficiently handle more than 6 parallel connections. So, it is recommended not to increase the concurrency beyond 6 in the Backup settings.
8. Click **Protect**.

Manage the Couchbase Backup Configuration Using Connector Agent

A backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Couchbase.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ in the **Objects** section.
5. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
6. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Couchbase
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a recovery run:

1. Navigate to **Data Protection > Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity UI.

To delete the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Couchbase.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
   - Delete Protection Group Only
   - Delete Protection Group and Snapshots

Recover Couchbase Using Connector Agent

You can recover the objects such as buckets, scopes, and collections in Couchbase to the same Couchbase cluster or a different Couchbase cluster.

> **Note:** With Cohesity Connector Agent, you can now backup and restore Couchbase buckets and Ephemeral buckets.

Recover Couchbase Buckets

To recover Couchbase buckets:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** at the top right of the page and then select **Universal Data Adapter**.
3. Search for the bucket that needs to be recovered by entering characters of the bucket name, or by specifying the wildcard character *.
4. From the list of search results, select the object and the desired snapshots to recover.
5. Click **Next: Recover Options**.
6. In the **Recover As** section, based on your requirements, select any one of the following options:

Options	Description
Replace Original	Overwrites the original object in your primary environment. Type **Yes**, if you want to overwrite the original object.
New Object	To recover to a different Couchbase cluster. Select the **Target** Couchbase cluster to which the data needs to be recovered. Also, enable **Overwrite existing object with the same name** and type **Yes**, if you want to overwrite the original object in your primary environment.

7. In the **Restore Settings** section, select **DDL Only Restore** or **Disable GSI Indexes** based on your requirements. **DDL Only Restore** restores only the bucket metadata, and **Disable GSI Indexes** skips GSI indexes during restore.
8. Toggle the button to enable the Filtering Options section.

   In the filter keys, enter the document key or document key regex.

   In the filter values, enter any document value regex or the value to match.

   > **Note:** The regular expression must be compatible with the RE2 syntax.

9. In the **Recovery Options** section, based on your requirements, select any one of the following options:

Options	Description
Mounts/VIPs	N/A
Concurrency	The maximum number of recovery streams that will be created to exchange data with the cluster. Couchbase servers do not efficiently handle more than 6 parallel connections. It is recommended not to increase the concurrency beyond 6 in the Recovery settings.

Options	Description
Rename	If you select **New Object** in the **Recover As** section, this option allows you to rename any one of the objects (bucket or its objects such as scopes and collections). The original name of the object is displayed in the **Original Name** field. Enter the new name for the object in the **New Name** field. For example, if a bucket has a scope with 2 collections, bucket1.scope1.col1 and bucket1.scope1.col2 then during recovery the scope can be renamed as follows: • bucket1.scope1Ret.col1 • bucket1.scope1Ret.col2 **Note:** Make sure to rename both collections according to the scope name.
Task Name	Change the default name of the recovery task.

10. Click **Recover**.

Cancel a Recovery Run

When you cancel a recovery run, the Couchbase connector cancels the job by terminating the recovery processes.

To cancel a recovery run:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click the action icon (⋮) next to the recovery run and click **Cancel Run**.
3. In the **Cancel Recovery** dialog box, select any one of the following:
   - **Continue Recovery** if you want to continue to recovery run.
   - **Cancel Recovery** if you want to cancel the recovery run.

MongoDB

9 January 2026

The Cohesity MongoDB DataProtect solution natively integrates with MongoDB to provide consistent backup and recovery for MongoDB deployments.

Based on the policy settings, the Cohesity NoSQL and Hadoop Service initiates a backup of the MongoDB Database. The first backup is a full backup and everything after that is an incremental backup only. Occasionally, a full backup will be required if the oplog rollsover between two incremental backups. This can be avoided by increasing the frequency of backups or by increasing the size of the oplogs. The service also automatically determines the number of backup channels, based on the compute resources on Cohesity and the

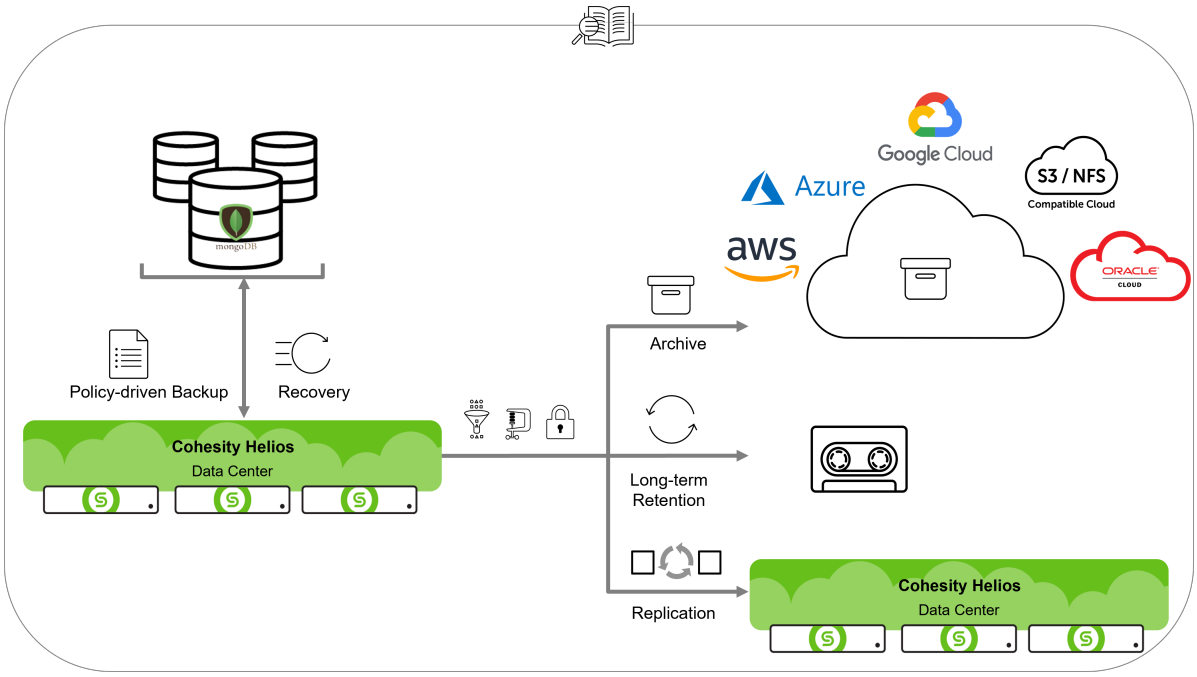
topology of the MongoDB cluster. The necessary Cohesity Views are automatically generated where the backups are going to be written. Communication between Cohesity and the MongoDB Databases is managed by the Cohesity NoSQL and Hadoop Service as described in the section below. See the following topics for details:

Core components

The following lists the core components of the Cohesity MongoDB solution:

- Physical or virtual MongoDB instance.
- Cohesity Data Cloud.
- Cohesity Compute Nodes.
- Cohesity NoSQL and Hadoop Service running on Cohesity Compute Nodes.
- Optional. Archive or tiering target at your data center or cloud provider of choice.

As illustrated in the figure below, you can integrate Cohesity with an existing MongoDB infrastructure by installing the Cohesity NoSQL and Hadoop Service on Compute Nodes. Once the service is installed and running, you can create protection policies, Protection Groups, and replication schedules for the MongoDB database. Once the data is protected, it can be archived, sent to tape, and or replicated to another instance running in the cloud or on-premises as shown in the image below.



MongoDB Features

Following are the key MongoDB-specific features of the solution:

- Support replica sets and sharded clusters
- Granular backup and recovery - backup and recover individual collections
- Index definitions are backed up and restored
- Option to back up from secondary MongoDB nodes
- Handle topology changes seamlessly (node addition, removal, IP changes, etc.)
- Support Kerberos, LDAP, and SCRAM authenticated clusters
- Support SSL-enabled clusters.
- Support Continuous Data Protection (CDP).

Plan and Prepare for MongoDB Protection

9 January 2026

The following topics provide guidance that helps you get ready to implement the MongoDB DataProtect Solution.

Supported Versions

For more information, see NoSQL and Hadoop Platforms.

Prerequisites

Make sure the following prerequisites are met before backing up MongoDB databases:

- Configuring Continuous Data Protection (CDP) for MongoDB
- The NoSQL and Hadoop Service is in Running status. See NoSQL and Hadoop Service for details.
- Refer to the NoSQL and Hadoop Service - Post Installation Procedures to get a general idea about the following operations:
  - Manage SSL enabled NoSQL primary clusters
  - Work with Kerberos Security enabled primaries for data protection
- Ensuring all Nodes in MongoDB Cluster are Reachable
- Syncing Time Between MongoDB Cluster and Cohesity Cluster
- Ensuring Unique Value of _id in a Collection

Configuring Continuous Data Protection (CDP) for MongoDB

Ensure that the NoSQL and Hadoop Service app is installed and running.

To enable MongoDB CDP service, use the following command:

```
$ imanis_cli.sh -c mongocdp enable --cpu <cpu-cores> --memory <memory-GB> --
replica <num-replicas>
```

- **cpu-cores**: Number of CPU cores allocated to each MongoCDP service instance
- **memory-GB**: Amount of memory allocated to each MongoCDP service instance
- **num-replicas**: Number of MongoCDP service instances. Depending on the load on MongoDB primary and the recovery point objective, one or more MongoDB CDP services can be provisioned. The use of multiple smaller CDP services can help RPO in case of nodes going down.

For example, the below command enables MongoDB CDP with single replicas of 1core/2GB memory.

```
$ imanis_cli.sh -c mongocdp enable --cpu 1 --memory 2 --replica 1
INFO : Checking reachability of pod imanis-nodemanager-0
INFO : Log File : /tmp/imanis-cli-workdir.10686/cli/imanis-mongo-cdp.log
INFO : Enabling MongoCDP pods deployment
INFO : Reading allocatable cluster resources
INFO : Total allocatable Memory(GB) : 239
INFO : Total allocatable CPUs : 47
INFO : Number of MongoCDP replicas : 1
INFO : CPUs per MongoCDP replica : 1
INFO : Memory per MongoCDP replica(GB) : 2
INFO : Total CPUs for MongoCDP replicas : 1
INFO : Total Memory for MongoCDP replicas(GB): 2
INFO : Total Memory for Other Services(GB) : 15
INFO : Total CPUs for Other Services : 10
INFO : Small-Nodemanager instance config : 16GB/4 CPUs
INFO : Medium-Nodemanage instance config : 32GB/8 CPUs
INFO : Large-Nodemanager instance config : 40GB/10 CPUs
Please confirm above configurations for 'NoSQL & Hadoop Service' app
deployment with MongoCDP Pods
Do you want to continue (yes/no) yes ? yes
--------------------------------------------------------------------------
----
mongocdp : service(s) will be stopped (if running)
--------------------------------------------------------------------------
----
service : mongocdp is being stopped
```

```
Stopping MongoCDP services on imanis-mongocdp-0

MongoCDP services stopped successfully

Setting up MongoCDP services...

Configuring MongoCDP services...

MongoCDP services configured successfully

Deleting stale pod directory:
/cohesity/mount/sharedview/imanis/cdp/mongo/v1/pods/imanis-mongocdp-1

Starting MongoCDP service on imanis-mongocdp-0

MongoCDP service is running on [imanis-mongocdp-0]

MongoCDP service is running

Setting up MongoCDP service successfull

Requested number of pods with given memory and cpu cores is updated
successfully
```

To verify, once the app is Running, run the following command to check the pod status:

```
$ kubectl.sh  get pods  -A
```

Example:

```
$ kubectl.sh get pods -A
NAMESPACE                NAME
 READY   STATUS    RESTARTS   AGE
athena-6                 imanis-api-server-0
 1/1     Running   0          102m
athena-6                 imanis-api-server-1

cohesity-infraoperator    infra-operator-controller-manager-787dbddd76-qqd96
 2/2     Running   0          12d
cohesity-magnus           magnus-actor-f8b5fbcc-q6fgb
 1/1     Running   0          12d
cohesity-magnus           magnus-server-0
 1/1     Running   0          12d
```

To disable MongoDB CDP:

1. Run the following command:

   $ imanis_cli.sh -c mongocdp disable

2. Check the pod status from Cohesity node with command "kubectl.sh get pods -A" and verify that no mongocdp pods are running.

> **Note:** Once MongoCDP service is disabled, MongoDB data protection would no longer work.

Ensuring all Nodes in MongoDB Cluster are Reachable

Make sure that all nodes in the MongoDB cluster are reachable through hostname and IP address from all containers running the NoSQL and Hadoop Services. Generally this is not a problem if the MongoDB servers are registered in DNS. If this is not the case, then refer To Manage the NoSQL and Hadoop Services.

Sizing the Primary Oplog of MongoDB Primary

Ensure that the oplog of MongoDB primary is sized to hold at least 30 minutes of data even when there is heavy load. This means, MongoDB primary would need a larger oplog if it has a larger maximum ingestion rate.

Syncing Time Between MongoDB Cluster and Cohesity Cluster

Ensure that the time on MongoDB cluster and Cohesity cluster is in sync. This is a mandatory requirement as NoSQL and Hadoop Services access MongoDB Oplogs for incremental backups.

Ensuring Unique Value of _id in a Collection

This prerequisite is to verify that all collections have a unique value for `_id`.

The field name _id is reserved for use as a primary key for a document and its value must be unique in the collection.

> **Warning:** If a collection has more than one document with the same _id, it can cause data corruption as we cannot identify the documents uniquely. Even with data corruptions backup/restore will succeed without any errors.

Refer to the following MongoDB documentation for more information:

- Field Names
- Unique Indexes

Firewall Ports

The following table lists the required firewall ports that are to be open to enable communication between Cohesity and MongoDB DataProtect Solution.

MongoDB Connector connects to MongoS and MongoD processes for backup and recovery. The ports associated with these processes should be open and accessible from the Cohesity nodes.

Port	Source	Target	Direction (From Node)	Network Protocol	Usage Notes	Type of Traffic
27017	Cohesity cluster	MongoDB Nodes	Outgoing	TCP	Used for MongoDB backups and recovery.	Backup and Recovery
27018	Cohesity cluster	MongoDB Nodes	Outgoing	TCP	Used for MongoDB backups and recovery.	Backup and Recovery
27019	Cohesity cluster	MongoDB Nodes	Outgoing	TCP	Used for MongoDB backups and recovery.	Backup and Recovery

Minimum Permissions

This section describes the minimum set of permissions needed for the MongoDB DataProtect Solution to communicate with the source.

MongoDB User & Roles

The user specified in the MongoDB source registration page must have clusterAdmin and readWriteAnyDatabase roles. For example:

```
db.createUser(
{
user: "username",
pwd: "password",
roles : [
{ role: "clusterAdmin", db: "admin" },
{ role: "readWriteAnyDatabase", db: "admin" }
]
}
)
The user must exist in all replicas. For a sharded environment, the user must exist in all replicas across all shards.
```

For more information on the preceding roles, refer to the MongoDB documentation on Built-In Roles.

> **Note:** This Is applicable for LDAP authentication as well.

Best Practices

- Ensure that the oplog of MongoDB primary is sized to hold at least 30 minutes of data even when there is heavy load. If you notice that a full backup is occurring frequently, consider increasing the size of the oplogs.
- MongoDB Data Protection solution uses replica set oplog to capture incremental data. Standalone MongoDB clusters do not have an Oplog so they must be converted to replica sets using the process outlined in Convert a Standalone to a Replica Set.

Considerations

- Re-creating a collection between two successive backups (drop a collection and re-create a collection with the same name) is not supported. The Protection Group must be re-created in that case.

- MongoDB supports a special type of collection called 'Capped Collections'. A full backup is performed for capped collections in every run.
- Backup and recovery of MongoDB Views are not supported.
- Distributed transactions (introduced in MongoDB 4.2) are not supported.
- If a shard is added to a MongoDB cluster, the shard should not be removed before the next backup run. Removing the shard results in data loss and the user should re-create the workflow.
- If the shard key of a collection is modified using the refineCollectionShardKey command, the latest shard Key may not be recovered in PITR. PITR will recover the shardKey which was assigned to the collection at the time of the last incremental backup.
- If a collection is resharded, PITR is not supported after reshardCollection till the next backup. The next backup will automatically take a full backup of the resharded collection.
- The available PITR timeline starts from the oldest incremental or full backup run which is within the CDP retention period set in the policy.
- If you upgrade the NoSQL and Hadoop Service from a version older than 5.2, PITR will only be available after the next policy-based incremental run. To use PITR, the protection group policy should be modified to include CDP. For more information, see Using MongoDB CDP.
- Backup and recovery of collections with non-unique values in the _id field is not supported.
- Standalone MongoDB clusters are not supported because they do not have an Oplog. Standalone clusters must be converted to replica sets using the process outlined in the reference link - Convert a Standalone to a Replica Set.
- Meta operations like collection addition or deletion are captured in the backup run immediately following the operation. For this reason, the list of collections on a MongoDB database selected for point-in-time recovery is captured in the latest backup run before the selected time (called base backup). The point-in-time recovery recovers only those collections that are available in the base backup. If any such collection is deleted before the selected point in time, it is still recovered.
- Cohesity recommends taking a periodic full backup at least once per week or whenever more than 150 million documents are inserted, updated, or deleted in any of the collections being protected by the Protection Group. Additionally, in order to reclaim space, the interval between two full backups must be less than the retention period set in the policy.
- The support for MongoDB time series collections has the following considerations.

    - Sharded time series collections are not supported.
    - Secondary indexes on time series collections are not supported.
- The backup process might not work during MongoDB upgrades.
- The Pause Future Run function does not work for MongoDB protection groups if a run is in progress.
- Cohesity does not support registering a MongoDB cluster using a mix of IPv4 and IPv6 addresses.
- For IPv6, Kerberos authentication is not supported.

Register a MongoDB Source

9 January 2026

Register MongoDB as a Source

To configure MongoDB for data protection on Cohesity, you need to register it as a source.

Before you register MongoDB as a source, ensure that you have reviewed and completed the instructions provided in the Plan and Prepare for MongoDB Protection topic.

To register MongoDB as a source:

1. Navigate to **Data Protection > Sources**.
2. Click **Register** on the top-right of the page and then select **Databases > MongoDB**. The **Register MongoDB** dialog is displayed.
3. Enter the required details. Refer the table below for the field descriptions.
4. Click **Register**.

If the registration is successful, the registered cluster appears in the list on the **Sources** page.

> **Note:** Registering a faulty source triggers an error. The user must Update MongoDB Configuration to correct the information and save it to resolve the errors.

Field Descriptions

Field	Description
MongoDB Seeds	Specify the MongoS hosts for a sharded cluster and the MongoD hosts for a non-sharded cluster. You can specify one host or multiple hosts in a comma separated list. It is recommended to specify a list of hosts in which at least one will be up at all times and MongoDB will discover the rest. Both IPv4 and IPv6 addresses are supported. **IPv4 Format**: `<IPv4 address>:<port_number>` **Example**: `10.14.58.2:27017,10.14.58.3:27017` **IPv6 Format**: `[<IPv6 address>]:<port_number>` **Example**: `[2400::9000:0:0:500:12]:27017, [2400::9000:0:0:500:13]:27017`
Authentication	Select one from the below authentication types: • None • LDAP • SCRAM • Kerberos
Username	Specifies the username of the MongoDB cluster. • In case of authentication type = LDAP, this will be the LDAP username/password. • In case of authentication type = SCRAM, this will be the MongoDB username/password. • No username/password required for Authentication type = NONE.
Kerberos Principal	In case of authentication type = Kerberos, specify the Kerberos principal to access the MongoDB primary.
Password	Specifies the password for the MongoDB cluster.
Authentication Database	Authenticating Database for the MongoDB cluster. Displayed only for LDAP and SCRAM authentications.
Backup from Primary node	Select to backup from the primary node.
Backup from Secondary Node	Select to backup from the secondary node.

Field	Description
Secondary Node Tag	The tag assigned to the intended MongoDB Secondary node. Required only if **Backup from Secondary Node** is selected. The system will use this to identify the secondary nodes for reading backup data. Exactly one secondary node in each replica set should have the tag. Once a unique tag is assigned to the secondary nodes that are planned to be used as a backup, the same need to be mentioned in the **Secondary Node Tag** field. For example: If the secondary nodes are marked with the tag: **"usefor": "cohesitybackup"**, then enter **usefor:cohesitybackup** in the **Secondary Node Tag** field. A tags document contains user-defined tag field and value pairs for the replica set member. For more information on how to configure tags, see Configure Replica Set Tag Sets.
SSL Requirement	Toggle **YES** if connection to MongoDB has to be over SSL.

Update MongoDB Configuration

You can update the MongoDB details that you provided during the registration process with the latest MongoDB configuration.

To edit the MongoDB Source Configuration:

1. Navigate to **Data Protection > Sources**.
2. Browse to the required MongoDB source you want to edit and click ⋮ > **Edit**. The **Edit MongoDB Registration** dialog is displayed.
3. Edit the required details. Refer Field Descriptions for more details.
4. To update the details, click **Update**.

Refresh the MongoDB Source

Refresh automatically happens in the background but you can also manually refresh the MongoDB source and fetch the latest changes on the source.

To refresh the MongoDB Source:

1. Navigate to **Data Protection > Sources**.
2. Click ⋮ next to the MongoDB source and select **Refresh**.

Unregister the MongoDB Source

If you want to stop taking backups of the MongoDB source, you can unregister the source from Cohesity.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the MongoDB source.

To unregister the MongoDB Source:

1. Navigate to **Data Protection > Sources**.
2. Click ⋮ next to the MongoDB source and select **Unregister**.

Backup MongoDB

9 January 2026

Cohesity provides a simple sequence of tasks that constitute the procedure for backing up your MongoDB source. Once MongoDB is registered as a source on Cohesity, you can start configuring your backups.

> **Note:** In case of the full backup, the Sharded Cluster Balancer is automatically disabled. Disabling the balancer for the duration of the backup procedure is a recommended practice. For more information, refer to the MongoDB documentation on Disabling Balancer During Backups.
> If the balancer is active when the full backup starts, then Cohesity disables the balancer. After the full backup is complete, Cohesity automatically reactivates the balancer if it was originally running when the full backup started. However, in a rare scenario, if MongoDB fails or if a running backup workflow is killed, the balancer does not get reactivated. In this case, it is recommended that users manually enable the balancer on the MongoDB cluster. Refer to the MongoDB documentation on Manage Sharded Cluster Balancer.

Continuous Data Protection (CDP)

The Cohesity Continuous Data Protection (CDP) provides near-zero RPOs for MongoDB environments. The CDP captures and protects the application data every time there is a change in data so that it can be restored to a point in time as opposed to periodic snapshots available with regular backups.

For MongoDB CDP, Cohesity uses a specialized CDP Service which runs on the Cohesity cluster. The CDP Service captures changes from MongoDB oplog in real time and continuously backs up the changes to the Cohesity cluster. These changes are saved on the Cohesity cluster in a write-ahead-log (WAL) which can be used to recover collections to any point-in-time as long as all the previous changes are available.

Cohesity manages rare instances of oplog rollover by doing a full backup instead of an incremental one.

Using MongoDB CDP

> **Note:** Ensure that the Prerequisites are met before using MongoDB CDP.

To enable CDP, create a new protection policy and attach the Continuous Data Protection option to the policy. Within the CDP option specify the retain point in time configuration, and associate this policy with the MongoDB source's Protection Group.

After associating the protection policy with the Protection Group, the protection run will first initiate a full backup. The initial full backup is followed by an incremental protection run and the continuous protection of the source will begin from this point on. You can view all the continuously protected sources from the Cohesity UI.

To create a new protection policy with the **Continuous Data Protection** option, see Create or Edit a Standard Policy.

Protect MongoDB Objects

MongoDB Objects are protected using a Protection Group and a Protection Policy. A Protection Group enables you to select the objects that you want to back up. It uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured, retained, archived, and replicated .

A Protection Policy is a reusable list of settings that define the type of backup, backup schedule and backup snapshot retention. Also, for Disaster Recovery, you can add replication for the Protection Group using the Protection Policy. For detailed instructions on how to create a Protection Policy, see Create or Edit a Standard Policy.

To protect a MongoDB object:

1. **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then select **Databases** > **MongoDB**. The **New Protection** page is displayed.
3. Select the required **Data Source** from the drop-down menu.
4. Select the required objects to protect.
5. To auto protect an object, click adjacent to it. All the databases under this object are also auto protected.
6. Click **Save Selection**.
7. Under **Protection Group**, enter a protection group name. Existing protection groups cannot be used while creating a new MongoDB protection.

8. Under **Protection Policies**, select an existing protection policy or create a New Policy if the available policies do not meet your schedule and retention needs. For more information on creating policies with Continuous Data Protection, see Continuous Data Protection (CDP).
9. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains .
10. Enter the **Start time** and select the appropriate **Time Zone**. This option is available only if the selected policy is set to **Backup Daily** and indicates when the protection group should run. The default time zone is the browser's time zone.
11. After selecting a Storage Domain, if you need to change any of the additional settings on the MongoDB Protection page, scroll down and click **Edit** on the right. For more information, see Additional Settings.
12. Click **Protect**.

Your new Protection Group is now active and running.

Additional Settings

Fields	Description
Storage Domain	Select default storage domain or add a storage domain.
Start Time	Available only if the selected policy is set to Backup Daily. Indicates when the protection group should run. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection group by selecting a different time zone.
Pause Future Runs	Once enabled, no protection runs will be scheduled.
End Date	Optional. Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts prior to this date runs until completion even if it completes after this date.

Fields	Description
QoS Policy	Select an appropriate quality of service (QoS) policy. **Note:** Cohesity recommends specifying **Backup HDD**, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Concurrency	Maximum number of backup streams that will be created to exchange data with the cluster. By default, maximum scaling is capped at 16.
Bandwidth Throttling	Maximum network bandwidth that each backup stream can use for exchanging data with the cluster.
Alerts	Optional. Select one or more of the following settings if you want alerts to be created for the following triggers: • Success: Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • Failure: Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • SLA Violation: Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts . You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.

Fields	Description
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection groups exceeds the ability to process protection groups, this will be the priority of implementation of the protection groups: • High-priority protection groups • Medium-priority protection groups • Low-priority protection groups.
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • Incremental: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. • Full: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).
Description	Optional. Enter a brief description about the Protection Group.

Manage Backup Configuration

A backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Objects to an existing Protection Group

You can add new objects to the Protection Group created for MongoDB protection. The newly added objects are backed up from the next protection run.

To add objects to the Protection Group:

1. **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for MongoDB.
3. Click ⋮ next to the Protection Group and select **Edit**.
4. On the Edit Protection page, Click ✎ next to **Objects**.
5. Make the required changes. For more information, refer Protect MongoDB Objects.
6. Click **Protect**.

Enable or Disable Auto Protect

The Auto Protect option enables you to automatically protect the objects that are added to the MongoDB source. You can auto protect either the entire cluster or a database.

When the Auto Protect option is enabled:

- All the objects that are added to the MongoDB source in the future are automatically added to the Protection Group and are protected from the next protection run.
- All the objects that are removed from the MongoDB source in the future are automatically removed from the Protection Group and are not protected from the next protection run. The existing backups are preserved until the snapshot expires.

When the Auto Protect option is disabled, you need to manually:

- Add newly added objects, in the MongoDB source, to the Protection Group.
- Remove existing objects, that are removed from the MongoDB source, from the Protection Group. The existing backups are preserved until the snapshot expires.

To enable or disable Auto Protect:

1. **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for MongoDB. For more information, see Protect MongoDB Objects.
3. Click ⋮ next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** area, click **Edit**.
5. In the pop-up window , toggle the to enable or disable Auto Protect.
6. Click **Protect**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group in the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for MongoDB. For more information, see Protect MongoDB Objects.
3. Click ⋮ next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Protect**.

Start an On-demand Protection run

You can manually start a run for the Protection Group that you have created to backup MongoDB objects. It provides you with options to:

- Back up all the objects in the Protection Group.
- Select an incremental or full backup.
- Add replication and archive.

To start a protection run:

1. **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for MongoDB.
3. Click ⋮ next to the Protection Group and select **Run Now**.
4. In the pop-up window, perform the following:
    1. The **Backup** drop-down list is defaulted to **Backup all Objects in the Protection Group**.
    2. In the **Backup Type** drop-down list, select the backup type.
    3. If required add details for Replication and Archival.
5. Click **Backup Now**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group. However, if a protection run is in progress, it continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for MongoDB.
3. Click ⋮ next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired then a full backup is triggered.

To resume future protection run:

1. **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click ⋮ next to the Protection Group and select **Resume**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the snapshots (local, archived, and replicated) that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete the Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived snapshots generated by the Protection Group and reclaim the space utilized by the Protection Group.

> **Note:** The storage space reclaimed by deleting the Protection Group takes some time to reflect.

To delete the Protection Group:

1. **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for MongoDB.
3. Click ⋮ next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Delete Protection Group Only
    - Delete Protection Group and Snapshots

Recover MongoDB

9 January 2026

You can recover the protected MongoDB Objects using Cohesity. You can recover to the same location or an alternate location.

Considerations

- Recovering from different protection groups in a single recovery is not supported for MongoDB.
- Recovering items in the same protection group but from different recovery points is not supported in the same recovery task. You need to create different recovery tasks for different recovery points.

Recover MongoDB Objects

To recover MongoDB objects you can search through the backups using the Protection Group, databases or collections you plan to recover, and then start the recovery.

To recover MongoDB objects:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** on the top-right of the page and then select **Databases > MongoDB**. The **Databases | MongoDB** dialog is displayed.
3. In the **Recover** page, search for the MongoDB protection groups or objects that need to be recovered.

   > **Note:** Wildcards are supported in the search.

4. Accept the latest Recovery Point or click and select a different recovery point.

   By default, the option to select the snapshot is displayed in **Timeline** mode. You can also choose to view the option in **List** mode by clicking the **List** tab in the top-right corner of the page.

   To select a snapshot or a point in time from the Timeline mode:

   > **Note:** To select a point in time recovery, CDP should be enabled in the protection policy. For more information, see Using MongoDB CDP.

   a. From the **Choose a date** drop-down, select a date.

      The snapshots available on the selected date are displayed in blue dots on the timeline bar.

   b. For snapshot recovery, Select the snapshot to be recovered by clicking the corresponding blue dot.

   c. For Point in time recovery, select the point-in-time restore. You can specify the exact point-in-time recovery by sliding the timeline bar or by entering the exact time in the Time input field. You can recover collections or databases to a point in time.

   d. By default, the snapshot is recovered from the local cluster. You can also select the snapshot archived in the cloud by clicking the cloud ( ) icon if available in the **Location** option.

   e. Click **Select Recovery Point**.

- Snapshots: Select a different recovery point. You can change the time zone before or after selecting a new restore time.

5. Click **Next: Recover Options**. The recovery details are displayed.
6. Under **Recover As** select **Replace Original** or **New Object**.
   - **Replace Original** - Replace the original object source.
   - **New Object** - Specify the target for the recovered object.
7. Toggle **Overwrite existing object with the same name**. A warning is displayed, enter **YES** to proceed.
8. Under **Recovery Options**, select the required options for the recovery. For more information, see Recovery Options.
9. Click **Recover** to start the recovery operation.

Recovery Options

Option	Description
Rename	Rename objects. Choose **Bulk Rename** to append a suffix to all the selected objects, or choose **Rename Individual Objects**.
Concurrency	Maximum number of recovery streams that will be created to exchange data with the cluster. By default, maximum scaling is capped at 8.
Bandwidth Throttling	Maximum network bandwidth that each recovery stream can use for exchanging data with the cluster.
Zones/Shard tags	If the toggle option Is enabled, the ZoneKeyRanges associated with the original collections will be preserved. **Note:** If this option is enabled, it is required that the association of a shard with the zone is already done in the destination MongoDB. Recovery may fail otherwise.
Task Name	Recovery task name.

MongoDB via Ops Manager

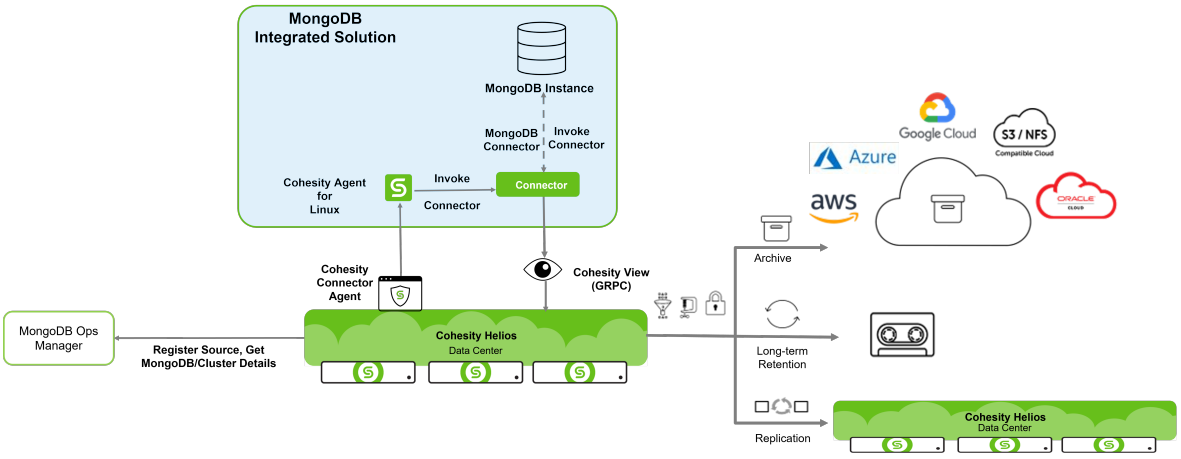
The Cohesity MongoDB Integrated Solution integrates with MongoDB Ops Manager to provide full backup, incremental backup and recovery for MongoDB deployments.

Core Components

The following are the core components for protecting MongoDB objects:

- Ops Manager
- MongoDB cluster

As illustrated, you can integrate Cohesity with your MongoDB deployments.



MongoDB Features

Following are the key MongoDB-specific features of the solution:

- Support replica sets and sharded clusters
- Automatically discover and protect all clusters deployed in a MongoDB OpsManager
- Backup and recovery - backup and recover individual clusters
- Schemas and index definitions are backed up and recovered
- Option to back up from secondary, primary or preferred MongoDB nodes
- Support SSL-enabled MongoDB OpsManager
- Support Point In Time recovery using oplog backups
- Support OpsManager running in HA mode

Plan and Prepare for MongoDB Protection via Ops Manager

The following topics provide guidance that helps you get ready to implement the MongoDB DataProtect Solution via Ops Manager.

Supported MongoDB Versions

For more information, see MongoDB via Ops Manager.

Port Requirements

Ensure that you open the following ports in the firewall to allow data transfer between MongoDB and the Cohesity cluster:

Port	Source	Target	Direction	Network Protocol
50051	Cohesity	MongoDB Host	Omnidirectional	gRPC
8080/ 8443/ 80	Cohesity	Ops Manager	Cohesity to Ops Manager	HTTP/ HTTPS
11121	MongoDB Host	Cohesity	Omnidirectional	gRPC
11117	MongoDB Host	Cohesity	Omnidirectional	gRPC
11113	MongoDB Host	Cohesity	Omnidirectional	Insecure gRPC

Minimum Permissions

To use the Cohesity Connector for MongoDB backup, the Cohesity agent and MongoDB connector executables must be installed and run on each MongoDB host node.

Both the Cohesity agent and the MongoDB connector come as Installer RPM packages and need to be installed as root. Based on the options selected during installation, the service can run in one of the following modes:

1. Default: Run as a user with User ID 0 (root privileges).
2. Run as a service user (non-root) with sudo privileges.
3. Run as a service user (non-root) configured with specific capabilities using setcap (use this if sudo/root access is not permitted).

Relevant command line options must be set while installing the RPMs. For more details, refer to Install Cohesity Linux Agent RPM Package.

Considerations

Review and understand the following recommendations before protecting your MongoDB cluster:

- MongoDB recommends that if any node in the cluster goes down, the backup process fails, requiring a full backup to be triggered again.
- MongoDB strongly recommends scheduling periodic full backups at least once per week to prevent data inconsistency scenarios.
- MongoDB backup protection jobs might fail during high-ingestion periods with significant application writes.
- The Cohesity solution does not support the use of Organization-level API keys. This is because the solution is designed to protect the entire OpsManager instance rather than individual organizations. You must generate and use a Global API Key for successful registration and integration.

- MongoDB recomments not running a resync on any node while a backup is active, as this will cause the snapshot and backup workflow to fail.
- Do not perform a primary stepdown during an active backup, as it may result in snapshot failure.
- The amount of data backed up in an incremental backup may not exactly match the data ingested in the source during that period. This amount depends on multiple factors such as source side compaction, the distribution of the changes, etc.
- Standalone MongoDB deployments are not supported and are filtered out by Cohesity.
- Multiple concurrent operations within the same project are not allowed. For example, if a project has two clusters, A and B, and a recovery operation is in progress on cluster A, then any backup or recovery operations for cluster B must wait until cluster A's recovery is complete.
- Non-ASCII or special characters in dbPath are not supported.
- The in-memory storage engine is not supported.
- MongoDB deployment configuration options must be the same for both the source (backup) and destination (recovery) clusters.
- Before recovery, make sure that the destination hosts have adequate storage available.
- If a protection group is edited to add a new collection or a new cluster gets protected as part of autoprotect, the immediate log backup for those collections is not enforced. Log backups for them would run at the next policy-defined time, and the restore timeline would be available from the first incremental backup that happens after at least one log backup is taken following a recovery.
- Once an Ops Manager source is created, the hostname and port cannot be edited. However, the authentication details can still be edited.

Download and Install Cohesity Agent and Connector

Install the Cohesity Agent on each MongoDB node in the cluster you want to protect.

Install Cohesity Linux Agent

The Cohesity Linux Agent is available in the bundle with support for RHEL based Linux distributions. You will need to install the RPM package for your Linux distribution.

> **Note:** Currently, only RHEL8 and RHEL9 are supported.

The installer packages and Linux distributions on which the installer package is supported are:

Installer Package	Linux Distribution
(Default) RPM	RHEL and its derivatives

The Cohesity Linux Agent has dependencies on the following packages, which must be installed on the Linux server:

Command/Package	RHEL and its derivatives
rsync	rsync
mount	util-linux
lvm2	lvm2
sudo	sudo
coreutils	coreutils
util-linux	util-linux
nfs client	nfs-utils
lsof	lsof
wget	wget

Install Cohesity Linux Agent RPM Package

1. Download the Cohesity Linux agent package (el-cohesity-agent) from the Cohesity Download portal and copy it to all MongoDB nodes.
2. Choose the execution mode. The Cohesity Linux agent supports the following execution modes:
    - Option 1: Run as a user with User ID 0 (root user).
    - Option 2: Run as a service user (non-root) with sudo privileges.
    - Option 3: Run as a service user (non-root) configured with specific capabilities using setcap.

    > **Note:** In all execution modes, the RPM installation must be done as the root user.

Option 1: For running the Linux agent as the root user, install using the following command:

```
For example:
[root@hostname.example.com ~]$ rpm -ivh el-cohesity-agent-7.2.2_
u2_wf_mongo_ga_spl-1.x86_64.rpm
```

Option 2: For running the Linux agent as a non-root service user with sudo access, install using the following command:

```
For example:
[root@hostname.example.com ~]$ export COHESITYUSER=<service-user>
; ; rpm -ivh el-cohesity-agent-7.2.2_u2_wf_mongo_ga_spl-1.x86_
64.rpm
```

> **Note:**
> - Ensure the service user is an existing user on the host.
> - In addition, it is necessary to create and preserve the following settings in the /etc/sudoers file for the service user:
>
> ```
> <username> ALL=(ALL) NOPASSWD:ALL
> Defaults:<username> !requiretty
> ```

Option 3: For running the Linux agent as a non-root service user without sudo access, install using the following commands:

```
For example:
[root@hostname.example.com ~]$ export COHESITYUSER=<service-user>
; export COHESITY_AGENT_SKIP_ALL_NO_SUDO=1 ; rpm -ivh el-cohesity-
agent-7.2.2_u2_wf_mongo_ga_spl-1.x86_64.rpm
```

> **Note:**
> - Ensure the service user is an existing user on the host.
> - Setting capabilities using setcap is a one-time activity and is performed only during RPM installation or upgrade scenarios. Once capabilities are set using setcap, during regular execution of agent and connector, sudo access is not required.

Install Cohesity MongoDB Connector RPM package

1. Download the Cohesity MongoDB connector RPM package (e.g. cohesity-mongodb-connector-XXX-1.x86_64.rpm) from the Cohesity Download portal and copy it to all

MongoDB host nodes.

2. Install the MongoDB connector RPM on each node of MongoDB cluster using the following command:

```
[root@hostname.example.com ~]$ rpm -ivh cohesity-mongodb-connector-XXX-1.x86_64.rpm
```

Prerequisites

The following configurations are necessary prerequisites for the protection and recovery of MongoDB deployments via Ops Manager:

- Enable third-party backup management for the relevant projects in the Ops Manager.
- Enable the Ops Manager Backup daemon on the admin page.
- Install and configure the MongoDB Ops Manager agent on each server in the deployment to be protected. Also, make sure that the agent has read/write access to any of the configured directories. Make sure to configure the Oplog export path for MongoDB to store the Oplog Data.
- Synchronize system clocks to ensure consistent timestamps across machines using Network Time Protocol.
- Activate monitoring and backup services on the MongoDB deployment to be protected. Make sure the Monitoring, Backup, and automation are enabled on the Ops Manager agent for each host of the MongoDB Deployment to be protected.
- Create a Global API key with Global Backup Admin, Global User Admin, and Global Owner permissions if not already present. Make a note of the public and private keys, as these credentials will be needed for registering MongoDB Ops Manager on Cohesity.

For more details, refer to MongoDB product documentation.

Configure VIP's & FQDN

Ensure that Cohesity VIPs are configured on the Cohesity Cluster and that an FQDN is assigned and resolvable from all MongoDB Replica Set sources, Ops Manager clusters, and Load Balancer nodes.

Register MongoDB Ops Manager Source

To protect your MongoDB objects, you need to register your MongoDB Ops Manager deployment as a source on the Cohesity cluster.

To register MongoDB Ops Manager as a source:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Register** on the top-right of the page and then select **Databases** > **MongoDB Ops Manager**.
3. On the **Register MongoDB Ops Manager** page, perform the following:
    a. In the **Hostname** field, enter the hostname.
    b. In the **Port** field, enter the port number configured for your Ops Manager instance.
    c. Enable **SSL Requirement** to ensure a secure connection between the Cohesity cluster and the MongoDB Ops Manager deployment.
    d. If the Ops Manager server uses custom CA, add the custom CA certificate in the text box or upload a local copy of the CA cert in pem format using the upload option.
    e. Enter the **Public Key** and **Private Key** for the Ops Manager API keys.
    f. Click **Register**.

Update MongoDB Ops Manager Source Configuration

After registering MongoDB as a source on the Cohesity cluster, you can update the MongoDB source configuration.

To update the MongoDB source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the MongoDB source and select **Edit**.
3. On the **Edit MongoDB Ops Manager** page, update the required configurations.

    > **Note:** The host name and port cannot be changed.

4. Click **Update**.

Unregister MongoDB Ops Manager Source

If you plan to stop protecting your MongoDB objects, you can unregister the MongoDB source from the Cohesity cluster.

To unregister the MongoDB source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the MongoDB source and select **Unregister**.

> **Note:** For instructions on performing multi-cluster registration of the MongoDB Ops Manager source, contact Cohesity Support.

Backup MongoDB via Ops Manager

Cohesity provides a simple workflow to back up your MongoDB source. After registering MongoDB Ops Manager source on Cohesity, you can start configuring your backups.

Protect MongoDB Objects via Ops Manager

MongoDB deployments are protected using a Protection Group and a Protection Policy. A Protection Group enables you to specify the objects that you want to back up.

The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select which standard or custom policy to use when creating a Protection Group. For more information, see Manage Protection Policy .

To protect MongoDB deployments:

1. Select **Data Protection** > **Protection**. Click **Protect** on the top-right of the page and then select **Databases** > **MongoDB via Ops Manager**.

   The **New Protection** dialog appears.
2. Under **Add Objects**, from the **Registered Source** drop-down list, select the registered MongoDB Ops Manager source.
3. Select the required objects to protect.
4. To auto protect an object, click adjacent to it. All the deployments under this object are also auto protected.
5. Click **Continue**.
6. Under **Protection Group**, enter a protection group name. Existing protection groups cannot be used while creating a new MongoDB protection.
7. Under **Policy**, select an existing protection policy or create a new policy if the available policies do not meet your schedule and retention needs.
   1. To enable oplog backup, select the policy that specifies the Log backup. Enabling oplog backup is a requirement for point-in-time recovery.
   2. As per MongoDB requirements, ensure that the policy has periodic full backup enabled with a frequency of at least once a week.
8. Click **More options** to provide additional settings.
9. Click **Protect**.

Your new Protection Group is now active and running.

Additional Settings

Fields	Description
Storage Domain	Select the default storage domain or add a storage domain.
Start Time	Available only if the selected policy is set to Backup Daily. Indicates when the protection group should run. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection group by selecting a different time zone.
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • Incremental: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. • Full: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).
Pause Future Runs	Once enabled, no protection runs will be scheduled.
Convert to Full Backup on Node Failure	Enabling this option ensures that if the same node cannot be selected for an incremental backup, it is automatically converted to a full backup.
Preferred Backup Node	Choose your backup preference: Prioritize the primary or secondary node with automatic fallback, or restrict backups exclusively to the secondary node. • **Primary Preferred:** Backups prioritize the primary node but switch to the secondary node if needed. • **Secondary Preferred:** Backups prioritize the secondary node but switch to the primary node if needed. • **Secondary Only:** Backups are restricted exclusively to the secondary node, with no fallback to the primary node.
Preferred Backup Nodes List	To enable, click the I**Include Preferred backup node list** toggle. In the text box, enter a comma-separated list of host names to be used as preferred backup sources, in order of priority. These host names must exactly match those shown in the cluster status in Ops Manager. Once enabled, only the specified nodes will be considered for backups.

Fields	Description
End Date	Optional. Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts prior to this date runs until completion even if it completes after this date.
QoS Policy	Select an appropriate quality of service (QoS) policy. **Note:** Cohesity recommends specifying **Backup HDD**, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Alerts	Optional. Select one or more of the following settings if you want alerts to be created for the following triggers: • Success: Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • Failure: Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • SLA Violation: Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.

Fields	Description
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection groups exceeds the ability to process protection groups, this will be the priority of implementation of the protection groups: • High-priority protection groups • Medium-priority protection groups • Low-priority protection groups.
Description	Optional. Enter a brief description about the Protection Group.

Manage Backup Configuration

A backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Enable or Disable Auto Protect

The Auto Protect option enables you to automatically protect the objects that are added to the MongoDB source. You can auto-protect either the entire ops manager instance, the entire organization or an ops manager project.

When the Auto Protect option is enabled:

- All the objects that are added to the MongoDB Ops Manager entity in the future are automatically added to the Protection Group and are protected from the next protection run.

  > **Note:** The Cohesity agent must be installed on all hosts in the newly added clusters.

- All the objects that are removed from the MongoDB source in the future are automatically removed from the Protection Group and are not protected from the next protection run. The existing backups are preserved until the snapshot expires.

When the Auto Protect option is disabled, you need to manually:

- Add newly added objects, in the MongoDB source, to the Protection Group.
- Remove existing objects, that are removed from the MongoDB source, from the Protection Group. The existing backups are preserved until the snapshot expires.

To enable or disable Auto Protect:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for MongoDB.
3. Click (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** area, click **Edit**.
5. In the pop-up window , toggle to enable or disable Auto Protect.
6. Click **Protect**.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for MongoDB.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ in the **Objects** section.
5. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
6. Click **Save**.

Start On-demand Protection run

You can manually start a run for the Protection Group that you have created to back up MongoDB objects. It provides you with options to:

- Back up all the objects in the Protection Group.
- Select an incremental or full backup.
- Add replication and archive.

To start a protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for MongoDB.
3. Click (⋮) next to the Protection Group and select **Run Now**.
4. In the pop-up window, perform the following:
    1. The **Backup** drop-down list is defaulted to **Backup all Objects in the Protection Group**.
    2. In the **Backup Type** drop-down list, select the backup type.

3. If required add details for Replication and Archival.

5. Click **Backup Now**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group. However, if a protection run is in progress, it continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for MongoDB.
3. Click (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Delete Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the snapshots (local, archived, and replicated) that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete the Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived snapshots generated by the Protection Group and reclaim the space utilized by the Protection Group.

> **Note:** The storage space reclaimed by deleting the Protection Group takes some time to reflect.

To delete the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for MongoDB.
3. Click (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog, select any one of the following options:
    1. Delete Protection Group Only
    2. Delete Protection Group and Snapshots

Recover MongoDB via Ops Manager

You can recover the protected MongoDB Objects using Cohesity.

Recover MongoDB Objects

To recover MongoDB objects, you can search through the backups for a specific MongoDB cluster using filters such as Ops Manager source and Protection Group name. Once located, you can start the recovery process.

To recover MongoDB objects:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** on the top-right of the page and then select **Databases** > **MongoDB via Ops Manager**. The **Clusters | MongoDB** dialog is displayed.
3. On the **Recover** page, search for the MongoDB protection groups or sources that need to be recovered.

    > **Note:** Wildcards are supported in the search.

4. Accept the latest Recovery Point or click ✎ and select a different recovery point.

    By default, the option to select the snapshot is displayed in **Timeline** mode. You can also choose to view the option in **List** mode by clicking the **List** tab in the top-right corner of the page.

    To select a snapshot or a point in time from the Timeline mode:

    > **Note:** To select a point in time recovery, log backup must be enabled in the protection policy.

    a. From the **Choose a date** drop-down, select a date.

    The snapshots available on the selected date are displayed in blue dots on the timeline bar.

b. For snapshot recovery, Select the snapshot to be recovered by clicking the corresponding blue dot.

c. For Point in time recovery, select the point-in-time restore. You can specify the exact point-in-time recovery by selecting a point the timeline bar or by entering the exact time in the Time input field.

d. Click **Select Recovery Point**.

- Snapshots: Select a different recovery point. You can change the time zone before or after selecting a new recovery time.

5. Click **Next: Recover Options**. The recovery details are displayed.
6. Under **Recover As** select **Replace Original** or **New Object**.
   - **Replace Original** - Replace the original object source.
   - **New Object** - Specify the target for the recovered object.
7. Under **Recovery Options**, select the required options for the recovery. For more information, see Recovery Options.
8. Click **Start Recovery** to start the recovery operation.

Recovery options

Field	Description
Staging Directory Path	Specify the full directory path where oplog files will be temporarily stored during point-in-time recovery. This path must exist and be writable by the Cohesity service user on every host in the destination MongoDB deployment. Ensure sufficient disk space is available. The staging directory must have enough free space to store the oplog data generated since the earliest snapshot backup within the selected point-in-time recovery (PITR) window. You can estimate the required space by multiplying the average data change rate by the duration of the PITR window. Note that the change rate may vary throughout the day due to spikes in data ingestion. For example, if the change rate is 1 MB/s and the PITR window spans 6,000 seconds, you will need at least 6 GB of free space. Cohesity recommends allocating additional space as a buffer to prevent potential issues. (This option is available only if a specific point in time is selected for recovery).
Task Name	Specify a name for the recovery task. A default name is pre-populated, which can be changed.

Cancel a Recovery Run

When you cancel a recovery run, MongoDB cancels the job by terminating the recovery processes.

To cancel a recovery run:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click the action icon (⋮) next to the recovery run and click **Cancel Run**.
3. In the **Cancel Recovery** dialog box, select any one of the following:
    - **Continue Recovery** if you want to continue to recovery run.
    - **Cancel Recovery** if you want to cancel the recovery run.

Microsoft SQL Server

This chapter includes the following topics:

Planning and Preparation for Microsoft SQL Server Protection

The following topics provide guidance that helps you get ready to implement MS SQL Server:

Requirements for Microsoft SQL Server Protection

Supported Software for Microsoft SQL Server Protection

For more information, see Supported Software.

Agent Minimum Permissions for Microsoft SQL Server Protection

You can use either the host LOCAL SYSTEM account or an account that meets the requirements to install the Cohesity agent.

It is recommended to run the Cohesity Agent service with an Active Directory domain user account that is a member of the local administrator of the SQL Server host. The AD domain user account must be a member of the SQL sysadmin server role. The user account must have log-on rights to the SQL Server host in the local security policy of the SQL Server host.

If you do not use the LOCAL SYSTEM account, ensure the following for the chosen account:

- The account must be a member of the local Windows Administrators group. For example, qa01\tme-backup is an Active Directory user account in the data center. If the backup admin plans to use this account, qa01\tme-backup must be part of the local Windows Administrators group on the SQL server.
- The account must have Log on as a service in the User Rights Assignment on the MS SQL server to install the Cohesity agent.
- The account must have the sysadmin role in the MS SQL Server instance.

Ports Used for Communication

- On physical servers or VMs with an ephemeral or installed agent, open the ports 445, 11113, 11117, and 50051. For more information, see Manage Firewall Ports.
- If the Windows Firewall is used:
  - Inbound rules:
    - Add a rule to accept SQL Server traffic and TCP connections on local port 1433.
    - Set Remote Port to All Ports.
  - Outbound rules (for MS SQL Server 2016 running on Windows 2016):

    Update the "Block network access for R local user accounts in SQL server instance MSSQLSERVER" rule by going to General tab > Action window > select "Allow the connection".

Prerequisites for Microsoft SQL Server Protection

- Verify MS SQL Server services are running.
- The **Readable Secondary** field in the Availability Group Properties of the SQL Server Availability Group (AAG) must be set to **Yes** if you have selected **Secondary Only** as the **Backup Preference setting for AAG**.
- MS SQL database and instance names must meet the Microsoft SQL Server naming requirements. Names containing illegal Windows file characters, such as double quotes, pipe symbols, greater than and less than signs (" | > <), a space at the beginning or end of the database name (applicable only for VDI-based backup) are not supported. For more information, see Naming Files, Paths, and Namespaces.
- On the Server's Windows system, Cohesity recommends to set the Power Plan to High performance.

Credentials and Privileges for Microsoft SQL Server Protection

There are three accounts you must consider when installing the Cohesity Agent:

- **Installation Account**: The account you use to log in to the host and run the installer.
- **Service Account**: The account under which the Cohesity Agent service runs on the SQL Server host. (Selected at the time of installation.)
- **SQL Server login account**: The SQL Server account by which the Cohesity Agent has access to the databases. (Configured after installation.)

Installation Account

When installing the Cohesity Agent on a Microsoft Windows host, you must log onto the SQL Server host with an account that has local administrator privileges. This is because the Windows agent installer installs the Cohesity Agent service. Microsoft requires the installation account to have administrator privileges on the host.

Choose the Service Account

The installer gives you the option between two types of service accounts:

- The LocalSystem account.
- A user account. Assigning privileges to the service account will differ depending on which type of account you choose. Cohesity recommends using either the LocalSystem account or an Active Directory Domain User account. See the chart below for a comparison of service account types.

Comparison of Service Account Types

SERVICE ACCOUNT	TYPE	DEFINITION	RECOMMENDATION
LocalSystem (Default)	LocalSystem Account (Built-in Host Account)	The LocalSystem account is a predefined local account on the host computer.	Recommended: The Local System account is a predefined local account used by the service control manager. It has extensive privileges on the local computer, and acts as the computer on the network. Its token includes the NT AUTHORITY\SYSTEM and BUILTIN\Administrators SIDs; these accounts have access to most system objects.
User Account	Domain User Account (Active Directory)	A user whose username and password are stored in Active Directory.	Recommended: A domain user account enables the service to take full advantage of the service security features of Windows and Microsoft Active Directory Domain Services. The service has whatever local and network access is granted to the account, or to any groups of which the account is a member.
	Local User Account (Host account)	In Windows, a local user is one whose username and encrypted password are stored locally, only on the computer itself.	Not recommended: When you log in as a local user, the computer checks its own list of users and its own password file to see if you are allowed to log in to the computer. The computer itself then applies all the permissions and restrictions that are assigned to you for that computer.

> **Note:** If you are unsure which account to use, choose the LocalSystem account. This account already has most of the required permissions. The agent service account can be changed later if needed.

Microsoft SQL Server on Linux OS

Cohesity provides backup and recovery solutions for Microsoft SQL Server databases running on the Linux Operating System.

Requirements

Operating System	Database	Notes
Linux OS RHEL 8 and higher versions **Note:** This is an Early Access feature. Contact Cohesity Support to enable the feature.	Microsoft SQL Server 2019	• Only VDI-based backups are currently supported on Linux OS. • High Availability Microsoft SQL Server configurations like FCI and AG are not supported.

Considerations

- Cross-platform database restores between Windows and Linux are currently not supported.
- For VDI-based backups to work, Microsoft requires the backup application account (Cohesity Agent's service account) and the Microsoft SQL Server service account to be added to each other's primary groups using the usermod command.

  For example:

  sudo usermod -a -G mssql cohesityagent

  sudo usermod -a -G cohesityagent mssql

  where, mssql is the user account of the mssql-server service and cohesityagent is the user account of the Cohesity Agent service.

  Following this, the Microsoft SQL Server and the Cohesity Agent services must be restarted for the changes to take effect.

  > **Note:** The usermod -a -G command may not work for domain accounts.

- Currently, only password-based SQL Server authentication is supported and Active Directory-based authentication is not supported for Linux.

  For supported features of SQL Server 2019 on Linux, see Editions and supported features of SQL Server 2019 on Linux.

Register SQL Server on Linux OS

1. Navigate to **Data Protection > Sources**.
2. Click **Register > Microsoft SQL Server**.
   The **Register a Microsoft SQL Server** page is displayed.
3. In the **Hostname or IP Address** field, enter the IP address or FQDN of the server. We recommend you to provide the FQDN of the server.
4. Select the **Server Type** as Linux.
5. Provide the username and password for the **Database Authentication**.
6. Click **Register**.

Supported Database Types for Microsoft SQL Server

Before proceeding to deploy the Cohesity agent for SQL data protection, we recommend you correctly identify the type of SQL database you want to protect. Below is a table of SQL database types that are supported by the Cohesity SQL agent, and the recommended protection methods.

To understand the concept of each method, see About Microsoft SQL Server Backup.

Database Types	Definition	Adapter-based Protection Method		
		Volume-based Protection	File-based Protection	VDI-based Protection
Stand Alone	A SQL Server User database.	✓	✓	✓
AG	A database that belongs to an availability group (AG). For each availability database, the availability group maintains a single read-write copy (the primary replica) and one to four read-only copies (secondary replicas). For details, see Always On availability groups: a high-availability and disaster-recovery solution in the Microsoft documentation.	✓	✓	✓
FCI	A database that belongs to a Failover Cluster Instance (FCI), which is a single instance of SQL Server that is installed across Windows Server Failover Clustering (WSFC) nodes.	✓	✓	✓

Database Types	Definition	Adapter-based Protection Method		
		Volume-based Protection	File-based Protection	VDI-based Protection
CDC	A change data capture (CDC) enabled SQL database records activity and is applied to an internal table. This makes the details of the changes available in an easily consumed relational format. For details, see About Change Data Capture (SQL Server) in the Microsoft documentation.	✓	✓	✓
TDE	A Transparent Data Encryption (TDE) enabled SQL database has its data files encrypted, known as encrypting data at rest. TDE performs real-time I/O encryption and decryption of the data and log files. For details, see Transparent Data Encryption (TDE) in the Microsoft documentation. **NOTE**: Cohesity does not manage the keys associated with the TDE database.	✓	✓	✓
File Stream	A Filestream enabled SQL Database is a database that contains a table that stores its data outside the database on the host file system. SQL Filestream leverages the OS file system's ability to handle large objects like images, PDFs, Binary, Bmp, Docs, and other unstructured data. For details, see FILESTREAM (SQL Server) in the Microsoft documentation.	✓	✗	✓

Database Types	Definition	Adapter-based Protection Method		
		Volume-based Protection	File-based Protection	VDI-based Protection
SQL System	SQL Server maintains a set of four system-level databases (*master, model, msdb, tempdb*), which are essential for the operation of a server instance. System databases must be backed up after every significant update. The system databases that you must always back up include msdb, master, and model. System databases are not supported for log backups. For details, see Backup & restore: system databases (SQL Server) in the Microsoft documentation.	✓	✓	✓

Now that you can identify the type of SQL database you want to protect, you can register it as a Cohesity source.

Microsoft SQL Server Dashboard

Access the MS SQL Dashboard by going to **Dashboard** and from the drop-down, select **MS SQL**.

The page's upper portion displays information such as metrics, status and recovery history. In the page's lower portion, you can start the different actions from the Hosts tab and the Databases tab. The MS SQL Dashboard displays local MS SQL databases only. To restore or clone replicated or CloudRetrieved databases, use their respective restore or clone workflows.

From the Hosts tab, mouse over the actions menu for the following actions (some actions are available for physical servers only):

- **Protect Databases** ( )—Create a Protection Group using this server.
- **Unregister MS SQL** ( )—Unregister the MS SQL application. The server remains registered with the Cohesity cluster.
- **Edit** ( )—Configure the settings of a registered MS SQL server.
- **Unregister** ( )—Unregister this server from the Cohesity cluster.
- **Refresh** ( )—Manually force a refresh of the object hierarchy.

- **Upgrade Agents** ( )—Upgrade the Cohesity agent on the server if an upgrade is available.

From the Databases tab, mouse over the actions menu for the following actions (some actions are not available for system databases):

- **Protect** ( )—Create a Protection Group using this database.
- **Run Now** ( )—Start a run of this Protection Group. You have the option to back up one or more objects.

  If the policy associated with the Protection Group is configured with replication and archive targets, you can select those targets. If the policy supports multiple backup types, you can select an incremental, full or log backup.

  VM MS SQL Protection Groups do not support selecting individual databases for run now; only the entire VM is selectable.
- **Pause Future Runs/Resume Future Runs** ( )
  - Select **Pause Future Runs** to stop new runs of this Protection Group from executing. However, if the job is currently executing a run, the current run continues to execute and only future runs of this job are paused.
  - Select **Resume Future Runs** to restore the Protection Group to a running state. The runs resume as specified in the schedule defined in the policy associated with this job.
- **Cancel this Protection Group Run** ( )—Cancel the current run of this Protection Group. (This option is only available when a Protection Group run is executing.) This cancellation only affects the current run of the Protection Group and not future runs.
- **Clone** ( )—Make a copy of the database. The clone database is a unique copy of the original database taken from the backup.
- Follow the instructions provided in Clone Microsoft SQL Server Databases.
- **Recover** ( )—Restore a database. Follow the instructions provided in Recover Microsoft SQL Server.
- **Migrate** ( )—Migrate a database. Follow the instructions provided in Migrate Microsoft SQL Server Databases.

Database Recover and Clone Actions

In the Databases tab click a protected database to display available recover and clone actions.

To recover or clone the latest snapshot, click the arrow next to the **Protect** button at the top right corner and select an action.

By default, the latest snapshot is selected. You can optionally choose to restore from a different snapshot by clicking Edit ( ).

You can also provide a specific time to restore to if transaction logs are available.

Click a date on the calendar to select a snapshot from that date. The default point selected will be the latest log transaction or the latest full or incremental, whichever is the latest. The slider also displays available points in time and displays snapshots as circles. Manually select a point on the slider if you want to restore to a specific point in time. Selecting an invalid time from the slider automatically changes to the closest available snapshot. If your manual selection is within 10 minutes of a snapshot, your selection automatically snaps to it. You can also select a specific point in time by entering it in the time fields.

After selecting the desired recover point, click **Recover**. You can choose to clone the selected recover point by clicking the arrow adjacent to recover and selecting **Clone**.

In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

Register and Manage Microsoft SQL Server

To start protecting SQL Server databases, you need to register the SQL Server as a source in Cohesity. The following topics provide guidance that helps you register and manage SQL Server:

Auto-discover Microsoft SQL Server Topology when Registering Microsoft SQL Server

To register an MS SQL Server, MS SQL FCI, or an MS SQL AG of a Windows cluster, you can provide the IP address of the server, FQDN of the server, or VIP of the SQL FCI. The Cohesity cluster discovers the entire MS SQL topology on the Windows cluster and displays the relevant subset based on the MS SQL address you provide while registering. From the topology list, you can select the servers you want to register with the Cohesity cluster. To display the entire MS SQL topology, use the Windows Cluster IP/FQDN.

Prerequisites

Before you register the MS SQL, ensure to meet the following:

- MS SQL prerequisites. For more information, see Requirements for Microsoft SQL Server Protection.
- Download and Install the Agent.

Download and Install the Agent

Install the Cohesity agent on each SQL server that you want Cohesity to protect.

1. Select **Data Protection > Sources**.
2. Click **Download Cohesity Agent**. Ensure the agent has been downloaded to the appropriate server.
3. As an administrator with local system privileges on that server, run the executable and complete the installation using the following steps:
4. **Volume CBT (Changed Block Tracker):** Install this component to leverage Cohesity's built-in CBT technology. Without this component, only full backups can be performed. Installing this component requires a one-time reboot to load the Cohesity CBT driver. Until a reboot, only full backups can be performed.

   File System CBT (Changed Block Tracker): Install this component to perform MS SQL file-based protection.

   > **Note:** Installing the Volume CBT or File System CBT is not necessary for MS SQL VDI-based protection.

5. **Service Account Credentials:** You can use either the LOCAL SYSTEM account or an account that meets the requirements to install the Cohesity agent.

   If you do not use the LOCAL SYSTEM account, ensure the following:

   - The account must be a member of the local Windows Administrators group. For example, qa01\tme-backup is an Active Directory user account in the data center. If the backup admin plans to use this account, qa01\tme-backup must be part of the local Windows Administrators group on the SQL server.
   - The account must have Log on as a service in the User Rights Assignment on the MS SQL server to install the Cohesity agent.

6. Wait for the installation to finish.

   In the SQL Server Management Studio (SSMS), ensure that the account used to install the Cohesity agent has **Server Roles: sysadmin** in the SQL server instances.
7. The agent starts automatically.
8. Reboot the machine if you have installed the Volume CBT component.
9. Repeat the agent installation process on each SQL server you want to protect. This includes any standalone MS SQL servers and Microsoft SQL Server nodes with AGs.

Register MS SQL Server

1. Select **Data Protection > Sources**.
2. Click **Register** > **Databases** > **MS SQL Server (early access: auto-detect)**.

   The Register an MS SQL Server page appears.

> **Note:** Ensure that the agent is installed on all the nodes that are part of the Always on Availability Group (AG) and Failover Cluster Instance (FCI). For more details, Download and Install the Agent.

3. In the **Hostname or IP Address** field, enter the IP address of the server, FQDN of the server, or VIP of the SQL FCI. Cohesity recommends you to provide the FQDN of the server.
4. Select the **Server Type**: Windows or Linux.

   For Linux, provide the username and password for the Database Authentication.

   > **Note:** This is an Early Access feature. Contact Cohesity Support to enable the feature.

5. Click **Register**.

   The Cohesity cluster auto-discovers the entire MS SQL topology on the cluster. Based on the MS SQL address you provide while registering, the Cohesity cluster displays the relevant subset of that MS SQL server. The Cohesity cluster also displays which version of the Cohesity agent is running on each of the servers.

   For AG and FCI, ensure to register all the nodes that are part of the AG and FCI.
6. From the topology list, select the entities you want to register with the Cohesity cluster and select **Complete Registration**.

   The selected entities are registered with the Cohesity cluster and are displayed on the source page of the Cohesity cluster UI.

Set Up Standalone Microsoft SQL Server or Microsoft SQL Server AGs

This topic describes how to set up standalone MS SQL servers and MS SQL Server Always On Availability Groups (AGs) to be protected by a Cohesity cluster.

> **Note:** The **Readable Secondary** field in the Availability Group Properties of the SQL Server Availability Group (AG) must be set to "Yes" or "Read-intent only".

The following are the different methods to register your physical or virtual MS SQL Servers allowing you to protect your MS SQL server databases:

- **Registering a SQL Server using the Cohesity SQL Agent**:

  This option is the preferred method to protect your MS SQL server databases on physical or virtual hardware. This option can be used to protect any SQL server

configurations such as MS MSQL standalone, FCI, and AG. For more information, see Set Up MS SQL on Virtual or Physical Servers using the Agent.

To set up an MS SQL FCI, follow the steps described in Set Up Microsoft SQL Server FCI.

- **Registering a Hypervisor for SQL Server**:

  Cohesity provides an additional option to protect your MS SQL server at the hypervisor level. While this option is available, it is not the preferred method to protect your SQL server databases. Following are the two available registration methods:

  - **Persistent Agent**—For more information, see Set Up MS SQL on VMs as a VMware vCenter application with the Installed Agent.
  - **Auto-Deployed Agent (non-Persistent)**—For more information, see Set Up MS SQL on VMs as a VMware vCenter application with the Auto-deployed Agent.

Ensure Prerequisites are Met

Ensure the prerequisites listed in Prerequisites for Microsoft SQL Server Protection are met.

Set Up MS SQL on Virtual or Physical Servers using the Agent

This option can be used for both physical or virtual servers that are in standalone or AG configurations. Cohesity recommends you use this method to protect the MS SQL Servers with the Cohesity cluster. For more information, see Set Up MS SQL on Virtual or Physical Servers using the Agent.

Download and Install the Agent

Install the Cohesity agent on each SQL server that you want Cohesity to protect.

1. Select **Data Protection > Sources**.
2. Click **Download Cohesity Agent**. Ensure the agent has been downloaded to the appropriate server.
3. As an administrator with local system privileges on that server, run the executable and complete the installation using the following steps:
4. **Volume CBT (Changed Block Tracker):** Install this component to leverage Cohesity's built-in CBT technology. Without this component, only full backups can be performed. Installing this component requires a one-time reboot to load the Cohesity CBT driver. Until a reboot, only full backups can be performed.

   File System CBT (Changed Block Tracker): Install this component to perform MS SQL file-based protection.

   > **Note:** Installing the Volume CBT or File System CBT is not necessary for MS SQL VDI-based protection.

5. **Service Account Credentials:** You can use either the LOCAL SYSTEM account or an account that meets the requirements to install the Cohesity agent.

   If you do not use the LOCAL SYSTEM account, ensure the following:

   - The account must be a member of the local Windows Administrators group. For example, qa01\tme-backup is an Active Directory user account in the data center. If the backup admin plans to use this account, qa01\tme-backup must be part of the local Windows Administrators group on the SQL server.
   - The account must have Log on as a service in the User Rights Assignment on the MS SQL server to install the Cohesity agent.
6. Wait for the installation to finish.

   In the SQL Server Management Studio (SSMS), ensure that the account used to install the Cohesity agent has **Server Roles: sysadmin** in the SQL server instances.
7. The agent starts automatically.
8. Reboot the machine if you have installed the Volume CBT component.
9. Repeat the agent installation process on each SQL server you want to protect. This includes any standalone MS SQL servers and Microsoft SQL Server nodes with AGs.

Register a Physical MS SQL Server

> **Important:** If the server contains one or more databases that belong to an Always On Availability Group (AAG), all remaining servers within the AAG must also be registered with the Cohesity cluster as MS SQL Server in order to be backed up. Navigate to **Data Protection > Sources > click on the required source > All Objects > Show AAG Nodes** to display the registered AAG nodes and any warnings about unregistered servers. If a replica is added to an existing AAG, the replica is automatically backed up by the next Protection Group run that protects that AAG, even if the AAG node list does not display it.

1. Select **Data Protection > Sources**.
2. Click **Register** > **Physical Server**.
3. Specify the hostname (FQDN) or server IP of the server to register. Cohesity recommends using the FQDN.
4. Select the **Server Type**: Windows or Linux.

   For Linux, provide the username and password for the Database Authentication.

   > **Note:** This is an Early Access feature. Contact Cohesity Support to enable the feature.

5. Click **Register**.

   When registration finishes, a new entry appears in the physical section of the Sources page.

6. Next to the newly added physical server, mouse over the actions menu (⋮) and click **Register as MS SQL Server**.

   When registration finishes successfully, the MS SQL Server information is displayed when you click the icon.

> **Note:**
> You can throttle the CPU capacity on the MS SQL physical servers (running on Windows 2012R2 and later) you registered with the Cohesity cluster. Throttling optimizes the CPU capacity utilized when a Protection Group with source-side deduplication is run on the server. However, for MS SQL Protection Group, source-side deduplication is not enabled by default. You must contact Cohesity Support for enabling the source-side deduplication for a Protection Group. CPU throttling does not affect the MS SQL Server if source-side deduplication in a SQL Protection Group is not enabled. For more information on enabling CPU throttling, see Network Bandwidth and CPU Throttling for Physical Server.

> **Note:**
> - AGs discovered on the registered standalone physical hosts or failovercluster are registered as sources internally.
> - Volume-based backup and VMware VSS-based backup are not supported for AG FCC (First-Class Citizen) sources.

Set Up MS SQL on VMs as a VMware vCenter application with the Installed Agent

This method must be used only when you are registering SQL Server at the hypervisor-level. You can use this option for standalone SQL or SQL servers in AG running on the VMware vCenter.

Download and Install the Agent

Before registering the MSSQL server at the hypervisor-level, you must first install the Cohesity agent on each SQL server that you want Cohesity to protect.

You can optionally use the auto-deployed Cohesity agent, which does not require agent installation. Cohesity, however, recommends installing the agent because this avoids additional configuration such as disabling Windows User Account Control (UAC). If you still

want to use the auto-deployed agent, follow the steps described in Set Up MS SQL on VMs as a VMware vCenter application with the Auto-deployed Agent.

1. Select **Data Protection > Sources**.
2. Click **Download Cohesity Agent**. Ensure the agent has been downloaded to the appropriate server.
3. As an administrator with local system privileges on that server, run the executable and complete the installation wizard.
4. You do not need to install any components. Backups leverage VMware VADP CBT or Hyper-V 2016 RCT.
5. **Service Account Credentials:** You can use either the LOCAL SYSTEM account or an account that meets the requirements to install the Cohesity agent.

   If you do not use the LOCAL SYSTEM account, ensure the following:

   - The account must be a member of the local Windows Administrators group. For example, qa01\tme-backup is an Active Directory user account in the data center. If the backup admin plans to use this account, qa01\tme-backup must be part of the local Windows Administrators group on the SQL server.
   - The account must have Log on as a service in the User Rights Assignment on the MS SQL server to install the Cohesity agent.
6. Wait for the installation to finish.

   In the SQL Server Management Studio (SSMS), ensure that the account used to install the Cohesity agent has **Server Roles: sysadmin** in the SQL server instances.
7. The agent starts automatically.
8. Repeat the agent installation process on each SQL server you want to protect. This includes any standalone MS SQL servers and MS SQL Server nodes with AGs.

Register MS SQL

> **Important:** If the server contains one or more databases that belong to an Always On Availability Group (AAG), all remaining servers within the AAG must also be registered with the Cohesity cluster as MS SQL Server in order to be backed up. Navigate to **Data Protection > Sources > click on the required source > All Objects > Show AAG Nodes** to display the registered AAG nodes and any warnings about unregistered servers. If a replica is added to an existing AAG, the replica is automatically backed up by the next Protection Group run that protects that AAG, even if the AAG node list does not display it.

1. Select **Data Protection > Sources**.
2. Navigate the hierarchy to the server that is running MS SQL.

3. Mouse over the server's actions menu (⋮) and click **Register Applications**.
4. Select **Installed Agent**.

   If the agent is not already installed, registration fails.
5. Select MS SQL.
6. Click **Register**.

   The agent starts automatically.

   The server's MS SQL and agent information display when you click the icon.

Set Up MS SQL on VMs as a VMware vCenter application with the Auto-deployed Agent

> **Important:** If the server contains one or more databases that belong to an Always On Availability Group (AAG), all remaining servers within the AAG must also be registered with the Cohesity cluster as MS SQL Server in order to be backed up. Navigate to **Data Protection > Sources > click on the required source > All Objects > Show AAG Nodes** to display the registered AAG nodes and any warnings about unregistered servers. If a replica is added to an existing AAG, the replica is automatically backed up by the next Protection Group run that protects that AAG, even if the AAG node list does not display it.

1. Select **Data Protection > Sources**.
2. Navigate the hierarchy to the server that is running MS SQL.
3. Mouse over the server's actions menu (⋮) and click **Register Applications**.
4. Select **Auto-Deployed Agent**.

   Enter the Windows administrator **Username** and **Password** for the server that is running MS SQL. Windows administrator privileges are required. Ensure that the user account used for auto-deploying the agent is added to all the MS SQL server's SQL instances' **Security > Logins** with Windows Integrated Authentication.

   Disable the UAC property Admin Approval Mode

   1. Click **Start**, type secpol.msc in the Search programs and files box, and then press Enter.
   2. If the User Account Control dialog box appears, confirm that the action it displays is what you want, and then click **Yes**.
   3. In the console tree, expand Local Policies, and click **Security Options**.
   4. In the details pane, scroll down and double-click the **Group Policy** setting that you want to change. This opens the UAC policy settings that a local administrator can modify.

5. Disable **User Account Control: Run all administrators in Admin Approval Mode** for the Administrator account.
6. Ensure that **User Account Control: Admin Approval Mode for Built-in Administrator Account** is set to Disabled.
7. Ensure that **User Account Control: Behavior of elevation prompt for administrators in Admin Approval Mode** is set to Elevate without Prompting.
8. Restart/reboot the Windows server for the changes to take effect.
9. Provide the Administrator/Domain Administrator user that has Admin Approval Mode disabled.

5. Select MS SQL.
6. Click **Register**.

   The server's MS SQL information displays when you click the icon.

Upgrade the Cohesity Agent and Add the File System CBT Component

If necessary, you can upgrade the agent and add the File System Changed Block Tracking (CBT) manually. Start the upgrade and select the option to include the File System CBT component in the upgrade.

Troubleshoot

- The log backup of AG MS SQL Server fails with the following error if there is a break in the log chain.

  ```
  Log chain break error: Discovered a break in the log chain for
  <Database Names>
  ```

  Resolution: To resolve this issue, ensure that no other third-party applications are running a log backup, and then perform a full backup run to reset the log chain.

- The log backup of the AG MS SQL Server fails with the following error if a database is added or removed from the AG MS SQL Server.

  ```
  AG relationship error: Discovered a AG relationship error for database
  <Database Names>
  ```

  Resolution: To resolve this error, perform a full backup run.

For more troubleshooting information, see the following KB article:

- Collecting troubleshooting information for MS SQL issues

Log in to the Cohesity Support Portal to see more KB articles.

Set Up Microsoft SQL Server FCI

This topic describes how to set up an MS SQL Failover Cluster Instance (FCI) to be protected by a Cohesity cluster. To set up a standalone MS SQL Server or MS SQL AG, follow the steps

described in Set Up Standalone Microsoft SQL Server or Microsoft SQL Server AGs.

MS SQL FCI - Overview

An MS SQL FCI is an MS SQL instance installed on a Windows server that is part of a Windows Server Failover Cluster (WSFC or simply Windows Cluster for short). The SQL instance physically exists on (and is accessible from) only one node of the WSFC at any given time. If the FCI's current node goes down, the FCI moves to another node in the WSFC. The FCI is addressed by a Virtual IP (VIP) which points to the physical IP of the node on which it currently resides.

Set Up MS SQL FCI Overview

MS SQL FCI setup has the following steps:

1. Ensure Prerequisites Are Met
2. Download and Install the Agent on Each Node
3. Register an MS SQL FCI as a Source
4. Register an MS SQL FCI as MS SQL

Ensure Prerequisites Are Met

Ensure the prerequisites listed in Prerequisites for Microsoft SQL Server Protection are met.

Download and Install the Agent on Each Node

Before registering an MS SQL Server FCI, you must download and install the Cohesity agent on each node within the MS SQL FCI.

1. Select **Data Protection > Sources**.
2. Click **Download Cohesity Agent**. Ensure the agent has been downloaded to the appropriate server.
3. As an administrator with local system privileges on that server, run the executable and complete the installation using the following steps:
4. **Volume CBT (Changed Block Tracker):** Install this component to leverage Cohesity's built-in CBT technology. Without this component, only full backups can be performed. Installing this component requires a one-time reboot to load the Cohesity CBT driver. Until a reboot, only full backups can be performed.

   File System CBT (Changed Block Tracker): Install this component to perform MS SQL file-based protection.

   > **Note:** Installing the Volume CBT or File System CBT is not necessary for MS SQL VDI-based protection.

5. **Service Account Credentials:** You can use either the LOCAL SYSTEM account or an account that meets the requirements to install the Cohesity agent.

   If you do not use the LOCAL SYSTEM account, ensure the following:

   - The account must be a member of the local Windows Administrators group. For example, qa01\tme-backup is an Active Directory user account in the data center. If the backup admin plans to use this account, qa01\tme-backup must be part of the local Windows Administrators group on the SQL server.
   - The account must have Log on as a service in the User Rights Assignment on the MS SQL server to install the Cohesity agent.
6. Wait for the installation to finish.

   In the SQL Server Management Studio (SSMS), ensure that the account used to install the Cohesity agent has **Server Roles: sysadmin** in the SQL server instances.
7. The agent starts automatically.
8. Reboot the machine if you have installed the Volume CBT component.
9. Repeat the agent installation process on each node within the MS SQL FCI.

   After you install the agent on each node within the FCI, the MS SQL FCI can be registered as a source with the Cohesity cluster.

Register an MS SQL FCI as a Source

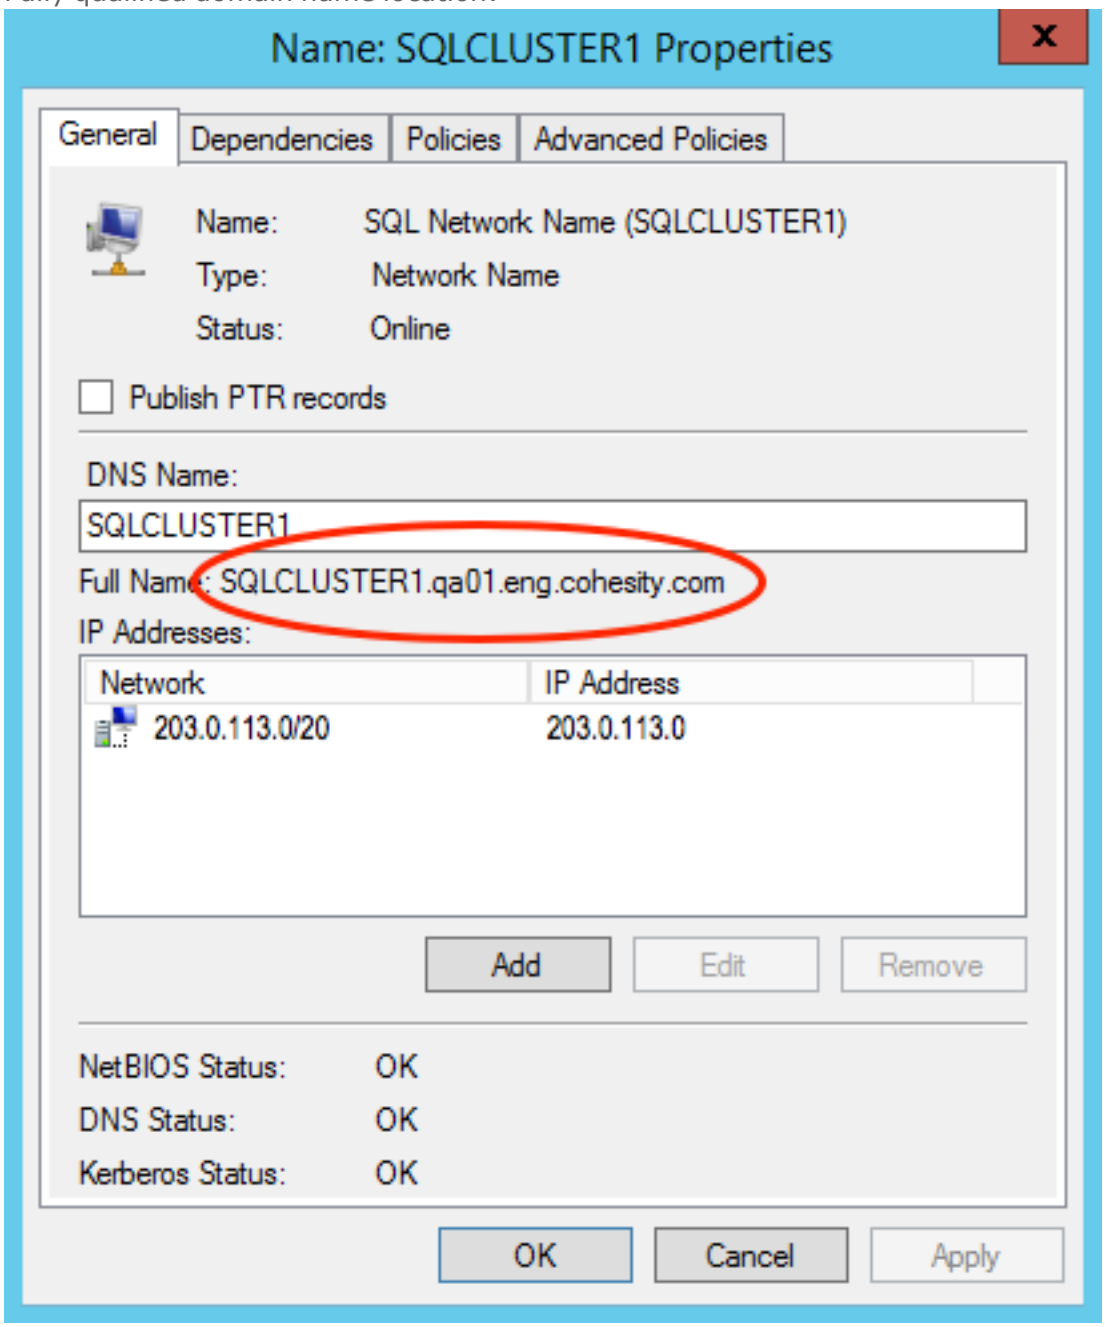
This registration step makes an MS SQL FCI visible to the Cohesity cluster so that its content is eligible to be protected or backed up.

> **Note:**
> - An MS SQL FCI can be registered with only one Cohesity cluster at a time.
> - Each MS SQL FCI must be registered separately.

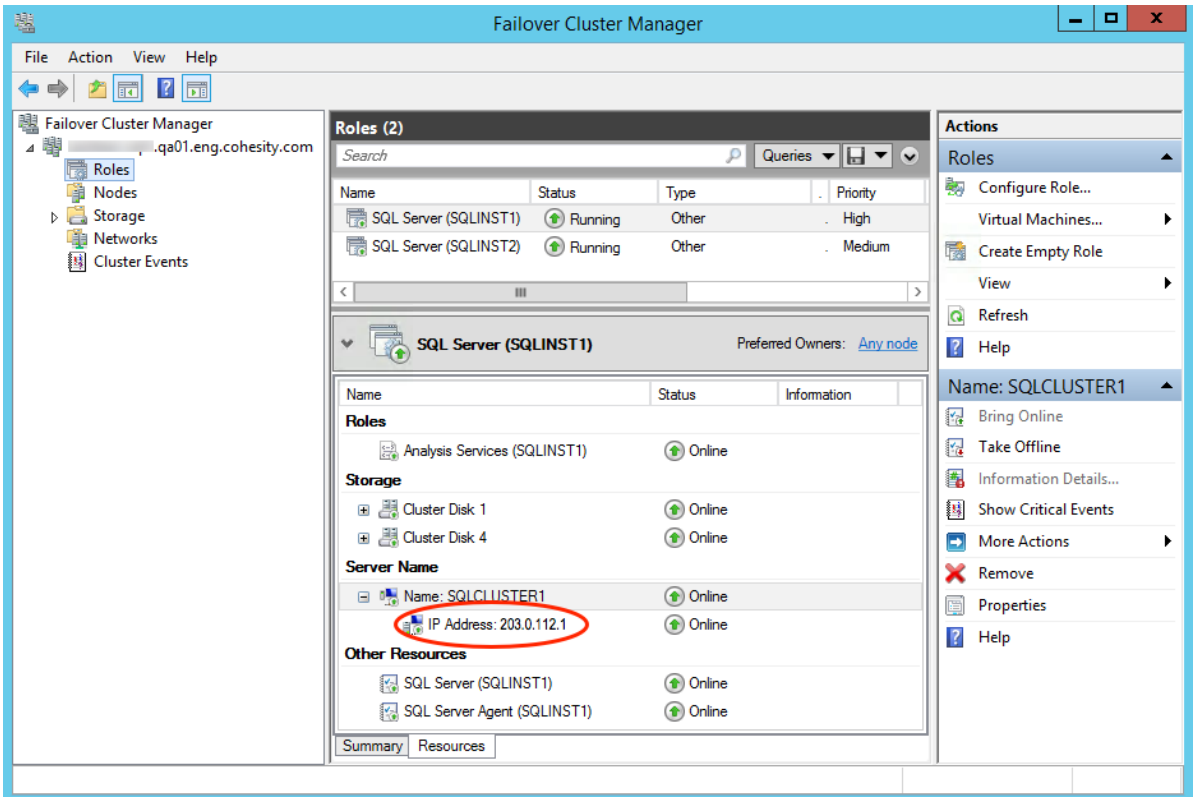
1. Select **Data Protection > Sources**.
2. Click **Register** > **Databases** > **MS SQL Cluster**.
3. Enter the **Hostname**.

   Cohesity recommends that you specify the fully qualified domain name of the MS SQL FCI to register. Or you can specify the virtual IP address (VIP) of the MS SQL FCI present under SQL Role.

Fully qualified domain name location:



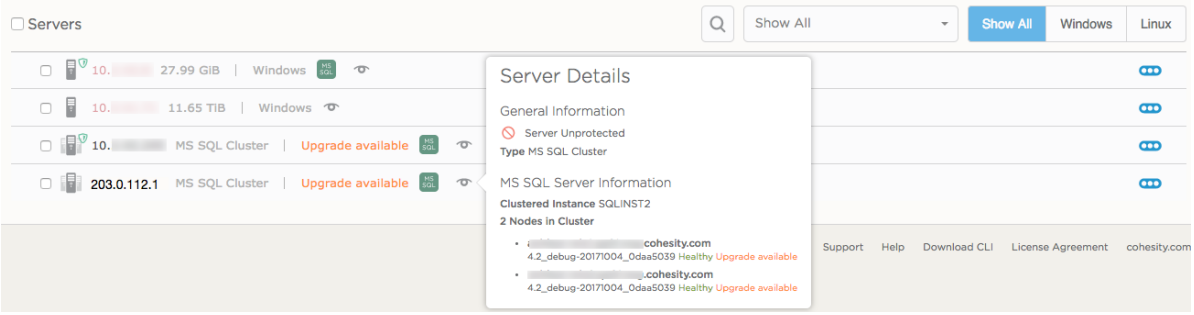
Virtual IP address location:



> **Note:** If the MS SQL FCI is not registered using an FQDN and all its nodes are not configured with FQDNs (for example, it is a test environment), changing the IP address of a registered node or adding/removing nodes may not update the FCI's registration configuration information, which could prevent some Cohesity SQL workflows. If you change the configuration information or add/remove nodes under these conditions, Cohesity recommends that you unregister and then reregister the MS SQL FCI. MS SQL FCIs that are registered using an FQDN do not have limitations when updating configuration information such as node IP address changes or adding/removing nodes.

4. Click **Register**.

   When registration finishes, a new entry appears in the physical section on the Sources page.



The MS SQL FCI is now registered as a physical server.

Register an MS SQL FCI as MS SQL

This registration step takes an MS SQL FCI source that is already visible (as a physical server) to the Cohesity cluster and registers it as MS SQL Server.

Next to the newly added MS SQL FCI (displayed as a physical server), mouse over the MS SQL FCI's actions menu and click **Register as MS SQL Server**.

When registration finishes successfully, MS SQL Server information displays when you click the icon.

FCI Standalone Multi-Registration

You can register and back up a Windows Server that participates in an MS SQL FCI. You can separately register the FCI clusters and their standalone nodes. This allows you to backup local drives for physical server backups.

Prerequisites

- Ensure that all the SQL agents are upgraded.
- Ensure that the following unsupported protection groups are not present:
  - A volume-based protection group that protects SQL servers participating in a WSFC and is either configured to back up all volumes.
  - A protection group that auto-protects a standalone SQL host participating in a WSFC.
  - A protection group that explicitly protects FCI databases on a SQL server participating in an MS SQL FCI.

Error Messages

- The following error message is displayed when unsupported protection groups are present:
  Error
  FCI-node multi-registration cannot proceed, please correct the following protection groups:

- <protectiongroupname1>, <protectiongroupname2> - volume-based jobs that back up all volumes of Windows Cluster node(s).
- <protectiongroupname1>, <protectiongroupname2> - jobs that autoprotect Windows Cluster node(s).
- <protectiongroupname1>, <protectiongroupname2> - jobs that explicitly back up some FCI databases from Windows Cluster node(s).

Solution

Either delete or fix the protection groups such that they no longer fit the unsupported criteria, and continue the procedure.

- The following error message is displayed when the agent on the Windows cluster node has not been upgraded to a version that supports this feature:
  Error
  Agents on the following sources do not support FCI-node multi-registration: <server1>, <server2>
  Solution
  Upgrade the agent on the Windows cluster node to a version that supports this feature.

Best Practices for Microsoft SQL Server

Cohesity recommends the following best practices when protecting MS SQL:

- Cohesity recommends triggering a full backup whenever a database file (.mdf, .ndf, .ldf) is added or removed from the database.
- Multiple Cohesity clusters concurrently backing up an MS SQL VM is not recommended because the jobs will interfere with the other's log chain.
- For MS SQL point in time restores, the Full Recovery Model is recommended as a best practice. For more information, see Choosing the Recovery Model for a Database.
- Set MS SQL Server to autostart.
- To accurately report the size of transaction log data read/written during log backups, the Windows local or domain Administrator account that is registered with Cohesity for backup must be added as a user to the 'model' system database. Use the following query:

```
-- Configures accurate reporting of the size of transaction log data
read/written during log backup
USE [model]
GO
CREATE USER [HOSTNAME\Administrator] FOR LOGIN [HOSTNAME\Administrator]

GO
```

  Where HOSTNAME is the hostname of the SQL server.
  This assumes that the Administrator account used to register MS SQL is already

registered in the SQL server instance's Security Logins and has the "sysadmin" role per documentation. If privileges are not correct, the logical bytes read stat ("Size" column on the Job's details page) for MS SQL log backups will be the same as the physical bytes read stat ("Read" column on the Job's details page). If privileges are correct, then the size reported will be the sum of the sizes of all the .ldf files for the database.

Considerations for Microsoft SQL Server

General

- For file-based Protection Group, object-level granularity is not supported for Role-based access control (RBAC), such as setting access to objects through Active Directory and roles.
- If using native or third-party backup software to back up an application (such as MS SQL), note that the following behavior breaks the differential chain for the application on that server:
  - Performing an app-consistent backup on a VMware SQL VM.
  - Backing up a physical server using a (non-SQL) volume-based physical server Protection Group. You are allowed to run a file-based physical server Protection Group with a SQL Protection Group or 3rd party SQL protection tools.
    This is a Microsoft limitation. For more information, see Various Causes of Log Chains Breaking Issue in SQL Server.
- The SQL Server VDI log backup and restore operations require Sysadmin privileges which is a Microsoft requirement. For more details, see Microsoft Documentation on SQL Server VDI backup.

Protection

- Ensure that all AG databases you want to protect are selected from the respective replica.
- For file-based backups, Cohesity operations rely on default MS SQL file extensions (.mdf, .ndf, .ldf).
- SQL Database and logs residing on SMB/NFS can be protected using the MS SQL Native method.
- SQL Database and logs residing on Clustered Shared Volumes (CSV) can be protected using the MS SQL Native and MS SQL VDI methods.
- CBT information does not persist after a reboot for the file-based backup method.
- As per Microsoft requirements, VDI backups executed on secondary replicas are copy-only full backups. Copy-only backups on secondary replicas do not impact the log chain. For more information, see Offload supported backups to secondary replicas of an availability group.

- Overwriting Filestream database is not supported; this may prevent the completion of recovery.
- Generally, volume-based backups over Resilient File System (ReFS) are not supported. But if the volume is presented through the Windows Cluster Shared Volume (CSV) layer, the ReFS file system detection fails causing the volume-based backups to succeed.
- You can run log backups in parallel with existing log backup runs. This helps reduce storage buildup on the primary SQL Server when multiple large backups are in progress.

  This feature is supported only for file-based, VDI-based, and Filestream (backed up using VDI-based method) backups.

  > **Note:** When you run a log backup for a database backup job, any preceding backup job for the same database may skip the log backup if the new backup job is completed before the previous backup job for the database is started.

  The resource manager reserves additional slots specifically for Run Now based log backups to start immediately. The databases in queue are skipped, and the log backup is initiated.

Recovery

- Performing a point-in-time restore of an Always On Availability Group replica requires full backups from that replica.

  Log backups are merged across all replicas; full backups are not. During restore, the user sees multiple results for the same database from different replicas. Each replica shows a set of Snapshots for full backups done on that particular replica. For point in time restore to a specific replica, the user must select a full backup Snapshot from that replica only. If a full backup does not exist, point in time restore is not possible.

  Restore the database to the desired MS SQL Server instance on a replica that has a full backup.
- Using the "Restore to Original SQL Server instance" option is not supported if any of the following occurs:
  - The Windows host name changed and you attempt to restore a snapshot that was taken before the host name change.
  - Granular DB restore performed from a higher SQL Server version to a lower version. This is a Microsoft limitation.

You can, toggle off "**Restore to Original SQL Server Instance**" and perform a database restore.

For more information, see Rename computer hosting instance - SQL Server.

Restoring a snapshot taken after the name change or upgrade is supported.

- Restoring MS SQL Server from backups of dynamic disks to the same machine is not supported.
- Use File-based or VDI-based backup methods to protect TDE databases. Follow the Microsoft TDE best practices for key and cert management.
- If multiple restore tasks are run on the same target host, the restore tasks will be serialized.
- **For system database recovery**:
  - Recovering the system database to an alternate instance is not supported.
  - When recovering to the original database, the original database is deleted before the recovery. Therefore, a recovery failure will also lead to the loss of the original database.
  - If you are recovering the system databases individually, then the recovery of the system database must be in the following order:
    1. Master
    2. MSDB
    3. Model
  - You cannot recover a system database along with a user database.
  - If you are recovering more than one system databases in a recovery task, then the recovery point for the selected system databases must be the same.
  - For recovering a database to an Amazon RDS Custom SQL Server, the recovery destination path must be under the **D:\rdsdbdata** folder.

Clone

- Cloning an MS SQL database and renaming the database via SSMS can leave the cloned database in the "Recovery Pending" state during a clone teardown task. This is because the Cohesity cluster database clone operation assumes the cloned database name and files are associated with the original clone operation. To prevent a disconnect between the Cohesity cluster and SQL Server operation, it is recommended to clone a new database with the intended database name rather than rename a cloned database.

Migration

- Cohesity does not support the migration of MS SQL FILESTREAM databases.
- Once a migration task is configured and created, the target SQL Server or database paths cannot be modified for the existing migration task.
- Cohesity does not detect changes/deletions to the target database with a running migration task. Changes made external to the migration task before finalizing can cause the migration task to fail.
- Cohesity does not support the migration of MS SQL databases that are replicated to an alternate Cohesity cluster.

General Recommendations for Microsoft SQL Server Backup Methods

FILESTREAM databases can be protected using the following approaches, listed in the order of recommendation:

- VDI-based
- Volume-based

Normal databases can be protected using the following approaches, listed in the order of recommendation:

- File-based
- VDI-based
- Volume-based

The following table can help you select the appropriate backup type:

	File-based Backup	VDI-based Backup	Volume-based Backup
Microsoft Approach	Leverages Microsoft VSS approach	Leverages Microsoft SQL Server native backup and restore commands through API calls	Leverages Microsoft VSS approach
Built-in Change Block Tracking (CBT)	Leverages Cohesity's built-in CBT technology	Leverages SQL server's differential backups	Leverages Cohesity's built-in CBT technology
Database clone from backup	Supported	Not Supported	Supported

	File-based Backup	VDI-based Backup	Volume-based Backup
Recovery: Cross-domain AD without trust	Supported (GRPC is used to transfer data)	Supported (GRPC is used to transfer data)	Not Supported (Recovery uses SMB and cross-domain trust is required for SMB access)
