Database clone: Cross-domain AD without trust	Not Supported (Clone uses SMB and cross-domain trust is required for SMB access)	-	Not Supported (Clone uses SMB and cross-domain trust is required for SMB access)
Implicit Full backup after SQL host restart	The first backup after the SQL server reboot will be a full backup (incremental backup automatically switches to full backup)	-	-
Memory Optimized Filestream Database	Not Supported	Supported	Not Supported
SQL server-side compression	Not Supported	Supported but not recommended to use, since it may cause low deduplication rate on the Cohesity clusters, which leads to high storage utilization on the Cohesity cluster.	Not Supported
Parallel Log Backup to Full/ Incremental Backup	Supported	Supported	Not Supported
Fast Backup (multi-node)	Supported	Supported	Supported
Fast Restore (multi-node)	Supported	Supported	Not Supported. The restore throughput is limited by the single cluster node throughput.

	File-based Backup	VDI-based Backup	Volume-based Backup
Database-level recovery from archived backup	Supported (Beta till 7.0)	Supported (Beta till 7.0)	Not supported via workflow; can be performed manually.
CAD Policy	Supported	Supported	Not Supported
Transparent Data Encryption (TDE) Databases	Supported	Supported	Not Supported
Database on ReFS volumes	Supported	Supported	Not Supported
Quiesce Support	SQL Database goes through quiesce (freeze/thaw)	Not required. The SQL server performs consistent backup	SQL database goes through quiesce (freeze/thaw)
Free Space on SQL Host (VSS shadow storage requirement)	At least 10% is recommended for each volume on the SQL host by MSFT. Large databases with high IO rates may require additional space.	-	At least 10% is recommended for each volume on the SQL host by MSFT. Large databases with high IO rates may require additional space.
Must-Have	-	Must have Full and incremental (differential). NOTE: Setting extended retention is required for full backup to avoid expiry before the incremental backup expiry.	-
Parallel run-now backups (same type) for the same job	When the host is already part of a previous run-now submitted, the backup is queued until the previous submitted run is complete.	Backup of the selected database runs in parallel with the existing run-now request.	Not Supported

	File-based Backup	VDI-based Backup	Volume-based Backup
Known Issues that lead to backup failure	Very High transaction rate on databases may occur resulting in backup failure. This is due to Microsoft's VSS system provider not being able to maintain the VSS snapshot on SQL host with very high transactions. This is very rare. Configuring the shadow storage on volume with no/less IO helps to mitigate the issue.	Agent/SQL host may restart during backup.	Very High transaction rate on databases may occur resulting in backup failure. This is due to Microsoft's VSS system provider not being able to maintain the VSS snapshot on SQL host with very high transactions. This is very rare. Configuring the shadow storage on volume with no/less IO helps to mitigate the issue.
Known Issues that lead to incremental backup converting to full backup	First backup after SQL server reboot will be a full backup (incremental backup automatically switches to full backup)	If no explicit policy is available for full backup, incremental backup is converted to full backup after 7 days.	-
Known issues that lead to PIT clone failure	-	-	PIT clone may fail if enough free space is not available (at least equal to the database being cloned) on the primary volume during backup.
FortKnox	Supported	Supported	Not supported

> **Note:** REFS is supported by VDI-based and File-based SQL server.

Backup Microsoft SQL Server

The following topics provide guidance to help you protect MS SQL databases:

For more information on MS SQL deployments, See Protect SQL Server with Cohesity—Deployment Considerations Guide.

About Microsoft SQL Server Backup

Cohesity supports the following MS SQL Server backups:

- Volume-based Backup
- File-based Backup
- VDI-based Backup

Cohesity also supports VM-based Backup and SQL Native Backup.

Volume-based Backup

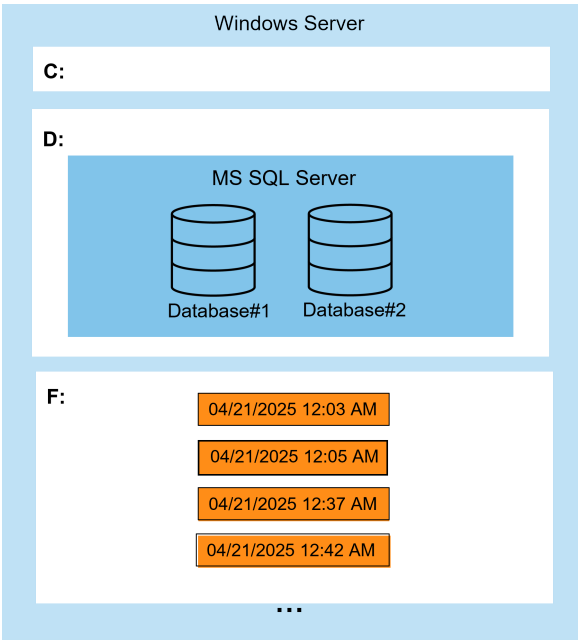
A Cohesity MS SQL volume-based backup captures all MS SQL databases running on a VMware or Physical Server, whose files reside on one or more volumes, as well as all other files that are stored on the corresponding OS volume. This approach contrasts with a file-based MS SQL backup, which includes only the selected databases. The Cohesity cluster captures full database server backups and can optionally back up database transaction logs, so you can roll forward to any point in time.

For information on performing MS SQL volume-based backup, see Backup Microsoft SQL Server (Volume-based).

All configurations are for illustrative purposes only. Cohesity recommends following MS SQL best practices.

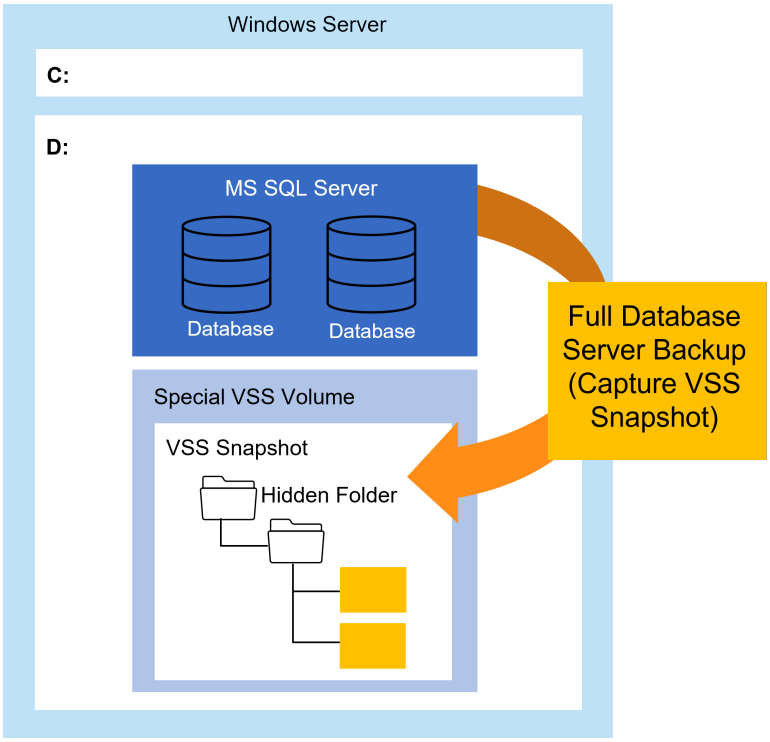
An example of MS SQL running on a Windows server that contains the following:

- Multiple volumes, C, D and F in the figure below
- Volume D is running multiple MS SQL databases
- Volume F contains database logs

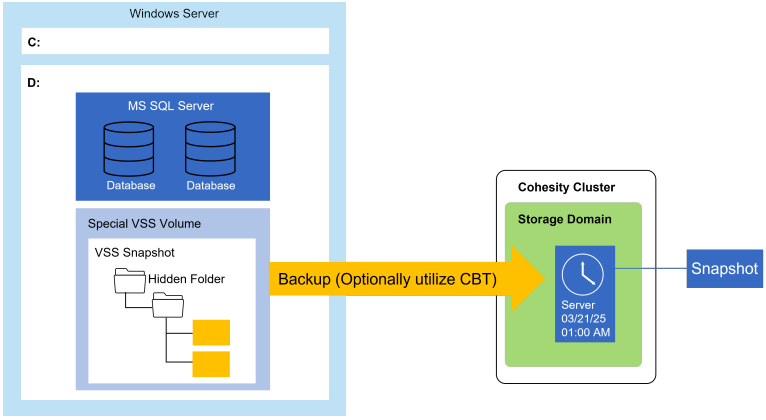


The MS SQL volume-based backup task consists of the following actions:

1. During an MS SQL protection run, a VSS snapshot of MS SQL is captured using Volume Shadow Copy Service (VSS). The VSS snapshot resides on the local drive as a special VSS volume. This capturing of the VSS snapshot is a full database server backup. This is the same for MS SQL running on VMware and physical servers.

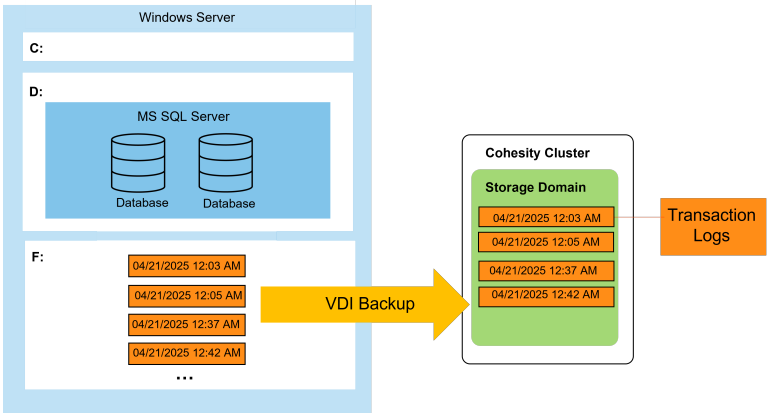


2. The snapshot is captured and saved on the Cohesity cluster with a date and time stamp. You can optionally choose for the Cohesity cluster to utilize Change Block Tracking (CBT) when backing up the snapshot. VMware VMs leverage VMware CBT to back up the snapshot. Physical servers leverage Cohesity CBT to back up the snapshot.



3. If specified in the policy, the database transaction logs are backed up to the Cohesity cluster using MS SQL Server Virtual Device Interface (VDI). The logs allow you to roll

back to a specific point in time. MS SQL Server automatically truncates the SQL logs after a successful SQL log backup and marks the Virtual Log Files (VLFs) for reuse.



File-based Backup

A Cohesity cluster MS SQL file-based backup protects only the MS SQL databases you choose. It captures only the database files for those selected databases. This approach contrasts with a volume-based backup, which captures any and all the files contained on the volume. The Cohesity cluster captures full database server backups and can optionally back up database transaction logs, so you can roll forward to any point in time.

The advantage of a file-based backup is that a smaller amount of data is captured, which allows the Protection Group to run more quickly.

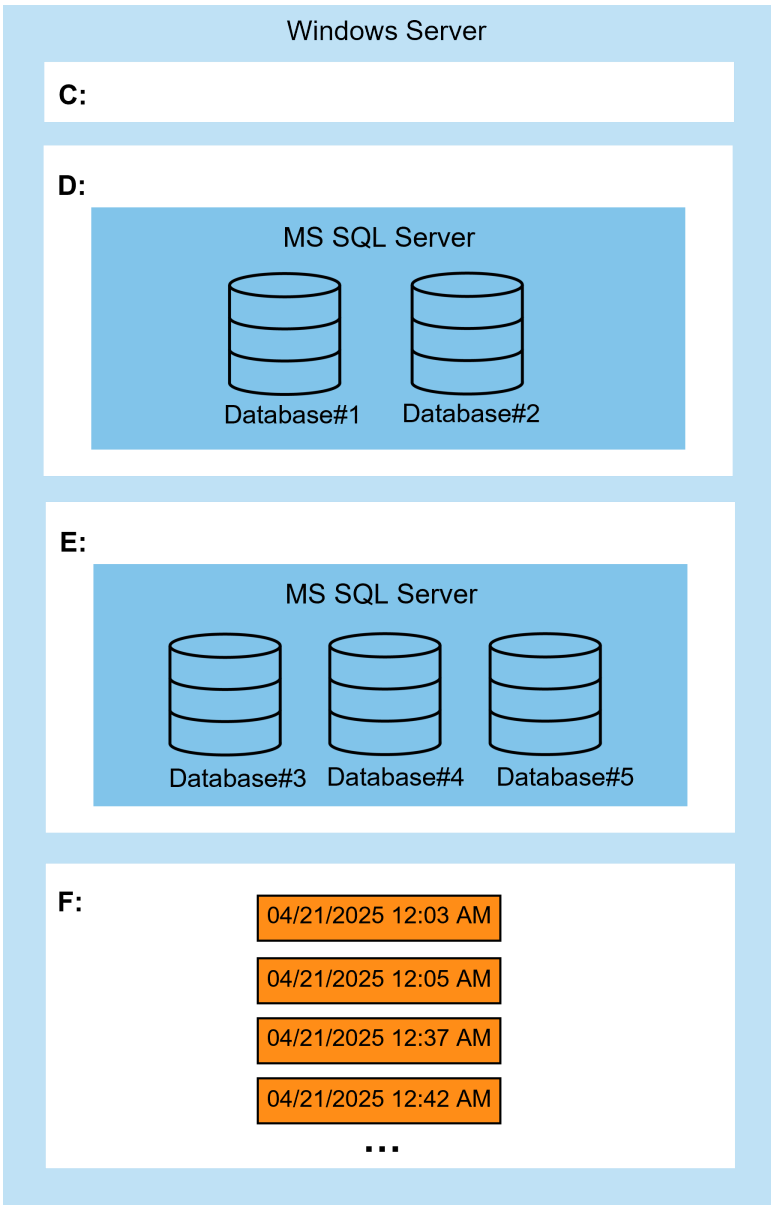
> **Note:** To enable file-based backup, you must install the File System CBT component during Cohesity agent installation.

For information on performing MS SQL file-based backup, see Backup Microsoft SQL Server (File-based).

All configurations are for illustrative purposes only. Cohesity recommends following MS SQL best practices.

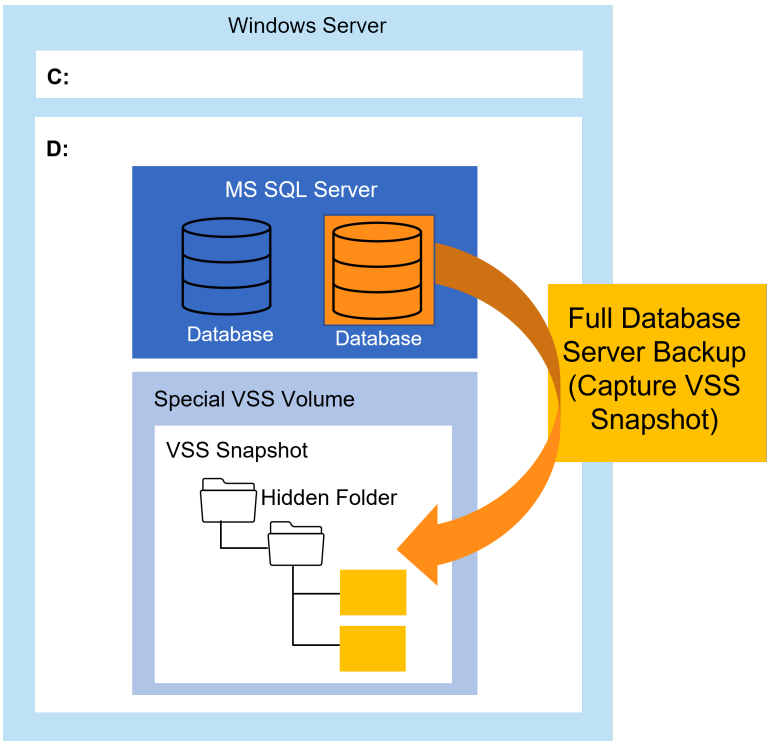
An example of MS SQL running on a Windows server that contains the following:

- Multiple volumes, C, D, E and F in the figure below
- Volume D is running two MS SQL databases
- Volume E is running three MS SQL databases
- Volume F contains database logs

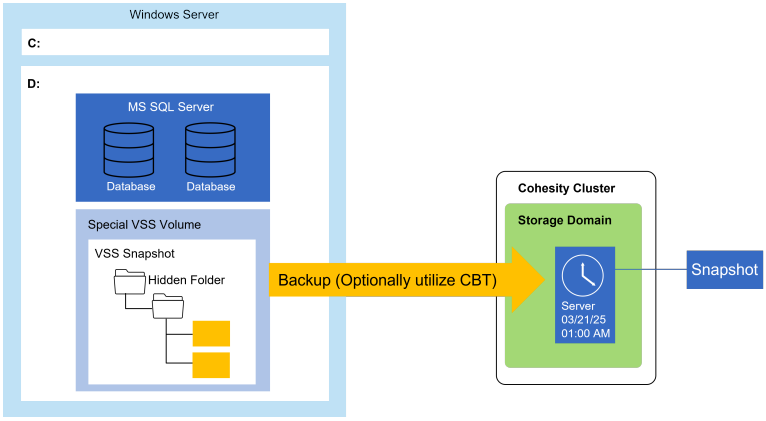


The MS SQL file-based backup task consists of the following actions:

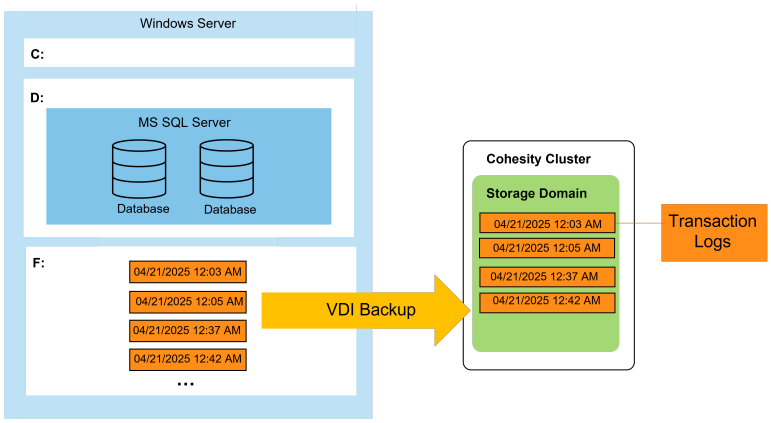
1. During SQL database protection run, a VSS snapshot of the specified MS SQL databases is captured using Volume Shadow Copy Service (VSS). The VSS snapshot resides on the local drive as a special VSS volume. This VSS snapshot is a full database server backup.



2. The snapshot is captured and saved on the Cohesity cluster with a date and time stamp. You can optionally choose for the Cohesity cluster to utilize Change Block Tracking (CBT) when backing up the snapshot. VMware VMs leverage VMware CBT to back up the snapshot. Physical servers leverage Cohesity CBT to back up the snapshot.



3. Backups of database transaction logs use MS SQL Server Virtual Device Interface (VDI) and are stored on the Cohesity cluster. The logs allow you to roll back to a specific point in time. MS SQL Server automatically truncates the SQL logs after a successful SQL log backup and marks the Virtual Log Files (VLFs) for reuse.



VDI-based Backup

A Cohesity cluster MS SQL VDI-based backup captures the native MS SQL server backups. It captures VDI-based backups of a specific database on a SQL Server instance running on a VMware or physical server.

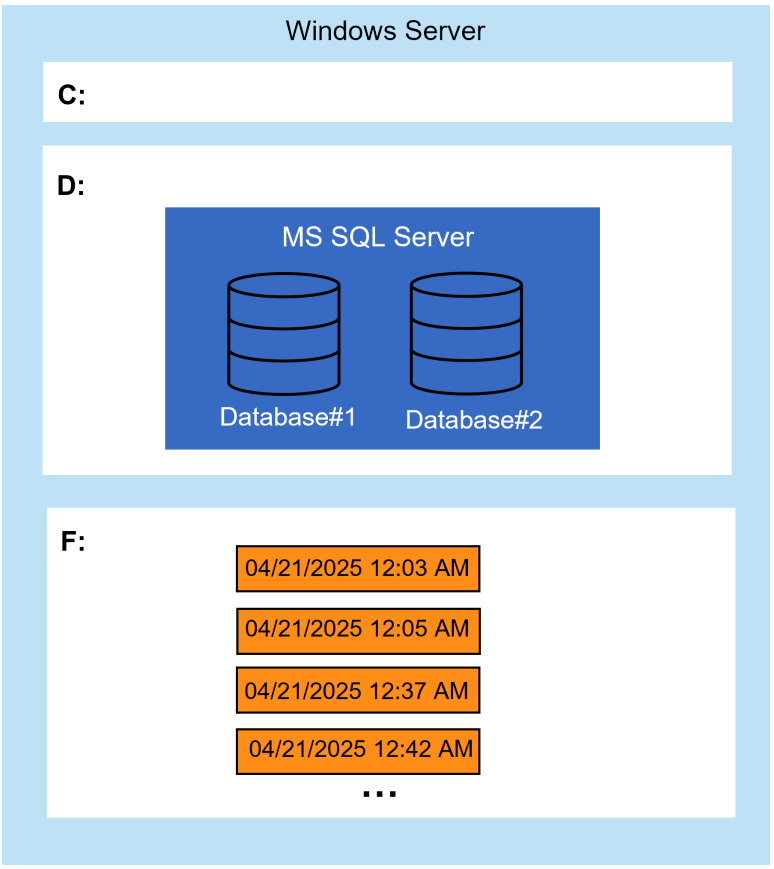
The Virtual Device Interface (VDI) is a Microsoft interface that allows the Cohesity agent to execute SQL Server Native backup and restore commands. This backup type produces a standard SQL Server Native backup of type (.BAK), transaction logs, (.TRN), and differentials, (.DIFF). These backup files are stored on a Cohesity View and take advantage of View compression, deduplication, encryption, replication, and archiving features.

For information on performing MS SQL VDI-based backup, see, see Backup Microsoft SQL Server (VDI-based).

All configurations are for illustrative purposes only. Cohesity recommends following MS SQL best practices.

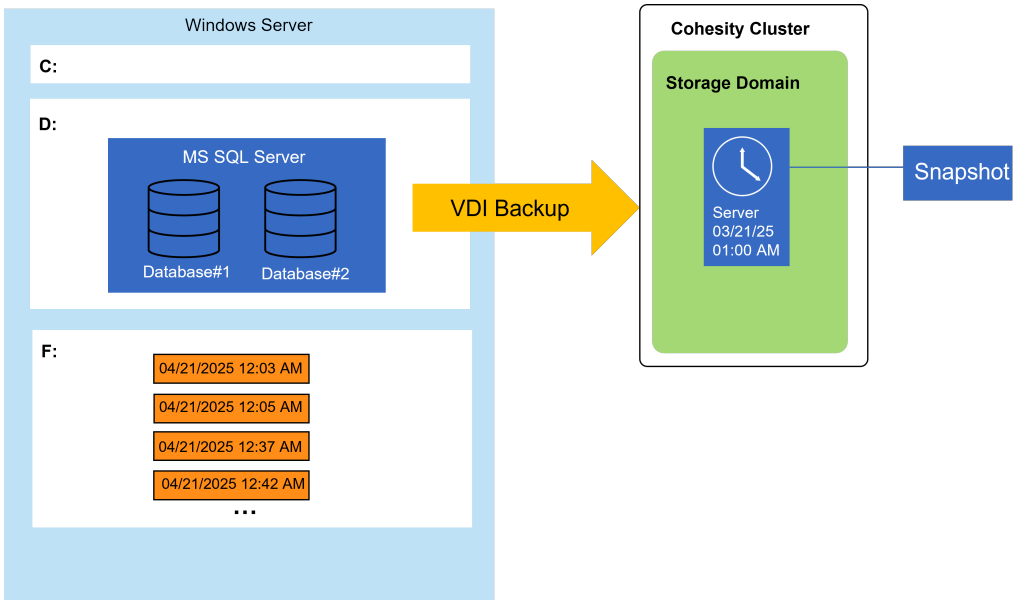
An example of MS SQL running on a Windows server that contains the following:

- Multiple volumes, C, D and F in the figure below
- Volume D is running multiple MS SQL databases
- Volume F contains database logs

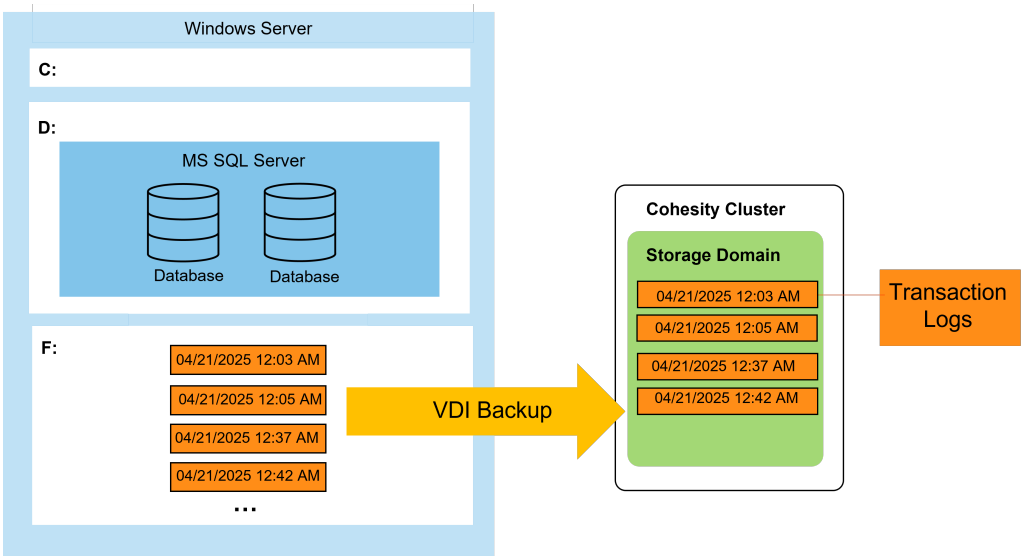


The MS SQL VDI-based backup task consists of the following actions:

1. During an MS SQL protection run, a "BACKUP DATABASE" command for the specified MS SQL databases is initiated using MS SQL Server Virtual Device Interface (VDI). The generated backup file is saved on the Cohesity cluster with a date and time stamp.



2. If the policy is configured to take incremental database backups, it translates to differential backups in case of VDI-based backup.
3. If transaction log backups are specified in the policy, the database transaction logs are backed up to the Cohesity cluster using MS SQL Server Virtual Device Interface (VDI). The logs allow you to roll back to a specific point in time. MS SQL Server automatically truncates the SQL logs after a successful SQL log backup and marks the Virtual Log Files (VLFs) for reuse.



Compare File-Based, VDI-Based, Volume-Based Backup Methods

The following table compares the implications of each method.

Cohesity Facet	File-based backup	VDI-based backup	Volume-based backup
Technology Employed	Cohesity Agent uses Vss and Cohesity technology for file CBT, and VDI for T-logs.	Cohesity agent uses SQL Native backup commands.	Cohesity Agent uses Vss, for volume CBT, and VDI for T-logs.

Cohesity Facet	File-based backup	VDI-based backup	Volume-based backup
What does it capture?	Captures database files.	Captures the database in a SQL Server standard .BAK, .TRN, or .Diff file.	Captures all the volumes attached to the server and everything on those volumes. **Note:** Often, there are other files, like old .bak files, that sit on the volume along with the active database files. A large amount of other files will increase the duration of the protection group because these files will be captured along with the database files.
Logs	Yes. Captures a SQL log backup of the database.	Yes. Captures a SQL Server native log backup of the database.	Yes. Captures a SQL log backup of the database.
Cohesity Source Registration	Register as a SQL Server application.	Register as a SQL Server application.	Register as a SQL Server application.

Cohesity Facet	File-based backup	VDI-based backup	Volume-based backup
Compatibility with SQL Server High Availability Features	**Windows Failover Cluster**: **Yes**, backup will succeed if a failover occurs. Must be registered as a Cohesity "SQL Cluster" source. **AG**: **Yes**, backup on the correct replica will succeed after an AG failover occurs. **Mirroring**: **Yes** Each SQL instance must have its own Protection Group. **Log Shipping**: **Yes**. Each SQL instance must have its own Protection Group. **Note:** While Cohesity currently does not include specific features for mirroring and log shipping, it does not conflict with these SQL Server features. **Note:** Log shipping via SQL Server Management Studio supports only full/incremental backup and not log backup since it can break the log chain.	**Windows Failover Cluster**: **Yes**, backup will succeed if a failover occurs. Must be registered as a Cohesity "SQL Cluster" source. **AG**: **Yes**, backup on the correct replica will succeed after an AG failover occurs. Mirroring: No. Log Shipping: No	**Windows Failover Cluster**: **Yes**, backup will succeed if a failover occurs. Must be registered as a Cohesity "SQL Cluster" source. **AAG**: **Yes**, backup on the correct replica will succeed after an AAG failover occurs. **Mirroring**: **Yes** Each SQL instance must have its own Protection Group. **Log Shipping**: **Yes**. Each SQL instance must have its own Protection Group. **Note:** While Cohesity currently does not include specific features for mirroring and log shipping, it does not conflict with these SQL Server features. **Note:** Log shipping via SQL Server Management Studio supports only full/incremental backup and not log backup since it can break the log chain.

Cohesity Facet	File-based backup	VDI-based backup	Volume-based backup
Method	This is an MS SQL Server database backup at the **file level**. Allows for FULL SQL Server backups with logs, but only the database files are captured. The Cohesity Agent uses Vss, the Cohesity File CBT, and VDI to take an application-consistent snapshot of the volumes on that server. Faster because it's not backing up extraneous files. **Note:** Cannot browse files or folders as in a volume-based backup.	This is a native MS SQL Server database backup at the **file level**. Allows for FULL SQL Server backups with logs and Differentials, but only the database is captured. Agent uses SQL Server native backup and restore commands , to take an application-consistent backup of the database.	This is an MS SQL Server database backup at the **volume level**. Allows for FULL SQL Server backups – all databases, logs, and files/folders on the volumes are backed up. MS SQL Server is registered as a Cohesity source and MS SQL application. The Cohesity Agent uses Vss, the Cohesity Volume CBT, and VDI to take an application-consistent snapshot of the volumes on that server.
Recovery/Restore	The database host server should be backed up and restored via a different protection group. Supports Point-in-Time (PIT) restore of the database from across the entire backup history.		

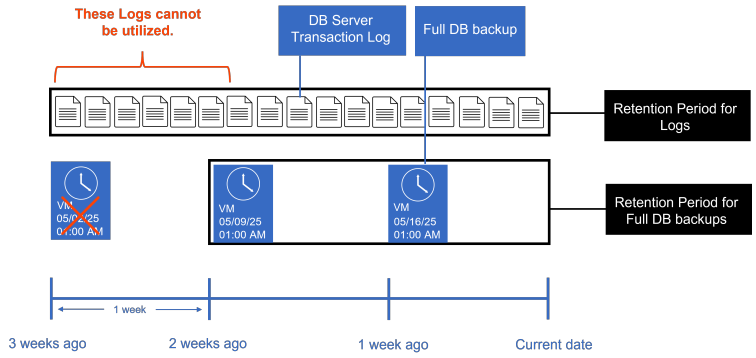
Cohesity Facet	File-based backup	VDI-based backup	Volume-based backup
Cloning	**Yes**. Can produce a representative database. *Advantage*: Applications can be tested with data that is as close to the production environment as possible: Can reproduce a database. *Advantage*: Applications can be tested with databases that can be destroyed and re-created on demand. No load on Production servers. The backup is NOT modified and therefore always safe. A successful clone is immediate validation of the backup's integrity. Uses storage resources on Cohesity cluster.	**Cloning is scheduled as a future enhancement.**	**Yes**. Can produce a representative volume. *Advantage*: Applications can be tested with data that is as close to the production environment as possible. Can reproduce a volume. *Advantage*: Applications can be tested in an environment that can be destroyed and recreated on demand. No load on Production servers. The backup is NOT modified and therefore always safe. Uses storage resources on Cohesity cluster.
Source-side deduplication	Supported	Not supported	Not supported
Archival	**CloudArchive**: Cohesity supports the ability to send backups to public cloud providers like AWS, Azure, and Google Cloud Platform. It also supports search and restore from them, back to the local site when needed.		
Replication	**Managing Copies of backups on another Cohesity cluster**: Backups, files, and volumes can be replicated to a second Cohesity cluster.		

About Log and Full DB Backup Retention Periods

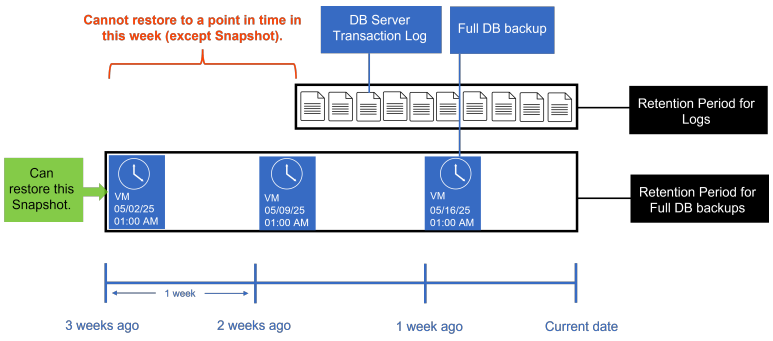
The retention periods of log files and full database server backups are independent of each other. Consider the following examples to help determine the best retention periods for your database server backups. These retention guidelines also apply to full database server and log replication schedules. Retention periods of log files and full database backups must adhere to Microsoft rules for restoring databases.

1. A point-in-time restore using SQL log backups is dependent on a full backup because a full database server backup must also be available to apply the logs.

   When the Cohesity cluster restores to a specific point in time, it must first restore a full database server backup and then apply the appropriate set of logs. If a full database server backup is not available because the retention period of the full database server backup is too short, the Cohesity cluster cannot restore to a point in time within the specified log retention period. For example if the log retention period is three weeks and the full database server backup captures snapshots weekly with a retention period of two weeks, the Cohesity cluster will not be able to restore to any point in time from three weeks ago. In addition, the logs from three weeks ago cannot be utilized and are using disk space.

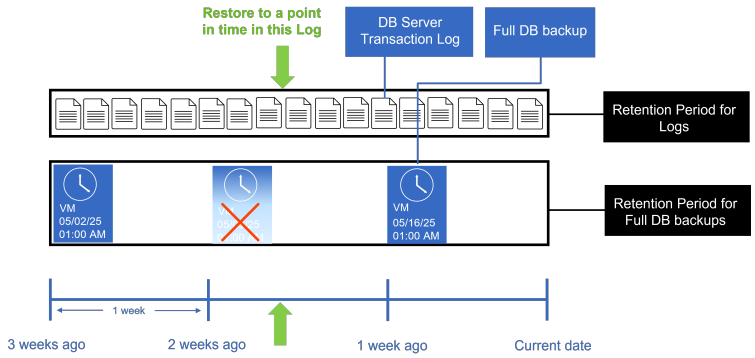


2. If the log retention period is shorter than the full database server backup retention period, the Cohesity cluster cannot restore to a point in time where the logs are not saved. For example, if the log retention period is two weeks and the full database server backup captures snapshots weekly with a retention period of three weeks, the Cohesity cluster will not be able to restore to any point in time between two and three weeks ago. The Cohesity cluster can, however, restore to the snapshot from three weeks ago.

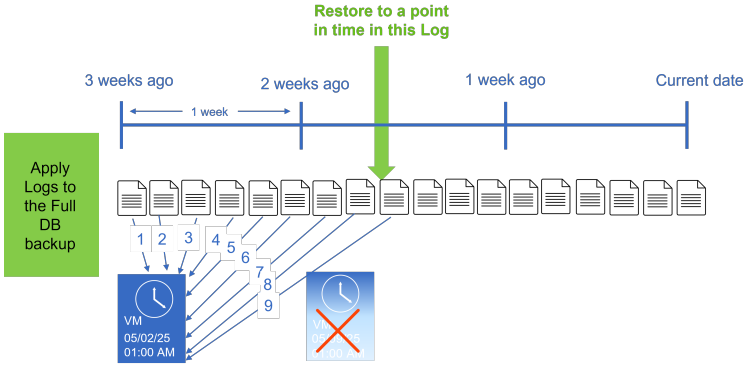


3. Cohesity recommends specifying a log retention period with extra time to allow for failed full database server backups as demonstrated by the following example. A full database server backup is scheduled weekly with a three-week retention period for both full database server and logs. If the full database server backup failed two weeks ago, the Cohesity cluster can still restore to the point in time from the log indicated by

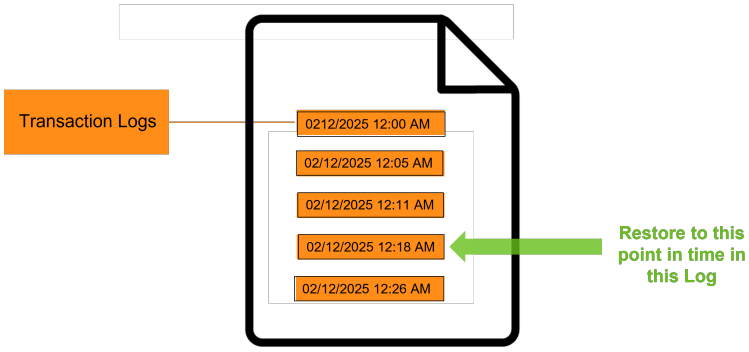
the green arrow.



The Cohesity cluster restores full database server backup from three weeks ago and applies the appropriate logs to restore the state to a point.



You can restore to a specific transaction in the log.



> **Note:** A full database backup is not a transaction log backup. Ensure that your SQL Server protection policy has transaction log backup for full and bulk-logged recovery model requirements.

Backup Microsoft SQL Server (Volume-based)

This topic describes how to protect MS SQL with a volume-based job. Volume-based jobs protect MS SQL at the server level, meaning all databases on a server. File-based jobs protect only the specific MS SQL databases that you select. To use a file-based job, follow the steps described in Backup Microsoft SQL Server (File-based).

MS SQL Protection Group Support

The following table describes supported job types for MS SQL running on physical servers and VMs.

	File-based Jobs	Volume-based Jobs	VDI-based Jobs	Both Job Types Using the Same Server but Protecting Distinct Databases
Physical MS SQL	Multiple file-based jobs protecting all or a subset of DBs	One volume-based job protecting all or a subset of DBs	Multiple VDI-based jobs protecting all or a subset of databases	Supported
SQL Server Virtual Machine Backup	NA	Volume-base with Hypervisor to provide application-consistent backup	NA	NA

Note:

- (*Applies to both standalone MS SQL and MS SQL FCI*.) If the VM SQL you registered has physical VMware RDM disks attached, then the MS SQL databases located on these disks will not be backed up and the following message is displayed in the Protection page:

  ```
  Identified <Number> physical RDM disks attached to this VM. Backup of physical RDM disks is not supported using VADP. Databases located on any of these disks are not backed up.
  ```

- (*Applies only to both standalone MS SQL and MS SQL FCI*.) If the VM SQL you registered has virtual VMware RDM disks attached, then the MS SQL databases located on these disks will not be backed up and the following message is displayed in the Protection page:

  ```
  Identified < Number> virtual RDM disks attached to this VM. Backup of virtual RDM disks is not supported. Databases located on any of these disks are not backed up.
  ```

- (*Applies only to standalone MS SQL*.) If the VM VM SQL you registered has iSCSI devices attached and if there are SQL databases having their database files on these iSCSI disks, then those SQL databases will not be backed up. The following message is displayed on the Protection page:

  ```
  Found < Number> databases with files on external storage. These databases cannot be backed up. Please use alternate backup methods like native dumps, Cohesity file base backup, or Cohesity's SQL VDI to protect the databases
  ```

Note: Converting an existing volume-based Protection Group to a file-based Protection Group is not supported. You must delete the existing Protection Group and create a new one.

Protect MS SQL Overview

Perform the following steps in the Cohesity cluster to protect SQL Server:

1. Register the SQL Server you want to protect as a source with the Cohesity cluster. See Set Up Standalone Microsoft SQL Server or Microsoft SQL Server AGs or Set Up Microsoft SQL Server FCI.
2. Select **Dashboard** and from the drop-down, select **MS SQL**.

3. From the **Hosts** tab, you can protect all databases on a host. Select **Protect Databases** from the host's actions menu.

   From the **Databases** tab, you can protect a single database. Select **Protect** from the database's actions menu.

   You can change which objects you want to protect when creating the job.

You can also protect MS SQL by performing the following steps:

1. Navigate to **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then select **Databases** > **MS SQL Server**.
3. Select the objects to protect.

Create a Volume-based MS SQL Protection Group

1. Navigate to **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then select **Databases** > **MS SQL Server**.
3. In the **New Protection** pop-up, do one of the following:
   - Protect MS SQL by specifying a subset of options such as objects, protection group and policy by clicking the edit icon corresponding to the following options:
     i. **Add Objects**: Select the registered MS SQL source or click Register Source to register an MS SQL source. Select the objects to protect .
     ii. **Protection Group**: Specify a name for the Protection Group.
     iii. **Policy**: Select an existing policy or click **Create Policy** to create a new protection policy.
     iv. **Storage Domain**: Select the appropriate storage domain.

     > **Note:** This option is visible on the **New Protection** pop-up only if there is more than one storage domain.

     v. **Backup Type**: From the drop-down, select **Volume-based**.
     vi. Click **Protect**.
   - To protect MS SQL by specifying all the options, click **More Options**.
4. **Source:** Select the objects to protect.

   Select the source objects to back up or exclude. By default, all objects in the source are excluded as indicated by the unselected check box. Expand the source objects

and select the objects you want to include in the Protection Group. A selected check box ( ) indicates the object is selected to be backed up.

> **Note:** If you have registered a physical server that is a part of the registered MS SQL Failover Cluster, then the MS SQL Failover Cluster Instance will not appear as a source in the object list of the registered physical server.

If appropriate for your organization, enable Auto Protect.

Click to turn on **Auto Protect**. By enabling this option:

- All the SQL databases that are added to the SQL server in the future are automatically added to the Protection Group and are protected from the next protection run.
- All the SQL databases that are removed from the SQL server in the future are automatically removed from the Protection Group and are not protected from the next protection run. The existing backup for the user is preserved until the snapshot expires.

For example, you create a Protection Group that backs up a SQL Server. The Protection Group runs for two weeks and then a new database is added to the SQL Server. The next time the Protection Group runs, if the object hierarchy has been refreshed on the Cohesity cluster, the new database is also backed up even though the new database has not been explicitly selected to be included in the Protection Group. The object hierarchy is automatically refreshed every four hours.

To manually refresh the object hierarchy, select **Data Protection > Sources**, find the source in the list and click . To exclude an object from Auto Protect, click .

- Indicates an Auto Protected object.
- Use this option to exclude SQL databases from the protection group. Excluded objects are not protected. The icon indicates that an ancestor of the object is Auto Protected but this object is explicitly excluded.

  To exclude a database from the protection group, specify the absolute path of the database to be excluded from the backup at a protection job level. You can optionally use:

  - **Wildcard Exclusion** - You can optionally use the Wildcard * in any location in the search string to exclude all the matching databases from the backup at a protection job level.

- **Regex Exclusion** - You can use the RegEx string name match and manual user selection to exclude DBs from backup at a protection job level.

> **Note:** You can use the exclude SQL database feature only if Auto Protect is enabled for a backup job.

Protection of dismounted databases, recovery database types, and deleted databases are automatically skipped by the Protection Group.

After defining the filer click **Apply** to save the selection.

The following table lists the examples for excluding objects in an MS SQL database:

Sample Configuration		
10.2.157.20 (Host)		
*** SQL2012**	*** SQL2014**	*** MSSQLSERVER**
(SQL Server Instance)	(SQL Server Instance)	(SQL Server Instance)
- UserDB1	- UserDB3	- ProdDB1
- UserDB2	- UserDB4	- ProdDB2
- TestDB1	- TestDB3	
- TestDB2	- TestDB4	

Example of Absolute Path

- **10.2.157.20/SQL2012/UserDB1** - Excludes the database 'UserDB1' from the SQL server instance 'SQL2012' on the host 10.2.157.20.
- **10.2.157.20/SQL2012/** - Excludes the 'SQL2012' from the SQL server instance and its databases.

> **Note:** The absolute instance path must end with '/' and the plain text instance path must contain two or more slashes.

Example of Wildcard Exclusion

- **10.2.157.20/SQL2012/User*** - Excludes the databases 'UserDB1' and 'UserDB2' from the SQL server instance 'SQL2012' on the host 10.2.157.20.
- **10.2.157.20/SQL201?/*** - Excludes the SQL server instances 'SQL2012' and 'SQL2014' from the host 10.2.157.20.

Example of Regex Exclusion

10.2.157.20/SQL.*/.* - Excludes the SQL server instances 'SQL2012' and 'SQL2014' from the host 10.2.157.20.

Considerations

Consider the following when using the **Auto Protect** option on the backup job

- If new databases are added to the host, the existing filters are applied to the newly added databases. For example, if the exclude filter matches the newly added databases then these databases will be excluded in the backup job.
- If any system databases are excluded by the filters in an SQL server, it will exclude all the system databases belonging to that SQL server.
- When defining filters to exclude AG databases, ensure that the filters are configured on all the AG hosts. For example, to exclude an AG database and if the AG database has 4 hosts, then ensure that the filters are defined on all the four AG hosts.
- Auto protect functionality is supported only for physical SQL jobs (file-based, Native, and volume-based)
- To selectively exclude a SQL database from the protection job, you must upgrade all the cluster nodes to version 6.5.1 and later.

If MS SQL belongs to an AG network, selecting that server displays options for protecting the AG.

- Select all servers that belong to this AG network.

  > **Note:** If backing up VMs within an AG, protecting the AG databases requires that all servers within the AG are registered with the Cohesity cluster and are selected for protection. Otherwise AG databases are skipped and only local databases will be backed up. New servers added to AG are not automatically protected.

  When using this option when there are multiple AGs, only interlinked AG nodes are automatically selected. For example:

  - If there are AGs that use only Node1 and Node2 and other AGs that use Node3 and Node4, if you select Node2 as a source, only Node1 is added automatically.
  - If AG1 uses Node1 and Node2, AG2 uses Node2 and Node4, AG3 uses Node3 and Node5. If you select Node2, then these nodes are selected: Node1, Node2 and Node4. Node3 and Node5 are not selected.

  When adding nodes to an AG that is protected by Cohesity, ensure you register the node with Cohesity and add it to the Protection Group. Otherwise the AG databases will not be protected.

  When removing nodes from an AG that is protected by Cohesity, you can remove it from the Protection Group or keep it in the job; the AG databases remain protected in either case. If the removed node remains in the Protection

Group, only its local databases are backed up. If you do not want to back up the removed node, you can safely remove it.

- Select only this server.

Click **Select**.

Click **Add**.

5. If appropriate, set options for specific objects by clicking (**Edit Server Options**) next to the object. A successful SQL log backup automatically truncates the SQL logs.
6. **Name:** Enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.

   > **Note:** This page displays registered MS SQL objects only, so only MS SQL servers are selected regardless of the other servers within the source object hierarchy.

7. **Policy:** Select an existing protection policy or create a new one by selecting **New Policy**.

   Storage Domain: Select an existing storage domain or create a new one by selecting **New Storage Domain**.

   > **Note:** Once you create a Protection Group, you cannot change the Storage Domain you selected for that job.

   The selected storage domain stores the snapshots and logs created by this Protection Group.
8. **Backup Method:** Select **Volume-based**. This method protects MS SQL at the server level, meaning all databases on a server.

   If you changed the backup method to volume-based after objects were selected, you must select a server object.
9. **Make Full Backup Copy-only:** Toggle on if you want full backups to be copy-only backups so they do not affect the differential base.

   Copy-only full backups do not take log backups even if they are scheduled by the policy.
10. **User Databases:** Select how to handle AG databases during backup.
11. **AG Backup Preferences:** Select this option if AG databases will be backed up.

- **Use Server Preferences** uses MS SQL preferences.
- **Override Preferences** enables you to override MS SQL's preferences with your selection.

AAG replica preference for MS SQL backups

Cohesity uses "replica priority" to select the best replica when more than one qualified replica matches the backup preference. For the following AAG Backup Preference settings, Cohesity uses replicas in the indicated order of preference to back up MS SQL databases:

Backup Preference Setting	Replica Used for MS SQL Backup
Prefer Secondary or Any	1. Sync Secondary Replica 2. Async Secondary Replica 3. Primary Replica
Secondary Only*	1. Sync Secondary Replica 2. Async Secondary Replica
Primary Only	1. Primary Replica

* If the AAG uses the **Secondary Only** Backup Preference setting, ensure the AAG replicas are set to "**Readable secondary**=**Yes**". If all replicas are set to "**Readable secondary**=**No**" with **Secondary Only** as the Backup Preference setting, then the backup of AAG databases fails with "*unavailable_for_vss*".

You can set the **Readable Secondary** field to **No** if the Backup Preference Setting is set to **Prefer Secondary or Any** or **Primary Only**.

> **Note:** You must apply the exclusion filter on each AAG replica to ensure the database is excluded when an SQL Server failover occurs.

12. **System Databases:** Select whether to back up or skip system databases.
13. **Volume Backup:** Optionally select **Back up only the volumes associated with selected databases** to back up only volumes that are associated with selected databases. This option is not used for MS SQL FCI; only volumes with databases are backed up. For MS SQL running on VMs, all volumes are always backed up.
14. **Start Time:** Indicates when the Protection Group should run. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting.

The default time zone is the browser's time zone. You can change the time zone by selecting a different time zone.

15. **End Date:** Optional. Toggle on and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
16. **QoS Policy:** Select an appropriate quality of service (QoS) policy.

    > **Note:** Cohesity recommends specifying **Backup HDD**, which is the default.

    - **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group.
    - **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups.
    - **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy.
    - **TestAndDev High:** The Cohesity cluster writes the data to an SSD drive for this Protection Group. The I/Os with this QoS policy are given higher priority compared to other QoS policies. Use this policy for workloads that require lower I/O latency.
17. **Cancel Runs at Quiet Time Start:** Available only if the selected policy has at least one quiet time period. Toggle it on to specify that all currently executing protection runs should abort if a quiet time period specified for the Protection Group starts. By default this toggle is off, which means after a protection run starts, it continues to execute even when a quiet time period specified for this protection run starts. However, a new protection run will not start during a quiet time period.
18. **Pre & Post Scripts:** Edit this option to run scripts on the protected server before and/or after a Protection Group runs. If configured, the scripts are run every time an object is backed up by a Protection Group run.

    For configuration details, see Configure Pre & Post Scripts.
19. **Incremental After Restart:** For Windows physical servers, toggle on if you prefer incremental backup for the first scheduled backup job, which runs after an intentional server restart. If an incremental backup is not possible, a full backup is performed. For example, if the server restarts after a power failure, a full backup is performed.

> **Note:** Incremental backup consistency across reboots is not guaranteed if I/O operations are performed on the volume outside of the fully functional state of the server. This includes I/O operations that are performed by booting into the recovery mode. For example, if a server is shut down and its volume is attached to another server that does not have the Cohesity agent, ensure that the next backup is a full backup operation.

This option is not available for file-based backups.

20. **Indexing:** Indexing is enabled by default and required for file recovery. The Cohesity cluster will scan all the files in the Protection Group and create an internal index that can be used later by a recover task to locate files by name.

    For information about customizing indexing, see Customize Indexing.

    Indexing is not supported for file-based Jobs. Without indexing, file/folder-level recovery and searching are not supported.

21. **Alerts:** Optional. Select one or more of the following settings if you want alerts to be created for the following triggers:

    - **Success:** Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created.
    - **Failure:** Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created.
    - **SLA Violation:** Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created.

    For more information, see Alerts.

22. **Priority:** Select a priority for the Protection Group execution. Cohesity supports concurrent backups, but if the number of Protection Groups exceeds the ability to process them, those with **High** priority are given the highest priority to execute, **Medium** the second-highest priority, and **Low** the lowest priority.

23. **Email Recipients**: You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the Protection Group.

> **Note:**
> The connection to the SMTP Server must be enabled to send email notification. You can enable the SMTP Server connection in the configuration settings page (Cohesity UI > **Settings** > **Summary** > **Configure** > **Enable SMTP Server**).

24. **SLA:** The service-level agreement (SLA) defines the expected time to complete either a full backup or incremental backup. The backup completion time depends on the Windows volume size on AD, objects changed between incremental backups, network speed, and other Protection Groups running on the Cohesity cluster.
    - **Incremental:** Enter the number of minutes you expect an incremental protection run to complete. An incremental backup captures only the differences (changed blocks) since the last protection run.
    - **Full:** Enter the number of minutes you expect a full backup protection run to complete. A full backup captures the entire object (all blocks).
25. Click **Protect**.

    The Protection page is displayed and includes the new Protection Group.

In the Protection page, the following message will be displayed when you mouse over the run status of the MS SQL databases that are located on the attached disks:

```
<database_name> has files located on external storage. Cannot backup the database. Please use alternate backup methods like native dumps to protect the databases.
```

Edit an MS SQL Protection Group

1. Select **Data Protection > Protection**.
2. Locate the Protection Group you want to edit.
3. Mouse over the action icon (⋮) next to the job and select one of the following:
    1. **Run Now** - Start a run of this Protection Group. You have the option to back up one or more objects.
        1. **Backup all Objects in the Protection Group** - Select this option to backup all the databases in the protection group. Any databases excluded from the backup will not be included in the protection job run.
        2. **Backup only Selected Objects in the Protection Group** - you can manually select the databases to be backed up at the protection job level. However, the selection of the database that is excluded at the backup job level is not supported.

        You can run log backups in parallel with existing log backup runs. This helps reduce storage buildup on the primary SQL Server when multiple large backups are in progress.

        This feature is supported only for file-based, VDI-based, and Filestream (backed up using VDI-based method) backups.

> **Note:** When you run a log backup for a database backup job, any preceding backup job for the same database may skip the log backup if the new backup job is completed before the previous backup job for the database is started.

2. **Pause Future Runs**
    1. Select **Pause Future Runs** to stop new runs of this Protection Group from executing. However, if the job is currently executing a run, the current run continues to execute and only future runs of this job are paused.
    2. Select **Resume Future Runs** to restore the Protection Group to a running state. The runs resume as specified in the schedule defined in the policy associated with this job.
3. **Edit** - Edit job settings of the protection group and click Protect.
4. **Delete** - Deletes the protection group.

4. Save the job settings by clicking **Protect**.

Backup Microsoft SQL Server (File-based)

This topic describes how to protect MS SQL with a file-based Protection Group. File-based Protection Groups protect only the specific MS SQL databases that you select. Volume-based Protection Groups protect MS SQL at the server level, meaning all databases on a server. To use a volume-based Protection Group, follow the steps described in Backup Microsoft SQL Server (Volume-based).

MS SQL Protection Group Support

The following table describes supported job types for MS SQL running on physical servers and VMs.

	File-based Jobs	Volume-based Jobs	VDI-based Jobs	Both Job Types Using the Same Server but Protecting Distinct Databases
Physical MS SQL	Multiple file-based jobs protecting all or a subset of DBs	One volume-based job protecting all or a subset of DBs	Multiple VDI-based jobs protecting all or a subset of databases	Supported
SQL Server Virtual Machine Backup	NA	Volume-base with Hypervisor to provide application-consistent backup	NA	NA

Protect MS SQL Overview

Perform the following steps in the Cohesity cluster to protect SQL Server:

1. Register the SQL Server you want to protect as a source with the Cohesity cluster. See Set Up Standalone Microsoft SQL Server or Microsoft SQL Server AGs or Set Up Microsoft SQL Server FCI.
2. Select **Dashboard** and from the drop-down, select **MS SQL**.
3. From the **Hosts** tab, you can protect all databases on a host. Select **Protect Databases** from the host's actions menu.

   From the **Databases** tab, you can protect a single database. Select **Protect** from the database's actions menu.

   You can change which objects you want to protect when creating the job.

You can also protect MS SQL by performing the following steps:

1. Navigate to **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then select **Databases** > **MS SQL Server**.
3. Select the objects to protect.

Create a File-based MS SQL Protection Group

Perform the following to create a file-based SQL Server Protection Group:

1. Navigate to **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then select **Databases** > **MS SQL Server**.
3. In the **New Protection** pop-up, do one of the following:
   - Protect MS SQL by specifying a subset of options such as objects, protection group and policy by clicking the edit icon corresponding to the following options:
     i. **Add Objects**: Select the registered MS SQL source or click Register Source to register an MS SQL source. Select the objects to protect.
     ii. **Protection Group**: Specify a name for the Protection Group.
     iii. **Policy**: Select an existing policy or click **Create Policy** to create a new protection policy.
     iv. **Storage Domain**: Select the appropriate storage domain.

     > **Note:** This option is visible on the **New Protection** pop-up only if there is more than one storage domain.

v. **Backup Type**: From the drop-down, select **File-based**.

vi. Click **Protect**.

- To protect MS SQL by specifying all the options, click **More Options**.

4. **Source:** Select the objects to protect.

   Select the source objects to back up or exclude. By default, all objects in the source are excluded as indicated by the unselected check box. Expand the source objects and select the objects you want to include in the Protection Group. A selected check box ( ) indicates the object is selected to be backed up.

   > **Note:** If you have registered a physical server that is a part of the registered MS SQL Failover Cluster, then the MS SQL Failover Cluster Instance will not appear as a source in the object list of the registered physical server.

   If appropriate for your organization, enable Auto Protect.

   Click to turn on **Auto Protect**. By enabling this option:

   - All the SQL databases that are added to the SQL server in the future are automatically added to the Protection Group and are protected from the next protection run.
   - All the SQL databases that are removed from the SQL server in the future are automatically removed from the Protection Group and are not protected from the next protection run. The existing backup for the user is preserved until the snapshot expires.

   For example, you create a Protection Group that backs up a SQL Server. The Protection Group runs for two weeks and then a new database is added to the SQL Server. The next time the Protection Group runs, if the object hierarchy has been refreshed on the Cohesity cluster, the new database is also backed up even though the new database has not been explicitly selected to be included in the Protection Group. The object hierarchy is automatically refreshed every four hours.

   To manually refresh the object hierarchy, select **Data Protection > Sources**, find the source in the list and click .

   Considerations

   Consider the following when using the **Auto Protect** option on the backup job

   - If new databases are added to the host, the existing filters are applied to the newly added databases. For example, if the exclude filter matches the newly added databases then these databases will be excluded in the backup job.

- If any system databases are excluded by the filters in an SQL server, it will exclude all the system databases belonging to that SQL server.
- When defining filters to exclude AG databases, ensure that the filters are configured on all the AG hosts. For example, to exclude an AG database and if the AG database has 4 hosts, then ensure that the filters are defined on all the four AG hosts.
- Auto protect functionality is supported only for physical SQL jobs (file-based, Native, and volume-based)
- To selectively exclude a SQL database from the protection job, you must upgrade all the cluster nodes to version 6.5.1 and later.

If MS SQL belongs to an AG network, selecting that server displays options for protecting the AG.

- Select all servers that belong to this AG network.

  > **Note:** If backing up VMs within an AG, protecting the AG databases requires that all servers within the AG are registered with the Cohesity cluster and are selected for protection. Otherwise AG databases are skipped and only local databases will be backed up. New servers added to AG are not automatically protected.

  When using this option when there are multiple AGs, only interlinked AG nodes are automatically selected. For example:

  - If there are AGs that use only Node1 and Node2 and other AGs that use Node3 and Node4, if you select Node2 as a source, only Node1 is added automatically.
  - If AG1 uses Node1 and Node2, AG2 uses Node2 and Node4, AG3 uses Node3 and Node5. If you select Node2, then these nodes are selected: Node1, Node2 and Node4. Node3 and Node5 are not selected.

  When adding nodes to an AG that is protected by Cohesity, ensure you register the node with Cohesity and add it to the Protection Group. Otherwise the AG databases will not be protected.

  When removing nodes from an AG that is protected by Cohesity, you can remove it from the Protection Group or keep it; the AG databases remain protected in either case. If the removed node remains in the Protection Group, only its local databases are backed up. If you do not want to back up the removed node, you can safely remove it.

- Select only this server.

Click **Select**.

Click **Add**.

5. If appropriate, set options for specific objects by clicking (**Edit Server Options**) next to the object. A successful SQL log backup automatically truncates the SQL logs.
6. **Name:** Enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.

   > **Note:** This page displays registered MS SQL objects only, so only MS SQL servers are selected regardless of the other servers within the source object hierarchy.

7. **Policy:** Select an existing protection policy or create a new one by selecting **New Policy**.
8. **Storage Domain:** Select an existing storage domain or create a new one by selecting **New Storage Domain**.

   > **Note:** Once you create a Protection Group, you cannot change the Storage Domain you selected for that job.

   The selected storage domain stores the snapshots and logs created by this Protection Group.
9. **Backup Method:** Select **File-based**. This method protects only the specific MS SQL databases that you select.

   If you want to change the backup method to volume-based after objects are selected, you must select a server object. A file-based Protection Group can protect any object.
10. **Make Full Backup Copy-only:** Toggle on if you want full backups to be copy-only backups so they do not affect the differential base.

    Copy-only full backups do not take log backups even if they are scheduled by the policy.
11. **Log Chain Break Auto-Trigger Out of Band Incremental Backup:** When toggled ON, the out of band incremental backup will be triggered at the end of the log backup when the log chain is broken.

    If a scheduled backup is already running for the protection group, the out of band incremental backup will be triggered after the scheduled backup.
12. **New Database Auto-Trigger Out of Band Incremental Backup:** When toggled ON, the out of band incremental backup will be triggered at the end of the log backup when the new database is detected.

    If a scheduled backup is already running for the protection group, the out of band incremental backup will be triggered after the scheduled backup.

13. **User Databases:** Does not apply to file-based Protection Groups. Only selected databases are backed up.
14. **AG Backup Preferences:** Select this option if AG databases will be backed up.
    - **Use Server Preferences** uses MS SQL preferences.
    - **Override Preferences** enables you to override MS SQL's preferences with your selection.

    AAG replica preference for MS SQL backups

    Cohesity uses "replica priority" to select the best replica when more than one qualified replica matches the backup preference. For the following AAG Backup Preference settings, Cohesity uses replicas in the indicated order of preference to back up MS SQL databases:

Backup Preference Setting	Replica Used for MS SQL Backup
Prefer Secondary or Any	1. Sync Secondary Replica 2. Async Secondary Replica 3. Primary Replica
Secondary Only*	1. Sync Secondary Replica 2. Async Secondary Replica
Primary Only	1. Primary Replica

    * If the AAG uses the **Secondary Only** Backup Preference setting, ensure the AAG replicas are set to "**Readable secondary**=**Yes**". If all replicas are set to "**Readable secondary**=**No**" with **Secondary Only** as the Backup Preference setting, then the backup of AAG databases fails with "*unavailable_for_vss*".

    You can set the **Readable Secondary** field to **No** if the Backup Preference Setting is set to **Prefer Secondary or Any** or **Primary Only**.

    > **Note:** You must apply the exclusion filter on each AAG replica to ensure the database is excluded when an SQL Server failover occurs.

15. **System Databases:** Does not apply to file-based Protection Groups. Only selected databases are backed up. When you select any system database, however, all system databases are selected automatically.
16. **Start Time:** Indicates when the Protection Group should run. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up

and down arrows on your keyboard. Verify the AM or PM setting.

The default time zone is the browser's time zone. You can change the time zone by selecting a different time zone.

17. **End Date:** Optional. Toggle on and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
18. **QoS Policy:** Select an appropriate quality of service (QoS) policy.

    > **Note:** Cohesity recommends specifying **Backup HDD**, which is the default.

    - **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group.
    - **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups.
    - **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy.
    - **TestAndDev High:** The Cohesity cluster writes the data to an SSD drive for this Protection Group. The I/Os with this QoS policy are given higher priority compared to other QoS policies. Use this policy for workloads that require lower I/O latency.
19. **Cancel Runs at Quiet Time Start:** Available only if the selected policy has at least one quiet time period. Toggle it on to specify that all currently executing protection runs should abort if a quiet time period specified for the Protection Group starts. By default this toggle is off, which means after a protection run starts, it continues to execute even when a quiet time period specified for this protection run starts. However, a new protection run will not start during a quiet time period.
20.
21. **Source Side Deduplication**: Toggle ON **Source Side Deduplication** and select the **Exclusions** from the drop-down, to optimize the full backup time when CBT data is lost. The exclusions are supported at the source level. When you select a source as exclusion, source side deduplication will not be applicable for that source in the protection group.
22. **Pre & Post Scripts:** Edit this option to run scripts on the protected server before and/or after a Protection Group runs. If configured, the scripts are run every time an object is backed up by a Protection Group run.

For configuration details, see Configure Pre & Post Scripts.

23. **Indexing:** Indexing is enabled by default and required for file recovery. The Cohesity cluster will scan all the files in the Protection Group and create an internal index that can be used later by a recover task to locate files by name.

    For information about customizing indexing, see Customize Indexing.

    Indexing is not supported for file-based Protection Groups. Without indexing, file/folder-level recovery and searching are not supported.

24. **Alerts:** Optional. Select one or more of the following settings if you want alerts to be created for the following triggers:

    - **Success:** Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created.
    - **Failure:** Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created.
    - **SLA Violation:** Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created.

    For more information, see Alerts.

25. **Priority:** Select a priority for the Protection Group execution. Cohesity supports concurrent backups, but if the number of Protection Groups exceeds the ability to process them, those with **High** priority are given the highest priority to execute, **Medium** the second-highest priority, and **Low** the lowest priority.

26. **Email Recipients**: You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the Protection Group.

    > **Note:**
    > The connection to the SMTP Server must be enabled to send email notification. You can enable the SMTP Server connection in the configuration settings page (Cohesity UI > **Settings** > **Summary** > **Configure** > **Enable SMTP Server**).

27. **SLA:** The service-level agreement (SLA) defines the expected time to complete either a full backup or incremental backup. The backup completion time depends on the Windows volume size on AD, objects changed between incremental backups, network speed, and other Protection Groups running on the Cohesity cluster.

    - **Incremental:** Enter the number of minutes you expect an incremental protection run to complete. An incremental backup captures only the differences (changed blocks) since the last protection run.

- **Full:** Enter the number of minutes you expect a full backup protection run to complete. A full backup captures the entire object (all blocks).

28. Click **Protect**.

    The Protection page is displayed and includes the new Protection Group.

Edit an MS SQL Protection Group

Perform the following to edit a SQL Server Protection Group:

1. Select **Data Protection > Protection**.
2. Locate the Protection Group you want to edit.
3. Mouse over the action icon (⋮) next to the Protection Group and select one of the following:
    1. **Run Now** - Start a run of this Protection Group. You have the option to back up one or more objects.
        1. **Backup all Objects in the Protection Group** - Select this option to backup all the databases in the protection group. Any databases excluded from the backup will not be included in the protection run.
        2. **Backup only Selected Objects in the Protection Group** - you can manually select the databases to be backed up at the Protection Group level.
           If the host (parent of the selected database) is already part of a previous run-now submitted, the backup will be queued until the previous run submitted is complete.

           > **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

           You can run log backups in parallel with existing log backup runs. This helps reduce storage buildup on the primary SQL Server when multiple large backups are in progress.

           This feature is supported only for file-based, VDI-based, and Filestream (backed up using VDI-based method) backups.

           > **Note:** When you run a log backup for a database backup job, any preceding backup job for the same database may skip the log backup if the new backup job is completed before the previous backup job for the database is started.
    2. **Pause Future Runs**

1. Select **Pause Future Runs** to stop new runs of this Protection Group from executing. However, if the Protection Group is currently executing a run, the current run continues to execute and only future runs of this Protection Group are paused.
2. Select **Resume Future Runs** to restore the Protection Group to a running state. The runs resume as specified in the schedule defined in the policy associated with this Protection Group.

3. **Edit** - Edit the Protection Group settings of the protection group and click Protect.
4. **Delete** - Deletes the protection group.

4. Save the Protection Group settings by clicking **Protect**.

Deduplication in SQL Server File-based Backup

Cohesity supports an efficient Source-Side Deduplication mechanism (to detect changed blocks) for SQL Server File-based backups, that tracks the block-level changes and maintains CPU efficiency even when CBT (Change Block Tracking) is unavailable.

When a host reboot occurs during backup, the CBT map is cleared, and the CBT data is lost. This forces you to run a full backup instead of an incremental backup which can be very time-consuming for large SQL Server databases.

With this deduplication mechanism enabled for protection groups, if the CBT data is lost due to a Windows host server restart, the changed blocks are identified and transferred from the source. This reduces backup time and ensures efficient CPU utilization.

After the next full backup, CBT is re-established and used for subsequent backups.

> **Note:** Source-side deduplication functionality increases the CPU usage during backup operation (when CBT is lost).

The functionality is only supported for new protection groups. The backup of existing protection groups that already use source-side deduplication will complete with a warning which includes the instructions to use the efficient version of source-side deduplication.

You can set the deduplication for a protection group using the **Source Side Deduplication** option in the **Additional Settings** of a protection.

Backup Microsoft SQL Server (VDI-based)

This topic describes how to protect MS SQL with a VDI-based Protection Group.

MS SQL Protection Group Support

The following table describes supported job types for MS SQL running on physical servers and VMs.

	File-based Jobs	Volume-based Jobs	VDI-based Jobs	Both Job Types Using the Same Server but Protecting Distinct Databases
Physical MS SQL	Multiple file-based jobs protecting all or a subset of DBs	One volume-based job protecting all or a subset of DBs	Multiple VDI-based jobs protecting all or a subset of databases	Supported
SQL Server Virtual Machine Backup	NA	Volume-base with Hypervisor to provide application-consistent backup	NA	NA

Protect MS SQL Overview

Perform the following steps in the Cohesity cluster to protect SQL Server:

1. Register the SQL Server you want to protect as a source with the Cohesity cluster. See Set Up Standalone Microsoft SQL Server or Microsoft SQL Server AGs or Set Up Microsoft SQL Server FCI.
2. Select **Dashboard** and from the drop-down, select **MS SQL**.
3. From the **Hosts** tab, you can protect all databases on a host. Select **Protect Databases** from the host's actions menu.

   From the **Databases** tab, you can protect a single database. Select **Protect** from the database's actions menu.

   You can change which objects you want to protect when creating the job.

You can also protect MS SQL by performing the following steps:

1. Navigate to **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then select **Databases** > **MS SQL Server**.
3. Select the objects to protect.

Create a VDI-based MS SQL Protection Group

Perform the following to create a VDI-based SQL Server Protection Group:

1. Navigate to **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then select **Databases** > **MS SQL Server**.
3. In the **New Protection** pop-up, do one of the following:

- Protect MS SQL by specifying a subset of options such as objects, protection group and policy by clicking the edit icon corresponding to the following options:
  i. **Add Objects**: Select the registered MS SQL source or click Register Source to register an MS SQL source. Select the objects to protect.
  ii. **Protection Group**: Specify a name for the Protection Group.
  iii. **Policy**: Select an existing policy or click **Create Policy** to create a new protection policy.
  iv. **Storage Domain**: Select the appropriate storage domain.

  > **Note:** This option is visible on the **New Protection** pop-up only if there is more than one storage domain.

  v. **Backup Type**: From the drop-down, select **VDI-based**.
  vi. Click **Protect**.
- To protect MS SQL by specifying all the options, click **More Options**.

4. **Source:** Select the objects to protect.

   Select the source objects to back up or exclude. By default, all objects in the source are excluded as indicated by the unselected check box. Expand the source objects and select the objects you want to include in the Protection Group. A selected check box ( ) indicates the object is selected to be backed up.

   > **Note:** If you have registered a physical server that is a part of the registered MS SQL Failover Cluster, then the MS SQL Failover Cluster Instance will not appear as a source in the object list of the registered physical server.

   If appropriate for your organization, enable Auto Protect.

   Click to turn on **Auto Protect**. By enabling this option:

   - All the SQL databases that are added to the SQL server in the future are automatically added to the Protection Group and are protected from the next protection run.
   - All the SQL databases that are removed from the SQL server in the future are automatically removed from the Protection Group and are not protected from

the next protection run. The existing backup for the user is preserved until the snapshot expires.

For example, you create a Protection Group that backs up a SQL Server. The Protection Group runs for two weeks and then a new database is added to the SQL Server. The next time the Protection Group runs, if the object hierarchy has been refreshed on the Cohesity cluster, the new database is also backed up even though the new database has not been explicitly selected to be included in the Protection Group. The object hierarchy is automatically refreshed every four hours.

To manually refresh the object hierarchy, select **Data Protection > Sources**, find the source in the list and click . To exclude an object from Auto Protect, click .

- Indicates an Auto Protected object.
- Use this option to exclude SQL databases from the protection group. Excluded objects are not protected. The icon indicates that an ancestor of the object is Auto Protected but this object is explicitly excluded.

  To exclude a database from the protection group, specify the absolute path of the database to be excluded from the backup at a protection job level. You can optionally use:

  - **Wildcard Exclusion** - You can optionally use the Wildcard * in any location in the search string to exclude all the matching databases from the backup at a protection job level.
  - **Regex Exclusion** - You can use the RegEx string name match and manual user selection to exclude DBs from backup at a protection job level.

> **Note:** You can use the exclude SQL database feature only if Auto Protect is enabled for a backup job.

Protection of dismounted databases, recovery database types, and deleted databases are automatically skipped by the Protection Group.

After defining the filer click **Apply** to save the selection.

The following table lists the examples for excluding objects in an MS SQL database:

Sample Configuration

10.2.157.20 (Host)

*** SQL2012**	*** SQL2014**	*** MSSQLSERVER**
(SQL Server Instance)	(SQL Server Instance)	(SQL Server Instance)
- UserDB1	- UserDB3	- ProdDB1
- UserDB2	- UserDB4	- ProdDB2
- TestDB1	- TestDB3	
- TestDB2	- TestDB4	

Example of Absolute Path

- **10.2.157.20/SQL2012/UserDB1** - Excludes the database 'UserDB1' from the SQL server instance 'SQL2012' on the host 10.2.157.20.
- **10.2.157.20/SQL2012/** - Excludes the 'SQL2012' from the SQL server instance and its databases.

> **Note:** The absolute instance path must end with '/' and the plain text instance path must contain two or more slashes.

Example of Wildcard Exclusion

- **10.2.157.20/SQL2012/User*** - Excludes the databases 'UserDB1' and 'UserDB2' from the SQL server instance 'SQL2012' on the host 10.2.157.20.
- **10.2.157.20/SQL201?/*** - Excludes the SQL server instances 'SQL2012' and 'SQL2014' from the host 10.2.157.20.

Example of Regex Exclusion

10.2.157.20/SQL.*/.* - Excludes the SQL server instances 'SQL2012' and 'SQL2014' from the host 10.2.157.20.

Considerations

Consider the following when using the **Auto Protect** option on the backup job

- If new databases are added to the host, the existing filters are applied to the newly added databases. For example, if the exclude filter matches the newly added databases then these databases will be excluded in the backup job.
- If any system databases are excluded by the filters in an SQL server, it will exclude all the system databases belonging to that SQL server.
- When defining filters to exclude AG databases, ensure that the filters are configured on all the AG hosts. For example, to exclude an AG database and if the AG database has 4 hosts, then ensure that the filters are defined on all the four AG hosts.
- Auto protect functionality is supported only for physical SQL jobs (file-based, Native, and volume-based)

- To selectively exclude a SQL database from the protection job, you must upgrade all the cluster nodes to version 6.5.1 and later.

If MS SQL belongs to an AG network, selecting that server displays options for protecting the AG.

- Select all servers that belong to this AG network.

  > **Note:** If backing up VMs within an AG, protecting the AG databases requires that all servers within the AG are registered with the Cohesity cluster and are selected for protection. Otherwise AG databases are skipped and only local databases will be backed up. New servers added to AG are not automatically protected.

  When using this option when there are multiple AGs, only interlinked AG nodes are automatically selected. For example:

  - If there are AGs that use only Node1 and Node2 and other AGs that use Node3 and Node4, if you select Node2 as a source, only Node1 is added automatically.
  - If AG1 uses Node1 and Node2, AG2 uses Node2 and Node4, AG3 uses Node3 and Node5. If you select Node2, then these nodes are selected: Node1, Node2 and Node4. Node3 and Node5 are not selected.

  When adding nodes to an AG that is protected by Cohesity, ensure you register the node with Cohesity and add it to the Protection Group. Otherwise the AG databases will not be protected.

  When removing nodes from an AG that is protected by Cohesity, you can remove it from the Protection Group or keep it; the AG databases remain protected in either case. If the removed node remains in the Protection Group, only its local databases are backed up. If you do not want to back up the removed node, you can safely remove it.

- Select only this server.

Click **Select**.

Click **Add**.

5. If appropriate, set options for specific objects by clicking (**Edit Server Options**) next to the object. A successful SQL log backup automatically truncates the SQL logs.
6. **Name:** Enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.

> **Note:** This page displays registered MS SQL objects only, so only MS SQL servers are selected regardless of the other servers within the source object hierarchy.

7. **Policy:** Select an existing protection policy or create a new one by selecting **New Policy**. Cohesity recommends you schedule periodic full backups for MS SQL VDI-based protection. For more information, see Create or Edit a Standard Policy.

   Storage Domain: Select an existing storage domain or create a new one by selecting **New Storage Domain**.

   > **Note:** Once you create a Protection Group, you cannot change the Storage Domain you selected for that job.

   The selected storage domain stores the snapshots and logs created by this Protection Group.
8. **Backup Method:** Select **VDI-based**. This method protects only the specific MS SQL databases that you select.
9. **WITH Clause:** Define the With clause that you want to use to customize the backup. For more information, see BACKUP (Transact-SQL).
10. **Number of Streams:** Define the number of Cohesity nodes that will be used for the backup process. Using multiple nodes provides more throughput for the backup process.
11. **Log Chain Break Auto-Trigger Out of Band Incremental Backup:** When toggled ON, the out of band incremental backup will be triggered at the end of the log backup when the log chain is broken.

    If a scheduled backup is already running for the protection group, the out of band incremental backup will be triggered after the scheduled backup.
12. **New Database Auto-Trigger Out of Band Incremental Backup:** When toggled ON, the out of band incremental backup will be triggered at the end of the log backup when the new database is detected.

    If a scheduled backup is already running for the protection group, the out of band incremental backup will be triggered after the scheduled backup.
13. **Make Full Backup Copy-only:** Toggle on if you want full backups to be copy-only backups so they do not affect the differential base.

    Copy-only full backups do not take log backups even if they are scheduled by the policy.
14. **User Databases:** Select how to handle AG databases during the backup.

15. **AG Backup Preferences:** Select this option if AG databases will be backed up.
    - **Use Server Preferences** uses MS SQL preferences.
    - **Override Preferences** enables you to override MS SQL's preferences with your selection.

    AAG replica preference for MS SQL backups

    Cohesity uses "replica priority" to select the best replica when more than one qualified replica matches the backup preference. For the following AAG Backup Preference settings, Cohesity uses replicas in the indicated order of preference to back up MS SQL databases:

Backup Preference Setting	Replica Used for MS SQL Backup
Prefer Secondary or Any	1. Sync Secondary Replica 2. Async Secondary Replica 3. Primary Replica
Secondary Only*	1. Sync Secondary Replica 2. Async Secondary Replica
Primary Only	1. Primary Replica

    * If the AAG uses the **Secondary Only** Backup Preference setting, ensure the AAG replicas are set to "**Readable secondary**=**Yes**". If all replicas are set to "**Readable secondary**=**No**" with **Secondary Only** as the Backup Preference setting, then the backup of AAG databases fails with "*unavailable_for_vss*".

    You can set the **Readable Secondary** field to **No** if the Backup Preference Setting is set to **Prefer Secondary or Any** or **Primary Only**.

    > **Note:** You must apply the exclusion filter on each AAG replica to ensure the database is excluded when an SQL Server failover occurs.

> **Note:** AG secondary replicas do not support regular full backups, and differential backups. If the policy is configured to take regular full backups, or differential backups, then select override preferences to backup only from the primary replica. All other AG backup preferences are only available if the policy is configured to take copy-only full backups, and log backups. Incremental backups are not supported on the AG secondary nodes. For more details, see Backup Types Supported on Secondary Replicas.

16. **System Databases:** Does not apply to VDI-based Protection Groups. Only selected databases are backed up. When you select any system database, however, all system databases are selected automatically.
17. **Start Time:** Indicates when the Protection Group should run. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting.

    The default time zone is the browser's time zone. You can change the time zone by selecting a different time zone.
18. **End Date:** Optional. Toggle on and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
19. **QoS Policy:** Select an appropriate quality of service (QoS) policy.

> **Note:** Cohesity recommends specifying **Backup HDD**, which is the default.

- **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group.
- **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups.
- **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy.
- **TestAndDev High:** The Cohesity cluster writes the data to an SSD drive for this Protection Group. The I/Os with this QoS policy are given higher priority compared to other QoS policies. Use this policy for workloads that require lower I/O latency.

20. **Cancel Runs at Quiet Time Start:** Available only if the selected policy has at least one quiet time period. Toggle it on to specify that all currently executing protection runs should abort if a quiet time period specified for the Protection Group starts. By default this toggle is off, which means after a protection run starts, it continues to execute even when a quiet time period specified for this protection run starts. However, a new protection run will not start during a quiet time period.
21. **Pre & Post Scripts:** Edit this option to run scripts on the protected server before and/or after a Protection Group runs. If configured, the scripts are run every time an object is backed up by a Protection Group run.

    For configuration details, see Configure Pre & Post Scripts.
22. **Indexing:** Indexing is enabled by default and required for file recovery. The Cohesity cluster will scan all the files in the Protection Group and create an internal index that can be used later by a recover task to locate files by name.

    For information about customizing indexing, see Customize Indexing.

    Indexing is not supported for VDI-based Protection Groups. Without indexing, file/folder-level recovery and searching are not supported.
23. **Alerts:** Optional. Select one or more of the following settings if you want alerts to be created for the following triggers:
    - **Success:** Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created.
    - **Failure:** Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created.
    - **SLA Violation:** Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created.

    For more information, see Alerts.
24. **Priority:** Select a priority for the Protection Group execution. Cohesity supports concurrent backups, but if the number of Protection Groups exceeds the ability to process them, those with **High** priority are given the highest priority to execute, **Medium** the second-highest priority, and **Low** the lowest priority.
25. **Email Recipients**: You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the Protection Group.

> **Note:**
> The connection to the SMTP Server must be enabled to send email notification. You can enable the SMTP Server connection in the configuration settings page (Cohesity UI > **Settings** > **Summary** > **Configure** > **Enable SMTP Server**).

26. **SLA:** The service-level agreement (SLA) defines the expected time to complete either a full backup or incremental backup. The backup completion time depends on the Windows volume size on AD, objects changed between incremental backups, network speed, and other Protection Groups running on the Cohesity cluster.
    - **Incremental:** Enter the number of minutes you expect an incremental protection run to complete. An incremental backup captures only the differences (changed blocks) since the last protection run.
    - **Full:** Enter the number of minutes you expect a full backup protection run to complete. A full backup captures the entire object (all blocks).
27. Click **Protect**.

    The Protection page is displayed and includes the new Protection Group.

Edit an MS SQL Protection Group

Perform the following to edit a SQL Server Protection Group:

1. Select **Data Protection > Protection**.
2. Locate the Protection Group you want to edit.
3. Mouse over the action icon (⋮) next to the Protection Group and select one of the following:
    1. **Run Now** - Start a run of this Protection Group. You have the option to back up one or more objects.
        1. **Backup all Objects in the Protection Group** - Select this option to backup all the databases in the protection group. Any databases excluded from the backup will not be included in the protection run.
        2. **Backup only Selected Objects in the Protection Group** - you can manually select the check box for the databases to be backed up at the Protection Group level.
           This backup of the selected database runs in parallel with the existing run-now request. However, if a subset of the selected database includes a run-now/scheduled backup already active, these databases will be skipped from the run-now being submitted.

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

You can run log backups in parallel with existing log backup runs. This helps reduce storage buildup on the primary SQL Server when multiple large backups are in progress.

This feature is supported only for file-based, VDI-based, and Filestream (backed up using VDI-based method) backups.

> **Note:** When you run a log backup for a database backup job, any preceding backup job for the same database may skip the log backup if the new backup job is completed before the previous backup job for the database is started.

2. **Pause Future Runs**
    1. Select **Pause Future Runs** to stop new runs of this Protection Group from executing. However, if the Protection Group is currently executing a run, the current run continues to execute and only future runs of this Protection Group are paused.
    2. Select **Resume Future Runs** to restore the Protection Group to a running state. The runs resume as specified in the schedule defined in the policy associated with this Protection Group.
3. **Edit** - Edit the Protection Group settings of the protection group and click Protect.
4. **Delete** - Deletes the protection group.
   Delete only the protection group and keep the snapshots or delete the snapshots also.

4. Save the Protection Group settings by clicking **Protect**.

Backup Microsoft SQL Server FILESTREAM Databases

This topic describes how to protect MS SQL FILESTREAM databases.

MS SQL Protection Group Support

The following table describes supported job types for MS SQL running on physical servers and VMs.

	File-based Jobs	Volume-based Jobs	VDI-based Jobs	Both Job Types Using the Same Server but Protecting Distinct Databases
Physical MS SQL	Not supported	One volume-based job protecting all or a subset of DBs	Multiple VDI-based jobs protecting all or a subset of databases	Supported
VM MS SQL	Not supported	Volume-based jobs protecting the entire VM	Not supported	Not supported

> **Note:** Protecting a FILESTREAM database (in general and not specific to memory-optimized) is performed only using a Volume-based backup or VDI-based backup.

Protect MS SQL Overview

Perform the following steps in the Cohesity cluster to protect SQL Server:

1. Register the SQL Server you want to protect as a source with the Cohesity cluster. See Set Up Standalone Microsoft SQL Server or Microsoft SQL Server AGs or Set Up Microsoft SQL Server FCI.
2. Select **Dashboard** and from the drop-down, select **MS SQL**.
3. From the **Hosts** tab, you can protect all databases on a host. Select **Protect Databases** from the host's actions menu.

   From the **Databases** tab, you can protect a single database. Select **Protect** from the database's actions menu.

   You can change which objects you want to protect when creating the job.

You can also protect MS SQL by performing the following steps:

1. Navigate to **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then select **Databases** > **MS SQL Server**.
3. Select the objects to protect.

Create an MS SQL Protection Group

1. **Name:** Enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.

> **Note:** This page displays registered MS SQL objects only, so only SQL servers are selected regardless of the other servers within the source object hierarchy.

2. **Source:** Select the objects to protect.

   Select the source objects to back up or exclude. By default, all objects in the source are excluded as indicated by the ☐ unselected check box. Expand the source objects and select the objects you want to include in the Protection Group. A selected check box (☑) indicates the object is selected to be backed up.

   If MS SQL belongs to an AG network, selecting that server displays options for protecting the AG.

   - Select all servers that belong to this AG network.

     > **Note:** If backing up VMs within an AG, protecting the AG databases requires that all servers within the AG are registered with the Cohesity cluster and are selected for protection. Otherwise AG databases are skipped and only local databases will be backed up. New servers added to AG are not automatically protected.

     When using this option when there are multiple AGs, only interlinked AG nodes are automatically selected. For example:

     - If there are AGs that use only Node1 and Node2 and other AGs that use Node3 and Node4, if you select Node2 as a source, only Node1 is added automatically.
     - If AG1 uses Node1 and Node2, AG2 uses Node2 and Node4, AG3 uses Node3 and Node5. If you select Node2, then these nodes are selected: Node1, Node2 and Node4. Node3 and Node5 are not selected.

     When adding nodes to an AG that is protected by Cohesity, ensure you register the node with Cohesity and add it to the Protection Group. Otherwise the AG databases will not be protected.

     When removing nodes from an AG that is protected by Cohesity, you can remove it from the Protection Group or keep it in the job; the AG databases remain protected in either case. If the removed node remains in the Protection Group, only its local databases are backed up. If you do not want to back up the removed node, you can safely remove it.

   - Select only this server.

Click **Select**.

Click **Add**.

3. If appropriate, set options for specific objects by clicking (**Edit Server Options**) next to the object. A successful SQL log backup automatically truncates the SQL logs.
4. **Policy:** Select an existing protection policy or create a new one by selecting **New Policy**.

   Storage Domain: Select an existing storage domain or create a new one by selecting **New Storage Domain**.

   > **Note:** Once you create a Protection Group, you cannot change the Storage Domain you selected for that job.

   The selected storage domain stores the snapshots and logs created by this Protection Group.
5. **Backup Method:** Select **Volume-based** or **VDI-based**. Both volume-based and VDI-based jobs can backup FILESTREAM databases.
6. **Make Full Backup Copy-only:** Ensure this is toggled off to ensure log backups are taken for FILESTREAM databases.
7. **User Databases:** Select how to handle AG databases during backup.
8. **System Databases:** Select whether to back up or skip system databases.
9. **Volume Backup:** Optionally select **Back up only the volumes associated with selected databases** to back up only volumes that are associated with selected databases. This option is not used for MS SQL FCI; only volumes with databases are backed up. For MS SQL running on VMs, all volumes are always backed up.
10. **Start Time:** Indicates when the Protection Group should run. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting.

    The default time zone is the browser's time zone. You can change the time zone by selecting a different time zone.
11. **End Date:** Optional. Toggle on and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
12. **QoS Policy:** Select an appropriate quality of service (QoS) policy.

    > **Note:** Cohesity recommends specifying **Backup HDD**, which is the default.

- **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group.
- **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups.
- **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy.
- **TestAndDev High:** The Cohesity cluster writes the data to an SSD drive for this Protection Group. The I/Os with this QoS policy are given higher priority compared to other QoS policies. Use this policy for workloads that require lower I/O latency.

13. **Cancel Runs at Quiet Time Start:** Available only if the selected policy has at least one quiet time period. Toggle it on to specify that all currently executing protection runs should abort if a quiet time period specified for the Protection Group starts. By default this toggle is off, which means after a protection run starts, it continues to execute even when a quiet time period specified for this protection run starts. However, a new protection run will not start during a quiet time period.
14. **Pre & Post Scripts:** Edit this option to run scripts on the protected server before and/or after a Protection Group runs. If configured, the scripts are run every time an object is backed up by a Protection Group run.

    For configuration details, see Configure Pre & Post Scripts.
15. **Indexing:** Indexing is enabled by default and required for file recovery. The Cohesity cluster will scan all the files in the Protection Group and create an internal index that can be used later by a recover task to locate files by name.

    For information about customizing indexing, see Customize Indexing.
16. **Alerts:** Optional. Select one or more of the following settings if you want alerts to be created for the following triggers:
    - **Success:** Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created.
    - **Failure:** Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created.
    - **SLA Violation:** Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created.

    For more information, see Alerts.

17. **Priority:** Select a priority for the Protection Group execution. Cohesity supports concurrent backups, but if the number of Protection Groups exceeds the ability to process them, those with **High** priority are given the highest priority to execute, **Medium** the second-highest priority, and **Low** the lowest priority.
18. **Email Recipients**: You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the Protection Group.

    > **Note:**
    > The connection to the SMTP Server must be enabled to send email notification. You can enable the SMTP Server connection in the configuration settings page (Cohesity UI > **Settings** > **Summary** > **Configure** > **Enable SMTP Server**).

19. **SLA:** The service-level agreement (SLA) defines the expected time to complete either a full backup or incremental backup. The backup completion time depends on the Windows volume size on AD, objects changed between incremental backups, network speed, and other Protection Groups running on the Cohesity cluster.
    - **Incremental:** Enter the number of minutes you expect an incremental protection run to complete. An incremental backup captures only the differences (changed blocks) since the last protection run.
    - **Full:** Enter the number of minutes you expect a full backup protection run to complete. A full backup captures the entire object (all blocks).
20. Click **Protect**.

    The Protection page is displayed and includes the new Protection Group.

Edit an MS SQL Protection Group

1. Select **Data Protection > Protection**.
2. Locate the Protection Group you want to edit.
3. Mouse over the action icon (⋮) next to the job and select one of the following:
    1. **Run Now** - Start a run of this Protection Group. You have the option to back up one or more objects.
        1. **Backup all Objects in the Protection Group** - Select this option to backup all the databases in the protection group. Any databases excluded from the backup will not be included in the protection job run.
        2. **Backup only Selected Objects in the Protection Group** - you can manually select the databases to be backed up at the protection job level. However, the selection of the database that is excluded at the backup job level is not supported.

You can run log backups in parallel with existing log backup runs. This helps reduce storage buildup on the primary SQL Server when multiple large backups are in progress.

This feature is supported only for file-based, VDI-based, and Filestream (backed up using VDI-based method) backups.

> **Note:** When you run a log backup for a database backup job, any preceding backup job for the same database may skip the log backup if the new backup job is completed before the previous backup job for the database is started.

2. **Pause Future Runs**
    1. Select **Pause Future Runs** to stop new runs of this Protection Group from executing. However, if the job is currently executing a run, the current run continues to execute and only future runs of this job are paused.
    2. Select **Resume Future Runs** to restore the Protection Group to a running state. The runs resume as specified in the schedule defined in the policy associated with this job.
3. **Edit** - Edit job settings of the protection group and click Protect.
4. **Delete** - Deletes the protection group.

4. Save the job settings by clicking **Protect**.

Configure Microsoft SQL Server T-log Backup

Cohesity enhances the SQL Server T-log backup and restoration performance by splitting the T-log backup into multiple backup files and ingesting them in parallel through the Cohesity nodes.

This feature is applicable for File-based, Volume-based, and VDI-based backups.

Follow the below steps to configure the T-log backup settings for a Protection Group:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. Click **Protect > Databases > MS SQL Server**.
3. Click **Objects** and select the required objects to be protected.
4. In the **Policy** drop-down list, select a policy that includes Log Backup (Database). The **Log Backup Settings** option will be enabled.
5. Optionally configure the following details:
    - **WITH Clause**: Define the WITH clause that you want to use to customize the backup. For more information, see BACKUP (Transact-SQL). The default WITH

clause is "*WITH MAXTRANSFERSIZE = 4194304, BUFFERCOUNT = 16*".

> **Important:** The WITH clause text box allows you to invoke the SQL Server general options during backups and restores. The text field accepts any SQL Server general backup or restore option like "ENCRYPTION". Note that specifying an option could add to the overall duration of the backup or restore process.

- **Number of Streams**: Define the number of Cohesity nodes that will be used for the backup process. Using multiple nodes provides more throughput for the backup process. The default number of streams is *1*.

For details on other settings, see Backup Microsoft SQL Server (VDI-based).

6. Click **Protect**.

> **Note:**
> - Ensure that the agents pre-installed on the SQL VMware source are upgraded to the latest version.
> - If a replication job is configured for the SQL VMware log backup, ensure that the replication cluster is upgraded to the latest version to enable seamless recovery.

Requirements

Ensure the following requirements are met for using SQL log backups:

- The Cohesity cluster's VIPs on **port 11117** must be reachable from the SQL source.
- In a multi-tenant environment, the Hybrid Extender IPs on **port 11117** must be reachable from the SQL source.

> **Note:** If the required port is unreachable, the log backup will fail to start, especially after upgrading from a version lower than 7.2.

Recover Microsoft SQL Server

Cohesity provides the ability to recover the MS SQL databases protected by a Protection Group.

- Recover Microsoft SQL Server Database Over the Original Database.
- Recover Microsoft SQL Server Database as a New Database in the Original Microsoft SQL Server Instance.
- Recover Microsoft SQL Server Database as a New Database in an Alternate Microsoft SQL Server Instance.

Prerequisites

- Before you can restore MS SQL databases, a full backup must exist.
- (*Applies for volume-based and VDI-based backed-up data.*) The cluster must be a member of the same or any trusted AD domain to which the MS SQL database is restored.
- Cohesity cluster VIPs must be reachable (DNS) and accessible (Ping) from the target MS SQL server.
- For recovery, the server and the cluster must be on the same VLAN.

The following topics provide guidance to help you restore MS SQL databases:

About Restoring Microsoft SQL Server Databases

A restore task copies a database from the backup copy and optionally applies transaction logs depending on the options you choose. Cohesity provides the ability to restore individual databases to a specific point in time.

The following options are supported when restoring an individual database:

- Restore to the original MS SQL server and original instance and overwrite the database.
- Restore to the original MS SQL server and original instance and rename the database.
- Restore to the original MS SQL server and an alternate instance as a specified database name.
- Restore to an alternate MS SQL server and instance as a specified database name.

Restoring physical server to physical server only is supported.

MS SQL DB Restore Example

The following example depicts restoring an individual MS SQL database running on a physical server to its original location and overwriting the existing database. The example assumes the following about the database:

- Failure has already occurred.
- Its MS SQL server is registered as MS SQL on the cluster.
- It was backed up by a Cohesity Protection Group that includes transaction logs.

The action steps in the following procedure are represented in the figure below with blue numbered time squares:

.

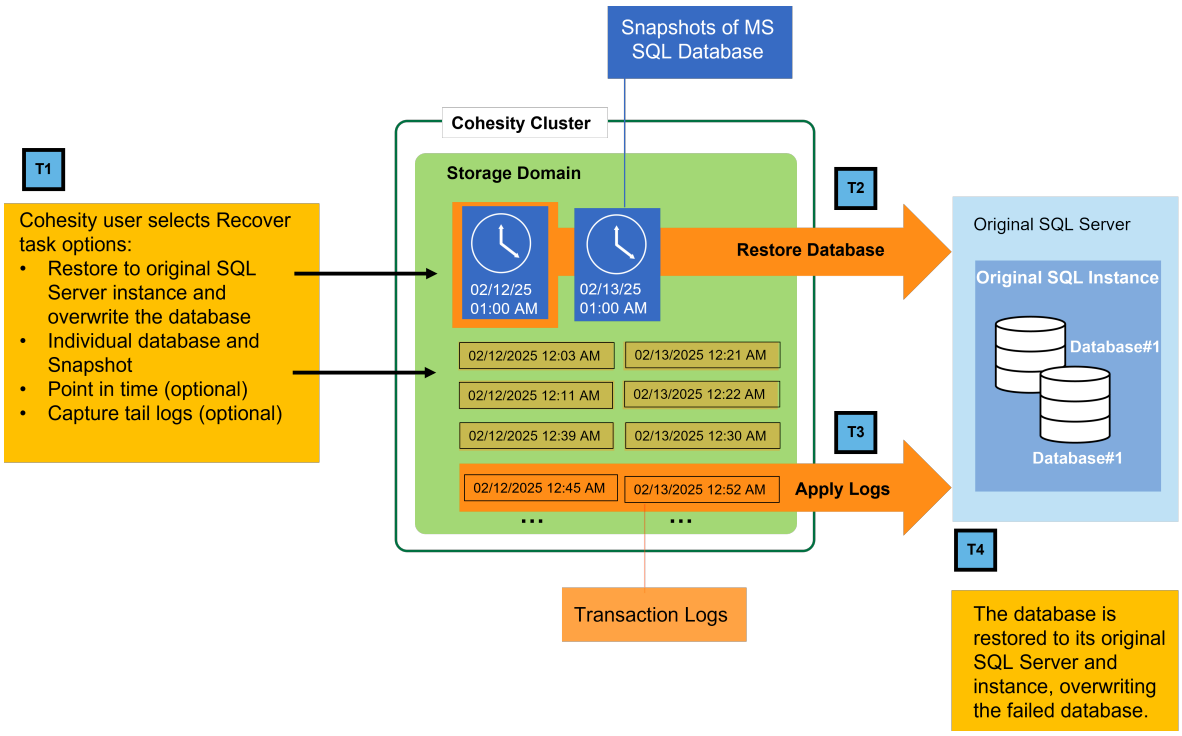
T1) The Cohesity user must select the following task options:

- Restore to the original SQL server and instance and overwrite the database
- An MS SQL database and snapshot
- Point in time (optional)
- Capture tail logs (optional)

T2) The Cohesity cluster copies the database files from the specified snapshot to the original location.

T3) If applicable, transaction logs are applied to the database for the specified point in time.

T4) The database is then brought online.



Resume MS SQL Database Recovery After Failure

You can resume a failed MS SQL Database recovery for databases in the following scenarios:

- If the databases are recovered using the WITH NORECOVERY option
- If the previous restore operation failed and the database remains in the restoring state.

This feature improves the RTO for database restore operations and is applicable only for point-in-time (PIT) restore operations.

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

Recover Microsoft SQL Server System Databases

System databases can be restored in case of system failures. The system databases are restored from the same instance and location where the system databases were backed up. You can also overwrite the existing system database files.

> **Note:**
> Restoring system databases to a different instance is not supported for the VM-based backup method.

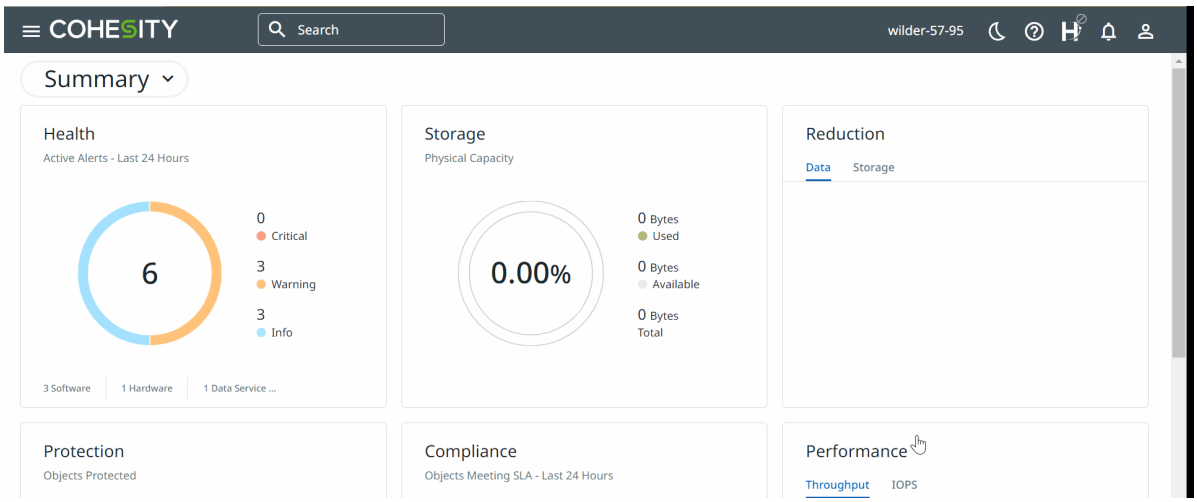
The SQL Server system databases are recovered in the following order:

1. Master
2. MSDB
3. Model

Recovery Workflow

You can recover the system databases to the original SQL Server instance.

The following animated image shows how to recover the system databases to the original server instance:



For the detailed steps on recovering system databases, see:

- Recover Microsoft SQL Server Database Over the Original Database

Consideration

- Recovering the system database to an alternate instance is not supported.
- When recovering to the original database, the original database is deleted before the recovery. Therefore, a recovery failure will also lead to the loss of the original database.
- If you are recovering the system databases individually, then the recovery of the system database must be in the following order:
  1. Master
  2. MSDB
  3. Model
- You cannot recover a system database along with a user database.
- If you are recovering more than one system database in a recovery task, then the recovery point for the selected system databases must be the same.

Recover Microsoft SQL Server Database Over the Original Database

Recovering an MS SQL database over the original database overwrites the original database. The recovered database will have the original database name.

> **Note:** The original database is deleted before the recovery. Therefore a recovery failure will also lead to the loss of the original database.

To recover the database to the original database:

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Click **Recover** located at the top right of the page and then select **Databases** > **MS SQL**.

   The Restore SQL page appears.
3. Search for the databases you want to recover from by entering the characters of the database name, Protection Group name, or by specifying the wildcard character *.

   A list of databases is displayed with details like Cohesity Cluster, Protection Group, Physical Server, and Create Date. The Create Date option indicates the date and timestamp when the database was created.

   > **Note:** Operations like rename may update the creation date at the SQL Server.
4. From the list of search results, select one or more databases you want to recover. You can select multiple MS SQL databases only if they are protected by the same

protection group.

> **Note:** The option to select multiple databases in a recovery task is an Early Access feature. Contact Cohesity Support for enabling this feature.

By default, the latest recovery point is selected. To select a different recovery point, from the selected lists, mouse over the recovery point, and then click the edit icon.

The Edit recovery point for <database_name> page appears.

By default, the option to select the recovery point is displayed in **Timeline** mode. You can also choose to view the option in **List** mode by clicking the **List** tab in the top-right corner of the page. The **Timeline** mode displays the full backups (recovery points) captured at the scheduled time and the CDP-based data available for point-in-time restore. The **List** tab displays only the full backups captured at a scheduled time.

- To select a recovery point from the Timeline mode:
    a. From the **Choose a date** drop-down, select a date.

       The recovery points available on the selected date are displayed in blue dots on the timeline bar and the point-in-time for restore is displayed in a solid green line on the timeline bar.

    b. To recover from a full backup, click the corresponding blue dot. For point-in-time restore, specify the exact point-in-time recovery by sliding the timeline bar.

    c. By default, the data is recovered from the local cluster. You can also select a recovery point archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.

    d. Click **Select Recovery Point** and then go to step 5.
- To select a recovery point from the List mode:
    a. Select the **List** tab from the top-right corner of the Edit recovery point for <database_name> page.

       By default, the page displays the recovery points available for the last 30 days.

    b. You can also select a recovery point from a different date range by selecting the date range from the Date drop-down list. The page displays the available recovery points in the specified range.

    c. Select the recovery points to be recovered.

    d. By default, the data is recovered from the local cluster. You can also select a recovery point archived to the cloud by clicking the cloud (

) icon if available in the **Location** option.

e. Click **Select Recovery Point** and then go to step 5.

5. Click **Next: Recover Options**.
6. From the **Targets** option, select **Overwrite Original Database** to recover the database to the original location.

> **Note:** The original database is deleted before the recovery. Therefore a recovery failure will also lead to the loss of the original database.

7. Specify the following **Recovery Options**:

Recovery Options	Description
VDI Restore Settings	Enable this option to specify the WITH clause that you want to use for the restore. **Note:** • This option is available only for restoring the databases that are protected using Backup Microsoft SQL Server (VDI-based). • This option is not available for system database restore.
Keep CDC	Enable this option to restore a protected database that has the change data capture (CDC) enabled. If the protected database is not CDC enabled and the user tries to restore it with Keep CDC then, the database will be restored without CDC. **Note:** • This option is available only if the database is restored with recovery. • This option is not available for system database restore.
Cluster Interface	By default, the **Auto Select** option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the **Interface Grou**p drop-down.
Task Name	Change the default name of the recovery task.

Recovery Options	Description
Capture Tail Logs	Enable this option to capture records that have not yet been protected. They are captured to ensure all transactions are protected before restoring the database. **Note:** This option is not available for system database restore.

8. Click **Start Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Microsoft SQL Server VDI-based Recovery Recommendations

The Virtual Device Interface (VDI) is a Microsoft interface that allows the Cohesity agent to execute SQL Server Native backup and restore commands. This backup type produces a standard SQL Server Native backup of type (.BAK), transaction logs, (.TRN), and differentials, (.DIFF). These backup files are stored on a Cohesity View and take advantage of View compression, deduplication, encryption, replication, and archiving features.

The aim of the SQL DBA is to have a combination of backups so that the database can be restored to any point in time. A good combination of backups consists of having a full backup, differential (in Cohesity, incremental) backups, and log backups. For example, all SQL database restores must begin with a full database backup, secondly, a differential can then be applied to the full, and finally, log backups can be applied in sequence to complete the database restore.

When the backups are applied during the database restore process, you are sequentially adding the captured changes to the database: FULL+DIFF+Log1+Log2+Log3 = Restored Database.

All Microsoft VDI backups, their differentials, and their logs are dependent on a full backup to perform a database restore. Microsoft requires that in order to restore a SQL database, you must start with a full backup, then its transaction logs can be applied. This means your backup retention policy must keep a full backup along with its log backups in order to successfully restore a database.

Simply put, a SQL VDI-based database restore requires a full backup to seed the database, then differential and/or log backups are applied to the specified point in time.

We recommend retaining two sets of full backups with their differential and log backups.

> **Note:** A good backup plan always includes a combination of full, differential, and log backups.

Recover Microsoft SQL Server Volume-based Backups from Archive

Follow one of the workflows described in the following sections to restore a volume-based MS SQL backups from the archive. Using standard MS SQL restore workflows are not supported when restoring from the archive. This is because the backup is volume-based which cannot extract the MDF, NDF, and LDF files from the archive workflow. The volumes that contain the database files must be retrieved from the archive.

> **Note:** When restoring from the archive for file-based MS SQL backups, you can use standard MS SQL restore from archive workflows. For file-based backup, the MDF, NDF, and LDF files can be directly extracted from the archive. For VDI-based backup, the .bak files can be directly extracted from the archive.

For file-based backup, the MDF, NDF, and LDF files can be directly extracted from the archive.

You can manually recover database files from a volume-based backup and then use them to manually create a new database in SQL Server.

> **Note:** This method is supported only for full and incremental backups and not log backups.

Files from volume-based backup can be recovered using the following workflows.

Restore to Original Cohesity Cluster (from where MS SQL was Archived)

Recover/Clone an Entire Snapshot (Protection Group run) or VM from the Archive to the Target vCenter

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Click **Recover** > **Virtual Machines** > **VMs**.
3. Select a Job or VM (crash consistent) to recover.
4. Select the Snapshot and recovery location.

Instant Mount a Volume of a Virtual or Physical Server from the Archive to the Target Server

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Click **Recover** > **Virtual Machines** > **Instant Volume Mount**.
3. Select the Server for instant volume mount.
4. Select the recover point, volumes to mount and the mount target.

5. Copy the database files to the desired MS SQL server.
6. Manually attach the database to the desired MS SQL instance.

Download Individual Files

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Click **Recover** > **Virtual Machines** > **Files or Folders**.
3. Select the database files to download.
4. Select the recover point and any additional recovery options.
5. Copy the database files to the desired MS SQL server.
6. Manually attach the database to the desired MS SQL instance.

Restore to Different Cohesity Cluster (CloudRetrieve from Remote Cluster)

1. In the Cohesity Dashboard, select **Data Protection > CloudRetrieve**.
2. Click **New Search**.

   Specify the archive to retrieve from, the Protection Group name and the Cluster where the Job originated.
3. After the search completes, download the Jobs to the Cluster. This may take some time to complete.
4. After the archived data is downloaded (an Inactive Job is created), you can use the standard restore/clone MS SQL database workflows. Do either of the following:
   - Click **Data Protection > CloudRetrieve > Downloaded Jobs**. Mouse over the actions menu and select an action.
   - Click **Data Protection > Recoveries Recover > MSSQL**.

Recover Microsoft SQL Server Database as a New Database in the Original Microsoft SQL Server Instance

To recover the database as a new database in the original MS SQL server instance:

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Click **Recover** located at the top right of the page and then select **Databases** > **MS SQL**.

   The Restore SQL page appears.
3. Search for the databases you want to recover from by entering characters of the database name, Protection Group name, or by specifying the wildcard character *. A list of databases is displayed with details like Cohesity Cluster, Protection Group, Physical Server, and Create Date. The Create Date option indicates the date and timestamp when the database was created.

> **Note:** Operations like rename may update the creation date at the SQL Server.

4. From the list of search results, select one or more databases you want to recover. You can select multiple MS SQL databases only if they are protected by the same protection group.

   > **Note:** The option to select multiple databases in a recovery task is an Early Access feature. Contact Cohesity Support for enabling this feature.

   By default, the latest recovery point is selected. To select a different recovery point, from the selected lists, mouse over the recovery point, and then click the edit icon.

   The Edit recovery point for <database_name> page appears.

   By default, the option to select the recovery point is displayed in **Timeline** mode. You can also choose to view the option in **List** mode by clicking the **List** tab in the top-right corner of the page. The **Timeline** mode displays the full backups (recovery points) captured at the scheduled time and the CDP-based data available for point-in-time restore. The **List** tab displays only the full backups captured at a scheduled time.

   - To select a recovery point from the Timeline mode:
     a. From the **Choose a date** drop-down, select a date.

        The recovery points available on the selected date are displayed in blue dots on the timeline bar and the point-in-time for restore is displayed in a solid green line on the timeline bar.

     b. To recover from a full backup, click the corresponding blue dot. For point-in-time restore, specify the exact point-in-time recovery by sliding the timeline bar.

     c. By default, the data is recovered from the local cluster. You can also select a recovery point archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.

     d. Click **Select Recovery Point** and then go to step 5.
   - To select a recovery point from the List mode:
     a. Select the **List** tab from the top-right corner of the Edit recovery point for <database_name> page.

        By default, the page displays the recovery points available for the last 30 days.

b. You can also select a recovery point from a different date range by selecting the date range from the Date drop-down list. The page displays the available recovery points in the specified range.

c. Select the recovery points to be recovered.

d. By default, the data is recovered from the local cluster. You can also select a recovery point archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.

e. Click **Select Recovery Point** and then go to step 5.

5. Click **Next: Recover Options**.
6. From the **Targets** option, select **Recover as a new Database** to recover the database as a new database.
7. Enable the **Restore to Original SQL Server Instance** option to restore the database in the original MS SQL Server instance.
8. In the **Data Files** field, specify the path to an existing directory. The newly created database files will reside in this path.

   > **Note:** If the database file names to be restored have a conflict with the existing database files of the database to which files are restored, then Cohesity resolves the conflict by appending a number to the file names.

9. In the **Log Files** field, provide the full path location to which the log files can be restored.
10. (Optional) Click **Add File Path Rules** to add custom rules for the data files.

    You can provide a full path or pattern for the original files and a location to restore to. When providing a location, use the standard path format. For example, use C:\path for Windows instead of the extended path format \\?\c:\path.

    Accept the file patterns and examples:

    - Wildcard character used for file matching such as *
      - **.ndf* - All ndf files. Useful if you want every ndf file to go to the same folder
      - *m:*.ndf* - Every ndf file on drive m:
      - *c:*1.ndf* - Every ndf file on drive c: that contains 1.ndf
    - Regex pattern
      - *.*\.ndf* - All files with the ndf extension
      - *^.*foo1.*\.ndf$* - All files with the word foo1 and the extension ndf
    - Full path to a source database file

Database files that have non-default file extensions or that do not match a specified filename or pattern are restored to the data file restore location.

Click **Add File Path Rule** to add multiple custom rules.

11. Specify the following **Recovery Options**:

Recovery Options	Description
Rename	Select one of the following options: • **Bulk Rename**: Select this option if you want to rename the restored databases in bulk. You can specify a string in the **Suffix** field. The restored databases will be renamed by adding this suffix string with the original database names. • **Rename Individual Objects**: Select this option if you want to individually rename the restored databases. You can specify the new name of the databases in the **New Name** field.
WITH RECOVERY	Disable the option to perform a restore WITH NO RECOVERY (the database will be offline when restored). By default, this option is enabled and the database is restored with recovery (the database will be online when restored).
VDI Restore Settings	Enable this option to specify the WITH clause that you want to use for the restore. **Note:** This option is available only for restoring the databases that are protected using Backup Microsoft SQL Server (VDI-based).
Keep CDC	Enable this option to restore a protected database that has the change data capture (CDC) enabled. If the protected database is not CDC enabled and the user tries to restore it with Keep CDC then, the database will be restored without CDC. **Note:** This option is available only if the database is restored with recovery.
Overwrite Alternate Database	Enable this option to recover the database by overwriting the existing database.
Cluster Interface	By default, the **Auto Select** option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the **Interface Grou**p drop-down.
Task Name	Change the default name of the recovery task.

12. Click **Start Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Recover Microsoft SQL Server Database as a New Database in an Alternate Microsoft SQL Server Instance

To recover the database as a new database in an alternate MS SQL server instance:

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Click **Recover** located at the top right of the page and then select **Databases** > **MS SQL**.

   The Restore SQL page appears.
3. Search for the databases you want to recover from by entering characters of the database name, Protection Group name, or by specifying the wildcard character *. A list of databases is displayed with details like Cohesity Cluster, Protection Group, Physical Server, and Create Date. The Create Date option indicates the date and timestamp when the database was created.

   > **Note:** Operations like rename may update the creation date at the SQL Server.
4. From the list of search results, select one or more databases you want to recover. You can select multiple MS SQL databases only if they are protected by the same protection group.

   By default, the latest recovery point is selected. To select a different recovery point, from the selected lists, mouse over the recovery point, and then click the edit icon.

   The Edit recovery point for <database_name> page appears.

   By default, the option to select the recovery point is displayed in **Timeline** mode. You can also choose to view the option in **List** mode by clicking the **List** tab in the top-right corner of the page. The **Timeline** mode displays the full backups (recovery points) captured at the scheduled time and the CDP-based data available for point-in-time restore. The **List** tab displays only the full backups captured at a scheduled time.

   - To select a recovery point from the Timeline mode:
     a. From the **Choose a date** drop-down, select a date.

        The recovery points available on the selected date are displayed in blue dots on the timeline bar and the point-in-time for restore is displayed in a solid green line on the timeline bar.

     b. To recover from a full backup, click the corresponding blue dot. For point-in-time restore, specify the exact point-in-time recovery by sliding the timeline bar.

     c. By default, the data is recovered from the local cluster. You can also select a recovery point archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.

d. Click **Select Recovery Point** and then go to step 5.

- To select a recovery point from the List mode:
  a. Select the **List** tab from the top-right corner of the Edit recovery point for <database_name> page.

     By default, the page displays the recovery points available for the last 30 days.

  b. You can also select a recovery point from a different date range by selecting the date range from the Date drop-down list. The page displays the available recovery points in the specified range.

  c. Select the recovery points to be recovered.

  d. By default, the data is recovered from the local cluster. You can also select a recovery point archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.

  e. Click **Select Recovery Point** and then go to step 5.

5. Click **Next: Recover Options**.
6. From the **Targets** option, select **Recover as a new Database** to recover the database as a new database.
7. Disable the **Restore to Original SQL Server Instance** option to restore the database to an alternate SQL Server instance.
8. From the **MS SQL Instance** drop-down, select an alternate SQL server instance.
9. In the **Data Files** field, specify the path to an existing directory. The newly created database files will reside in this path.

   > **Note:**
   > - If the database file names to be restored have a conflict with the existing database files of the database to which files are restored, then Cohesity resolves the conflict by appending a number to the file names.

10. In the **Log Files** field, provide the full path location to which the log files can be restored.
11. (Optional) Click **Add File Path Rules** add custom rules for the data files.

    You can provide a full path or pattern for the original files and a location to restore to. When providing a location, use the standard path format. For example, use C:\path for Windows instead of the extended path format \\?\c:\path.

This is only used for the destination path in a custom rule and not the source. File path rules are case sensitive. Partial file name or extension (not only directory path) are required for a match to be identified.

> **Note:** For VDI based backup, use two backslashes after the drive. For example, C:\\path.

Accept the file patterns and examples:

- Wildcard character used for file matching such as *
  - **.ndf* - All ndf files. Useful if you want every ndf file to go to the same folder
  - *m:*.ndf* - Every ndf file on drive m:
  - *c:*1.ndf* - Every ndf file on drive c: with a suffix of 1.ndf
- Regex pattern
  - *.*\.ndf* - All files with the ndf extension
  - *^.*foo1.*\.ndf$* - All files with the word foo1 and the extension ndf
- Full path to a source database file

Database files that have non-default file extensions or that do not match a specified filename or pattern are restored to the data file restore location.

Click **Add File Path Rule** to add multiple custom rules.

12. Specify the following **Recovery Options**:

Recovery Options	Description
Rename	Optional. Enable the Rename option and select one of the following options to rename the restored databases: • **Bulk Rename**: Select this option if you want to rename the restored databases in bulk. You can specify a string in the **Suffix** field. The restored databases will be renamed by adding this suffix string with the original database names. • **Rename Individual Objects**: Select this option if you want to individually rename the restored databases. You can specify the new name of the databases in the **New Name** field.

Recovery Options	Description
WITH RECOVERY	Disable the option to perform a restore WITH NO RECOVERY (the database will be offline when restored). By default, this option is enabled and the database is restored with recovery (the database will be online when restored). **Note:** When restoring a database to an alternate MS SQL server instance with no recovery, a staging directory is created under the database files and logs file directories. To overcome the filename conflict with existing files in the database, the recovered files are saved in this staging directory.
VDI Restore Settings	Enable this option to specify the WITH clause that you want to use for the restore. **Note:** • This option is available only for restoring the databases that are protected using Backup Microsoft SQL Server (VDI-based).
Keep CDC	Enable this option to restore a protected database that has the change data capture (CDC) enabled. If the protected database is not CDC enabled and the user tries to restore it with Keep CDC then, the database will be restored without CDC. **Note:** • This option is available only if the database is restored with recovery. • This option is not available for system database restore.
Overwrite Alternate Database	Enable this option to recover the database by overwriting the existing database.
Cluster Interface	By default, the **Auto Select** option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the **Interface Grou**p drop-down.
Task Name	Change the default name of the recovery task.

13. Click **Start Recovery**.

The recovery task is initiated. You can monitor the recovery task from the recoveries page.

Recover Microsoft SQL Server Database as Flat Files

Cohesity allows you to recover the SQL database backup files to the specified location on the target host, rather than as a database. This provides flexibility for self-service recovery where direct access to the backup files is required.

The backup files are recovered to a subdirectory in the specified destination path, with the following file name format: `<OriginalHostName>_<OriginalInstanceName>_<OriginalDatabaseName>`

For example, the backup files are recovered to **C:\RestoreDir\SQLHost01_MSSQLSERVER_AdventureWorks**
where,

- **C:\RestoreDir** is the destination path,
- **SQLHost01** is the host,
- **MSSQLSERVER** is the instance,
- **AdventureWorks** is the database.

> **Note:** This is applicable only for the SQL Servers backed up using file-based and VDI-based backup and not applicable to volume-based backup.

When you recover databases as flat files, the following backup files are recovered based on the backup method and recovery point:

Backup Type	Recovery Point	Recovered Files
File-Based	Incremental Backup	Database files - .mdf, .ldf., .ndf, VSS metadata
	Point In Time	• Database files - .mdf, .ldf., ndf, VSS metadata • Log backup files - .trn
VDI	Incremental Backup	• Full backup file - .bak • Differential backup file - .bak
	Point In Time	• Full backup files - .bak • Differential backup files - .bak • Log backup files - .trn

To recover SQL Server databases as flat files:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** located at the top right of the page and then select **Databases** > **Microsoft SQL**.

   The **New Recovery** page is displayed.

3. Search for the databases you want to recover from by entering characters of the database name, Protection Group name, or by specifying the wildcard character *. A list of databases is displayed with details like Cohesity Cluster, Protection Group, Physical Server, and Create Date. The Create Date option indicates the date and timestamp when the database was created.

   > **Note:** Operations like rename may update the creation date at the SQL Server.

4. From the list of search results, select one or more databases you want to recover. You can select multiple MS SQL databases only if they are protected by the same protection group.

   By default, the latest recovery point is selected. To select a different recovery point, from the selected lists, mouse over the recovery point, and then click the edit icon.

   The Edit recovery point for <database_name> page appears.

   By default, the option to select the recovery point is displayed in **Timeline** mode. You can also choose to view the option in **List** mode by clicking the **List** tab in the top-right corner of the page. The **Timeline** mode displays the full backups (recovery points) captured at the scheduled time and the CDP-based data available for point-in-time restore. The **List** tab displays only the full backups captured at a scheduled time.

   - To select a recovery point from the Timeline mode:
     a. From the **Choose a date** drop-down, select a date.

        The recovery points available on the selected date are displayed in blue dots on the timeline bar and the point-in-time for restore is displayed in a solid green line on the timeline bar.

     b. To recover from a full backup, click the corresponding blue dot. For point-in-time restore, specify the exact point-in-time recovery by sliding the timeline bar.

     c. By default, the data is recovered from the local cluster. You can also select a recovery point archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.

     d. Click **Select Recovery Point** and then go to step 5.
   - To select a recovery point from the List mode:
     a. Select the **List** tab from the top-right corner of the Edit recovery point for <database_name> page.

        By default, the page displays the recovery points available for the last 30 days.

b. You can also select a recovery point from a different date range by selecting the date range from the Date drop-down list. The page displays the available recovery points in the specified range.

c. Select the recovery points to be recovered.

d. By default, the data is recovered from the local cluster. You can also select a recovery point archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.

e. Click **Select Recovery Point** and then go to step 5.

5. Click **Next: Recover Options**.
6. From the **Targets** option, select Recover as a Flat File to recover the database files to the target location, rather than as a database.
7. Specify the following details:

Backup Type	Description
Physical Server	Windows server where the agent is installed and registered to the cluster.
Database File Path	Destination path in the physical server where the flat files will be recovered.
Overwrite Existing Files	Select to overwrite the existing files in the destination path. This is a destructive action and cannot be reverted.
Cluster Interface	By default, the **Auto Select** option is enabled, and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the **Interface Group** drop-down.
Task Name	Change the default name of the recovery task.

8. Click **Recover**.

The recovery task is initiated. You can monitor the recovery task from the **Recoveries** page.

Recover Microsoft SQL Server FILESTREAM Databases

Before you can restore MS SQL FILESTREAM databases, a snapshot must exist.

Restore Database Overview

1. Select **Dashboard** and from the drop-down, select **MS SQL**.
2. Click **Databases**.

3. Select **Recover** from the database's actions menu.
4. Set restore options.

You can also start a restore task by navigating to **Data Protection > Recoveries** > **Recover** > **Databases** > **MS SQL** and selecting a database to restore.

Set Restore Options

1. **Task Name:** Optionally change the default name for the task.
2. **Restore to Original SQL Server Instance:** Toggle on if you want to restore the database to its original instance.

   Overwriting a FILESTREAM database is not supported and prevents the restore from completing.

   a. Select a **SQL Host** and **SQL Instance** if restoring to an alternate MS SQL instance.

   > **Note:** Local MS SQL instances that are running within an MS SQL FCI do not display. You can, however, manually enter the local SQL instance name to restore to.

   b. Provide the full path location to restore all database files.

   You can optionally restore data files and log files to different locations. Click **Add Alternative Log File Locations and Custom Rules** to provide locations for data and log files and any custom rules. For data files, you can provide a full path or pattern for the original files and a location to restore to. When providing a location, use the standard path format. For example, use C:\path for Windows instead of the extended path format \\?\c:\path.

   This is only used for the destination path in a custom rule and not the source.

   Accept the file patterns and examples:

   - Wildcard character used for file matching such as *
     - **.ndf* - All ndf files. Useful if you want every ndf file to go to the same folder
     - *m:*.ndf* - Every ndf file on drive m:
     - *c:*1.ndf* - Every ndf file on drive c: with a suffix of 1.ndf
   - Regex pattern
     - *.*\.ndf* - All files with the ndf extension
     - *^.*foo1.*\.ndf$* - All files with the word foo1 and the extension ndf
   - Full path to a source database file

Database files that have non-default file extensions or that do not match a specified filename or pattern are restored to the data file restore location.

Click **Add Another Custom Rule** to add multiple custom rules.

> **Note:** Ensure to follow the standard regular expression rules. Specify a dot '.' before asterisk '*' to match all characters, for example, L:.*.ndf.

c. Provide a **Database Name** for the restored database.

3. By default, the latest snapshot is selected. You can optionally choose to restore from a different snapshot by clicking Edit ( ).

   You can also provide a specific time to restore to if transaction logs are available.

   Click a date on the calendar to select a snapshot from that date. The default point selected will be the latest log transaction or the latest full or incremental, whichever is the latest. The slider also displays available points in time and displays snapshots as circles. Manually select a point on the slider if you want to restore to a specific point in time. Selecting an invalid time from the slider automatically changes to the closest available snapshot. If your manual selection is within 10 minutes of a snapshot, your selection automatically snaps to it. You can also select a specific point in time by entering it in the time fields.

   After selecting the desired recover point, click **Recover**. You can choose to clone the selected recover point by clicking the arrow adjacent to recover and selecting **Clone**.

   In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

4. By default, an MS SQL restore WITH RECOVERY is performed. You can optionally toggle this off to perform a restore WITH NORECOVERY.

5. **Auto Select:** When enabled, the recovery task automatically selects the correct VLAN.

   > **Note:** If using VLANs and the cluster is joined to an AD domain—One of the machine accounts must be a DNS hostname for a virtual IP (VIP) of a VLAN configured on the cluster in order to recover to servers within that VLAN.

6. **Capture tail logs:** This option is available only when overwriting a database in its original location. This option is unavailable if the database's Protection Group has been paused or deleted.

   Tail logs capture records that have not yet been backed up. They are captured to ensure all transactions are backed up before restoring the database.

7. Click **Recover** to start the task.

SQL Maintenance Mode

You can enable maintenance mode for SQL Server instances and databases. Enabling maintenance mode skips any scheduled activities or manually initiated protection runs.

To place a SQL Server instance or database in maintenance mode:

1. Navigate to **Data Protection > Sources**.
2. Click on the action menu (⋮) of the source and select **Maintenance**.
3. You can initiate the maintenance mode immediately or later.

   To initiate the maintenance mode immediately:

   1. Select **Start Now**. The **Start Maintenance Now** dialog displays the list of Protection Groups available in the source.
   2. Review the list of Protection Groups and enter **Yes** to confirm.
   3. Optionally, you can enter a note.
   4. Click **Confirm**.

   To schedule the maintenance mode:

   1. Select **Schedule**.
   2. On the **Schedule Maintenance** dialog, enter the start date and time and the end date and time.
   3. Optionally, you can enter a note.
   4. Click **Save**.

The SQL Server instance or database will be set in maintenance mode accordingly.

AG in Maintenance Mode

When maintenance mode is enabled for a SQL instance hosting the AG database, the replica hosting the instance is not considered for the AG backup plan. This behavior is common to both legacy (non-first-class citizen) and first-class citizen features.

For legacy AG backup, only the replica for which maintenance mode is enabled will be skipped. You must enable maintenance mode on all the replicas to skip the entire backup.

Clone Microsoft SQL Server Data

The following topics provide guidance to help you clone MS SQL databases:

About Cloning Microsoft SQL Server Databases

A clone task instantiates a backup of an MS SQL database so it can run directly off the Cohesity. While cloning an MS SQL database, you can choose a destination server that is registered with Cohesity as MS SQL. Cloning physical servers to physical servers only is supported.

MS SQL DB Clone Example

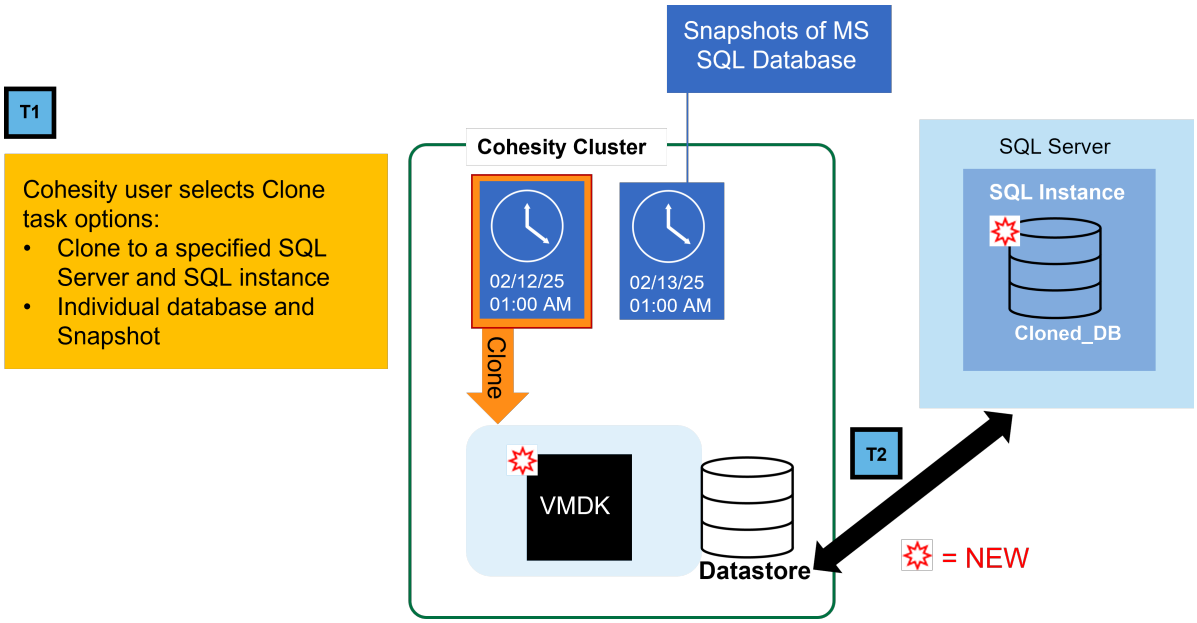
The following example depicts cloning a database from a physical SQL server to a SQL server instance running on a different physical server. The action steps in the following procedure are represented in the figure below with blue numbered time squares: T1 .

The process consists of the following actions:

T1) The Cohesity user must select the following task options:

- Clone to a specified SQL server and SQL instance
- An MS SQL database and snapshot

T2) The cloned database files are then brought online as a new database.



Clone Microsoft SQL Server Databases

Cohesity now provides the ability to clone an MS SQL database to a Standalone SQL Server, FCI, and AG. A major advantage is that the cloned MS SQL database files reside on the Storage Domain and require no additional storage from the MS SQL host. Multiple clones from a single source of MS SQL Database backup require little or no additional storage space in the Cohesity cluster.

> **Note:** Cloning an MS SQL database is supported with Volume-based and file-based backup methods.

Clone an MS SQL Database

1. Navigate to **Test & Dev** > **Clone** > **Databases**.
2. Search and select the MS SQL database. You can optionally perform a search by specifying the wildcard character *. You can also optionally narrow the search results by specifying filter criteria.
3. Provide the following information listed in the table, and then click **Clone**.

Options	Description
Task Name	(*Optional*) Change the default name for the Clone task.
Objects Being Cloned	By default, the database you selected for cloning is displayed. You can click the change icon to select a different database.
Clone Point	By default, the latest snapshot is cloned. Optionally click the Change icon to select a different snapshot to clone. The selected Restore Point is listed
SQL Host	Select the host to which you want to clone the database. By default, you can select only the physical servers as the host. If you want to select MS SQL FCI as the SQL host, Contact Cohesity Support. Cloning the MS SQL database to an MS SQL FCI is supported only if the following criteria are met: • Microsoft SQL Server version must be 2012 and above, supported on SMB file server. • The MS SQL database to be cloned is backed up with a file-based protection group.
SQL Instance	Select the instance for the cloned database.
Rename Database?	Enable this option if you want to rename the cloned database created by this task.
Cohesity Network interface	Select one of the following options: • **Auto Select**: By default, the **Auto Select** option is enabled and the clone task automatically selects the correct VLAN. • **Interface Group**: select a configured interface group from the **Interface Group** drop-down.

Cancel a Database Clone

You can cancel a running clone task for an individual database. Canceling the task may leave the database in an unusable state. You can delete the database manually and then start another clone task as needed.

1. Navigate to **Test & Dev**.
2. Click a Task Name link in the table to display the details page.
3. Click the **Cancel** button. (The Cancel button is available only if the task is running.)
4. Respond to the confirmation prompt.

Tear Down a Database Clone

To delete an MS SQL database clone from the Cohesity Storage Domain, perform the following steps:

1. Navigate to **Test & Dev**.
2. Click the cloned task or hover your mouse over the actions menu located next to the cloned task you want to delete.
3. Click **Tear Down Clone** > **Yes, Tear Down**.

The MS SQL database clone will be deleted from the Cohesity cluster Storage Domain.

> **Note:** The teardown of an MS SQL clone database removes it from the SQL server; the user does not have to do this beforehand. However, in the rare instance you created other additional databases with files on the mounted drive that the cloned database is on, those additional databases should be deleted first through the SQL Server Management Studio.

Migrate Microsoft SQL Server

The following topics provide guidance to help you migrate MS SQL databases:

About Migrating Microsoft SQL Server Databases

You can use MS SQL database migration for the following use cases:

- Back up and migrate a database from a single pane of glass.

  Leverage database backup to achieve database migration. No more shipping logs across multiple sites or multiple data centers.

  Upgrade the MS SQL Server version while minimizing application downtime and maintaining the ability to restore to any point in time.

- Staging a database on the target server for faster recovery with Cohesity's database migration.

  Stage a database on the target SQL server and perform only incremental updates at the file level to improve RPO.

Database migration for file-based MS SQL backups consists of the following actions, which must be initiated manually:

1. Perform the initial copy of database files to the target MS SQL server.
2. Sync forward to the latest incremental/full snapshot available on the cluster. You can trigger multiple syncs.

   For each sync, Cohesity performs incremental file updates to database files on the target MS SQL server. Syncs ensure files are up to date. The files are not attached to the database until you complete the finalized workflow. This ensures that the database is up to date when finalization occurs.
3. Finalize the migration. Finalizing is available only if the target database is synced to the latest snapshot.

   This brings the database online. After the database is online and the finalize step succeeds, the recovery task is completed successfully. You cannot perform syncs after this point because the migration workflow is complete.

Migrate Microsoft SQL Server Databases

Before you migrate an MS SQL database, ensure that a file-based snapshot exists on the cluster.

Migrate MS SQL Database

This section lists the steps to migrate an MS SQL database.

1. Select **Dashboard** and from the drop-down, select **MS SQL**.
2. Select **Migrate** from the database's actions menu.

   You can also start a restore task by navigating to **Data Protection > Recoveries> Recover > Migrate Database (MS SQL only)**.
3. Search for an MS SQL server or database. Enter characters of the name and a list of items displays. You can optionally specify the wildcard character *. You can also optionally narrow the search results by specifying filter criteria, for example, you can filter the search results by a specific Protection Group. Click the **Add Filters** icon, specify the filter and click **Add**.
4. Select a database and set the migration options for the MS SQL database you want to migrate.
   1. **Task Name:** Optionally change the default name for the task.
   2. **Objects Being Recovered**: This displays the database to be migrated.

3. **Sync Options**: Specify the sync options for the database to be migrated.

   > **Note:** Transaction log backup is not synced. Only the incremental and full backup is synced.

   - **Auto Sync Databases**: This option automatically keeps the database in sync with the latest available snapshot until you finalize the database and bring it online.
   - **Manually Sync Databases**: Once the initial database migration is completed, you can sync the migrated database files with newer snapshots available until you finalize the database and bring it online.
4. **Recover Point:** This displays the selected recover point for the migration.
5. **Settings:** Specify the **SQL Host** and **SQL Instance** to migrate the database to.

   Provide the full path location to restore all database files.

   You can optionally restore data files and log files to different locations. Click **Add Alternative Log File Locations and Custom Rules** to provide locations for data and log files and any custom rules. For data files, you can provide a full path or pattern for the original files and a location to restore to. When providing a location, use the standard path format. For example, use C:\path for Windows instead of the extended path format \\?\c:\path.

   This is only used for the destination path in a custom rule and not the source.

   Accept the file patterns and examples:

   - Wildcard character used for file matching such as *
     - **.ndf* - All ndf files. Useful if you want every ndf file to go to the same folder
     - *m:*.ndf* - Every ndf file on drive m:
     - *c:*1.ndf* - Every ndf file on drive c: with a suffix of 1.ndf
   - Regex pattern
     - *.*\.ndf* - All files with the ndf extension
     - *^.*foo1.*\.ndf$* - All files with the word foo1 and the extension ndf
   - Full path to a source database file

   Database files that have non-default file extensions or that do not match a specified filename or pattern are restored to the data file restore location.

   Click **Add Another Custom Rule** to add multiple custom rules.

> **Note:** Ensure to follow the standard regular expression rules. Specify a dot '.' before asterisk '*' to match all characters, for example, L:.*.ndf.

5. By default, an MS SQL restore WITH RECOVERY is performed. You can optionally toggle this off to perform a restore WITH NO RECOVERY.
6. Click **Start Migration**.

   The initial file copy task starts. This is the first step in the migration process.
7. After the file copy task is completed, the options available for the next migration step are displayed.
   - **Finalize** - Available if the target database is synchronized to the latest snapshot.
   - **Sync** - Available if there is a snapshot that is more recent than the target database.

   If you select the **Auto Sync Databases** option in Step 4, the **Auto Sync to latest** toggle is enabled by default. You can manually disable this option if required.

> **Note:** Database migration is not supported for AG databases.

Cancel Migration

You can cancel an in-progress migration task. Canceling the migration prevents syncing or finalizing the database and may leave it in an unusable state. Delete the database files manually and then start another migration task as needed.

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Find the migration task in the list and click the task name to display its detail page.
3. Click the **Cancel** button located at the top right of the page.
4. Respond to the confirmation prompt.

Oracle Database

Cohesity's software-defined platform provides a simple, fast, and cost-effective backup, recovery, and data management solution for growing Oracle database environments. Cohesity integrates with Oracle Recovery Manager (RMAN) to deliver an integrated and centralized approach to manage Oracle backup jobs. It provides a single location to register and schedule all RMAN scripts across the Oracle environment. See the following topics for details:

Our platform provides several integrations for protecting the Oracle Databases:

- **Cohesity Oracle Adapter**: Cohesity Oracle Adapter integrates with Oracle Recovery Manager (RMAN) to provide application-consistent backup and recovery for Oracle databases. The adapter provides a unified user interface allowing users to manage and provision all the Oracle database protection services, supporting Oracle single instance, RAC or Oracle Multitenant databases. For details, see Cohesity Oracle Adapter.
- **Cohesity Remote Adapter**: Cohesity Oracle Remote Adapter is a built-in component of Cohesity that offers flexible management of scripts running on remote hosts. This allows the Cohesity cluster to manage data protection processes and schedules as well as provide consolidated logs of all related activities. User-supplied Oracle RMAN scripts are hosted on the Oracle server with one extra step to register the scripts with the Cohesity cluster. Once registered, the RMAN scripts are remotely triggered and monitored for completion and activity logged on the cluster. For details, see Oracle Database Remote Adapter.
- **RMAN NFS Target**: Cohesity can be presented as an NFS volume to be used as inline-deduplication Oracle databases backup target. Oracle RMAN can use the Cohesity Data Cloud as a deduplication target and automatically leverage Cohesity's QoS policy for optimal data tiering as well as global deduplication and compression to reduce secondary storage consumption. For details, see RMAN NFS Target for Oracle Database.
- **Cohesity Oracle SBT Plug-in**: The Cohesity Oracle SBT Plug-in allows you to use Cohesity Data Cloud as target storage for backing up Oracle databases. For details, see Cohesity Oracle SBT Plug-in.

For detailed information on Cohesity's integration with RMAN, see Oracle Data Protection Deployment Using RMAN NFS Target.

Supported Features

The following table shows how each protection method supports different features.

Features	Cohesity Oracle Adapter	Remote Adapter	RMAN NFS Target	Cohesity Oracle SBT Plug-in
Database backup	Supported	Supported	Supported	Supported
SLA-driven policies	Supported	Cohesity and customer driven	Customer-driven	Customer-driven
Database backup automation	Cohesity driven	Customer-driven	Customer-driven	Customer-driven

Features	Cohesity Oracle Adapter	Remote Adapter	RMAN NFS Target	Cohesity Oracle SBT Plug-in
Oracle backup types	Image copy	All RMAN supported backup types	All RMAN supported backup types	Backup-set Only
Oracle database restore	Cohesity driven	Customer-driven	Customer-driven	Customer-driven
Clone	Cohesity driven	Customer-driven	Customer-driven	Not Supported
Dedupe	Cohesity driven (Windows only)	Source side dedupe library (Linux, AIX, and Windows)	Not Applicable	Source side dedupe library (Linux, AIX, and Windows)
Point-in-time recovery	Cohesity driven	Customer-driven	Customer-driven	Customer-driven
View expose	Cohesity driven	Customer-driven	Customer-driven	Customer-driven
RMAN channel configuration for performance	RMAN channels=MIN(2* # of Cohesity nodes, 2* # of target server CPU) The default value is 8. To configure more RMAN channels, contact Cohesity Support. You can also edit the Cohesity nodes and CPUs, if required.	Customer-driven	Customer-driven	Customer-driven

Cohesity Oracle Adapter

The Cohesity Oracle Adapter natively integrates with Oracle Recovery Manager (RMAN) to provide application-consistent backup and recovery for Oracle single-instance deployments, Oracle Exadata Databases Real Application Clusters (RAC), and Veritas Active-Passive.

Based on the policy settings, the Cohesity Oracle Adapter executes an RMAN backup command to initiate a backup of the Oracle Database. The adapter also automatically determines the optimal number of backup channels, based on the compute resources on the

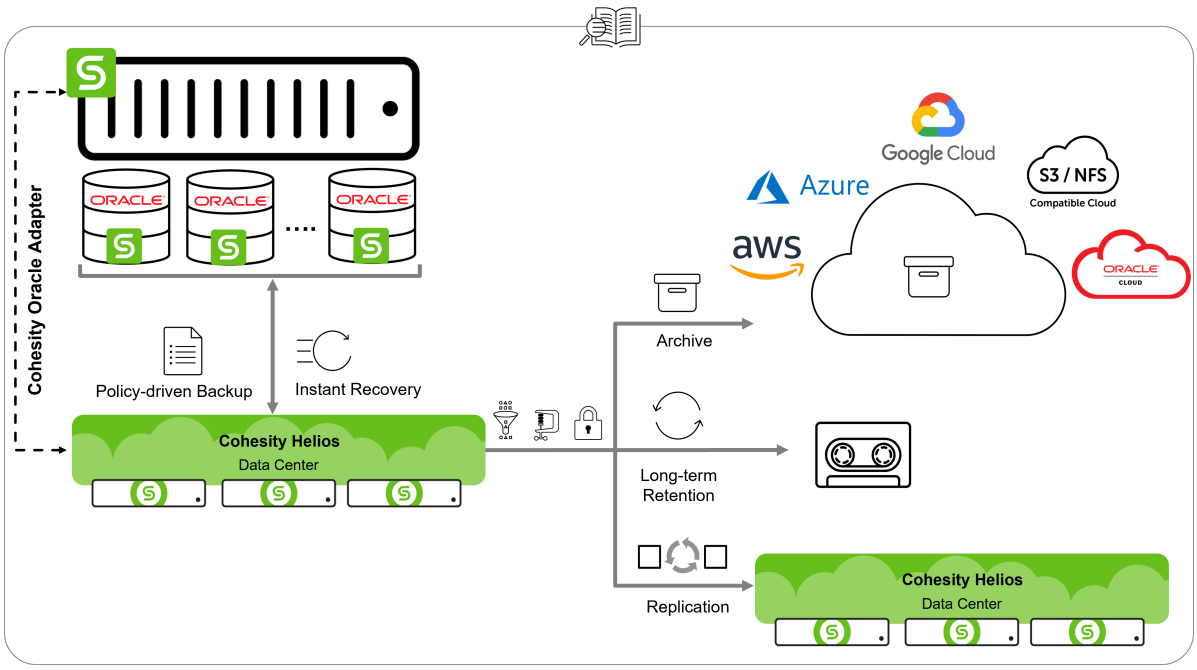
Oracle Database server and the number of nodes in the Cohesity cluster. The necessary Cohesity Views are automatically generated (that is, an NFS mount point on the client and an NFS View on Cohesity), where the backups are going to be written. Communication between Cohesity and the Oracle Databases is managed by the Cohesity Oracle Adapter as described in the section below.

Core components

The following lists the core components of the Cohesity Oracle adapter.

- Physical or virtual Oracle instance.
- Cohesity Data Cloud.
- Cohesity Oracle Adapter.
- Archive or tiering target at your data center or cloud provider of choice.

As illustrated in the below figure, you can integrate the Cohesity Data Cloud with a new or existing Oracle infrastructure by installing the Cohesity Oracle adapter. Once the agent is installed, you can create protection policies, jobs, and replication schedules for the Oracle database. Once the database is protected, it can be archived, sent to tape, and or replicated to another Cohesity cluster running in the cloud or on-premises as shown in the below image.



Cohesity Oracle Adapter Benefits

The following table highlights the benefits of using an Oracle Adapter for your Oracle database backup solution:

DB Backup and Storage Challenges	Solutions
Backup agent degrades database performance	The Cohesity Oracle Adapter is a lightweight agent on the target host and does not degrade the application performance.
Lack of point-in-time (PIT) Support for recovery and cloning	The Cohesity Oracle Adapter offers an intuitive user interface for PIT Recovery and Clone workflows.
Expensive usage of primary storage	The Cohesity Oracle Adapter supports auto-tiering and global dedupe or compression thereby offering flexibility and cost efficiencies.
Slow data restores	The Cohesity Oracle Adapter offers faster restores as every database backup is fully hydrated using Cohesity snapshots and Oracle incremental merge capabilities. The traditional backup workflow requires repeated time consuming full backup schedules and Cohesity does not require this because customers only need to do one full backup, then the rest is 'incremental forever'.
Protection against compromised data	Cohesity performs an incremental merge after each incremental backup and validates the backup image to achieve a 'fully hydrated' image copy of the backup. The backup image is stored internally on the Cohesity cluster as an immutable snapshot. The merge will fail if the incremental backup is corrupted.
Higher Total cost of ownership	The distributed web-scale platform is designed for secondary data. Performance and capacity can be scaled linearly simply by adding nodes that eliminates the need for forklift upgrades. You can use the Cohesity Oracle adapter like a pay-as-you-go architecture.
Complex data-protection environments	The Cohesity Oracle Adapter simplifies the data protection by replacing multiple data protection silos (target storage, media servers, master servers, and cloud gateways) with a single hyper-converged solution for backup, recovery, replication, cloud tiering, archiving, and target storage.
Inability to leverage public cloud for long-term retention	The Cohesity Oracle adapter provides native cloud integration with: • Amazon Web Services (AWS) • Microsoft Azure • Oracle Cloud • Google Cloud Platform (GCP) It supports long-term retention and tiering of cold data. If the snapshots are sent to the cloud, they can be downloaded on another Cohesity cluster and restores can be performed from this cluster.

DB Backup and Storage Challenges	Solutions
RMAN scripts maintenance overhead	No need to maintain any RMAN scripts.
No single dashboard to manage Oracle Database data protection	The Cohesity Oracle adapter offers a single dashboard to manage Oracle Database data protection.
Lack of Oracle point-in-time (PIT) restore from cloud archived snapshots	Cohesity supports the PIT restore and clones from cloud archived snapshots.
Mount Point Management	The Cohesity Oracle self-healing manager periodically checks the availability of all the mount points created by the Cohesity Oracle adapter. If a mount point is not available within a specific duration, the self-healing manager performs these actions: • Treats the mount point as a non-responsive mount point. • Unmount this mount point. • Clean the RMAN sessions associated with the non-responsive mount point.
Managing Standby Databases	Cohesity supports taking backup from standby databases and restore or clone from those backups to protect Oracle data from failures, disasters, human error, and data corruption while providing high availability for mission-critical applications • Physical StandBy Support We support physical standby databases for all Oracle Configurations. • Logical StandBy Support We support Oracle Logical Standby with single instance config (non-CDB, non TDE) for Linux only. Exceptions for Logical StandBy All restrictions for Logical Standby from Oracle will apply to Cohesity. For example, If a logical standby database is not a block-for-block copy of the primary database, you cannot use a logical standby database to back up the primary database. Supported Cohesity Versions We will support this for 6.5.1x, 6.6.x, and future versions only.

Planning and Preparation for Oracle Database

The following topics provide guidance that helps you get ready to implement the Oracle Adapter:

Supported Features for Oracle Database

The following table lists the supported features for the Cohesity Oracle Adapter on different OS platforms:

Supported Oracle Features	Linux	AIX	Solaris	Windows
Standalone DB Backup (Single-instance Oracle DB)	Yes	Yes	Yes	Yes
RAC Backup (Multi-node Oracle DB)	Yes	Yes	No	No
Restore to Original Server (a.k.a. Overwrite Restore)	Yes	Yes	Yes	Yes
Restore to Alternate Server	Yes	Yes	Yes	Yes
Cloning	Yes	Yes	Yes	No
Instant Restore	Yes	No	No	No
Data Guard	Yes	Yes	No	No
CDB/PDB Support	Yes	No	No	Yes*
TDE Support	Yes	No	No	No
Archive Log Restore	Yes	No	No	No
Customizable PFile	Yes	Yes	Yes	No

* Oracle Windows adapter supports only the CDB backup and overwrite restore of the original CDB.

Prerequisites for Oracle Database

Make sure the following prerequisites are met before using Oracle Adapter:

- **DBIDs**: All the Oracle Databases that are protected using theCohesity cluster should have a unique DBID on the Oracle source where the databases reside.
- **SCAN VIP** (*Applies only to Linux and AIX*): To register Oracle RAC, the user must use SCAN-NAME or SCAN-VIP, Otherwise, registration, backup, and recovery of the Oracle databases will fail.

- **Installation Agent Type**: You must use the same agent installation type (Script or RPM) on all the Oracle RAC nodes.
- **Authentication**: For database-level authentication, the tns-listener service name must be the same as the database name.
- **Archive Log Mode**: Archive Log mode must be enabled for the database opened in Read-Write mode, otherwise the backup task will fail.
- **Version**: The recovery source and target database must be the same version of the Oracle Database. For example, snapshots of the 11g Oracle Database cannot be recovered to the 12c Oracle Database.
- **Full Backup**: Cohesity recommends taking a full database backup after any activity that changes the control file (such as adding or removing a data file, restoring to the original location with overwrite, or changing the log file location).
- **Oracle Single Instance Deployment**:
  - For Oracle single instance database, the database must be entered into the `/etc/oratab` file for Linux and AIX and `/var/opt/oracle/oratab` file for Solaris. Otherwise, Cohesity will not be able to discover this database.
  - For Oracle single instance database running on Windows OS, `OracleService${ORACLE_SID}` service must be running.
- **VCS Deployment** (*Applies only to Linux and AIX*): For Veritas Cluster Server (VCS) deployments, the Oracle database environment should be configured in the `/etc/oratab` on all the VCS nodes.
- **Register Oracle RAC**: To register an Oracle RAC or a RAC node as a physical server, "host" command must be executed on each of the nodes of that RAC.

  The "noac" flag for NFS mounts must be set for Oracle RAC versions 11gR2 and 12cR1. If not set, Oracle RAC backup fails.
- **Oracle RAC Database** (*Applies only to Linux and AIX*)
  - Cohesity Linux Agent must be installed on all the Oracle servers that are part of an Oracle RAC.
  - The `GRID_HOME` must be mentioned in `/etc/oratab` or `/etc/oraInst.loc` file .
- **DB Authentication** If you choose DB authentication, then all the DBs on the system should have the same username and password. Special characters is not supported in the DB authentication password.
- **SBT Library** (*Applies only to Windows*): On the Windows Oracle Server, install the SBT library in the same directory where the Windows Agent is installed. By default, the agent is installed in the **c:\Program Files\Cohesity\oracle** directory. Contact Cohesity Support to obtain the SBT library installer.
- For Oracle alternate restore to the ASM disk group, check the following prerequisite before starting restores on the Cohesity cluster:

- **ASM Compatibility (COMPATIBLE.RDBMS)**

  The disk group attributes that determine compatibility are COMPATIBLE.ASM, COMPATIBLE.RDBMS. and COMPATIBLE.ADVM. The COMPATIBLE.ASM and COMPATIBLE.RDBMS attribute settings determine the minimum Oracle Database software version numbers that a system can use for Oracle ASM and the database instance types respectively.

  The value for the COMPATIBLE.RDBMS disk group attribute determines the minimum COMPATIBLE database initialization parameter setting for any database instance that is allowed to use the disk group. Before advancing the COMPATIBLE.RDBMS attribute, ensures that the values for the COMPATIBLE initialization parameter for all of the databases that access the disk group are set to at least the value of the new setting for COMPATIBLE.RDBMS.

  For example, if the COMPATIBLE initialization parameter of the databases is set to either 12.2, then COMPATIBLE.RDBMS can be set to any value between 10.1 and 12.2 inclusively. If the COMPATIBLE initialization parameter of the databases is set to 18.0, then COMPATIBLE.RDBMS can be set to any value between 10.1 and 18.0 inclusively.

  The following query can be used to check existing Compatibility for ASM Disk group

  select name, DATABASE_COMPATIBILITY, COMPATIBILITY from v$asm_ diskgroup;

  Examples of disk group compatibility attribute settings:

COMPATIBLE.ASM	COMPATIBLE.RDBMS	Oracle ASM Instance Version	COMPATIBLE Setting for RDBMS Instance
12.1	12.1	>= 12.1	>= 12.1
12.2	12.1	>= 12.2	>= 12.1
19.0	19.0	>=19.0	>=19.0

- Oracle Software owner and ASM Management owner

  If the Oracle Grid / Oracle Restart owner is different from the Oracle RDBMS owner, make sure that the Oracle Grid OS group added as a secondary group for the Oracle RDBMS owner.

  For example,

  Oracle Grid/ Oracle Restart --- oraasm - asmdba, asmadmin (OS user and group)

Oracle RDBMS --- oracle - oinstall, dba (OS user and group)

In the above case add asmdba as a secondary group to oracle user.

Credentials and Privileges for Oracle Database

Once you register your physical servers with Cohesity as Oracle servers, Cohesity will discover your Oracle Database automatically. For Cohesity to successfully discover your Oracle Databases, the user running the Cohesity agent must have the appropriate credentials and privileges.

The Cohesity Linux Agent can be installed as a ROOT user or with a separate OS user (also known as the 'OS Service Account user'). The AIX Java Agent and Solaris can be installed only as a ROOT user.

When connecting to the Oracle databases, Cohesity can use either the Oracle OS Authentication or Oracle DB Authentication method. These two types of Oracle authentication are possible for both cases where the Agent is run with the ROOT user or a separate OS Service Account user. Most Oracle Adapter operations can be done using either OS or DB authentication. Some specific operations would require either OS or DB authentication. For more information, see Oracle Authentication Method Option table.

Running Agent with ROOT

You can install Linux Agent or the AIX Java Agent, or Solaris Java Agent to run with the ROOT user:

1. The agent runs every command using the ROOT user, except for Oracle commands and utilities like RMAN or SQLPLUS. To run Oracle commands and utilities, the agent will 'su' to the user who is the owner of the Oracle binary in the current Oracle Home. If an Oracle operation is run against a source database that has DB Authentication configured (where the user has previously configured DB credential for this Oracle source database in the Cohesity Oracle Adapter), DB Authentication will be used to run Oracle commands and utilities. Otherwise, OS Authentication via the Oracle binary owner will be used.
2. To use Oracle RAC Multinode Multichannel Backup, you must configure the corresponding source RAC database with DB credentials to allow the Agent to use the required DB Authentication method to run this feature.
3. When you install the Cohesity agent to run with the ROOT user, there is no need to configure additional SUDOERS privileges.

Running Agent with OS Service Account User

The Linux Agent can be installed to run with a specific OS Service Account user that meets the following requirements:

1. The following environmental variables should be set to match the Oracle user when the Cohesity agent is running as non-root and not oracle:

- LD_LIBRARY_PATH
- ORACLE_HOME

2. This Service Account user must be granted additional Sudoers privileges to allow the Agent to run operations like NFS mounting Cohesity views. For the complete list of the required Sudoer commands, see Sudoers Permissions for Service Account User .
3. This Service Account user must be part of the OS group that enables this user to either to have the Oracle SYSDBA or SYSBACKUP privileges. For example, on a typical Linux operating system, the OS group 'DBA' (dba) often enables the corresponding Oracle SYSDBA privilege. Another customer-defined OS Group, example: 'BACKUPDBA' (backupdba), can enable the corresponding SYSBACKUP privilege. This gives the Service Account user the ability to use the OS Authentication method to connect to Oracle databases with the intended privilege level.
4. If the Agent is running on an Oracle host that is part of a RAC cluster that uses ASM, or a non-RAC Oracle host that uses ASM that is available to that Oracle instance, the Service Account user should also be part of the OSDBA group of your ASM environment. This gives the Service Account user the ability to use the OS Authentication method to indirectly connect to the ASM instance to do things like reading ASM files during backup or restoring files into ASM during database recovery.
5. To use Oracle RAC Multinode Multichannel Backup, you must configure the corresponding source database with DB credentials to allow the Agent to use the required DB Authentication method to run this feature.

Oracle Authentication Method Option

Whether you are installing the Cohesity agent to run with the ROOT user or a separate OS Service Account user, the following table lists the Oracle Authentication method requirements for all Oracle Adapter operations.

Operation	Authentication Required	Notes
Non-RAC Backup (Single-instance Oracle DB)	OS Authentication or DB Authentication	Non-RAC single node require OS Authentication or DB authentication.
RAC Backup (Multi-node Oracle DB)	OS Authentication or DB Authentication	RAC multinode and multichannel require OS / DB authentication.

Operation	Authentication Required	Notes
Restore to Original Server (a.k.a. Overwrite Restore)	OS Authentication or DB Authentication	Restoring data to the same server overwrites the original database.
Restore to Alternate Server	OS Authentication	DB Recovery or Restore onto a different server with Oracle binaries that has the same version as the source database backup it is restoring. target oracle server must have enough free space to store the newly created database files.
Cloning	OS Authentication	DB clones onto a target server with Oracle binaries that have the same version as the source database backup it is cloning from.

Windows Agent Authentication

Windows Adapter Operation	Authentication Required
Non-RAC Backup (Single-instance Oracle DB)	OS Authentication or DB Authentication
Restore to Alternate Server	OS Authentication
Restore to Original Server (a.k.a. Overwrite Restore)	OS Authentication or DB Authentication

Sudoers Permissions for Service Account User

The following tables list the sudoers permissions for the Oracle Linux agent for OS Service Account User.

Operating System	Oracle Deployment Mode		
	Stand Alone	**RAC**	**Active Passive**
Linux	Commands for both Oracle Adapter & Linux physical agent • mount • umount • cp • chown • chmod • mkdir • rm • tee • hostname • stat • timeout • ls • rsync • touch • cat • mv Additional commands only for Linux physical agent • blkid • lsof • losetup • dmsetup • lvs • vgs • lvcreate	<COHESITY_AGENT_INSTALLATION_BASE_PATH> /cohesityagent/software/crux/bin/oracle_scripts/srvctl_from_oracle_home.sh where, COHESITY_AGENT_INSTALLATION_PATH = indicates where the cohesityagent directory got created after the Cohesity agent installation. For each unique ORACLE_HOME present in the **/etc/oratab** there would be a following entry in the /etc/sudoers. ORACLE_HOME/bin/srvctl	• <PATH TO> lltconfig • <PATH TO> hagrp • <PATH TO> hares

Operating System	Oracle Deployment Mode		
	Stand Alone	RAC	Active Passive
	• lvremove • lvchange • kill		

You can also allowlist a variant of command in sudoers. For instance, for the timeout command, you may only want to allowlist certain options such as:

- `/usr/bin/timeout --kill-after 5 --signal 1 300s`
- `/usr/bin/timeout --kill-after 5 --signal 1 300s /sbin/lvcreate *`
- `/usr/bin/timeout --kill-after 5 --signal 1 300s /sbin/lvextend *`
- `/usr/bin/timeout --kill-after 5 --signal 1 300s /sbin/lvremove *`
- The location of these commands binaries is OS vendor (RHEL, CentOS) and OS version dependent. For instance, with OEL 7.6, `/usr/bin/mount` should be allowlisted for the mount command.
- The specific options for some of these commands can also be OS vendor, OS version and shell dependent. For instance, in the case of BASH shell, the timeout option can be `/usr/bin/timeout --kill-after 5 --signal 1 300s`.
- In the case of RHEL 6.10, the timeout option `preserve-status` is not supported.

Communication Ports for Oracle Database

The following tables list the ports used for external communication when using the Cohesity Oracle adapter.

Ports used for Oracle adapter for Linux and AIX

Port	Source	Target	Direction (from node)	Network Protocol	Usage Notes	Type of Traffic
50051	Cohesity cluster	Oracle Host	Bidirectional	TCP	Linux physical server backups. Used for Cohesity Agent and Agentless data transfer to the Cluster. Needs to be open on all Nodes in the Cluster and any backup target using the Cohesity Agent, such as physical servers and Linux servers running the Cohesity installed Agent.	Backup and Recovery
111	Oracle Host/Cluster	Cohesity cluster	Bidirectional	TCP	NFS restores on Linux physical servers. File restores.	Backup and Recovery
2049	Oracle Host	VIPs and VLAN IPs on Cohesity cluster	Bidirectional	TCP	NFS restores on Linux physical servers.	Backup and Recovery

Port	Source	Target	Direction (from node)	Network Protocol	Usage Notes	Type of Traffic
11111	Cohesity cluster	Disaster recovery cluster	Bidirectional	TCP	Data path handling, I/O Operation Services.	Management

Ports used for Oracle adapter for Windows

Port	Source	Target	Direction (from node)	Network Protocol	Usage Notes	Type of Traffic
50051	Oracle Host	Cohesity cluster	Bidirectional	TCP	Linux physical server backups. Used for Cohesity Agent and Agentless data transfer to the Cluster. Needs to be open on all Nodes in the Cluster and any backup target using the Cohesity Agent, such as physical servers and Linux servers running the Cohesity installed Agent.	Backup and Recovery

Port	Source	Target	Direction (from node)	Network Protocol	Usage Notes	Type of Traffic
11113	Server	Cohesity cluster	Bidirectional	TCP	Oracle backup to Cohesity Cluster	Backup and Recovery
11117 **Note:** If the tcp port 11117 closed while upgrading from 6.6.0d to 6.8.1 the Oracle backup might fail.	Server	Cohesity cluster	Bidirectional	TCP	Oracle backup to Cohesity Cluster	Backup and Recovery

Oracle Precheck Utility

When you perform an Oracle adapter workflow such as a backup, alternate restore, or clone operation, the precheck utility automatically checks permissions, disk space, ArchiveLog mode, and so on, based on the parameters you provided.

The Precheck utility supports both C++ and AIX Java agents for Oracle.

If there are discrepancies with the parameters or the environment (server) where the workflow will run, the precheck utility displays the cause of the discrepancies on the Cohesity Dashboard. You can then resolve the discrepancies and try the workflow again.

Oracle adapter precheck is a utility that performs environmental checks and reporting for the Oracle Adapter. This precheck ensures that all key criteria are met for running any Oracle Adapter workflow.

> **Note:** This feature is supported only for Oracle databases with Linux agent.

How Precheck Utility Works

Before running the Oracle workflows like backup, alternate restore, or clone, the precheck utility performs sanity checks (permission, disk space, ArchiveLog mode, and so on) based on the parameters you provided.

If there is any discrepancy in the parameters you provide or with the environment (server) where the workflow is going to get executed, then the precheck operation fails, resulting in the bailout of Oracle workflow. The precheck utility then displays the cause for the discrepancy on the Cohesity Dashboard to notify the user about the restrictions and prerequisites for the environment and the Oracle adapter workflow.

Performing Prechecks

The precheck utility performs sanity checks for the following Oracle Adapter workflows:

- Discovery
- Backup
- Alternate restore
- Clone

Common Checks

- Checks if the Oracle binaries, SQL Plus, RMAN, oraadm, and srvctl have required access permissions for the Oracle agent for work.
- Checks if the Oracle shared libraries (.so) libsql.so has required access permission for the Oracle agent to work.
- Checks if ORACLE_HOME has required RD/WR permission for the agent to run the backup, restore, and clone workflows.

Discovery

The utility performs the following checks while discovering the DBs on the Oracle Host:

- Checks the password in the case of DB based authentication in Oracle Registration.
- Checks if the Cohesityagent user is part of the DBA group.
- Oracle Home and Oracle Base binaries and libraries are accessible by Agent user and DBA group.
- Checks the access for ORACLE_HOME/rman ORACLE_BASE
- Checks if the ORATAB file is present on the system (generally/etc/oratab).
- For RAC, the precheck utility checks if there is +ASM entry the /etc/oratab.
- Checks if the /etc/oratab entries are valid.

Backup

The utility performs the following checks before running the backup workflow:

- If Archivelog is enabled: If Archivelog is not enabled, you cannot schedule a backup job.
- If Block Change Tracking (BCT) is enabled: If BCT is not enabled, a warning message is displayed on the Cohesity Dashboard and the backup process will experience high latency.
- SYSDBA privilege: Check if the Cohesityagent user (user running Cohesity agent) is part of the DBA group.
- Adequate permission checks on ORACLE_HOME, and Oracle binaries and libs.
- MultiNode-MultiChannel check: In the case of MNMC backup, the precheck utility tries to connect to all the nodes selected for a backup.
- Checks if DB is in READ-WRITE mode for backup.

Alternate Restore

The precheck utility performs the following checks before running the alternate restore workflow:

- Checks if the Cohesityagent user is part of the DBA group.
- Adequate permission checks on ORACLE_HOME, ORACLE_BASE, and Oracle binaries and libs.
- Oracle DBSID: Checks the database whether the same SID exists. If the SID exists, the restore will fail.
- Checks for the datafile space for Alternate Restore.
- Checks for permission and existence of BCT file (if BCT file location is given from Cohesity Dashboard).
- Checks for permission and existence of DIAG_DEST (if DIAG_DEST is provided from Cohesity Dashboard).
- Checks for permission and existence of AUDIT_LOG_DEST (if AUDIT_LOG_DEST is provided from Cohesity Dashboard).
- Checks if the spfile<NEW_DB_SID> or init<NEW_DB_SID>.ora exists in the new ORACLE_HOME when performing the Restore to alternate DB. This check is to safeguard against the existence of DB with the same name in Shutdown state or a deleted DB which is not cleared properly.
- Oracle version: Restore will fail if the source and destination database versions are not the same.
- Oracle DBNAME: Checks whether the database with the same name exists. If the name exists, restore will fail.

- Existence and permission of the path given at the time of alternate restore.
- Disk space availability while performing the alternate restore.
- Existence of Oracle Home, Oracle Base, and the required permissions for these directories.
- Checks if the total memory is more than the SGA target.
- Checks if the Cohesity agent is installed with a different user than the Owning user of Oracle binaries (SQL Plus, RMAN, NID).
- Check the database instance name in /etc/oratab. If it exists, the alternate restore will fail.

Clone

The utility performs the following checks before running the clone workflow:

- Checks if the Cohesityagent user is part of the DBA group.
- Adequate permission checks on ORACLE_HOME, ORACLE_BASE, and Oracle binaries and libs.
- Checks if the Cohesity view is mounted with the correct option (nolock or lock).
- Checks if the spfile<NEW_DB_SID> or init<NEW_DB_SID>.ora exists in the new ORACLE_HOME when performing the Restore to alternate DB. This check is to safeguard against the existence of a DB with the same name in a Shutdown state or a deleted DB which is not cleared properly.
- Oracle compatibility versions: The compatibility is performed by checking the version of SQL Plus in the given ORACLE_HOME_DIR.
- Checks if the total memory is more than the SGA target
- Oracle DBNAME: Checks whether the Database with the same name exists.
- Checks if the Cohesity agent is installed with a different user than the Owning user of Oracle binaries (SQL Plus, RMAN, NID).

Best Practices for Oracle Database

Cohesity recommends you follow these best practices when you plan to deploy the Cohesity Oracle adapter:

- If you use choose to DB authentication, then all the DBs on the system should have the same username and password.
- Optional: Create a database user for Cohesity Oracle backup and restore workflow.
- Both the Oracle and Cohesity user agents should have permission to write to the `adump` and `diag` directories, the control file, and the database restores locations.
- Archivelog mode needs to be enabled to do a backup of an Oracle database opened in Read-Write mode.

- Block Change Tracking (BCT) should be enabled to improve the incremental backup performance of the Oracle adapter.

The following best practices apply only for Oracle adapter for Linux and AIX:

- Assign sudoers to the user running the Cohesity agent.
- Make the Cohesity agent user part of the Oracle `dba` group.
- In the case of a RAC or if you are using an Oracle ASM environment, then the Cohesity agent user should be part of the OSDBA group for ASM (also known as ASMDBA group).

Considerations for Oracle Database

Review the following considerations:

- If the original database is unavailable (disaster recovery scenario) and no pfile/spfile is present, you should start an instance with the same db_name as the original database in NOMOUNT mode before proceeding with an overwrite recovery of the original database from Cohesity.
- Cohesity does not support the backup of Oracle databases on a physical standby (with open_mode set to 'READ ONLY WITH APPLY') in a Data Guard deployed on Windows.
- Cohesity supports restoring a database from Data Guard Standby to standalone oracle database.
- Our incremental forever backup workflow uses Oracle imagecopy. You have to consider that, if the backup is done with SECTION SIZE breaking up the imagecopy, restore of the imagecopy cannot be done in SECTION SIZE as Oracle RMAN restore does not support that. This results in longer restore time as one RMAN channel will have to restore a complete datafile, instead of the possibility of breaking down this datafile into different 'sections' using SECTION SIZE and have multiple RMAN channels to restore the same datafile in parallel.
- Cohesity does not currently support the backup of the Oracle RAC database and Oracle VCS on the Windows server.
- Parallel log backup is allowed only for policy-driven backup and not using the 'run now' option.
- If you are using the Oracle 21c version and the `Oracle Home` location is marked as read-only then the alternate restore and clone jobs on the Cohesity cluster may fail.
- Backup of the read-only database is only supported on the Standby role.
- A replication task of a log backup run of an Oracle Protection Group shows a high amount of "logical data transferred" as it replicates the last successful full/incremental backup data.
- Currently, a single instance is only supported with clones regardless of whether the source is Oracle single instance or Oracle RAC.

- Cohesity recommends performing a full backup before a log backup for the Oracle databases.

Windows

- For alternate recovery with Oracle on Windows adapter, You must use the "`oradim`" tool to create the target database service. You should run this service before the recovery, or the recoveries will fail.
- Before the 6.8.1_u2 release, for Oracle on Windows, if a full backup snapshot is deleted, then all subsequent incremental snapshots are not recoverable until the next full backup is available. From Cohesity release 6.8.1_u2 onwards, you can recover an incremental snapshot without the previous full backup on the Cohesity cluster.

AIX

- After cloning the Oracle database running on the AIX server, you must update `/etc/filesystem` manually to make the mount point used for clone persistent across reboot.
- Instant recovery is not supported for Oracle on AIX.

Install Agents for Oracle Database

This section lists the steps for installing the Oracle adapter agent, registering, and creating protection groups for the Cohesity Oracle adapter.

- Install the Cohesity Oracle Adapter Agent.
- Register the Oracle servers (physical Or virtual server).
- Register the Oracle Database server and authenticate (OS/DB authentication).
- Create a Cohesity Oracle Database Protection Group.
- Set the QoS Policy for the Protection Group.

The following table lists the operating systems and agent installation type when installing the agent on the Oracle server.

Operating System (64 Bit)	Agent Installation Type
RHEL OEL CentOS	Script installer

Operating System (64 Bit)	Agent Installation Type
SuSE Linux	SuSE RPM
AIX (IBM AIX)	BFF Installer
Windows	EXE Installer
Solaris	Solaris Package

For more information on installing the Oracle adapter agent, see:

> **Note:** You must use the same agent installation type (Script or RPM) on all the Oracle RAC nodes

- Installing the Linux Agent
- Installing the AIX Java Agent
- Install the Windows Agent for Oracle Database

Install the Linux Agent for Oracle Database

You can install the Linux agent to run with the ROOT user or a separate OS service account user. For complete details of Oracle Agent installation from different download packaging, please refer to Install and Manage the Agent on Linux Servers.

One of the popular installation packages offered is the Script Installer. Following is a summary of installing the Agent specifically using the Script Installer packaging.

> **Note:** You must use the same agent installation type (Script or RPM) on all the Oracle RAC nodes.

Download the Linux Agent

To download the Linux agent, perform the following steps:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Download Cohesity Agent** near the top-right of the page.
3. Select the **Linux Agent** and choose **Script Installer** as the packaging options
4. Click the download arrow to download the Linux Agent.

Install the Linux Agent to run with the ROOT User

> **Important:** Cohesity recommends installing the Linux Agent as a ROOT user.

For more information on credentials and privileges for ROOT user, see Credentials and Privileges.

For detailed steps on installing the Linux Agent as a ROOT user, Install and Manage the Agent on Linux Servers.

> **Note:** In the case of Oracle RAC deployment, if the Cohesity agent is installed using RPM on one of the nodes, then all the nodes should be installed with an RPM-based installer, and; it is the same for the script installer. You cannot install one of the RAC nodes with RPM and the other with a script installer.

Install the Linux Agent to run with an OS Service Account User

To install the Linux agent on the Oracle server:

1. Run the executable file as a sudo user using the following command syntax:

   ```
   sudo /<path_to_installer_file> -- --install
   ```

   By running the above command, the installer creates the user group, `cohesityagent` and installs the agent.

   If you are running the executable file using the following command options, then the agent will be installed on behalf of the specified user and group.

   - **-S** is the Oracle OS user.
   - **-G** is the group where oracle_user is a member.
   - **-c** prevents the user from being created if it already exists. In case the Customer is installing with -S <existing user> -G <existing Group> then -c should be 0.

   For example,

   ```
   ./cohesity_agent_6.0_x64_installer -- --install -S oracle -G oinstall -
   c 0
   ```

2. Grant sudo permission to the Service Account user who will run the agent.

   The Cohesity agent installer grants sudo permission for the following commands:

   ```
   cp, ls, rm, mount, umount, chown, chmod, mkdir, tee, hostname, stat,
   timeout, rsync, blkid, dmsetup, losetup, lsof, lvchange, lvcreate,
   ```

```
lvremove, lvs, vgs, vgcreate, grep, getcap, getent, service, systemctl,
initctl, systemd
```

Example of the sudoers file addition (actual paths may change):

```
NOPASSWD:/usr/bin/cp, /bin/cp, /usr/bin/ls, /bin/ls, /usr/bin/rm,
/bin/rm, /usr/bin/mount, /bin/mount, /usr/bin/umount, /bin/umount,
/usr/bin/chown, /bin/chown, /usr/bin/chmod, /bin/chmod, /usr/bin/mkdir,
/bin/mkdir, /usr/bin/tee, /usr/bin/hostname, /bin/hostname,
/usr/bin/stat, /usr/bin/timeout, /usr/bin/rsync, /usr/sbin/blkid,
/sbin/blkid, /usr/sbin/dmsetup, /sbin/dmsetup, /usr/sbin/losetup,
/sbin/losetup, /usr/sbin/lsof, /usr/sbin/lvchange, /sbin/lvchange,
/usr/sbin/lvcreate, /sbin/lvcreate, /usr/sbin/lvremove, /sbin/lvremove,
/usr/sbin/lvs, /sbin/lvs, /usr/sbin/vgs, /sbin/vgs, /usr/sbin/vgcreate,
/sbin/vgcreate
```

3. This user must be part of the OSDBA or OSBACKUPDBA group. For more information, see Credentials and Privileges for Oracle Database. Notice that this Service Account user can be a newly created OS user or the 'oracle' user itself.
4. The Agent starts automatically after the installation, as well as on subsequent Oracle host reboot.
5. At the end of the installation, the commands used to start, stop or get agent status will be displayed for future reference.

Install the AIX Java Agent for Oracle Database

You can install the AIX Java agent to run with the ROOT user.

Before You Start

Before you install the AIX Java agent on the server, make sure the following software is installed on the server:

- The latest Bash package. For more information, see AIX Toolbox for Linux Applications.
- Java version, JRE 1.8.0 AIX ppc-64 bit for the agent.

> **Note:** Before installing the AIX Java agent, Cohesity recommends logging in to SQL Plus and RMAN using appropriate credentials (OS Auth or User Based). If the login is successful, proceed with the installation. If not, obtain the required user credentials and verify that you can log in.

Download the AIX Java Agent

To download the AIX Java Agent, perform the following steps:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Download Cohesity Agent** near the top-right of the page.
3. Select the **AIX(java agent)**.
4. Click the download arrow to download the AIX Java Agent.

Install the Cohesity Java Agent to run with the Root User

For detailed steps on installing the AIX Agent as a ROOT user, Install and Manage the Cohesity Java Agent on AIX Servers.

Install the Windows Agent for Oracle Database

> **Note:** Cohesity does not support protection of Oracle RAC Cluster and VCS Cluster running on Windows.

To download and install Windows Agent, perform the following steps:

1. Navigate to **Data Protection > Sources**.
2. Click **Download Cohesity Agents** at the top right of the page.
3. Download the Windows Agent on the Oracle server.

   > **Note:**
   > The SBT plug-in required for Oracle on Windows Adapter will be installed with the Windows agent.

4. As an administrator with local system privileges on that server, run the executable and complete the installation wizard. Ensure that you *do not* select the **Add-ons** components, **Volume CBT (Changed Block Tracker)** and **File System CBT (Changed Block Tracker)** to be installed.

By default, the agent is installed in the **c:\Program Files\Cohesity** directory. Ensure to install the SBT library in the <Cohesity agent installation location>/oracle directory where the Windows Agent is installed.

Install the Solaris Agent for Oracle Database

You can install the Solaris agent to run with the ROOT user.

Before You Start

Before you install the Solaris agent on the server, make sure the following software is installed on the server:

- Oracle's latest bash package running on Oracle Solaris 11 or greater on SPARC v9 (64-bit).
- Java version, JRE 8 for Oracle Solaris SPARC (64 bit) for the agent.

> **Note:** Before installing the Solaris agent, Cohesity recommends logging in to SQL Plus and RMAN using appropriate credentials (OS Auth or User Based). If the login is successful, proceed with the installation. If not, obtain the required user credentials and verify that you can log in.

Download the Solaris Agent

To download the Solaris Agent, perform the following steps:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Download Cohesity Agent** near the top-right of the page.
3. Select the **Solaris**.
4. Click the download arrow to download the Solaris Agent.

Install the Cohesity Solaris to run with the Root User

To install the Solaris agent on the Oracle server:

1. Log in to the Solaris server as a root user and run the following command to install the package:

   ```
   sudo /usr/sbin/pkgadd -d <cohesity_agent_file_path>
   ```

   For example:

   ```
   sudo /usr/sbin/pkgadd -d cohesity_agent_solaris_6.8.1
   ```

2. The Cohesity Solaris Agent starts automatically after the installation. Now you can register the server with the Cohesity cluster. Reboot is not required. The Cohesity Solaris Agent starts automatically after subsequent Oracle host reboots.

Uninstall the Cohesity Solaris to run with the Root User

To uninstall the Solaris agent on the Oracle server:

Log in to the Solaris server as a root user and run the following command to uninstall the package:

```
sudo /usr/sbin/pkgrm cohesity-agent
```

Register Oracle Server

Registering an Oracle server and its databases makes them eligible to be backed up on the Cohesity cluster.

Register Oracle Standalone Source

> **Note:** To register the Oracle Dataguard standalone source, follow the same steps listed below.

1. Navigate to **Data Protection > Sources**.
2. Click **Register** > **Databases** > **Oracle Source**.

   > **Note:** A physical server refers to a bare metal server or a VM running the supported versions of the OS and Oracle Database with the Cohesity agent installed.

3. In the **Select Source Type** drop-down, select **Oracle Standalone Source**.
4. **Enter Host Address**, for an Oracle Standalone server, specify the Hostname, Server IP, or FQDN of the Oracle server.
5. **Authentication Type**, specify the Authentication Type to register the Oracle source.

   When connecting to the Oracle databases, Cohesity can use either the Oracle OS Authentication or Oracle DB Authentication method. If you use DB authentication, provide the database username and password.
6. Click **Register**.
7. Select one of the following options from the **Cohesity Network Interface**:
   - **Auto Select**: If you select this option, the system automatically selects the interface group to use for the VLAN.
   - **Interface Group**: If you select this option, you must select the interface group to use for the source.

   > **Note:** If You select a different interface group from what was selected during the Oracle source registration, the system will use this VLAN for all the objects in the protection job.

If the registration is successful, the registered physical server appears in the list on the **Sources** page. Register this physical server as an Oracle Server to register its databases.

Register Oracle Cluster

Before You Start

Verify the following before registering the RAC source:

1. The system will first scan `/etc/oraInst.loc` on each node of RAC to get the ORA inventory file path to get the GRID HOME location. If the GRID HOME location is present in the inventory file path, we do not need to parse the `/etc/oratab` file to look for GRID_HOME.
2. If GRID HOME is not found in the`/etc/oraInst.loc` file, Cohesity will proceed to look for GRID HOME from `/etc/oratab` file. Entries in the ORATAB file that starts with the '+' character will be considered as ORATAB entries referring to the GRID HOME. One of such example would be the ASM instance, which would have an entry that starts with '+ASM1:' in the ORATAB file. If multiple such entries are found, Cohesity will use the first entry to retrieve the GRID HOME. The following example indicates the ASM instance and its correspond GRID HOME: +ASM3:/u01/app/12.1.0/grid_1:N.
3. The registration should be done using SCAN IP or NAME (Short Name) so that the Cohesity agent will detect it as RAC.
4. The Cohesity agent must be running on all the nodes in the RAC cluster.
5. Choose your Oracle Authentication method: OS Authentication (default) or DB Authentication. For more information, see Credentials and Privileges for Oracle Database.

> **Note:** To register the Oracle Dataguard standalone source, follow the same steps listed below.

To register the Oracle cluster, follow the steps listed below:

1. Navigate to **Data Protection > Sources**.
2. For an Oracle cluster (RAC - Real Applications Clusters or AP - Active-Passive), Click **Register** > **Databases** > **Oracle Source**.
3. In the **Select Source Type** drop-down, select **Oracle Cluster**.
4. **Enter SCAN/VIP Address**, for an Oracle cluster, specify the SCAN IP or NAME (Short Name or FQDN) of the Oracle cluster.
5. **Enter Connect Endpoint (optional)**, specify a reachable endpoint for your Oracle cluster, this endpoint should be reachable the first time when Cohesity discovers the Oracle cluster. This optional endpoint can be provided if the Scan endpoints are not reachable from the Cohesity cluster.
6. **Authentication Type**, specify the Authentication Type to register the Oracle source.

   When connecting to the Oracle databases, Cohesity can use either the Oracle OS Authentication or Oracle DB Authentication method. If you use DB authentication, provide the database username and password.
7. **Cohesity Network Interface**, Select one of the following options to assign the interface group for the Oracle source.

- **Auto Select**: If you select this option, the system automatically selects the interface group to use for the VLAN.
- **Interface Group**: If you select this option, you must select the interface group to use for the source.

> **Note:** If You select a different interface group from what was selected during the Physical source registration, the system will use this VLAN for all the objects in the protection job.

8. Click **Register**.

If the registration is successful, the registered Oracle cluster appears in the list on the Sources page.

Register an Oracle Standalone Database

1. Register a physical server. For steps on how to register a physical server, see Register Oracle Standalone Source.
2. After registering a physical server, select **Data Protection > Sources**.
3. On the **Sources** page, find the server you added to the list.
4. Click the action icon (⋮) for the server and select **Register as Oracle Server**.

   The Register Oracle Source page opens, and some tables are populated automatically. Verify that the hostname is correct.

   > **Note:** If you registered without selecting Physical Server in the previous section, you should populate some of the fields in the Register Oracle Source page manually.

5. Proceed with the instance type discovered by the Oracle database. (Single Instance by default, Oracle RAC or VCS).
6. Choose your authentication preference: OS authentication (the default) or DB authentication. For details, see Credentials and Privileges for Oracle Database.
7. Click **Register**.

If the Oracle Database registration is successful, the discovered Oracle Database instance host appears on the **Sources** page, under **Oracle**.

Register an Oracle RAC Cluster

> **Note:** Cohesity does not support protection of Oracle RAC Cluster running on Windows.

Before You Start

Verify the following before registering the RAC source:

1. The system will first scan `/etc/oraInst.loc` on each node of RAC to get the ORA inventory file path to get the GRID HOME location. If the GRID HOME location is present in the inventory file path, we do not need to parse the `/etc/oratab` file to look for GRID_HOME.
2. If GRID HOME is not found in the`/etc/oraInst.loc` file, Cohesity will proceed to look for GRID HOME from `/etc/oratab` file. Entries in the ORATAB file that starts with the '`+`' character will be considered as ORATAB entries referring to the GRID HOME. One of such example would be the ASM instance, which would have an entry that starts with '`+ASM1:`' in the ORATAB file. If multiple such entries are found, Cohesity will use the first entry to retrieve the GRID HOME. The following example indicates the ASM instance and its correspond GRID HOME:

   ```
   +ASM3:/u01/app/12.1.0/grid_1:N
   ```

3. The registration should be done using `SCAN IP or NAME` (Short Name) so that the Cohesity agent will detect it as RAC.
4. The Cohesity agent must be running on all the nodes in the RAC cluster.
5. Choose your Oracle Authentication method: OS Authentication (default) or DB Authentication. For more information, see Credentials and Privileges for Oracle Database.

Register an Oracle RAC Cluster

The steps for registering an Oracle RAC cluster are the same as registering the Oracle standalone server. For more information, see Register Oracle Standalone Source.

Register an Oracle Veritas Cluster Server

> **Note:** Cohesity does not support protection of Oracle VCS Cluster running on Windows.

1. Navigate to **Data Protection > Sources**. On the **Sources** page, click **Register** > **Physical Server**.

> **Note:** A physical server refers to a bare metal server or a VM running the supported versions of the OS and Oracle Database with the Cohesity agent installed. If you register Oracle without selecting the Physical Server, you should populate some of the fields manually when you register the database.

2. Enter the **VCS VIP** of the VCS cluster and then click **Register**.

   > **Note:** You can enter only one IP address in the field.

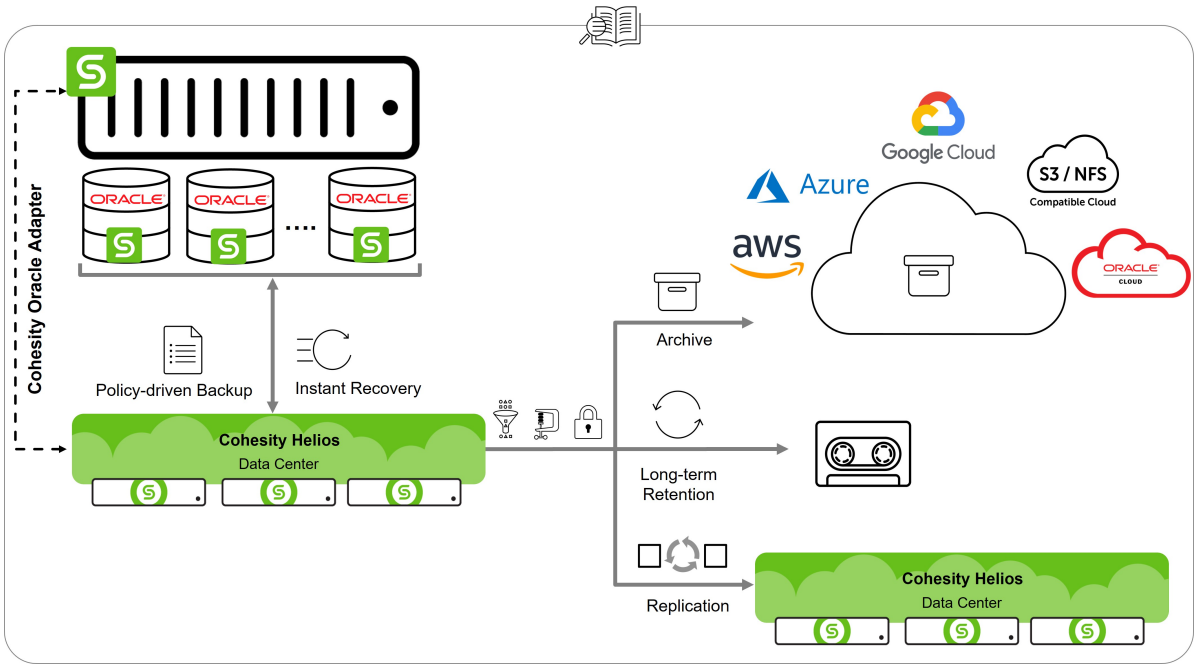
   Use the individual IP addresses or the nodes participating in a VCS cluster to register them as a standalone physical machine.

3. Select one of the following options from the Cohesity network interface:
   1. **Auto Select**: If you select this option, the system automatically selects the interface group to use for the VLAN.
   2. **Interface Group**: If you select this option, you must select the interface group to use for the source.

If the registration is successful, the registered server appears in the list on the Sources page.

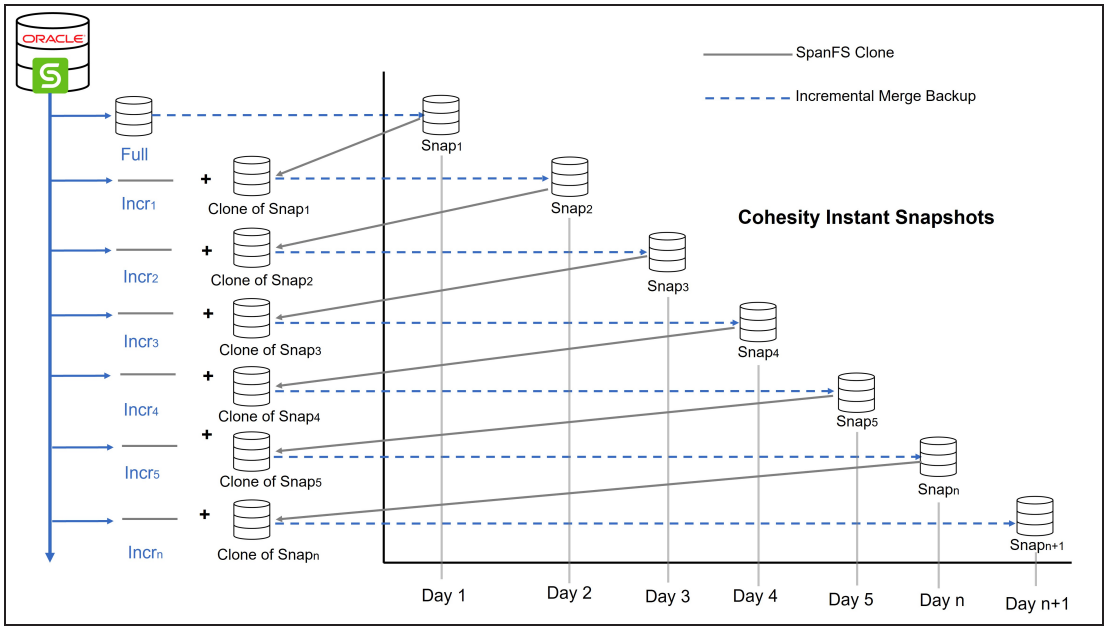
Backup Oracle Database

The Cohesity Oracle adapter performs backup and recovery procedures and protect your Oracle databases against data loss or corruption and reconstructs the data if a data loss occurs.



The Recovery Manager (RMAN) is an Oracle utility that can back up, restore, and recover database files. Cohesity Oracle adapter integrates with Oracle RMAN to deliver an integrated and centralized approach to manage Oracle backup jobs and recovery jobs using a single dashboard.

Cohesity uses the Incremental Merge capability of the Oracle database to create an image copy of a database and periodically update the image copy by merging incremental changes into a new backup copy. The resulting image copy can be used for restore and recovery, duplicating databases, and switching a database to the image copy as shown below.



Cohesity Oracle Adapter Performance

Cohesity Oracle adapter supports multi-threading using multiple RAC nodes and multiple channels for improving backup performance and uses RMAN channels creation Logic given below:

```
RMAN channels=MIN(2* # of Cohesity nodes, 2* # of target server CPU
```

> **Note:**
> From Cohesity version 6.4, the backup channels on a single instance and RAC database nodes can be increased from default to 64. (However, the limit from Oracle is 255 channels).

Protect Oracle Database

When you create a protection group, you can select an existing source, policy and storage domain or you can also register a new oracle source, or create a new policy or create a new storage domain while creating a new oracle protection group. However, you might find it easier to create them before creating the protection group, as described in the following topics.

- Register Oracle Server
- Create or Edit a Standard Policy
- Create or Edit Storage Domains

> **Note:** You can now protect Oracle databases through an Oracle adapter and SBT plugin on Linux Oracle servers running in dual-stack mode(IPV4 and IPV6). This applies to both RAC and standalone Oracle servers.

Create a Protection Group

Follow the steps listed below to create a Protection Group for the Cohesity Oracle adapter:

1. Navigate to **Data Protection > Protection** and do one of the following:
   - To create a job, click **Protect** > **Databases** > **Oracle Database**, where *Job Type* is the type of the Protection Group.
   - Alternatively, click the action icon (⋮) next to the job and select the appropriate options.
     - **Run Now**: Start a run of this Protection Group. You have the option to back up one or more objects.

- **Backup**: Select the objects you want to backup during the protection group run.
- **Backup Type**: If the policy supports multiple backup types, you can select an **incremental**, **full**, or **log** backup.

  If the policy associated with the Protection Group is configured with replication and archive targets, you can select those targets and set the archive parameters.

  If you select **Logs** as the backup type, after the log backup run is completed, the logs will be archived to the target configured in the policy.

  > **Note:** When archiving Oracle archive logs, the logs are stored locally and not archive retention specified in the policy.

- **Resume**: Resumes the paused protection job run.
- **Edit**: Edits the selected protection group.
- **Delete**: Deletes the selected protection group.

2. In the **New Protection** pop-up, do one of the following:
   - Protect the Oracle database by specifying a subset of options such as objects, protection group and policy by clicking the edit icon corresponding to the following options:
     i. **Add Objects**: Select the registered Oracle source or click **Register Source** to register an Oracle source. Select the database instances to protect.
     ii. **Protection Group**: Specify a name for the Protection Group.
     iii. **Policy**: Select an existing policy or click **Create Policy** to create a new protection policy.
     iv. **Storage Domain**: Select the appropriate storage domain.

     > **Note:** This option is visible on the **New Protection** pop-up only if there is more than one storage domain.

     v. Click **Protect**.
   - To protect the Oracle database by specifying all the options, click **More Options**.
3. On the New Oracle Job page, enter the **Job Title** and select the **Sources** from the list.

You can either specify an existing protection group or create a new one

4. On the Oracle Servers page, select the database instances to protect, and then click **Add**.

   When creating a new Protection Group, a shield next to the Object name indicates the Object is already been protected by another Protection Group.

   Click the icon to see details about the object.

   If the object name is in red, it is inaccessible, invalid, or orphaned. If the object is in one of the specified states when the Protection Group runs, no snapshot is created. If the object becomes accessible, a snapshot is created the next time the Protection Group runs.

   The New Oracle Job page returns. Under Objects, verify that the database instances you selected are listed.

5. Set the policy for your Protection Group. Under **Policy**, select the appropriate Protection Policy, choose one of the defaults (Bronze, Silver, or Gold), or create a New Policy if the available policies do not meet your schedule and retention needs.

   For Oracle databases running on Windows OS, you must create or select a policy with the **Periodic Full Backup** option set.

   > **Note:**
   > - For Oracle RAC databases, you can now choose one, some, or all of the RAC system nodes for backups or restores.
   > - If the protection job includes standby databases, there's a risk that incremental or full backups may miss some logs needed for recovery. These logs will be captured in later backups, depending on when the standby databases received them. To mitigate this, log backup snapshot retention should match that of incremental/full snapshots.
   >
   >   If the incremental/full snapshots lack all necessary logs for recovery, the backup process will issue a warning indicating that the "Backup may not be self-sufficient."

> **Tip:** If the object name is in red, it is inaccessible, invalid, or orphaned. If the object is in one of the specified error states, it can still be added to a Protection Group. However, during the Protection Group run, no snapshot for the object will be created. If the object becomes accessible, a snapshot is created the next time when the Protection Group runs.

6. Click the edit icon next to the selected Object and depending on the operating system of the server, set the following options for the Object, and then click **Save**.

Options	Description	
	Linux	**Windows**
System selects active node	Cohesity will auto-select an active RAC node and configure the number of RMAN channels for the database object. This option is enabled by default.	In the **SBT Library Path** field, specify the path to the Cohesity SBT Library. Cohesity SBT Library is installed on the Oracle Server along with the Cohesity Agent. This option is enabled by default.
Select specific nodes	For the RAC database, If you select this option, you can choose the number of RAC nodes and the number of RMAN channels and port to be used for each RAC node of the database object. For a standalone database, if you select this option, you can choose the number of RMAN channels and port to be used for the node of the database object.	You can also select this option and to specify the path to the Cohesity SBT Library and to configure the number of RMAN channels for the database object.
Update Database credentials	Enable this option to provide the updated database credentials of the user with SYSDBA privilege.	NA

Options	Description	
	Linux	Windows
Delete Archive Log	Toggle on and specify the days after which the archived logs on the source database should be deleted. If you specify the value as "0" days, source archived logs will be deleted immediately after each successful Cohesity backup. If you choose this option, Cohesity issues `RMAN DELETE ARCHIVELOG` command to delete archived logs after each successful Cohesity backup. Logs are deleted if they are backed up at least once by RMAN and they are older than the days specified in this option. In addition, if you have archived logs not backed up previously by Cohesity and the time satisfies the log delete eligibility, then these logs will be deleted. However, If you do not enable this option, Cohesity will not delete the archived logs after each Cohesity backup. If you are using the “Oracle RMAN archived log delete policy” to manage archived logs deletion on this database, depending on the policy, it may prevent Cohesity from deleting the archived logs as Oracle manages the policy. If you have upgraded Cohesity Data Cloud (both the Cohesity cluster and Cohesity agent) from a previous version, then the archived logs for the existing Protection Group will not be deleted. Starting with release 6.4.1, the archived logs are not deleted by default.	

Options	Description	
	Linux	Windows
Data Guard role-based backup	Enable the Data Guard role-based backup option to back up Oracle databases according to their role in the Data Guard configuration. Options include: • **Backup when in Primary role**: Choose this option to back up the database if it is in the Primary role only. • **Backup when in Standby role**: Choose this option to back up the database if it is in the Standby role only. Allow backup of archive logs in the Standby/Primary role: If your Protection Policy includes log backup configuration, this enables exclusive log backup based on the database role defined in the Data Guard configuration. If you choose the Backup when in the Primary role option, this allows backing up archive logs when the database is in the Standby role. Conversely, if you choose the Backup when in Standby role option, this allows backing up archive logs when the database is in the Primary role. This ensures the continuity of Cohesity's log backups during Data Guard role transitions and supports Oracle's archived log deletion, provided the feature is enabled on the Cohesity cluster. > **Note:** Enabling this option may increase backup storage requirements due to the additional log backups.	

7. Specify the number of channels to use for each node and a single instance DB.
8. Select the appropriate **Storage Domain**.

   A Storage Domain defines the level of storage efficiency, security, and resilience for the data being protected in Cohesity Data Cloud. In a Storage Domain, you can enable or disable deduplication, compression, and/or encryption for the domain, and select the necessary level of resilience (that is, the number of faults tolerated).

   If a Storage Domain with the right settings exists, select that one. Otherwise, create a new one with Add Storage Domain. See Create or Edit Storage Domains.

   If you need to create a new Storage Domain:

   - You can enable or disable deduplication and compression at any time.
   - You can enable or disable encryption only when you create the Storage Domain for the first time.

- There are no benefits if you perform deduplication and compression on the encrypted data.

9. After selecting a Storage Domain, if you need to change any of the Advanced settings on the New Oracle Job page, scroll down and click **Edit** on the right.

Advance Settings	Description
Start Time	Available only if the selected policy is set to Backup Daily. Indicates when the job should run. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the job by selecting a different time zone.
End Time	Optional. Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts prior to this date runs until completion even if it completes after this date.
QoS Policy	Select an appropriate quality of service (QoS) policy. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups. • **Backup Auto**: The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. This option is selected by default. > **Note:** In the 6.6.0a release, The Backup Auto option is available only on the C6000 Series. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.

Advance Settings	Description
Pre & Post Scripts	Edit this option to run scripts on the protected server before and/or after a Protection Group runs. If the Protection Group is protecting Oracle databases from different hosts, then the pre and post scripts are executed for each Oracle server. For more details, see Configure Pre & Post Scripts.
NFS Protocol	Select the NFS protocol version for the backup job. Options include NFSv3 and NFSv4.1. **Note:** • NFS protocol is not supported when performing an SBT backup. • NFS protocol is not supported for Windows and AIX databases.
Persist Mountpoints	If you enable this option, NFS mounts created during the Oracle database backup job are retained after the job is completed. Disabling this would remove the NFS mounts after the backup job is completed. By default, this option is enabled. You can disable this if needed.
Alerts and Priority	Optional. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts.
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of jobs exceeds the ability to process jobs, this will be the priority of implementation of the jobs: 1. High-priority jobs 2. Medium-priority jobs 3. Low-priority jobs.
Email Recipients	You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the job.

Advance Settings	Description
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).
Cluster Interface	Select one of the following options to assign the interface group for the protection group. • **Auto Select**: Toggle on this option if you want to use the same interface group that was selected during the Oracle source registration. • **Interface Group**: Select the interface group to use for the backup. **Note:** If You select a different interface group from what was selected during the Oracle source registration, the system will use this VLAN for all the objects in the protection job.
Description	Optional. Click the plus sign and enter a description for the Protection Group.

10. **Run Now**: Start a run of this Protection Group. You have the option to back up one or more objects.

    If the policy associated with the Protection Group is configured with replication and archive targets, you can select those targets. If the policy supports multiple backup types, you can select an **incremental**, **full**, or **log** backup.

    If you select **Logs** as the backup type, after the log backup run is completed, the logs will be archived to the target configured in the policy.
11. Click **Protect**.

Your Protection Group runs appear in the list on the Protection Groups page.

Download Debug Logs for Oracle Backup Jobs

You can now download the debug logs (`rman_shell.INFO`, `precheck_logs.INFO`, `alert_log.INFO`, `tnsnames_ora.INFO`, `sparse-db-config.txt`) as a compressed file for both successful and failed backup runs.

To download the debug logs:

- **For a job run**: To download the debug logs for a job run, click the **Options** (⋮) icon next to a completed or a failed job run and select **Download Debug Logs** to download debug logs for all the databases in the job.
- **For a Specific database within the job run**: Optionally, you can download logs for a specific database within the job run. Click the **Options** (⋮) icon next to a database and select **Download Debug Logs**.

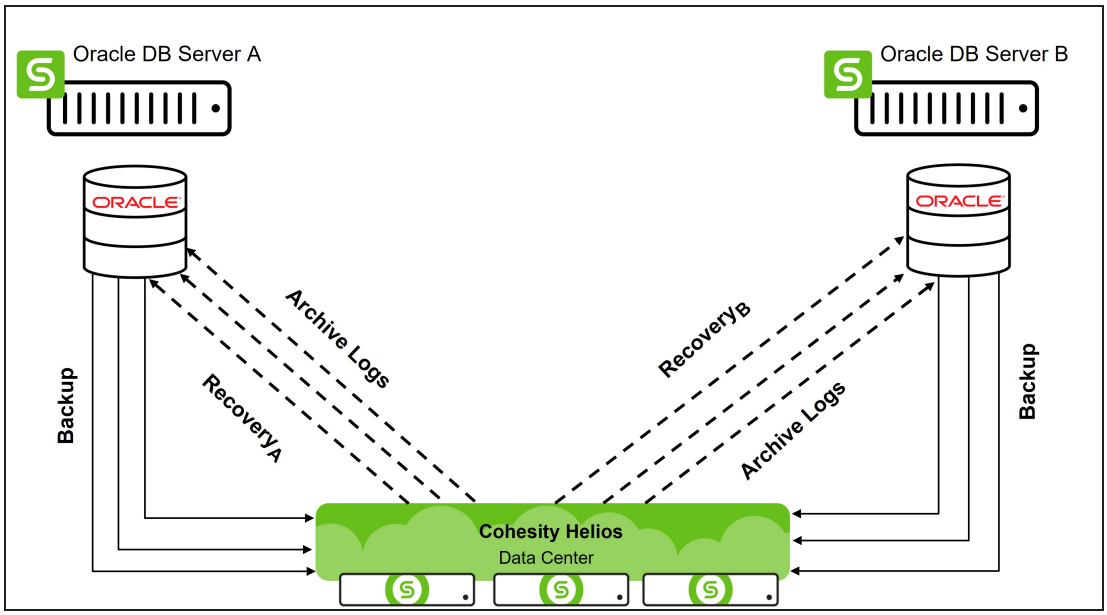
> **Note:** You can download the debug logs only if the local snapshot is available on the Cohesity cluster.

Once your Protection Group completes its first run, the database will be ready for recovery, replication, and archival.

Recover Oracle Database

The Cohesity Oracle adapter performs recovery procedures to restore a physical backup of a data file or control file and make it available to the Oracle database server using the Recovery Manager (RMAN).

Cohesity integrates with the Oracle Recovery Manager (RMAN) to restore data files from backup sets or image copies on disk, either to their current location or to a new location. RMAN automatically restores the archived logs that are needed for recovery and deletes them after the recovery is finished as shown in the illustration below.



The Cohesity Oracle adapter uses the Incremental Merge capability of the Oracle database to perform a backup of database files. The Incremental Merge process involves IMAGE COPY backups that are typically indistinct copies needing redo to be applied to make them consistent. The process makes use of a single RMAN script for backup and restore. The

merge process creates a single backup dump that you can use for instantaneous recovery of the backed-up data.

Oracle Database Restore Types

The following options are available for an Oracle database recovery:

Recovery Type	Single Instance	RAC	VCS
Overwrite Existing Database	Original Oracle Server	Original Oracle RAC Server	Original Oracle VCS Server
As a new database	Original Oracle Server*	Standalone DB on ASM	Original VCS Oracle Server
	Alternate Oracle Server	Standalone DB on ASM	Alternate VCS Oracle Server

*If you are restoring the Oracle database to the original server as a new database, then you must manually enter the new database name in the **tnsnames.ora** file.

Considerations for Oracle Restore

Review the following considerations before you restore from the Oracle RMAN tool and is applicable for the Cohesity Oracle Adapter.

- Cross-platform Oracle database restore is not supported. (for example, Linux vs Other : AIX, SLES, HP UNIX, etc.)
- Restore across versions is not supported (for example, restoring 11G database to 12c and vice versa)
- Restore from the incremental snapshot is not supported when there is no preceding full backup (as it might have expired) for Oracle on Windows backups.

Recover Oracle Database

Enterprise customers may choose to use the Oracle container Database (CDB) model to leverage the benefits in consolidation and data management. This configuration is also known as Oracle’s multitenant (MT) architecture.

A CDB includes zero, one, or many customer-created pluggable databases (PDBs). A PDB is a portable collection of schemas, schema objects, and non-schema objects that appear to an Oracle Net client as a non-CDB.

Cohesity now supports fully automated data protection and management for Oracle CDBs and PDBs Cohesity provides flexible data protection capabilities at both the CDB and PDB level.

To recover a recent or previous backup of an MT and non-MT Oracle Database, perform the steps listed below.

1. Navigate to **Data Protection > Recoveries** > **Recover** > **Databases** > **Oracle**.
2. In the Recover page, search for the Oracle instance that needs to be restored or use a wildcard name to search for a specific database instance.
    a. **CDB**: Search the Oracle CDB that you want to restore.
        i. Select the entire CDB (with all the PDBs) or a CDB and a subset of PDBs associated with that CDB for restore.
        ii. Select the CDB and click **Next**.
    b. **PDB**: Search for the Oracle PDB that you want to restore.
        i. You can either search for the parent CDB associated with the PDB or directly search for the PDB.
        ii. Select the PDB and click **Next**.
    c. **Oracle Database**: Search for the Oracle Database you want to restore.
3. Accept the latest **Recovery Point** or click the change icon ( ) and select a different recovery point.
    1. **Snapshots**: Select a different recovery point. You can change the time zone before or after selecting a new restore time.
    2. **Point in Time**: Use the slide control to adjust the date and time and click **Save**.
4. After you select an instance for recovery, configure these fields in the Recover page:

Alternate CDB/PDB

Provide the following information to **Alternate CDB/PDB/Database**:

> **Note:**
> - If restoring to an alternate Oracle server, the Oracle server must be registered with Cohesity before you perform the restore operations. Ensure that the Cohesity Oracle agent is installed on the Oracle server.
> - PDB alternate restore jobs will fail if the target CDB is registered with DB Authentication.

Field Name	Description

Alternate CDB/PDB	• **Oracle Host and RACs**: The host to which to restore the database.
	• **Configure Channels**: Click these options to configure the following:
	• **System selects active node**: If you select this option, Cohesity will select the channels for the recovery job.
	• **Select specific nodes**:
	  • **Hostname**: Select the hostname to which you want to perform the restore.
	  • **Node**: Select the node to which you want to perform the restore. This option is valid only in the case of a multi-node cluster.
	  > **Note:** In the case of PDB alternate restore it is mandatory to select the node as we have to provide the target CDB instance name.
	• **Channels**: Specify the number of channels to perform the restore job. The system will run these channels in parallel to improve the restore performance.

Field Name	Description

Recovery Options	• **Restore Database Files to**: Specify the path to an existing empty directory. The newly created database files will reside in this path.
	
	> **Note:** You can restore to an ASM path using this option. Specify just the ASM volume name instead of the entire path. Example: The restore path for ASM volume data1 is +data1. If you specify the entire path, +data1/dbname the restore job will fail.
	
	• **Oracle Home**: The ORACLE_HOME value for the host where the database is restored.
	• **Base Directory**: The directory for the restored database.
	• **Target Database Name**: The name for the alternate CDB database.
	
	If you are restoring a PDB, you must provide the target CDB on to which the PDB is restored.
	
	> **Note:** When recovering to an alternate location, make sure a database with the same name does not exist on the Oracle server instance. Otherwise, the recovery task will fail.
	
	• **Pfile Parameters**: The Pfile parameters option allows you to see the target database parameters before the restore job is initiated. The Pfile inherits some source database parameters to the target database and allows you to edit the target database parameters based on your requirement by specifying the additional parameters as a `key=value` pair.
	
	The Pfile lists the following parameters:
	
	  • **Default Parameters**: Default parameters of the target database and you can edit the default
	  • **Inherited Parameters**: Parameters from the source database and you can edit the inherited parameters, if required.
	  • **Restricted Parameters**: You cannot edit the restricted parameters in the Pfile. The following are the restricted parameters:
	  • INSTANCE_NAME
	  • DB_NAME
	  • DB_UNIQUE_NAME
	  • DB_BLOCK_SIZE

Field Name	Description
	• MAX_STRING_SIZE • COMPATIBLE If you edit the following values in the **Recover Oracle** GUI, You must click the **Reset** button on the top-right corner to reset the Pfile and get the updated parameter values in the Pfile box. • Restore database files to • Oracle Home • Oracle Base • Database Name Cohesity Platform will create a target database with the specified parameters in the Pfile. For example, if `SGA_TARGET` is specified as a part of the Pfile parameters, the restore operation will use the value specified in the Pfile during the restore. > **Note:** Customizable pfile functionality is not supported for archival backups. • **NFS Protocol** - Select the NFS protocol version for the recovery job. Options include NFSv3 and NFSv4.1. > **Note:** NFS protocol is not supported for Windows and AIX databases. • **Rename Database**: Rename the database, if required. • **Enable Archive Log mode for the Database**: Select the checkbox if you want to enable the redo log archiving on the recovered database. • **BCT File Path**: The BCT file path specifies the location where the block change tracking file will be created. If not provided, BCT is not enabled for the restored database. • **Number of Temporary Files to Use**: Number of temp files to rename from the source database. • **Redo Log Group Settings**: The Redo log group configuration stores all changes made to the database as they occur. Every instance of an Oracle Database has an associated redo log to protect the database in case of an instance failure. You can provide the number, size, and prefix of redo log groups along with the redo log group member path for the recovery database.

Field Name	Description

	• **Leave Database in Recovery Mode**: Select the checkbox if you do not want the recovered database to be opened.
	• **Shell Environment**: Toggle on the Shell Environment to configure your shell environment that executes the Cohesity restore workflow using this setting. For example, when restoring the Oracle EBS database, the restore environment often needs to define a different TNS_ADMIN value to use a different sqlnet.ora file in the same Oracle Home shared with other databases. You can use Shell Environment to define your TNS_ADMIN shell variable here to point to a different sqlnet.ora file to be used for your restored target database. For TDE support, the wallet location for your restore target database may depend on a shell variable. This is the case when your restored database wallet location is specified either by the ENCRYPTION_WALLET_LOCATION or WALLET_LOCATION keyword in your sqlnet.ora file. A typical value for these parameters will reference a shell variable.
	For Example,
	`ENCRYPTION_WALLET_LOCATION=(SOURCE=(METHOD=FILE) (METHOD_DATA=(DIRECTORY=/etc/ORACLE/WALLETS/$ORACLE_UNIQUE_NAME/)))`
	In this example, you will need to set ORACLE_UNIQUE_NAME in the SHELL ENVIRONMENT setting in the GUI to set up the Cohesity restore shell environment for the Oracle restore to find the Keystore.
	• **Source CDB Keystore Password**: The source CDB keystore password is the same as that of the source CDB, duplicated on the target CDB host. This duplicated keystore is necessary for the PDB alternate restore workflow, which temporarily clones the source CDB onto the target CDB host.
	You can configure the location of the duplicated keystore using the WALLET_ROOT pfile parameter or the ENCRYPTION_WALLET_LOCATION parameter in the sqlnet.ora file. Consider the following guidance to determine the best location for the duplicated keystore.
	Consider the following guidance to decide the location of the duplicated keystore.
	  • Configuring the keystore location using WALLET_ROOT is recommended if the database version is 18c or above.
	  • If WALLET_ROOT is configured in the pfile, TDE_CONFIGURATION must be set to 'KEYSTORE_CONFIGURATION=FILE'.
	  • If ENCRYPTION_WALLET_LOCATION of the sqlnet.ora file is used to determine the keystore location, don't include variables such as ORACLE_SID in the path because the temp cloned DB instance name/SID are dynamically

Field Name	Description
	generated. • If the sqlnet.ora file is not in the default directory $ORACLE_HOME/network/admin, add its directory to the shell environment variable in the Cohesity UI of the PDB alternate restore. • The duplicated keystore can be deleted after the PDB alternate restore is finished. **Use External Store** Enable this option to utilize the external store for the password of the duplicated keystore from the source CDB, rather than entering the password manually in the UI. The external store must be the 'file tde_seps/cwallet.so' at the path specified by the WALLET_ROOT pfile parameter or cwallet.so at the location indicated by the EXTERNAL_KEYSTORE_CREDENTIAL_LOCATION pfile parameter. • **Target CDB Keystore Password**: The Target CDB keystore password protects the Keystore for the Target CDB and must be unlocked before the PDB alternate restore. **Use External Store** Enable this option to utilize the external store for the password of the duplicated keystore from the target CDB, rather than entering the password manually in the UI. The external store must be the 'file tde_seps/cwallet.so' at the path specified by the WALLET_ROOT pfile parameter or cwallet.so at the location indicated by the EXTERNAL_KEYSTORE_CREDENTIAL_LOCATION pfile parameter. • **Cluster Interface**: Select one of the following options to assign the interface group for the recovery job. • **Auto Select**: Toggle on this option if you want to use the same interface group that was selected during the Oracle source registration. • **Interface Group**: Select the interface group to use for the recovery. If You select a different interface group from what was selected during the Oracle source registration, the system will use this VLAN for the recovery job. • **Use NOFILENAMECHECK**: Using NOFILENAMECHECK forces RMAN to skip checking whether target datafile names are the same as source datafile names. **Warning:** Use NOFILELNAMECHECK with caution, as this restore can inadvertently clobber the source datafiles if restored back to the source host.

Field Name	Description
	> **Note:** Some restore use case requires restoring the datafiles and/or online logfiles using the same names and file paths as the source database, but to a different host (i.e. not restoring back to the source database host). For example, using this restore to create a standby database of the source database with exactly the same directory structure on a different host. In this case, it is required to set the 'Use NOFILENAMECHECK' option for this Cohesity Alternate Restore. • **Customize Destination Paths with SET NEWNAME**: Use the SET NEWNAME command to define a new location for individual datafiles, tempfiles, tablespaces, or the whole database. If not specified, Cohesity uses DB_FILE_NAME_CONVERT, if not empty. Otherwise, it uses your input to restore the destination location. Use SET NEWNAME specifications to determine the location of your restored datafiles and logfiles You can specify DB_FILE_NAME_CONVERT together with this option to augment paths that are not affected by DB_FILE_NAME_CONVERT. Syntax Example: `SET NEWNAME FOR DATAFILE 1 TO 'u01/home/test_1.dbf';` • **Task Name**: (Optional) Provide the name for the recovery task.

Overwrite Original CDB/PDB/Database

> **Note:** For PDB overwrite restore, PDB can be rolled back only within the current CDBs set.

Provide the following information to **Overwrite Original CDB/PDB**:

Field Name	Description
Overwrite Original CDB/PDB	• **Oracle Host and RACs**: The host to which to restore the database.

Field Name	Description

Recovery Options	• **View Name Identifier**: A view will be created with this name as identity.
	• **Leave Database in Recovery Mode**: Select the checkbox if you do not want the recovered database to be opened.
	• **NFS Protocol** - Select the NFS protocol version for the recovery job. Options include NFSv3 and NFSv4.1.
	> **Note:** NFS protocol is not supported for Windows and AIX databases.
	• **Shell Environment**: Toggle on the Shell Environment to configure your shell environment that executes the Cohesity restore workflow using this setting. For example, when restoring the Oracle EBS database, the restore environment often needs to define a different TNS_ADMIN value to use a different sqlnet.ora file in the same Oracle Home shared with other databases. You can use Shell Environment to define your TNS_ADMIN shell variable here to point to a different sqlnet.ora file to be used for your restored target database. For TDE support, the wallet location for your restore target database may depend on a shell variable. This is the case when your restored database wallet location is specified either by the ENCRYPTION_WALLET_LOCATION or WALLET_LOCATION keyword in your sqlnet.ora file. A typical value for these parameters will reference a shell variable.
	For Example,
	`ENCRYPTION_WALLET_LOCATION=(SOURCE=(METHOD=FILE)(METHOD_DATA=(DIRECTORY=/etc/ORACLE/WALLETS/$ORACLE_UNIQUE_NAME/)))`
	In this example, you will need to set ORACLE_UNIQUE_NAME in the SHELL ENVIRONMENT setting in the GUI to set up the Cohesity restore shell environment for the Oracle restore to find the Keystore.
	• **Cluster Interface**: Select one of the following options to assign the interface group for the recovery job.
	  • **Auto Select**: Toggle on this option if you want to use the same interface group that was selected during the Oracle source registration.
	  • **Interface Group**: Select the interface group to use for the recovery.
	If You select a different interface group from what was selected during the Oracle source registration, the system will use this VLAN for the recovery job.
	• **Perform point-in-time incomplete recovery** - Select this option to recover the Oracle database from media failures, tablespace corruption, or tablespace being dropped

Field Name	Description
	accidentally. The database can be restored till the backup is available with Cohesity. Optionally the database can also be rolled forward, if archive logs are still available on the Oracle host . Using this option database will open with the RESETLOGS option. By default, this option is selected. • **Attempt complete recovery** - Select this option to roll forward the databases from the latest backup available with Cohesity. For a complete recovery to succeed, you must have the complete set of archived logs (after the last Cohesity backup), current control file, and online redo logs available on your source database host. If complete recovery is successful database will open with "ALTER DATABASE OPEN" and if the complete recovery attempt failed database will be open with the RESETLOGS option. • **Task Name**: (Optional) Provide the name for the recovery task.
Roll Forward	You can use the Roll Forward recovery option to restore the Oracle databases to the state it was in just before the failure occurred. We will auto-select the latest backup available and apply the provided archive logs to roll-forward the database. The following inputs will be needed: • **Archive log location**: Path at which archive logs are present on the source Oracle host. In the case of a clustered Oracle host, this location can be an ASM path or a path that is present (shared) in all the cluster nodes. • **Restore point-in-time**: Optional field to specify the date-time to which the database must be rolled forward. This date-time must be in the future of the latest Cohesity backup. If nothing is specified, then the database will be restored at the latest time possible. If the Roll Forward option is disabled the database will be restored to the selected point-in-time. **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

Create Cohesity View with DB Files - CDB/PDB/Database

Provide the following information to **Create Cohesity View with DB Files**:

Field Name	Description
Create Cohesity View with DB Files - CDB/PDB	• **Oracle Host and RACs**: The host to which to restore the database.

Recovery Options	• **View Name Identifier**: A view will be created with this name as identity.
	• **Cluster Interface**: Select one of the following options to assign the interface group for the recovery job.
	  • **Auto Select**: Toggle on this option if you want to use the same interface group that was selected during the Oracle source registration.
	  • **Interface Group**: Select the interface group to use for the recovery.
	If You select a different interface group from what was selected during the Oracle source registration, the system will use this VLAN for the recovery job.
	• **NFS Protocol** - Select the NFS protocol version for the recovery job. Options include NFSv3 and NFSv4.1.
	Note: NFS protocol is not supported for Windows and AIX databases.
	• **Task Name**: (Optional) Provide the name for the recovery task.

Instant Recovery - CDB/Oracle Database (Standalone and RAC)

Note:

- The Instant Recovery workflow is applicable only for CDB and Oracle Databases.
- Instant recovery will be slower as compared to running a DB on primary till the migration is completed.

Instant Recovery provides near-instant RTO for databases. This is particularly helpful in disaster recovery situations and in cases where complete database failure or downtime can have a significant business impact on the users.

With the Oracle Instant Restore functionality, you can quickly bring up the Oracle databases similar to the Clone operations. Once the database is successfully brought

up, you can choose to migrate the DATAFILES and LOGFILES from the Cohesity storage to the target Oracle host while the newly restored Oracle database is active and open for read-write operation.

The migration operation in the Instant Restore is seamless, and there is no downtime of the Oracle database. Hence using this functionality, you can achieve a near-instant RTO for the Oracle databases.

> **Note:** The Instant Recovery functionality is supported from Oracle 12c and later.

Provide the following information to **Instant Recovery**:

Select one of the following options to proceed with the instant recovery of the source database:

Instant Migration

If you select this option, the database will be brought up, but the DATAFILES and LOGFILES are present in the Cohesity storage. This is similar to the Clone procedure of the Cohesity recovery workflow for Oracle.

> **Note:** The Instant Recovery functionality is only applicable to Linux platform.

Manual Migration

In manual migration, you will need to manually migrate the DATAFILES from Cohesity storage to your source database. An option for migration will be available on the Restore page, after successful restore.

To start the database migration, provide the following details:

Field Name	Description
Instant Recovery	• **Oracle Host and RACs**: The host to which to restore the database. • **Disaster Recovery** - If this option is enabled, it creates a clone database using the same database name, database ID, and database parameters as the original database. After migration, all database files will be restored to the original location of the source database. > **Note:** If the disaster recovery option is selected, you cannot change the host to which the database is restored to. **Configure Channels** - If **Disaster Recovery** is enabled, the **Hostname** and **Node IP** of the host are selected by default. You can specify the number of Migration Streams to perform the restore job. If **Disaster Recovery** is disabled, then share the following details: • **System selects active node**: If you select this option, Cohesity will select the channels for the recovery job. • **Select specific nodes**: • **Hostname**: Select the hostname to which you want to perform the restore. • **Node IP**: Select the node to which you want to perform the restore. This option is valid only in the case of a multi-node cluster. > **Note:** In the case of PDB alternate restore it is mandatory to select the node as we have to provide the target CDB instance name. • **Channels**: Specify the number of channels to perform the restore job. The system will run these channels in parallel to improve the restore performance.

Field Name	Description
Recovery Options	• **Shell Environment**: Toggle on the Shell Environment to configure your shell environment that executes the Cohesity restore workflow using this setting. For example, when restoring the Oracle EBS database, the restore environment often needs to define a different TNS_ADMIN value to use a different sqlnet.ora file in the same Oracle Home shared with other databases. You can use Shell Environment to define your TNS_ADMIN shell variable here to point to a different sqlnet.ora file to be used for your restored target database. For TDE support, the wallet location for your restore target database may depend on a shell variable. This is the case when your restored database wallet location is specified either by the ENCRYPTION_WALLET_LOCATION or WALLET_LOCATION keyword in your sqlnet.ora file. A typical value for these parameters will reference a shell variable. For Example, `ENCRYPTION_WALLET_LOCATION=(SOURCE=(METHOD=FILE) (METHOD_DATA=(DIRECTORY=/etc/ORACLE/WALLETS/$ORACLE_UNIQUE_ NAME/)))` In this example, you will need to set ORACLE_UNIQUE_NAME in the SHELL ENVIRONMENT setting in the GUI to set up the Cohesity restore shell environment for the Oracle restore to find the Keystore. • **NFS Protocol** - Select the NFS protocol version for the recovery job. Options include NFSv3 and NFSv4.1. **Note:** NFS protocol is not supported for Windows and AIX databases.

5. Toggle on the **Shell Environment** to configure your shell environment that executes the Cohesity restore workflow using this setting. For example, when restoring the Oracle EBS database, the restore environment often needs to define a different TNS_ADMIN value to use a different sqlnet.ora file in the same Oracle Home shared with other databases. You can use Shell Environment to define your TNS_ADMIN shell variable here to point to a different sqlnet.ora file to be used for your restored target database. For TDE support, the wallet location for your restore target database may depend on a shell variable. This is the case when your restored database wallet location is specified either by the ENCRYPTION_WALLET_LOCATION or WALLET_LOCATION keyword in your sqlnet.ora file. A typical value for these parameters will reference a shell variable.

   For Example,

   ```
   ENCRYPTION_WALLET_LOCATION=(SOURCE=(METHOD=FILE)
   (METHOD_DATA=(DIRECTORY=/etc/ORACLE/WALLETS/$ORACLE_UNIQUE_NAME/)))
   ```

In this example, you will need to set ORACLE_UNIQUE_NAME in the SHELL ENVIRONMENT setting in the GUI to set up the Cohesity restore shell environment for the Oracle restore to find the Keystore.

6. Click **Recover** to initiate the restore process.

Your recovery job runs appears in the list on the **Recoveries** page.

Download Debug Logs for Oracle Recover Jobs

Debug logs are system-generated logs that are used in troubleshooting Oracle database backup, recovery, and performance issues. You can now download the debug logs (backup logs and restore logs) as a compressed file for both successful and failed recovery job runs.

To download the debug logs:

Click the **Options** (⋮) icon next to a completed or a failed recovery job run and select **Download Debug Logs**.

Recover Oracle TDE Database

Introduction

Transparent Data Encryption (TDE) enables you to encrypt sensitive data that you store in tables and tablespaces. After the data is encrypted, this data is transparently decrypted for authorized users or applications when they access this data. TDE helps protect data stored on media (also called data at rest) in the event that the storage media or data file is stolen.

You can encrypt sensitive data at the column level or the tablespace level. At the column level, you can encrypt data using selected table columns. TDE tablespace encryption enables you to encrypt all of the data that is stored in a tablespace.

Supported Oracle TDE Wallet types

Cohesity does not impose restriction on wallet types used by the source database for the backup workflow. Your source database can use hardware or software keystore, as well as Oracle Key Vault to centralize your wallet keys management.

For restore and clone workflow, Cohesity requires you to set up the appropriate duplicated keystore on your target hosts before using Cohesity restore or clone workflow. In these workflows, only software keystores are supported and keystores must be put into the auto log-in mode before issuing the Cohesity restore or clone workflow.

Recover TDE Database

When you recover a Transparent Data Encryption (TDE) database backup, Oracle performs media recovery on files restored from Cohesity. To perform media recovery on encrypted blocks, Oracle requires access to the respective TDE keystore.

TDE keystore considerations

- Oracle mandates each database has its own keystore.
- A cloned Oracle database must have its TDE keystore with keys that were used during the previous restore operation.
- Cohesity does not store, manage, or solicit any TDE keystore passwords from users.
- Cohesity requires users to manage the TDE keystore for your source and restore target databases.

This design allows you to control and manage the operation and placement of your TDE keystores to ensure it meets your organization's security requirements.

To use Cohesity to restore from a backup taken from a TDE database, you must set up a duplicate keystore on the restore target host with a chosen keystore configuration mechanism that is supported by Oracle.

To duplicate a keystore from your source database, you can use one of the following methods as recommended by Oracle:

- Backup and close your source keystore and physically copy the keystore to a new location.
- Use the `ADMINISTER KEY MANAGEMENT CREATE KEYSTORE` command to first create an empty keystore, then use the `ADMINISTER KEY MANAGEMENT MERGE KEYSTORE` command to populate your new keystore with the keys from the source keystore.

Oracle supports keystore configuration in the following ways:

- For Oracle versions 18c and later, you can use DB parameters `WALLET_ROOT` and `TDE_CONFIGURATION` to direct your database on how to locate your keystore for your database.
- Use the `ENCRYPTION_WALLET_LOCATION` parameter in `sqlnet.ora` to configure your keystore location. The file path of this `sqlnet` parameter can be made dependent on a shell variable that can uniquely identify your database. For example, the value of the shell variable can be your `DB UNIQUE NAME`.
- Place your keystore in one of the following default locations:

```
$ORACLE_BASE/admin/<db_unique_name>/wallet
```

```
$ORACLE_HOME/admin/<db_unique_name>/wallet
```

> **Note:** Cohesity requires the restore target keystore to be in auto log-in mode. You can create an auto log-in keystore from your duplicated password-protected keystore. For more information, see Creating an Auto-Login or a Local Auto-Login Software Keystore.

If your Oracle database version is 18c or above, and you would like to use the DB parameters `WALLET_ROOT` and `TDE_CONFIGURATION` to configure your restore target

database keystore, you can use the Cohesity Version 6.5.1 and later to add the configuration of these DB parameters as part of the restore workflow.

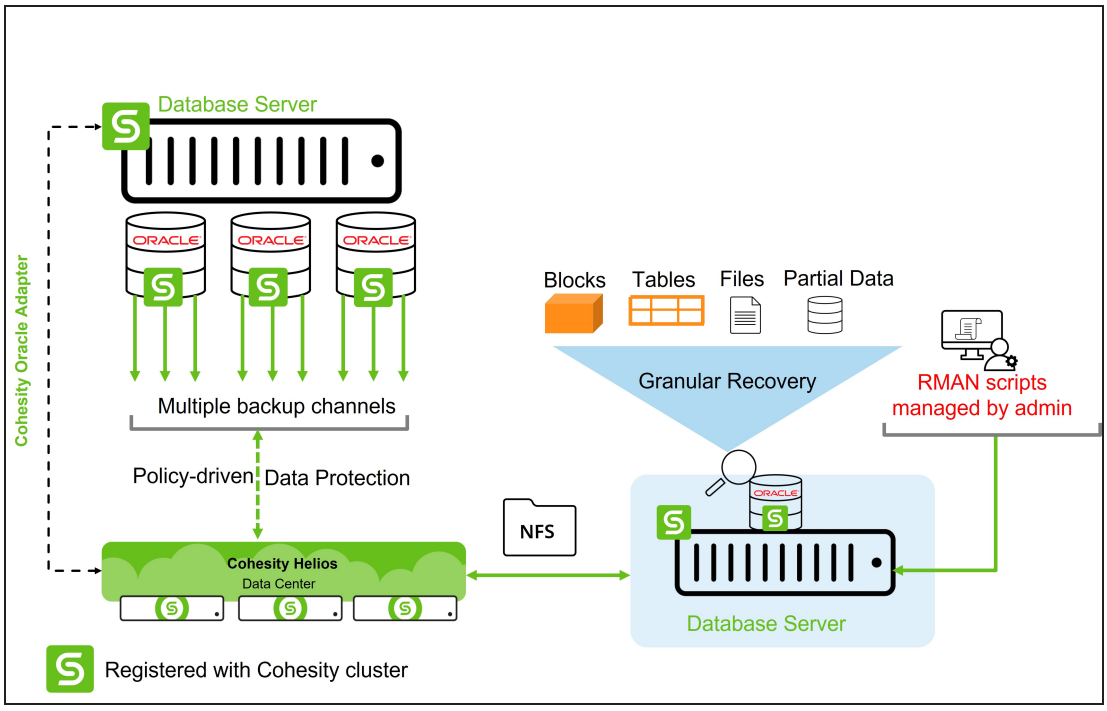
If you choose to configure your restore target database auto log in keystore using `sqlnet.ora` and you are using a shell variable as part of the file path of the wallet, you have to provide the variable name and its values to be used to the Cohesity Restore workflow. For more information, see Recover Oracle Database.

Source database key rotations considerations

- Cohesity does not store, manage, or solicit any TDE keystore passwords from users. Ensure that you manage the TDE keystore for your source and restore target databases. Refresh your duplicated keystore on the restore target host from time to time if master keys are changed in your source database.
- You can change your source database master keys because a new master key is created, or the keys are rotated.
- A successful Cohesity clone operation from a chosen point-in-time is only possible for a TDE database if your duplicate clone target host keystore has the correct set of master keys from that point-in-time. You do not need the exact set of keys for that point-in-time. It is sufficient if you have those keys as well as more keys than you need in your duplicated keystores. Therefore, the easiest way is to always refresh your duplicate keystore from the latest version of your source keystore.
- Oracle does not provide commands or APIs to delete old master keys from the keystore. Keys can only be added or re-used by key rotation.

Granular Recovery for Oracle Database

To perform Granular recovery of Oracle databases, mount the corresponding NFS Views from Cohesity. After the Oracle server is protected by Cohesity, you can leverage the simplicity of Cohesity to easily mount the NFS View in which the RMAN backup files are stored as an image copy.



You can perform these recovery actions using NFS mount:

- Block-level recovery
- Table and tablespace recovery
- DB files (controlfile, datafile, SPfile) recovery
- Partial data recovery
- Cohesity backup view projecting as NFS
- Restore Oracle Database in recovery mode.

> **Note:** To mount NFS to an alternate Oracle server, register the Oracle server with Cohesity Data Cloud. Ensure that the Oracle software is installed on the Oracle server and Recovery Admin should be self-sufficient with RMAN scripts needed for granular recovery. This feature requires the Cohesity Linux agent with version 6.4 and above.

To recover a recent or previous backup of an Oracle database, navigate to select **Data Protection > Recoveries** > **Recover** > **Databases** > **Oracle**. In the Recover Oracle page, search for the protected Oracle instance and select the database planned for granular recovery or use a wildcard name to search for a specific database instance.

After you select an instance for recovery, configure these fields in the Recover page:

Field	Description
Objects Being Recovered	Under **Objects Being Recovered**, verify that the database instances you selected are listed.
Recover Point	If there are multiple backups, select the point of time that corresponds to the desired restore point from the drop-down.
Settings	Click **Create Cohesity View with DB Files** and enter the server details to which Recovery View NFS mount is planned.
Oracle Host	From the drop-down list, browse for the host which is registered as Oracle Server. View expose works only with registered Oracle servers.
View Name Identifier	Provide a name to identify the View at the target server when mounted successfully.

Once all the fields are configured, click **Recover** to restore your Oracle Server.

Recovery Validation for Oracle Database

> **Note:** The recovery validation task will affect the CPU, memory, and other resources on the staging target you select.

The Recovery Validation option allows you to check for physical and logical corruptions in the database before you can initiate a recovery job for an Oracle database.

To perform a recovery validation of an MT and non-MT Oracle Database, perform the steps listed below.

1. Select **Data Protection** > **Recoveries** > **Recover** > **Databases** > **Oracle**.
2. On the Recover page, select **Validation**.
3. Accept the latest **Recovery Point** or click the change icon () and select a different recovery point.
4. After you select an instance for recovery validation, configure these fields in the Recover page:
    1. **Temporary Database**: Cohesity will create a temporary database on the selected host for this recovery validation task.
    2. **Oracle Home**: ORACLE_HOME specifies the directory containing the Oracle database software binary files. By default, Oracle Universal Installer (OUI) installs the Oracle Database software binary files by version and Oracle Home

Name in a subdirectory of the Oracle base directory.

3. **Base Directory**: ORACLE_BASE specifies the directory at the top of the Oracle software and administrative file structure. The Oracle base directory is the location where Oracle software and configuration files are stored.
4. **Task Name**: (Optional) Provide the name for the recovery task.

5. Click **Recover** to start the validation.

Recover Archive Logs for Oracle Database

You can also choose to recover the archive logs for a specific range of the target database. You can restore Archive logs using the LSN (Log Sequence Number), time range, and SCN (System Change Number).

To recover archive logs of an MT and non-MT Oracle Database, perform the steps listed below.

1. Select **Data Protection** > **Recoveries** > **Recover** > **Databases** > **Oracle**.
2. Select **Archive Logs** as the Recover Type.
3. Search for the Oracle instance that needs to be restored or use a wildcard name to search for a specific database instance.
4. Click the change icon (ICON) and select one of the following options:
    1. **Log Sequence Number**: Use this option to restore the Archive logs by the Log Sequence Number (LSN). Specify the LSN range to restore the archive logs.
    2. **Time**: Use this option to restore the Archive logs by time frame. Specify a time range between which you need the archive logs.
    3. **System Change Number**: Use this option to restore Archive logs by System Change Number (SCN). Specify the LSN range to restore the archive logs.
5. Click **Next: Recovery Options** and specify the recovery options.
    1. **Restore Archive Logs to**: Specify the path to an existing empty directory. The restored Archive logs will reside in this path.
    2. **Oracle Home**: The ORACLE_HOME value for the host where Archive logs are restored. This is required when recovering the archive logs to an alternate Oracle host.
    3. **Base Directory**: The directory for the restored database. This is required when recovering the archive logs to an alternate Oracle host.
    4. **Oracle SID(optional)**: The system identifier (SID) of the Oracle database instance on a specific host. This is required when recovering the archive logs to an alternate Oracle host.

> **Note:** Restoring archive logs to a database on an alternate host is supported only if that database has the same DB ID as the source DB ID.

5. **Cluster Interface**: Cluster Interface: Select one of the following options to assign the interface group for the recovery job.
    1. **Auto Select**: Toggle on this option if you want to use the same interface group that was selected during the Oracle source registration.
    2. **Interface Group**: Select the interface group to use for the recovery.
6. Click **Recover**.

Test Data Management for Oracle Database

Data and application retention is critical to organizations that seek to prevent data loss and meet security, legal, compliance, disaster-recovery, and business-continuity requirements. Cohesity provides the following solutions as part of the data management with Oracle Instances:

- Clone Oracle Database
- Refresh Clone
- Tear Down Clone

Clone Oracle Database

Cohesity provides the ability to clone Oracle databases (Standalone, RAC, Multi-container Database (CDB), and VCS). The Oracle database is cloned at Cohesity Storage Domains and requires no additional storage from the Oracle Host. Multiple clones from a single source of Oracle Database backup may require little to no additional storage space

in the Cohesity cluster.

Supported Oracle Release for TDM Cloning

Cohesity supports TDM cloning in the following Oracle releases:

Oracle Release	Clone Support for Oracle Database
11gR2	Supported
12cR1	Supported
12cR2	Supported
18c	Supported
19c	Supported

Prerequisites

- Install the latest Cohesity Agent on the system running the Oracle Database.
- Capture Snapshots of the Oracle database to be cloned. To create Snapshots, see create and run a Protection Group.

Clone an Oracle Database

1. Navigate to **Test & Dev** > **Clone** > **Databases**.
2. Search and select the Oracle database. (You can optionally specify the wildcard character *in the search.) You can also optionally narrow the search results by specifying filter criteria.
3. Provide the following information listed in the table, and then click **Clone**.

CLI Option	Description
Task Name	(Optional) Change the default name for the Clone task.
Objects Being Cloned	The Oracle database is being cloned. You can click the change icon to select a different database.
Clone Point	The latest clone point. You click the change icon and select a different clone point. Select the Snapshot to clone. By default, the latest Snapshot is cloned and the selected Restore Point is listed. You can optionally click **Edit** and choose the previous Snapshot to clone.
Oracle Host	The host to which you clone the database.
Oracle Home	The home directory for the cloned database.
Base Directory	The base directory for the cloned database.
Database Name	The name for the cloned database. The maximum number of characters for the database name is eight. The database name should be unique for the given Oracle Host.

CLI Option	Description

Pfile Parameters	The Pfile parameters option allows you to see the target database parameters before the clone job is initiated. The Pfile inherits some source database parameters to the target database and allows you to edit the target database parameters based on your requirement by specifying the additional parameters as a `key=value` pair.
	
	The Pfile lists the following parameters:
	
	• **Default Parameters**: Default parameters of the target database and you can edit the default
	• **Inherited Parameters**: Parameters from the source database and you can edit the inherited parameters, if required.
	• **Restricted Parameters**: You cannot edit the restricted parameters in the Pfile. The following are the restricted parameters:
	  • INSTANCE_NAME
	  • DB_NAME
	  • DB_UNIQUE_NAME
	  • DB_BLOCK_SIZE
	  • MAX_STRING_SIZE
	  • COMPATIBLE
	
	If you edit the following values in the Clone Oracle GUI, You must click the Reset button on the top-right corner to reset the Pfile and get the updated parameter values in the Pfile box.
	  • Oracle Home
	  • Oracle Base
	  • Database Name
	
	Target database will be created with the specified parameters in the Pfile. For example, if `SGA_TARGET` is specified as a part of the pfile parameters, the clone operation will use the value specified in the pfile during the cloning of the source database.

SGA (System Global Area)	The SGA is an area of memory (RAM) allocated to an Oracle Instance when it starts up. Ideally, SGA's value varies from 1024M to 102400M.

CLI Option	Description
Shell Environment	User can configure their shell environment that executes the Cohesity clone workflow using this setting. An example would be, define your TNS_ADMIN shell variable here to point to a different sqlnet.ora file to be used for your clone target database. For TDE support, the wallet location for your clone target database may depend on a shell variable. Use this to specify your wallet location for cloning a backup taken from a TDE database. For more information, see Clone Oracle TDE Database.
NFS Protocol	Select the NFS protocol version for the clone job. Options include NFSv3 and NFSv4.1. **Note:** NFS protocol is not supported for Windows and AIX databases.
Change DBID	If this option is disabled, the cloned database UUID will be the same as the source database and it will not be displayed on the Source page. Later, If the cloned databases are required to be discovered by Cohesity, then follow the steps below: 1. Start the database in MOUNT mode. 2. Run the following query to get the DBID: "select DBID from GV$database". 3. Change the database DBID using the NID command. 4. Run the following query "select DBID from GV$database" and confirm that the DBID is different from the one we obtained in step 2. 5. Once confirmed, start the database in OPEN mode. 6. Add the database entry in the oratab file. 7. Do a source refresh. 8. The database should be listed there now. If none of the other databases on the Oracle host have DBID the same as that of the cloned database then, skip steps 1 to 5.

You will be redirected to the status details page. Once the clone task that you initiated completes, the status will be displayed as "Success".

You can cancel a clone task for an individual database. Canceling the clone task leaves the database in an unusable state. You can delete this database manually at the Oracle host and then restart the clone task as needed.

Cancel an Oracle Database Clone Task

You can cancel a clone task for an individual database. Canceling the clone task leaves the database in an unusable state. You can delete this database manually at the Oracle host and

then restart the clone task as needed.

1. Navigate to **Test & Dev**.
2. Click a Task Name link in the table to display the details page.
3. Click the **Cancel** button. (The Cancel button is available only if the task is running.)
4. Respond to the confirmation prompt.

Refresh Oracle Database Clone

After you clone the Oracle database on the Cohesity cluster, you can refresh the cloned Oracle database with the latest snapshot, with a selected snapshot, or with a point in time snapshot.

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

Steps to Refresh a Clone

1. Navigate to **Test & Dev**.
2. Click the cloned task you want to refresh and then click **Refresh** located at the top right of the page. Alternatively, you can hover your mouse over the actions menu located next to the cloned task.
3. To refresh the cloned task with the latest snapshot, select **Refresh to Latest Snapshot**, and then click **Confirm**.

   To refresh the cloned task with an available snapshot, click Refresh to Snapshot, and then perform the following steps:

   a. From the **Recovery Point** column, select the snapshot to which the cloned task must be refreshed.
   b. To refresh the cloned task with a specific time of the selected snapshot, click **Restore to a New Time**, and then use the slide control to adjust the date and time.
   c. Click **Save**.

Tear Down Oracle Database Clone

Deletes the cloned Oracle database from the Oracle Host and remove the database files from the Cohesity Storage Domain.

To delete an Oracle database clone from the Cohesity Storage Domain, perform the following steps:

1. Navigate to **Test & Dev**.
2. Click the cloned task or hover your mouse over the actions menu located next to the

cloned task you want to delete.

3. Click **Tear Down Clone** > **Yes, Tear Down**.

The Oracle database clone will be deleted from the Cohesity cluster Storage Domain.

Clone Oracle TDE Database

Introduction

Transparent Data Encryption (TDE) enables you to encrypt sensitive data that you store in tables and tablespaces. After the data is encrypted, this data is transparently decrypted for authorized users or applications when they access this data. TDE helps protect data stored on media (also called data at rest) in the event that the storage media or data file is stolen.

You can encrypt sensitive data at the column level or the tablespace level. At the column level, you can encrypt data using selected table columns. TDE tablespace encryption enables you to encrypt all of the data that is stored in a tablespace.

Supported Oracle TDE Wallet types

Cohesity does not impose restriction on wallet types used by the source database for the clone workflow. Your source database can use hardware or software keystore, as well as Oracle Key Vault to centralize your wallet keys management.

For restore and clone workflow, Cohesity requires you to set up the appropriate duplicated keystore on your target hosts before using Cohesity restore or clone workflow. In these workflows, only software keystores are supported and keystores must be put into the auto log-in mode before issuing the Cohesity restore or clone workflow.

Clone TDE Database

When you clone a Transparent Data Encryption (TDE) database backup, Oracle performs media recovery on files cloned from Cohesity. To perform media recovery on encrypted blocks, Oracle requires access to the respective TDE keystore.

TDE keystore considerations

- Oracle mandates each database has its own keystore.
- A cloned Oracle database must have its TDE keystore with keys that were used during the previous clone operation.
- Cohesity does not store, manage, or solicit any TDE keystore passwords from users.
- Cohesity requires users to manage the TDE keystore for your source and clone target databases.

This design allows you to control and manage the operation and placement of your TDE keystores to ensure it meets your organization’s security requirements.

To use Cohesity to clone from a backup taken from a TDE database, you must set up a duplicate keystore on the clone target host with a chosen keystore configuration mechanism that is supported by Oracle.

To duplicate a keystore from your source database, you can use one of the following methods as recommended by Oracle:

- Backup and close your source keystore and physically copy the keystore to a new location.
- Use the `ADMINISTER KEY MANAGEMENT CREATE KEYSTORE` command to create an empty keystore, then use the `ADMINISTER KEY MANAGEMENT MERGE KEYSTORE` command to populate your new keystore with the keys from the source keystore.

Oracle supports keystore configuration in the following ways:

- For Oracle versions 18c and later, you can use DB parameters `WALLET_ROOT` and `TDE_CONFIGURATION` to direct your database on how to locate your keystore for your database.
- Use the `ENCRYPTION_WALLET_LOCATION` parameter in `sqlnet.ora` to configure your keystore location. The file path of this `sqlnet` parameter can be made dependent on a shell variable that can uniquely identify your database. For example, the value of the shell variable can be your `DB UNIQUE NAME`.
- Place your keystore in one of the following default locations:

```
$ORACLE_BASE/admin/<db_unique_name>/wallet
```

```
$ORACLE_HOME/admin/<db_unique_name>/wallet
```

> **Note:** Cohesity requires the clone target keystore to be in auto log-in mode. You can create an auto log-in keystore from your duplicated password-protected keystore. For more information, see Creating an Auto-Login or a Local Auto-Login Software Keystore.

If your Oracle database version is 18c or above, and you would like to use the DB parameters `WALLET_ROOT` and `TDE_CONFIGURATION` to configure your cloned target database keystore, you can use the Cohesity version 6.5.1 and later to add the configuration of these DB parameters as part of the cloning workflow.

If you choose to configure your clone target database auto log in keystore using `sqlnet.ora` and you are using a shell variable as part of the file path of the wallet, you have to provide the variable name and its values to be used to the Cohesity clone workflow. For more information, see Clone Oracle Database.

Source database key rotations considerations

- Cohesity does not store, manage, or solicit any TDE keystore passwords from users. Ensure that you manage the TDE keystore for your source and clone target databases. Refresh your duplicated keystore on the cloned target host from time to time if master keys are changed in your source database.

- You can change your source database master keys because a new master key is created, or the keys are rotated.
- A successful Cohesity clone operation from a chosen point-in-time is only possible for a TDE database if your duplicate clone target host keystore has the correct set of master keys from that point-in-time. You do not need the exact set of keys for that point-in-time. It is sufficient if you have those keys as well as more keys than you need in your duplicated keystores. Therefore, the easiest way is to always refresh your duplicate keystore from the latest version of your source keystore.
- Oracle does not provide commands or APIs to delete old master keys from the keystore. Keys can only be added or re-used by key rotation.

Unregister an Oracle Server

You can unregister an Oracle server from the Cohesity cluster. Before you unregister it, you must delete the Protection Groups associated with the Oracle database. Cohesity provides the following solutions as part of unregistering Oracle Instances:

- Delete a Protection Group
- Unregister Oracle Server
- Uninstall Cohesity Agent

Delete a Protection Group

Perform the following steps to delete a Protection Group:

> **Note:** If the protection group is deleted with snapshots, then no restores can be done from that job unless the snapshots are archived.

1. Select **Data Protection > Protection**.
2. Find the Job in the list and in the **Actions** column select **Delete**.

   Alternatively, drill-down on a Job name in the **Job** column of the list. In the Job Details page, click the (**Delete Job**) icon.
3. Choose one of the following:
   - **Delete Job Only:** Select this option to delete only the Protection Group. Any local snapshots and or archived snapshots stored on the external targets that were captured by this Job are not deleted.
   - **Delete Job and Snapshots:** If you select the option to delete the Job and all Snapshots, any local Snapshots captured by this Job and stored on this Cluster are deleted. In addition, any archived Snapshots stored on external targets that were captured by this Job are also deleted. (To selectively delete the Snapshots for specific protection runs without deleting the Job, see Deleting Snapshots or Objects.)

If the current job is replicating snapshots to a remote cluster or archiving snapshots to an external target, you should probably cancel these replication or archive tasks before deleting the job. For instructions, see Cancel Replication and Archive Copy Tasks of a Protection Group Run.

If the Job is replicating to a remote cluster, the inactive job created on the remote cluster is not deleted. In addition, the snapshots that were replicated (copied) to the remote cluster by this job are not deleted. You can log in to the remote cluster to delete the snapshots and the inactive job.

Unregister Oracle Server

Follow the steps listed below to unregister the Oracle server:

1. Select **Data Protection > Sources**.
2. Navigate the source hierarchy to the Oracle server, mouse over its actions menu, and click **Unregister**.
3. Click **Unregister**.

Uninstall Cohesity Agent

For information about uninstalling the Cohesity agent from an Oracle server (physical or VM), see Install and Manage the Agent on Linux Servers.

Oracle Database Remote Adapter

> **Note:** Cohesity Remote Adapter functionality is not supported if SmartFiles is not licensed on your Cohesity cluster.

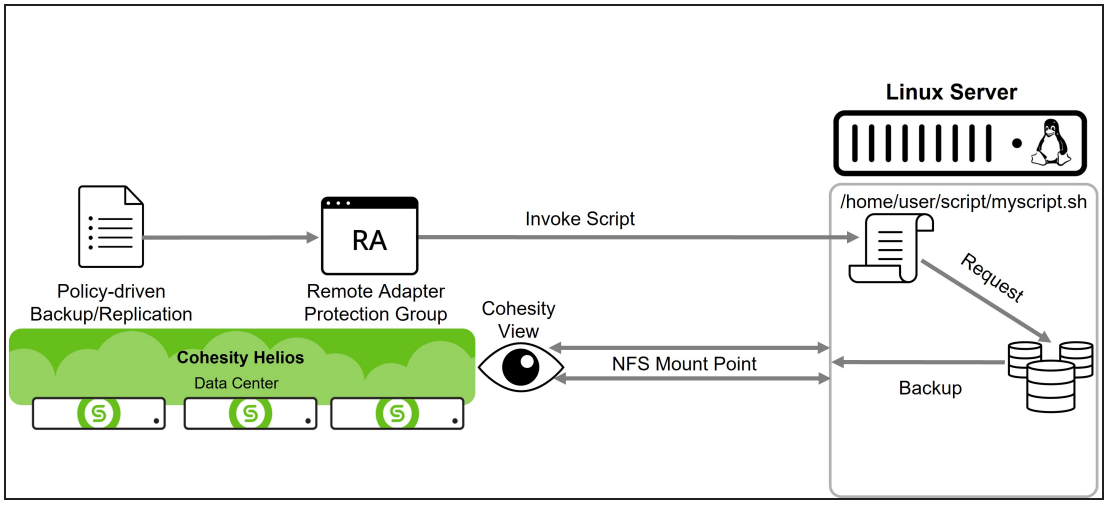
The Cohesity remote adapter is used for cases where you need to use custom RMAN scripts (not the one provided by the Cohesity adapter agent). You can schedule agentless Oracle backups with the remote adapter using your own scripts. However, the storage management and backup scheduling is from Cohesity.

Cohesity provides built-in support for Oracle databases. You can either use the Cohesity UI or Remote Adapter Jobs, depending on your preference and requirements for backing up your Oracle database.

The workflow for executing a Protection Group using the Oracle RMAN remote adapter is as follows:

- Create a Cohesity data Protection Group using the Cohesity Remote Adapter. You should add the SSH public key on the Oracle Database server so that the Cohesity cluster can connect to the remote adapter and trigger remote adapter jobs. For the complete set of instructions on how to add the SSH public on the Oracle database, see Add or Edit a Remote Adapter Protection Group.

- Mount the Cohesity Views 'NFS Mount Path' on the Oracle Database Server.
- Set a QoS Policy for the RMAN job.
- Run the RMAN Protection Group.



Ports Used for Communication

The following table lists the ports used for external communication when using the Cohesity Remote adapter.

Port	Source	Target	Direction (from node)	Network Protocol	Usage Notes	Type of Traffic
11113	Oracle Host	Cohesity cluster	Incoming	TCP		Backup and Recovery
22	Cohesity cluster	Oracle Host	Outgoing	TCP	SSH client to remotely trigger the scripts on the Oracle Host.	Backup and Recovery

Protecting Oracle Databases using Remote Adapter

When you create a Remote Adapter Protection Group, you will create a View or use an existing View to store the result of the scripts. You must then mount the View on your system and configure your script to write the results to a directory in the mounted View. At the end of the Remote Adapter protection run, the Cohesity cluster captures a Snapshot of the View.

When you create a Remote Adapter Protection Group, you can select an existing Policy, storage domain, and View. You can also create them while creating the job. However, it is easy to create them prior to creating the job, as described in the following topics.

- Create or Edit a Standard Policy
- Create or Edit Storage Domains
- Create a View

Creating Remote Adapter Job

1. You will create an RMAN data Protection Group leveraging a pre-existing RMAN script. Start by navigating to the Protection Group landing page through the Protection menu option and then click **Remote Adapter**. Then choose Remote Adapter as the job type. This will start the Protection Group setup workflow with each step of the workflow identified at the top of the screen. For the complete set of instructions on how to create a remote adapter Protection Group, see Add or Edit a Remote Adapter Protection Group.
2. From the New Remote Adapter Protection Group page, either select **New Policy** to create a new policy or select an existing "Protection Policy". With the existing policy, you can ignore the default "Protection Schedule and Options" as this schedule does not apply for Oracle backups. For more information, see Create or Edit a Standard Policy.
3. In the next **Specify Script Settings** page, specify the Oracle database host information, SSH keys, and script locations. Ensure the SSH key is verified to allow remote login and execution of scripts. This can be verified by running a test script that echoes an output. For more details, see Creating a NFS Export on the Cohesity Storage.
4. Specify a descriptive job name, an appropriate Cohesity storage domain, and a Cohesity View. For more details, see Create or Edit Views.

A summary of the settings appears. Review the summary to ensure that all the settings are correct.

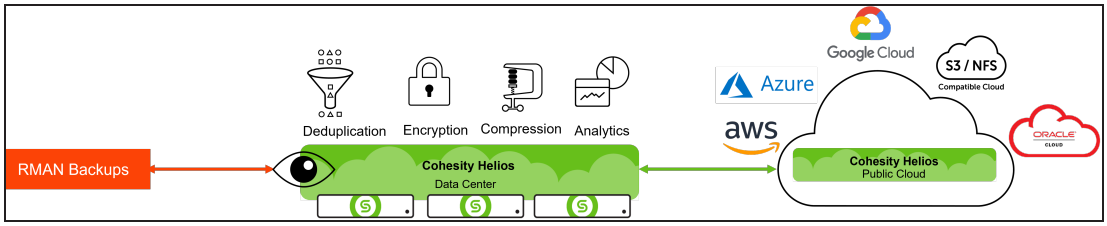
Remote Adapter Considerations for Oracle Database

- **Limited Support**: Remote Adapter is not supported for Windows.
- **Register Recovery Scripts**: There is no single location to register recovery scripts when using the remote adapter.
- **Tracking**: You cannot track and report all the recovery tasks and alerts from Cohesity UI when using the remote adapter.
- **Data Read Column**: The Data Read column in the Protection Group Run details page shows the total size of the Oracle Databases protected by the job. This is because of an RMAN limitation.

RMAN NFS Target for Oracle Database

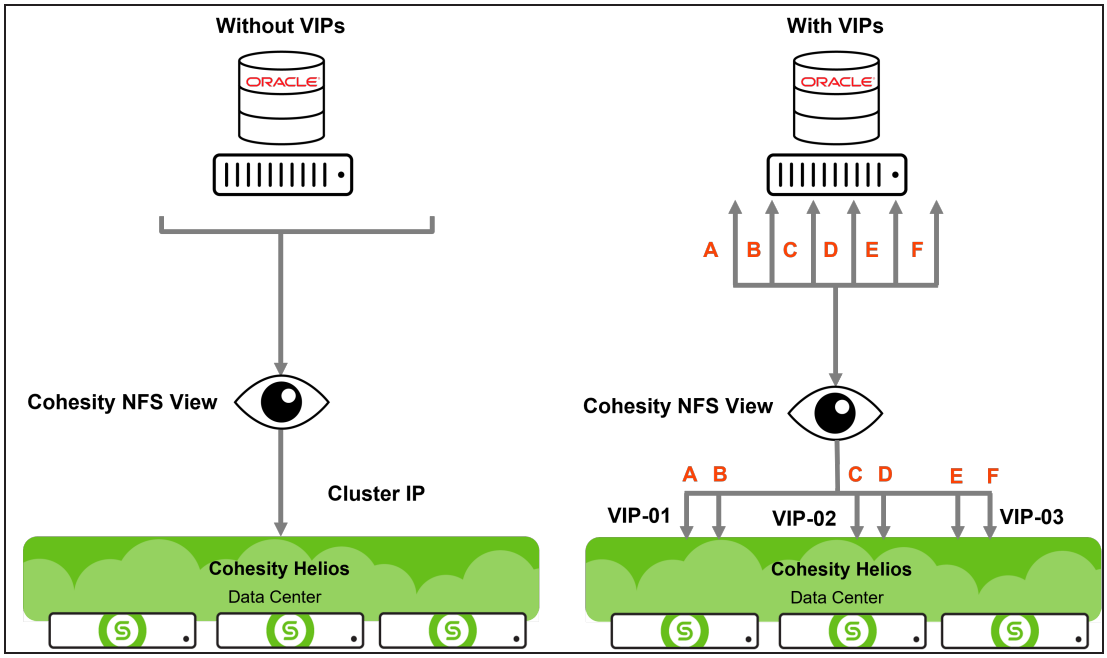
Cohesity provides an efficient integration option with Oracle's Recovery Manager (RMAN) using the NFS mount points. You can present Cohesity as an NFS target for native RMAN backups using the NFS mounts.

To store your RMAN backups on the Cohesity cluster, you need to create a Cohesity View. The View allows you to set the appropriate options for deduplication, compression, and QoS Policies and lets you use NFS mounts to assign channels to every node in a Cohesity cluster.



Each node in a Cohesity cluster has a Virtual IP (VIP). You can use these VIPs in your RMAN scripts when you allocate channels to every node in a Cohesity cluster. By assigning separate channels to every node, you are assigning parallel resources of each node to share the workload and thus making your backups faster.

You can use multiple backup RMAN channels in the backup operation and map several channels to the same VIP to increase the parallel processing. A combination of multiple channels and multiple mount points (defined using VIPs) will yield faster backup performance.



> **Tip:** For best performance, create a mount point for each node in your Cohesity cluster using that node's unique VIP.

Allocating too many or too few channels can degrade the backup performance. Cohesity recommends that you determine the optimal combination of channels and mount points based on the backup operation on the Oracle side to give you the best performance. The number of channels should be in multiples based on your cluster node count.

For example, if your Cohesity cluster has 3 nodes, then use channels in multiples of 3 (3, 6, 9, 12).

Create NFS Export on Cohesity Storage for Oracle Database

In order to create an NFS export from the Cohesity Data Cloud, follow the steps listed below:

1. Create a storage domain to define the policy settings on the exported shares. For more information, see Create or Edit Storage Domains.
2. Set the data management policies within the storage domain, such as enabling data reduction functionality, the type of data deduplication, and whether inline or post process.
3. Create a View and enter the View Name. The View name is also used to create the exported share name. In the Advanced Settings, select a specific protocol such as NFS. In this example, NFS is the protocol choice for Linux and Unix. For more details, Create a View.
4. Associate this view with the Storage Domain you created. This View inherits the policies associated with the Storage Domain.
5. Allowlist the IP subnet of the Oracle database server. Add the IP address or IP subnet of the Oracle database servers that are allowed to access exported NFS share in the Cohesity View. For more information, see Add Subnets to Allowlists.

Backup and restore for NFS are completely driven at the user or customer end. If you choose Cohesity Data Cloud as NFS target, it just acts as storage.

RMAN NFS Best Practices for Oracle Database

For Oracle RMAN backup configured with NFS Export, the capacity savings are extremely dependent on how RMAN is used. Oracle datafiles contain data blocks, which have block headers at the start of the block. These contain numbers, which are unique for each datafile, making deduplication impossible at the database block size. Also, the end of each block contains a tail check section that features a number generated using data such as the SCN. Even if the block is divided into two, the second half would offer a limited opportunity for deduplication while the first half would offer none. To maximize deduplication efficiency when using RMAN, understand these settings and best practices:

- **FILESPERSET=1**

  This setting suppresses Oracle multiplexing of more than one data file into a backup set. When you suppress Oracle multiplexing, Oracle creates the backup set identically each time the backup runs and maximizes the dedupe rate.

```
BACKUP
FILESPERSET=1
%BACKUP_TYPE%
FORMAT 'bk_u%%u_s%%s_p%%p_t%%t'
DATABASE;
```

- **Compression/Encryption**

  Both compression and encryption must be disabled in RMAN to see effective deduplication. However, compression should be enabled when backing up transaction logs and control files because they don't see good deduplication rates.

```
RMAN> CONFIGURE BACKUP OPTIMIZATION OFF;
RMAN> CONFIGURE ENCRYPTION FOR DATABASE OFF;
```

- **Mount options for NFS client**

  Depending on the Oracle Server OS, different NFS client mount options are required for successful backup and recovery of Oracle database. The following table lists the NFS mount options for the supported Oracle Server OS:

<table>
<tr><th>OS</th><th>Deployment Type</th><th>Version</th><th>Default Mount Options</th><th>Full/Incremental Backup</th><th>Log Backup</th><th>Overwrite Restore</th><th>Alternate Restore</th><th>Clone</th></tr>
<tr><td>AIX</td><td rowspan="3">RAC</td><td>12c</td><td rowspan="4">bg,hard,intr,rsize=32768,wsize=32768,vers=3,proto=tcp,sec=sys,rw,acdirmax=30</td><td></td><td></td><td rowspan="3">noac</td><td></td><td>noac</td></tr>
<tr><td></td><td>11g</td><td>noac</td><td></td><td></td><td>llock</td></tr>
<tr><td></td><td rowspan="2">Standalone</td><td>12c</td><td></td><td></td><td></td><td></td><td></td></tr>
<tr><td></td><td>11g</td><td></td><td></td><td></td><td></td><td></td></tr>
</table>

OS	Deployment Type	Version	Default Mount Options	Full/Incremental Backup	Log Backup	Overwrite Restore	Alternate Restore	Clone
Linux	RAC	12c	rw,relatime,vers=3,rsize=1048576,wsize=1048576,namlen=255,hard,proto=tcp,timeo=600,retrans=2,sec=sys,mountvers=3,mountproto=tcp,local_lock=none					noac llock
		11g		noac				
	Standalone	12c						llock
		11g						

- **QoS settings for NFS view**

  NFS view should be created with TestAndDev High QoS settings. This will provide higher priority when Cohesity runs other tasks such as VM backup jobs.

  The following table lists the QoS policies in the increasing order of QoS and helps in I/O tuning.

QoS Policy	Description
Backup Target Low	Use this policy for non-latency sensitive workloads such as backups, which keep many I/Os outstanding. Data is written to HDD and has higher latency compared to other QoS policies writing to a SSD.
Backup Target High	The same as **Backup Target Low**, except that the priority for processing workloads with this policy is higher than workloads with Backup Target Low when there is contention.
Backup Target SSD	Use this policy for workloads such as backups, which keep many I/Os outstanding. However, in this case, Cohesity sends both sequential and random I/Os to SSD. The latency is lower than other Backup Target policies.
Backup Target CommVault	Use this policy to intelligently detect and exclude application-specific markers to achieve better deduplication when CommVault backup application is writing to a Cohesity View. Data is written to SSD and has the same priority and latency as **TestAndDev High**.

QoS Policy	Description
TestAndDev Low	Use this policy for workloads that require lower I/O latency or do not keep many I/Os outstanding, as the I/Os are given higher priority compared to other QoS policies. Data is written to SSD and has lower latency compared to Backup Target SSD.
TestAndDev High	The same as **TestAndDev Low**, except that the I/Os with this QoS policy are given higher priority compared to I/Os with TestAndDev Low when there is contention.

- **Load balancing RMAN jobs**

  To get the best performance with Oracle RMAN, the load from backup and restore jobs should be distributed between all the Cohesity nodes in the cluster. To load balance work between the nodes, create multiple mount points with different VIP of the Cohesity Data Cloud on the Oracle Server as RMAN target.

  For example, assume a view named `nfs_view` created (using Step 4) by selecting the suitable QoS at Cohesity Domain. The same view is used to create multiple mount points with different VIP of the Cohesity Data Cloud.

  This is an example how the mount is performed:

```
create directory structure

                                    mkdir -p /orcl1
mkdir -p /orcl2
mkdir -p /orcl3
mkdir -p /orcl4

The following Linux NFS settings are the recommended options for the
Cohesity as they provide the best performance:

noatime,vers=3,proto=tcp,rsize=1048576,wsize=1048576,hard,intr,nolock
```

  Example: Mount VIPs using the options above:

```
sudo mount -t nfs -o
noatime,vers=3,proto=tcp,rsize=1048576,wsize=1048576,hard,intr,nolock
192.10.2.10:/nfs_view /orcl1
sudo mount -t nfs -o
noatime,vers=3,proto=tcp,rsize=1048576,wsize=1048576,hard,intr,nolock
192.10.2.11:/nfs_view /orcl2
sudo mount -t nfs -o
noatime,vers=3,proto=tcp,rsize=1048576,wsize=1048576,hard,intr,nolock
192.10.2.12:/nfs_view /orcl3
```

```
sudo mount -t nfs -o
noatime,vers=3,proto=tcp,rsize=1048576,wsize=1048576,hard,intr,nolock
192.10.2.13:/nfs_view /orcl4
```

> **Note:** Ensure that you update the `/etc/fstab` file with above mount options to make the changes persistent across server reboots.

RMAN Full backup script looks similar to this example:

```
CONFIGURE DEFAULT DEVICE TYPE TO DISK;
CONFIGURE DEVICE TYPE DISK PARALLELISM 4 BACKUP TYPE TO BACKUPSET;

run {
allocate channel t1 type disk FORMAT '/orcl1/%d_%T_%U';
allocate channel t2 type disk FORMAT '/orcl2/%d_%T_%U';
allocate channel t3 type disk FORMAT '/orcl3/%d_%T_%U';
allocate channel t4 type disk FORMAT '/orcl4/%d_%T_%U';

sql 'alter system archive log current';
backup spfile tag 'spfile';
CONFIGURE CONTROLFILE AUTOBACKUP OFF;
backup current controlfile tag 'controlfile_1';
backup incremental level 1 for recover of copy with tag 'Full_1'
database plus archivelog delete input;
RECOVER COPY OF DATABASE WITH TAG 'Full_1';
}
```

- **Archive Logs and Control Files**

  By default, RMAN interleaves archive (transaction) logs and control files with database content. This defeats deduplication because it changes the alignment of the data. When used with deduplication, these additional files should be written to separate streams.

- The Cohesity cluster will work with Oracle compression and encryption functionality. If encryption and compression are turned on, make sure to disable data deduplication on the Cohesity View.
- When the native deduplication built-in to the Cohesity Data Cloud is not used, the alternate storage and time-saving option is native Oracle compression with the multi-channel target. For storage, RMAN compression shows around 50% reduction and also shows a good backup time reduction. However, these are dependent highly on Oracle RMAN performance and tuning. This may cause extra load to the Oracle DB server.

For more information, see Cohesity and Oracle RMAN Guide.

Cohesity Oracle SBT Plug-in

The Cohesity Oracle SBT Plug-in allows you to use Cohesity as target storage for backing up Oracle databases.

Cohesity Oracle SBT Plug-in protects the Oracle databases using the Oracle Recovery Manager (RMAN) script. Cohesity natively integrates with Oracle Recovery Manager (RMAN) to provide application-consistent backup and recovery for Oracle databases including single instance or Real Application Clusters (RAC).

Check the **Databases** section in the Supported Software topic for a complete list of supported Oracle versions for Cohesity SBT Plug-in and the supported Cohesity cluster versions.

Backup and Restore using Cohesity Oracle SBT Plug-In

> **Note:**
> - Cohesity recommends you schedule periodic full backups for the Oracle database protection using Oracle SBT Plug-In.
> - For Oracle 19c, the Oracle SBT plug-in supports backing up of containerized databases (CDB/PDB).

To back up a database:

1. Create views as the target where the databases need to be backed up.
2. Add the Oracle host(s) to the allowlist of the view or global allowlist.
3. Allocate SBT channels in the RMAN scripts to include the Cohesity-specific parameters.

   For example:

   ```
   'ALLOCATE CHANNEL c1 DEVICE TYPE SBT_TAPE PARMS 'SBT_
   LIBRARY=/opt/cohesity_sbt/lib/libsbt_linux_x86_64.so, SBT_PARMS=(mount_
   path=192.0.2.1:/SbtView1/db1,vips=192.0.2.1)'
   ```

4. Schedule the backup with Cohesity Remote Adapter or external scheduler by running the script from the previous step.

To restore a database:

1. Select the view or snapshot where the backup data exists for a specific Database for restore.
2. Expose the snapshot to a view if necessary and optionally mount to a target source if the customer wants to see the backup pieces on the view.
3. Write RMAN restore scripts to include the Cohesity-specific parameters same as the

backup.

4. Run the script manually to perform the restore.

The following table lists the ports used for communication between the Cohesity cluster and the Oracle server. Please open the port based on your choice of protocol. The default protocol is gRPC and the TCP port is 11113.

Port	Source	Target	Direction (from node)	Network Protocol	Usage Notes	Type of Traffic
11113	Oracle Server	Cohesity cluster	Incoming	TCP	gRPC used by Oracle SBT	Backup and Recovery
11117	Oracle Server	Cohesity cluster	Incoming	TCP	Secure gRPC used by Oracle SBT	Backup and Recovery
11111	Oracle Server	Cohesity cluster	Incoming	TCP	SunRPC used by Oracle SBT (Linux only)	Backup and Recovery

Installing Cohesity Oracle SBT Plug-in

The Cohesity Oracle SBT Plug-in can be installed on the Linux, AIX, and Windows platforms.

- Install Cohesity Oracle SBT Plug-in (For Linux)
- Install Cohesity Oracle SBT Plug-in (For AIX)
- Install Cohesity Oracle SBT Plug-in (For Windows)

> **Note:**
> - Cohesity recommends using the latest download package available on the downloads portal.
> - The latest version of the SBT plugin is compatible with all the previous versions. You can replace the plugin to upgrade to the latest version without changing the RMAN scripts.
> - If Packet Inspection is enabled on the firewall between the Oracle host and the Cohesity cluster, the backup performance with gRPC is affected. To resolve this issue, either turn off the Packet Inspection on the firewall or use SunRPC or secure gRPC instead of gRPC.

Install Cohesity Oracle SBT Plug-in (For Linux)

1. Download the Cohesity Oracle SBT Plug-in for Linux from the Cohesity Package Download page.
2. Place the `libsbt_linux_x86_64.so` file in any directory of the Oracle server. For the Oracle RAC setup, the file should be put in the same directory in all the Oracle RAC nodes.

Install Cohesity Oracle SBT Plug-in (For AIX)

There are two ways to download and install Cohesity Oracle SBT Plug-in for AIX.

Install from the single library file

1. Download the Cohesity Oracle SBT Plug-in for AIX from the Cohesity Package Download page.

   > **Note:** Perform this step for each Oracle Database that is protected by Cohesity.

2. Place the `libsbt_aix_powerpc.so` file in any directory of the Oracle server. For the Oracle RAC setup, the file should be put in the same directory in all the Oracle RAC nodes.

Install from the installer

1. Download the Cohesity Oracle SBT Plug-in installer for AIX.
   1. Download the installer `cohesity_plugin_sbt_release-<yyyymmdd>_<commit_id>_aix_powerpc_installer` from the Cohesity Package Download page.
2. Add the executable permission to the downloaded installer file then execute it.
   1. Install to default location `/opt/cohesity/plugins/sbt`.

      Run the following command with root privilege.

      ```
      sh <installer_name>
      ```

   2. Optionally, You can install to a customized location by defining the installation directory to which you have the write permission.

      ```
      sh <installer_name> -- -d <installation_dir>
      ```

3. For the Oracle RAC setup, repeat the steps above for all the nodes.

> **Note:** To use Cohesity SBT Plugin on AIX 7.3, the AIX largesend attribute of the network interface should be disabled.

To disable the `largesend`, run the following command. This configuration will be lost after rebooting.

```
ifconfig <interface> -largesend
```

To persist the configure after rebooting, run the following command.

```
chdev -l <interface> -a mtu_bypass=off
```

To check if the `largsend` is enabled, run the following command.

```
ifconfig <interface> |grep LARGESEND
```

Install Cohesity Oracle SBT Plug-in (For Windows)

1. Download the Cohesity Oracle SBT Plug-in library for Windows Server 2012 and later from the Cohesity Package Download page. The RPC library shared on the Cohesity Downloads page is applicable for Cohesity versions 6.5.1 and later. Alternatively, you can install the Cohesity Oracle SBT Plug-in library by selecting the **Install SBT** option checkbox while installing the Cohesity agent.

   > **Note:** There are two files for the library. `Cohesity_sbt.dll` and `Cohesity_sbt.exe`.

2. Place the two files in the same directory of the Oracle server. Ensure the directory is accessible by Oracle services and the directory path does not contain space.
3. For Oracle RAC setup, repeat the steps above for all the nodes.

Creating Cohesity View and Configuring RMAN script

1. Create views on the Cohesity cluster and add the following to the allowlist of the view:
   a. The Oracle host IP for a DB server. If there are multiple IPs on the Oracle server, suggest adding all the IPs to the allowlist.

      The read-only option does not apply when creating a view for use with sbt, as the sbt plugin can modify files in the view regardless of this setting.
2. Edit the RMAN script to include the following information:
   a. Parameters that indicate backups will be sent to a tape library and the library's location:
      i. Device Type is SBT_TAPE
      ii. **For Linux**

      ```
      SBT_LIBRARY=<library_directory>/libsbt_linux-x86_64.so
      ```

      iii. **For AIX**

      ```
      SBT_LIBRARY=<library_directory>/libsbt_aix_powerpc.so
      ```

iv. **For Windows**

```
SBT_LIBRARY=<library_directory>\cohesity_sbt.dll
```

b. Provide the required Cohesity specific details:

i. **mount_path**: <any of the Cohesity cluster VIPs>:/<view name>/<path>, for example, `192.0.2.0:/SbtView1/db1`.

ii. **vips**: One of the VIPs configured for the Cohesity cluster, for example, `192.0.2.1`.

iii. For IPv6 only environment, add `sbt_use_ipv6=true` in the `SBT_PARMS` list.

iv. To enable enable security certificates, perform the following steps.

a. Make sure the TCP port 11117 is reachable from the Oracle host.

b. log in to the Cohesity cluster backend and run the following commands:

```
/home/cohesity/bin/client_tls_cert_generator_exec -
validity_days <days> -ca_type <cohesity_ca|self_signed>
```

By default, Cohesity will generate a certificate with 7300 days validity of type `cohesity_ca`.

If you want to fall back to generate a self-signed certificate, specify the option `-ca_type self_signed` when running the command.

> **Note:** SBT library will now try to renew the certificate automatically if the cert type is `cohesity_ca` and it will expire in 60 days. To disable the auto renewal, specify `sbt_certificate_auto_renew=false` in the `SBT_PARMS` when configure or allocate RMAN channels.

c. Copy the generated certificate file `/tmp/cert.cfg` to Oracle host.

d. Add the `sbt_certificate_file=<path of the certificate file>` to the SBT_PARMS.

> **Note:** The IPv6 and TLS features are supported on the cluster version to be 6.5.1 and later and only support Linux platforms.

3. Run the RMAN script either by Cohesity Remote Adapter jobs or customer external schedulers. If an external scheduler is used to invoke the RMAN script, make sure to

take snapshots of the target view after each successful backup run. This can be configured by calling the Cohesity REST API in the script or by scheduling the view protection job in the policy.

4. Cohesity SBT plug-in supports single node single channel, single node multi-channel, and multi-node multi-channel based on the VIPS settings in the RMAN scripts. You must use the same `mount_path` for all the channels.

Sample Scripts

For sample scripts, see Oracle Scripts.

Linux Tools

For information on debug tools, see SBT Linux Tools.

SBT Channel Parameters

The following table lists the Oracle SBT Channel Parameters.

Name	Value	Mandatory/Optional	Notes	Example
vips	string	Mandatory	List of host names or VIPs of the Cohesity cluster. Separated by","for IPv4 or"|"for IPv6 if there are multiple vips are provided.	vips=sac01-broadwell28-p1-vip.eng.cohesity.com vips=10.14.53.42 **Note**: vips can be specified with FQDN
mount_path or data_view	string	Mandatory	mount_path or path of the view.	mount_path=sac01-broadwell28-p1-vip.eng.cohesity.com:/sbt_view/db1 data_view=sbt_view/db1
sbt_certificate_file	string	Optional	The full path on the Oracle host of the certificate file copied from the Cohesity cluster Note: Specifying this option will imply using secure gRPC	sbt_certificate_file=/opt/cohesity_sbt/cert.cfg

Name	Value	Mandatory/Optional	Notes	Example
sbt_use_grpc	bool	Optional	Set this value to false to use SunRPC, this option only applies for Linux platform.	sbt_use_grpc=false
disable_ source_side_ dedup	bool	Optional	Set this value to true to disable source side dedup for full/incremental backups. Archivelog backups will not do source side dedup regardless of this value. You can separately enable or disable source side dedup for your full and incremental backup, if you use different script or RMAN run block to run different types of backup.	disable_source_side_ dedup=true
sbt_use_ipv6	bool	Optional	Enable ipv6 for SBT	sbt_use_ipv6=true

Source-Side Deduplication for Oracle Database

The source-side deduplication feature is built into the Cohesity SBT plugin. As long as you use the SBT plugin, the source-side deduplication will be enabled automatically by default.

The Cohesity source-side deduplication provides storage-efficient deduplication that enhances your Oracle environment with faster backups and reduced network traffic between Oracle servers and the Cohesity.

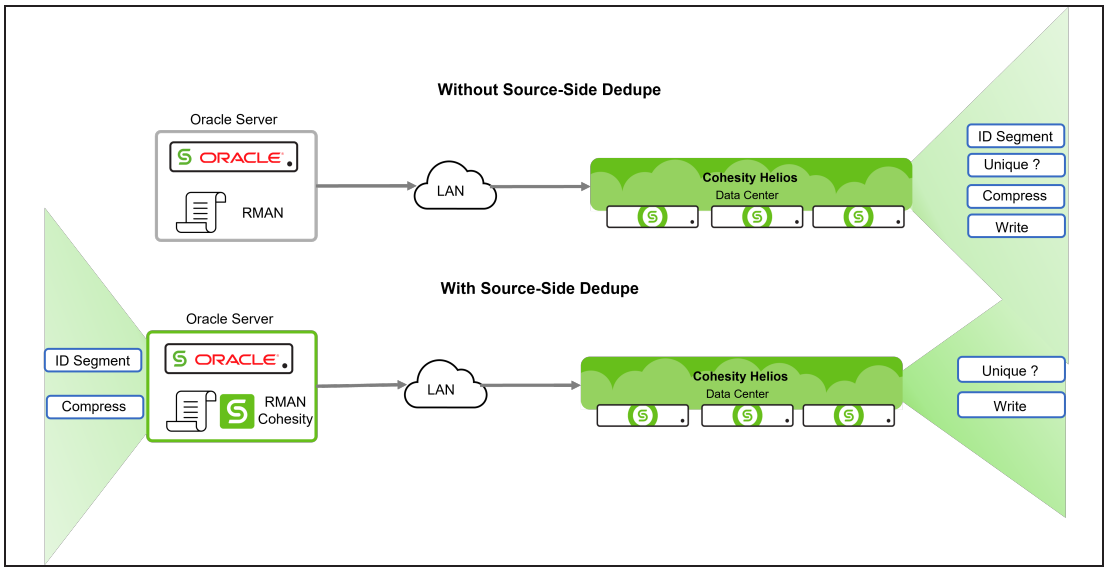
This functionality is enabled by default on the Cohesity cluster. It shifts the deduplication processes to the Oracle server and reduces CPU consumption on the Cohesity allowing further scaling to support more workloads. Additionally, the source-side deduplication plugin Cohesity integrates with the Platform’s built-in deduplication and minimizes data traffic by moving only the new data blocks.

Advantages of the Source-Side Deduplication Plugin

- Faster backups
- Reduce network traffic between Oracle servers and Cohesity
- Enables more frequent backups resulting in higher RPOs

- Offloading deduplication reduces the CPU consumption and enables the Cohesity to run more backup workload sessions.

The following diagram illustrates how source-side deduplication reduces CPU consumption by offloading the deduplication to the source client.

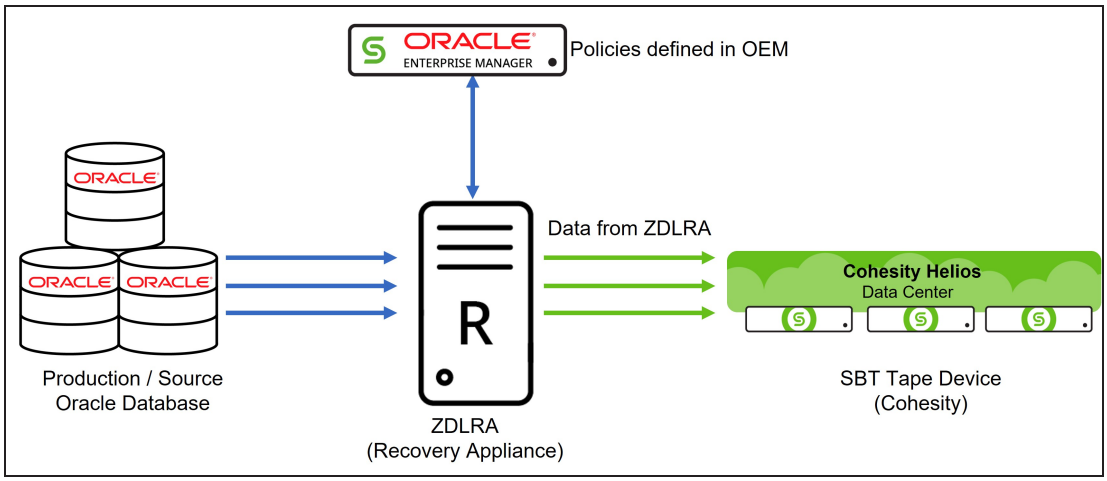


Enable Source-Side Deduplication for Oracle

For a complete set of instructions on how to enable source-side deduplication for Oracle when using the Remote Adapter RMAN script, see Install Cohesity Oracle SBT Plug-in (For Linux).

Cohesity Oracle SBT Plug-In for ZDLRA

The Cohesity SBT plug-in for ZDLRA will be used in the customer data center to facilitate ZDLRA copy jobs to the Cohesity. These copy jobs are queued and executed by ZDLRA according to the configured copy job policies.



Cohesity acts as a tape device for the ZDLRA appliance and provides cost-efficiency by offloading backups to Cohesity for long-term storage. Backups are stored on Cohesity cluster and snapshotted into immutable views to guarantee data protection. Cohesity does its cataloging of backups by collecting metadata of backups and stores this metadata in the Catalog View.

Once the backup is on the Cohesity cluster, protection jobs can be configured to replicate **backups** to other Cohesity clusters, or archived to Cloud storage. Cohesity provides flexible restore options through ZDLRA or directly from Cohesity without ZDLRA. Refer to the Restore section for more details.

Roles

There are 3 roles in a ZDLRA environment with a Cohesity cluster. Cohesity administrator, ZDLRA administrator, and Oracle DBA.

- **Cohesity Administrator**: Cohesity administrator manages the views and protection jobs for ZDLRA to copy the backup data to and restore from the Cohesity cluster.
- **ZDLRA Administrator**: ZDLRA administrator configures ZDLRA copy jobs to copy the backup data to the Cohesity views created by the Cohesity administrator.
- **Oracle DBA**: Oracle DBA performs the restore from ZDLRA or directly from Cohesity with the view information provided by the Cohesity administrator.

Cohesity Views for ZDLRA

A view provides a storage location in a storage domain on the Cohesity cluster. These views can only be accessed by machines specified in the allowlisted subnets. A view that is created and used specifically as a storage location for the ZDLRA copy job is only accessible via the Cohesity SBT driver that is installed on the ZDLRA.

Two distinct types of views are required for ZDLRA backups.

Data View

a. A Data View is used to store the backup data that is copied to the Cohesity cluster through ZDLRA.

b. Multiple Data Views can be configured for one ZDLRA. Each Data View can be used for more than one database.

c. The Cohesity administrator will provide the ZDLRA administrator the information about the view that is required to configure the ZDLRA copy job attributes.

d. The data view name needs to be configured as the value of the parameter `data_view` in the ZDLRA copy job Attribute Set.

Catalog View

a. A Catalog View is used for storing the metadata of the backup data that is copied to the Cohesity Data Views through ZDLRA.

b. This metadata is used by the Cohesity SBT code when ZDLRA issues a restore or crosscheck operation to the Cohesity SBT.

c. The Cohesity administrator will provide the ZDLRA administrator with information about the Catalog View. The ZDLRA administrator will need to know this information to correctly install the Cohesity ZDLRA Package on ZDLRA.

d. The Catalog View name needs to be configured as the value of the parameter a part of `catalog_view` in the ZDLRA copy job Attribute Set and in the configuration file `/opt/cohesity_sbt/config/sbt_config.cfg` on ZDLRA hosts.

Data Flow

When the copy job runs on the ZDLRA, via the SBT library, it will write data to two separate locations on the Cohesity. Each backup piece received from ZDLRA will be written to the Data View and its corresponding metadata will be written to the Catalog View with a filename that is the same name as the backup piece filename.

> **Note:** The file names on both views are the same; however, the contents of the files are different. Do not configure the Data View and Catalog View as the same view, or else your copy job execution will fail.

Prerequisites

This section lists the prerequisites for ZDLRA and Oracle host.

ZDLRA Requirements

The following files are required on the ZDLRA:

1. **SBT Library File**: The SBT library file is a single .so file extracted from the ZDLRA Package.
2. **Configuration File**: The configuration file is a text file created by the ZDLRA administrator on ZDLRA hosts to set the catalog view for ZDLRA copy jobs.
3. **ZDLRA Utility File**: The ZDLRA utility file is an executable that can be run on ZDLRA to list the total number of files and the total size of the data copied to Cohesity for each DB in a particular time range. This file is an optional tool. The ZDLRA backup and restore are not affected without this tool.

Oracle Host Requirements

The following files are required on the Oracle host when restoring directly from Cohesity:

1. **RMAN Script**: Oracle DBA needs to write a restore script based on the sample RMAN script provided by the Cohesity administrator.
2. **SBT Library File**: The SBT library file is a single .so file extracted from the ZDLRA Package.

Installation and Configuration

This section lists the configuration steps for both the Cohesity cluster and the ZDLRA appliance.

- Configuring Cohesity Cluster
- Configuring ZDLRA

Configuring Cohesity Cluster

The steps listed in this section are performed by the Cohesity Administrator.

1. Verify the Cohesity Cluster Version.

   The cluster must be running with the locked view and apiKey features. Cluster versions 6.5.1 or above support these features. If your cluster runs on a special version, contact Cohesity support to confirm if it supports ZDLRA. If your cluster is running on another version, contact Cohesity Support to confirm if it supports ZDLRA.
2. Configure View Indexing.
3. Create a Cohesity Protection Policy.

   Create Cohesity Protection Policies to be used for the view protection jobs for both the catalog view and all the data views. The retention period of the data views should be equal or greater than the retention period of the corresponding SBT copy job. For more information, see Protect Oracle Database.

   > **Note:** The schedule of the Cohesity protection policy for data views will be ignored because the protection jobs are triggered by ZDLRA instead of Cohesity. Cohesity will expire the data based on the retention of the Cohesity protection policy, it won't affect the data and metadata on the ZDLRA end. If the SBT retention on the ZDLRA side is less than the one on the Cohesity side, the catalog entries in the Cohesity catalog view will be deleted when ZDLRA expires the data but the data in the Cohesity snapshots of the data view will NOT be deleted.
4. Install the ZDLRA Package on a Linux host which will be used to manage the Cohesity views and jobs for ZDLRA/SBT backups.
   a. Download the ZDLRA package cohesity_zdlra.tar.gz from the Cohesity Downloads Site to the management Linux host.
   b. Run the following command to extract the file:

      ```
      tar xvf cohesity_zdlra.tar.gz
      ```

c. Run the following command to install the installer in the extracted directory cohesity_zdlra:

`sudo ./cohesity_zdlra_sbt_linux_x86_64_installer` for default installation which will install the package to `/opt/cohesity_sbt` or `./cohesity_zdlra_sbt_linux_x86_64_installer -- -d <install_dir>` for customized installation.

d. Refer to the "Cohesity Installer Details" section in the Appendix for more information about what the package installs.

5. Create a Cohesity Data Security user.

Log in to Cohesity UI as an admin. Create a user with a Data Security role. The user will be used to manage the views for the ZDLRA copy and restore jobs. For more information, see Manage Roles.

Optionally, you can generate an API key by running the following CLI command in the Cohesity CLI:

```
<install_dir>/bin/view_cli generate --host <cluster_name_or_ip> --
username <user_with_admin_role> --password <password> --apikeyusername
<data_security_username> --apikeyname <choose_your_own_keyname>
```

For more information on arguments description, see ZDLRA CLI Commands.

6. Create Cohesity Views and Protection Jobs.

There are two ways to create the Cohesity views and view protection jobs for ZDLRA copy jobs. One is to run the script from the Cohesity admin's Linux host. The other is to create them from Cohesity UI.

a. Create Cohesity Views and Protection Jobs with Script

The ZDLRA package installer contains a convenient script that will create the Cohesity View and Protection Job at the same time. The script is called `cohesity_create_view_for_zdlra.sh`. It is located in `/opt/cohesity_sbt/bin` for default installation or `<install_dir>/bin` for customized installation.

The parameters that can be used with this script are explained in detail in the Appendix section of this document. The `-u` and `-p` options are not needed if the API key (generated in step 5) is supplied. Each ZDLRA can have one Catalog View and one or more Data Views.

i. As a user with the Data Security Role, create a **Catalog View** by running the following command:

```
./cohesity_create_view_for_zdlra.sh -V <zdlra_catalog_view_
name> -I <cluster_ip> -P <policy_name> -W <allowlist/subnet_
```

```
mask> -s <storage_domain> [-u <user_with_data_security_role>
-p <password_for_user> -J <job_name>]
```

ii. As a user with the Data Security Role, create a **Data View** by running the following command:

```
./cohesity_create_view_for_zdlra.sh -V <zdlra_data_view_name>
-I <cluster_ip> -P <policy_name> -W <allowlist/subnet_mask> -
s <storage_domain> -C <zdlra_catalog_view_name> [-u <user_
with_data_security_role> -p <password_for_user> -J <job_
name>]
```

> **Note:** A data view can only be created after the catalog view is created and must set the catalog view name with the `-C` option.

The views created using the script are locked views that cannot be deleted or updated from Cohesity UI.

The allowlist should be a valid IPv4 address and the subnet_mask should be an integer between 0 and 32. If the value of `subnet_mask` is 32, it is for the single IP, in this case, the "/32" can be omitted. If multiple IPs need to be allowlisted, separate them with ",".

For example,

```
./cohesity_create_view_for_zdlra.sh -V zdlra_catalog -I
cluster01 -P zdlra_365 -W 169.22.61.10,169.22.61.12/24 -s
DefaultStorageDomain
```

b. Create Cohesity Views and Protection Jobs from Cohesity UI.

This section lists the to create the views and jobs for ZDLRA from Cohesity UI. Please note the views created from Cohesity UI are not locked views so that they can be updated from Cohesity UI.

i. Create the catalog view as a regular view

I. From the Cohesity UI, navigate to **File Services** > **Views**, then click the **+** button in the upper-right corner and click **New View** from the dropdown list.

II. Provide the view attributes and click the **Create** button.

ii. Create a view protection job for the catalog view

I. From the Cohesity UI, navigate to **Data Protection** > **Protection**, then click the **+** button in the upper-right corner and click the **View** menu from the dropdown list.

II. Select the catalog view name and click the **Save Selection** button.

III. Provide the job attributes and click the **Protect** button.

iii. Create the data view from the ZDLRA view template

I. From the Cohesity UI, navigate to **File Services** > **Views**, then click the **+** button in the upper-right corner and click the **New View from Template** menu from the dropdown list.

II. Select **ZDLRA** from the dropdown list.

III. Provide the view attributes and click the **Create** button.

iv. Create a view protection job for the data view

I. From the Cohesity UI, navigate to **Data Protection** > **Protection**, then click the **+** button in the upper-right corner and click the **View** menu from the dropdown list.

II. Select the data view name and click the **Save Selection** button.

III. In addition to the job name and policy, configure the catalog view by clicking the **Additional Settings** dropdown and select **SBT** as the client type of **Externally Triggered Settings** and set the catalog name to the **Catalog View** option.

IV. Click the **Protect** button to create the job.

7. Share the following Information for the ZDLRA administrator:

a. **Data View name and VIPs**

Data View name and VIPs are used in the configuration of the environment variables for the ZDLRA copy job Attribute Set on the ZDLRA.

b. **Catalog View name and VIPs**

The ZDLRA administrator can set the catalog view name and VIPs in the configuration file `/opt/cohesity_sbt/config/sbt_config.cfg` on ZDLRA hosts.

Configuring ZDLRA

The steps listed in this section are performed by the ZDLRA Administrator.

1. Install the Cohesity ZDLRA Plug-in.

Optionally, obtain the file `libst_linux_x86_64.so` from the Cohesity administrator and place it any directory.

For example:

```
/opt/cohesity_sbt/lib.
```

2. Create the configuration file.

Manually create a configuration file called `/opt/cohesity_sbt/config/sbt_config.cfg` and add the following entry to this file for each Cohesity cluster:

```
Cohesity_cluster : {
catalog_view: "<catalog_view_name>"
catalog_vips: "<cluster_VIPs>"
}
```

- The `catalog_vips` could be one or more IP addresses or hostnames of the Cohesity cluster VIPs. If more than one VIPs are specified, separate them with `:`. For example:

  ```
  catalog_vips:"10.2.100.178:10.2.100.180:10.2.100.182"
  ```

- By default, the SBT log will be written to the `sbtio.log` of ZDLRA, you may add the optional parameter `log_dir` to the configuration file to redirect the logs to any directory of your choice. For example:

  ```
  log_dir: "/opt/cohesit_sbt/logs"
  ```

- By default, the `SBT log_level` is `1` which will generate normal information such as the file names, speed, parameters, etc. This value can be set to `0` in the configuration file to allow only error messages to be generated. For example:

  ```
  log_level: 0    #log_level: 0 for error, 1 for info, 2 for debug
  ```

  The `log_level` can also be configured in the copy job attribute by adding `log_level=n` in the ENV of PARMS. In this case, the `log_level` only applies to the specific copy job.

  A sample `sbt_config.cfg` file is given below:

  ```
  [oracle@rack110dbadm01 ~]$ cat /opt/cohesity_sbt/config/sbt_
  config.cfg
  log_level: 1

  cohesity_cluster: {
    catalog_view: "catalog"
    catalog_vips: "10.14.25.96:10.14.25.97:10.14.25.98"
  }

  cohesity_cluster: {
    catalog_view: "catalog"
    catalog_vips: "10.14.53.50:10.14.53.103:10.14.53.111"
  }

  cohesity_cluster: {
    catalog_view: "catalog_400d"
  ```

```
  catalog_vips: "10.2.200.64"
}
```

This file should only be created on the ZDLRA, not on the Oracle hosts.

3. Create the ZDLRA SBT library using `DBMS_RA.CREATE_SBT_LIBRARY`.

   For example:

```
DBMS_RA.CREATE_SBT_LIBRARY(
            LIB_NAM             => 'COHESITY_SBT',
            DRIVE                       => 24,
            RESTORE_DRIVES      => 8,
PARMS                   => 'SBT_LIBRARY=/opt/cohesity_sbt/lib/libsbt_linux_x86_64.so'
         );
```

4. Create the ZDLRA copy job Attribute Set. Coordinate with your Cohesity administrator on the data views and catalog views to be used for copy jobs.

   For example:

```
'ENV=(data_view=<data_view_name>,vips=<cluster_vips>,catalog_
view=<catalog_view_name>,is_zdlra_copy_job=true,<log_level=<log_
level>>)'
    );
```

The VIPs could be one or more IP addresses of the Cohesity cluster VIPs. If more than one VIPs are specified, separate them with ":".

> **Note:** All the VIPs configured in the ZDLRA copy job attributes must exist in the corresponding cluster entry in the configuration file `/opt/cohesity_sbt/config/sbt_config.cfg` on the ZDLRA hosts.

By default, the `log_level` is `1`, which will generate normal information such as the file names, speed, parameters, etc. This value can be set to `0` to allow only errors to be generated or set to `2` for debug logs.

Example 1: Single VIP

```
 DBMS_RA.CREATE_SBT_ATTRIBUTE_SET (
     LIB_NAME           => 'COHESITY_SBT',
     ATTRIBUTE_SET_NAME         => 'ZDLRA_TEST',
     STREAMS                    => 16,
            PARAMS                      => 'ENV=(data_view=zdlra_
35,vips=10.2.32.123,catalog_view=zdlra_400d,is_zdlra_copy_job=true)'

    );
```

Example 2: Multiple VIPs

```
DBMS_RA.CREATE_SBT_ATTRIBUTE_SET (
     LIB_NAME          => 'COHESITY_SBT',
     ATTRIBUTE_SET_NAME        => 'ZDLRA_TEST',
     STREAMS                   => 16,
            PARAMS                      => 'ENV=(data_view=zdlra_
100,vips=10.2.32.123:10.2.32.125:10.2.32.127:10.2.32.129,catalog_
view=zdlra_400d,is_zdlra_copy_job=true)'
```

Example 3: Multiple VIPs and disable regular logs

```
DBMS_RA.CREATE_SBT_ATTRIBUTE_SET (
     LIB_NAME          => 'COHESITY_SBT',
     ATTRIBUTE_SET_NAME        => 'ZDLRA_TEST',
     STREAMS                   => 16,
            PARAMS                      => 'ENV=(data_view=zdlra_
100,vips=10.2.32.123:10.2.32.125:10.2.32.127:10.2.32.129,catalog_
view=zdlra_400d,is_zdlra_copy_job=true,log_level=0)'
```

5. Create a ZDLRA copy job template for each copy job.

   For example:

```
DBMS_RA.CREATE_SBT_JOB_TEMPLATE (
    TEMPLATE_NAME                    => 'DB123_FULL',
    PROTECTION_POLICY_NAME     => '90_DAYS',
    ATTRIBUTE_SET_NAME               => 'ZDLRA_TEST',
    BACKUP_TTYPE                     => 'FULL, ARCH');
```

6. Queue the copy job using a `Cron job` or the `DBMS_SCHEDULER` package. Use the following `DBMS_RA` call to queue the SBT copy job to ZDLRA:

```
DBMS_RA.QUEUE_SBT_BACKUP_TAST('DB123_FULL');
```

Restore

This section lists the steps for restoring data from ZDLRA and direct restore without ZDLRA, using the Cohesity cluster.

- Restore through ZDLRA from the Local Cohesity Cluster
- Restore through ZDLRA from Replicated Cohesity Cluster
- Direct Restore without ZDLRA
- Direct Restore from the Remote Cluster without ZDLRA
- Restore from the Remote Cluster through ZDLRA
- Direct Restore from Archival without ZDLRA
- Restore from Archival through ZDLRA

Restore through ZDLRA from the Local Cohesity Cluster

Connect to the ZDLRA catalog to run the restore. ZDLRA will automatically read the backup data from the Cohesity cluster if they were copied to Cohesity and the local copy has been deleted.

Restore through ZDLRA from Replicated Cohesity Cluster

Cohesity administrator updates the whitelists of both replicated data view and catalog view to the IP addresses of the ZDLRA nodes.

ZDLRA administrator adds the replicate Cohesity cluster VIPs and replicated catalog view name in the configuration file /opt/cohesity_sbt/config/sbt_config.cfg on the ZDLRA hosts.

Connect to the ZDLRA catalog to run the restore. ZDLRA will automatically read the backup data from the replicated Cohesity cluster if they were copied to Cohesity and the local copy has been deleted.

Note: The files already expired on the local Cohesity cluster can not be restored by this way. To restore the files older than the retention of the policy on the local cluster, please follow the direct restore from Cohesity instructions.

Direct Restore without ZDLRA

The steps listed in this section are performed by the Oracle DBA and Cohesity Administrator.

1. Oracle DBA requests the `cohesity_zdlra.tar.gz` tar file from the Cohesity administrator and extract the Cohesity SBT plug-in `libsbt_linux_x86_64.so` file.

   The `libsbt_linux_x86_64.so` file is then placed in the directory of their choice. For example:

   ```
   /opt/cohesity_sbt/lib.
   ```

2. Oracle DBA provides the following information to the Cohesity administrator:
   i. The path of the Cohesity SBT plugin. For example:

      ```
      /opt/cohesity_sbt/lib/libsbt_linux_x86_64.so.
      ```

   ii. The DB name to be restored.
   iii. The time range of the files to be used for restore. The time is determined by the time point when the files were copied to the Cohesity cluster.
   iv. The IP address of the database server to which the files need to be restored. If the database server has more than one IP address, provide the IP address used to connect the Cohesity cluster. If you are not sure which one is used for connecting to the Cohesity cluster, all the IP addresses can be provided.
3. The Cohesity administrator generates an RMAN re-catalog script by running the `cohesity_prepare_restore.sh` script and with the information provided by the Oracle DBA.

The following example generates the re-catalog script for database `testdb` for backup pieces within the time range `2020/04/14-23:53:01` to `2020/07/16-19:48:43`.

```
./cohesity_prepare_restore.sh -I 10.2.148.135 -S /opt/cohesity_
sbt/lib/libsbt_linux_x86_64.so -D testdb -W 0.0.0.0/0 -s 2020/04/14-
23:53:01 -e 2020/07/16-19:48:43 -J jobname
```

4. The Cohesity administrator provides the sample script generated by the `cohesity_prepare_restore.sh` to the Oracle DBA.

   The sample script can be found from /`tmp/cohesity_sbt_<timestamp>/cohesity_catalog_sbt.<dbname>.rman`.

5. Oracle DBA performs the re-catalog and restores the database based on the sample script provided by the Cohesity administrator by following steps below:

   i. Oracle DBA opens the RMAN script to read the comments, which contains the list of available backup pieces, each with an associated time stamp and file size, that matches your input to the script.

   ii. Identify the control file name that needs to be restored and write an RMAN script to restore the control file according to the SBT parameters in the sample script.

   iii. Use RMAN to directly restore from individual backup pieces, or run the sample script in RMAN to re-catalog all the backup pieces if the target Oracle database is already mounted or open.

   iv. Write an RMAN script to restore the database according to the SBT parameters in the sample script.

6. After the restore/recovery is finished, the Cohesity administrator cleans the cloned views and temp files with the script `cohesity_end_restore.sh`.

   For example:

```
./cohesity_end_restore.sh -I 10.2.148.135 -d /tmp/cohesity_sbt_
20200611_100424
```

Direct Restore from the Remote Cluster without ZDLRA

To restore the files replicated to the remote cluster, follow the same procedure of Restore through ZDLRA from the Local Cohesity Cluster from the local cluster but set the cluster IP to the remote cluster.

Restore from the Remote Cluster through ZDLRA

To restore the files replicated to the remote cluster, follow the following steps.

1. The Cohesity administrator runs the script `cohesity_prepare_restore.sh` as described in the section Direct restore without ZDLRA and adds the option -Z.

   For example:

```
./cohesity_prepare_restore.sh -Z -I 10.2.148.135 -S /opt/cohesity_
sbt/lib/libsbt_linux_x86_64.so -D testdb -W 0.0.0.0/0 -s 2020/04/14-
23:53:01 -e 2020/07/16-19:48:43 -J jobname
```

2. ZDLRA administrator adds the remote cluster vip and the catalog view created in the previous step to the `/opt/cohesity_sbt/config/sbt_config.cfg` files on all the ZDLRA nodes.
3. Oracle DBA runs the restore on the target Oracle host against ZDLRA.
4. After the restore, the Cohesity administrator runs the script `cohesity_end_restore.sh` to clean up the cloned views and the ZDLRA administrator deletes the catalog view entries from the files `/opt/cohesity_sbt/config/sbt_config.cfg` on all the ZDLRA nodes.

Direct Restore from Archival without ZDLRA

To restore the files archived to the cloud, follow the same procedure of Direct restore without ZDLRA from the local cluster and add the `-A <archival_target>` option to the `cohesity_prepare_restore.sh` command.

Restore from Archival through ZDLRA

To restore the files archived to the cloud through ZDLRA, follow the same procedure of Direct Restore from Archival without ZDLRA from the local cluster and add the `-Z` option to the `cohesity_prepare_restore.sh` command.

ZDLRA and SBT restore visibility

The ZDLRA and SBT restore visibility feature allows you to check the reading activities against externally triggered views through the Cohesity SBT plugin. Typically the reading happens when restoring Oracle databases from the data view snapshots or clones of them.

To enable the ZDLRA and SBT restore visibility feature, you have to configure the File Service Audit Logs on the cluster and upgrade both the SBT plugin and the ZDLRA package to the latest version.

Enable or Disable File Services Audit Logs

By default, the File Services Audit setting is disabled. You should enable the File Services Audit option for Cohesity to start logging the Cohesity SBT read events.

You can disable or enable it back from the Settings tab of the Audit Logs page. When you disable the option, the old logs are retained until the retention period ends.

To enable or disable File Services Audit, complete the following:

1. Navigate to **System** > **Audit Logs** > **Log Settings**.
2. In the **Log Settings** tab, turn on/off the **File Services Audit** toggle to enable or disable.

After enabling the **File Services Audit**, the **Log Retention Period** audit information option appears. Use this option to set the audit logs retention period.

Set Log Retention Period for File Services Audit Logs

You can set the retention period for file services audit logs on the Cohesity cluster.

> **Note:** The default retention period is 90 days. You can increase or decrease the renewal period. Once the retention period expires, the audit logs are deleted automatically.

To set a retention period for File Services Audit Logs, complete the following:

1. Navigate to **System** > **Audit Logs** > **Log Settings**.
2. In the **File Services Audit** section of the **Log Settings** tab, click the icon for the **Log Retention Period** option, type the desired number, and select the retention period (Days, Weeks, Months, or Years).

   The Log Retention Period is displayed in days as Cohesity converts weeks, months, or years into days.
3. Click **Save**.

Add IP Allowlist for File Services Audit Logs

The host that installed the ZDLRA package has to be included in the IP allowlist of the File Service Audit Logs to print the SBT read report. By default, every client that is part of the Global Allowlist set at the cluster level can access the File Services audit logs. You can change access permission by the Override Allowlist option to allow or deny access to a subnet. To override the global IP allowlist set at the cluster level and add a subnet to the allowlist for file service audit:

1. Navigate to **System** > **Audit Logs** > **Log Settings**.
2. In the **IP Allowlist** section of the **Log Settings** page, turn on the **Override Global IP Allowlist** toggle.
3. Click **Add**.
4. In the **Add Allowlist** dialog, complete the following:
   a. Type the **Subnet IP** address in CIDR format.

      Example: Subnet in CIDR format (IPv4 - 10.0.0.0/24 or IPv6 - FE80:CD00::211E:729C/60).

   b. The **NFS Permissions**, **SMB Permissions**, or **S3 Permissions** can be any value. (Read/Write, Read Only, or Disabled).

c. Optionally, type a description.

d. Click **Add**.

5. The added allowlist IP subnet details appear in the File Services Audit section of the page.

Print the SBT Read Report

The utility sbt_report delivered in the ZDLRA package can be used to print the SBT reading report. For example:

```
/opt/cohesity_sbt/bin/sbt_report -vips=CohesityCluster

START_TIME            END_TIME              DB_NAME               CLIENT_IP
          STATUS                FILE_SIZE            READ_SIZE
 FILE_NAME
2024/01/21-07:28:01   2024/01/21-07:28:09   CDB
10.14.53.99           Success               2301362176            2301362176
            132h4flq_1_1
2024/01/21-07:28:16   2024/01/21-07:28:18   CDB
10.14.53.99           Success               617873408             617873408
            142h4fmj_1_1
2024/01/21-07:28:19   2024/01/21-07:28:21   CDB
10.14.53.99           Success               563871744             563871744
            152h4fn3_1_1
```

Refer to Appendix for the detailed usage of the sbt_report.

Enabling SSL/TLS for ZDLRA

Cohesity SBT supports SSL/TLS by transferring the encrypted data through secure gRPC.

- Enable SSL/TLS for ZDLRA Copy Job
- Enable SSL/TLS for Restore from Cohesity

Enable SSL/TLS for ZDLRA Copy Job

To enable the SSL/TLS for ZDLRA copy job, follow the steps below:

1. Log in to the Cohesity cluster and run the following command to generate the certificate file for ZDLRA.

   ```
   ./client_tls_cert_generator_exec -cert_name <certificate_name> -
   validity_days <expire_days> -output_file <certificate_file_name>
   ```

   For Example,

   ```
   [cohesity@zdlra-cluster-bqkp82500972-node-2 bin]$ client_tls_cert_
   generator_exec -cert_name zdlra1 -validity_days 3650 -output_file
   /tmp/zdlra1.cert
   ```

```

config change, version=583
I0811 09:10:16.382551 15601 nexus_proxy_service.go:669] Request to
watch for cluster config change version=583
I0811 09:10:16.557071 15601 certificate_utils.go:80] Generated new
client TLS certificate configuration.
I0811 09:10:16.558456 15601 cluster_config_service.go:402] Received
request to stop cluster config service
I0811 09:10:16.558804 15601 cluster_config_service.go:283] Received
notification to stop the config service
I0811 09:10:16.558815 15601 config_watcher.go:114] Received
notification to stop the config watch
I0811 09:10:16.558824 15601 cluster_config_service.go:414] Cluster
config service successfully stopped
I0811 09:10:16.558828 15601 client_tls_cert_generator.go:145] Saved
3650 days validity client TLS certification to /tmp/zdlra1.cert
successfully.
```

2. Copy the generated certificate file to all the ZDLRA nodes and add the full path of the generated certificate file in the `field sbt_certificate_file` attribute of the `/opt/cohesity_sbt/config/sbt_config.cfg` on all the ZDLRA nodes.

   For Example,

```
$ cat /opt/cohesity_sbt/config/sbt_config.cfg
cohesity_cluster: {
catalog_view: "catalog"
catalog_vips: "10.14.25.96:10.14.25.97:10.14.25.98"

sbt_certificate_file: "/opt/cohesity_sbt/config/zdlra1.cert"
}
```

Enable SSL/TLS for Restore from Cohesity

To enable the SSL/TLS for restore from Cohesity, follow the steps below:

1. Log in to the Cohesity cluster and run the following command to generate the certificate file for the Oracle host which the DB to be restored to.

   ```
   ./client_tls_cert_generator_exec -cert_name <certificate_name> -
   validity_days <expire_days> -output_file <certificate_file_name>
   ```

   For Example,

   ```
   [cohesity@zdlra-cluster-bqkp82500972-node-2 ~]$ client_tls_cert_
   generator_exec -cert_name zdlra1 -validity_days 3650 -output_file
   /tmp/oracle1.cert
   I0811 11:58:44.593153 23873 cluster_config_service.go:246] Starting
   cluster config service...
   I0811 11:58:44.593205 23873 cluster_config_service.go:255] Cluster
   config service successfully started

   I0811 11:58:44.600283 23873 config_watcher.go:207] Config change
   notification sent
   I0811 11:58:44.600299 23873 config_watcher.go:84] Load cluster config
   done
   I0811 11:58:44.600314 23873 cluster_config_service.go:313] Config
   change notification received
   I0811 11:58:44.600354 23873 config_watcher.go:155] Watch for cluster
   config change, version=583
   I0811 11:58:44.600439 23873 nexus_proxy_service.go:669] Request to
   watch for cluster config change version=583
   I0811 11:58:44.866526 23873 certificate_utils.go:80] Generated new
   client TLS certificate configuration.
   I0811 11:58:44.867805 23873 cluster_config_service.go:402] Received
   request to stop cluster config service
   I0811 11:58:44.867827 23873 cluster_config_service.go:283] Received
   notification to stop the config service
   I0811 11:58:44.867845 23873 config_watcher.go:114] Received
   notification to stop the config watch
   I0811 11:58:44.867862 23873 cluster_config_service.go:414] Cluster
   config service successfully stopped
   I0811 11:58:44.867868 23873 client_tls_cert_generator.go:145] Saved
   3650 days validity client TLS certification to /tmp/oracle1.cert
   successfully.
   ```

2. Copy the generated certificate file to the Oracle hosts and add the `-c <full path of the certificate file>` when running the script `cohesity_prepare_restore.sh`.

   For Example,

   ```
   $ ./cohesity_prepare_restore.sh -I konacluster -S /opt/cohesity_
   sbt/lib/libsbt_linux_x86_64.so -D OL7312C -W 10.0.0.0/1 -c
   /opt/cohesity_sbt/config/oracle1.cert
   /tmp/cohesity_sbt_20210811_150508/cohesity_catalog_sbt.OL7312C.rman is
   the sample RMAN script to catalog your requested backup for the
   database OL7312C
   ```

Non-ZDLRA Backup and Restore

Backup Oracle Database without ZDLRA

The following steps can be used to back up Oracle databases to immutable views on a Cohesity cluster.

1. Oracle DBA provides the IP addresses of the Oracle servers which are used to connect to the Cohesity cluster to the Cohesity administrator.
2. The Cohesity administrator creates the data view and catalog view for the database to be backed up and adds the IP addresses to both the data view and catalog view for the database and provides the vips, data view name and catalog view name to the DBA.
3. DBA puts the SBT library to any directory and writes RMAN scripts with vips, data_view and catalog_view in the parameters of the RMAN channels in the following format.

   ```
   SBT_PARMS=(vips=<vips of the cluster>, data_view=<data view name>,
   catalog_view=<catalog view name>)
   ```

   or

   ```
   ENV=(vips=<vips of the cluster>, data_view=<data view name>, catalog_
   view=<catalog view name>)
   ```

   For example

   ```
   run {
   ALLOCATE CHANNEL c1 DEVICE TYPE sbt PARMS   'SBT_LIBRARY=/opt/cohesity_
   sbt/lib/libsbt_linux_x86_64.so, SBT_PARMS=(data_
   view=data,vips=10.14.53.50,catalog_view=catalog)';
   ALLOCATE CHANNEL c2 DEVICE TYPE sbt PARMS  'SBT_LIBRARY=/opt/cohesity_
   sbt/lib/libsbt_linux_x86_64.so, SBT_PARMS=(data_
   view=data,vips=10.14.53.103,catalog_view=catalog)';
   backup database;
   }
   ```

> **Note:**
> If restoring the database to a host other than the one used for backup, the Cohesity administrator needs to whitelist the IPs of the destination host to both the catalog and data views.
>
> For example:
>
> ```
> ./view_cli update -host test_cluster -whitelist
> 10.14.56.80,10.14.58.241 -view catalog
> ```
>
> ```
> ./view_cli update -host test_cluster -whitelist
> 10.14.56.80,10.14.58.241 -view data
> ```

Restore Oracle Database from Non-ZDLRA Backups

There are two scenarios to restore an Oracle database from the Non-ZDLRA backups. One is that the RMAN catalog is available. The other is that the RMAN catalog is not available.

Restore Database with RMAN Catalog from Local Cluster to Alternate Host

If restoring the database to a host other than the one used for backup, the Cohesity administrator needs to whitelist the IPs of the destination host to both the catalog and data views with the command `view_cli update -host <cluster_name> -view <view_name> -whitelist <new_whitelists>.

For example:

```
./view_cli update -host test_cluster -whitelist 10.14.56.80,10.14.58.241 -
view catalog
```

For the catalog view, the view update command will only update the live view, while for the data view, the command will update the snapshots of the view protection job associated with the data view as well by iterating all the runs of the job. To avoid scanning all the job runs, -start_time and/or -end_time options can be used to limit the runs to be updated. The time format is yyyy/mm/dd-HH24:MI:SS>.

For example:

```
./view_cli update -host test_cluster -whitelist 10.14.56.80,10.14.58.241 -
view data -start_time=2020/01/01-00:00:00 -end_time=2020/01/08-00:00:00
```

The view_cli update command will overwrite the existing whitelist of the views. To keep the existing whitelist, first run the view_cli listWhistlist command to get the existing whitelist and then append the new IPs to the existing one for the update.

For example:

```
./view_cli listWhitelist -host test_cluster -view catalog 10.0.0.1/32
```

```
./view_cli update -host test_cluster -whitelist
10.0.0.1/32,10.14.56.80,10.14.58.241 -view catalog
```

Restore Database Without RMAN Catalog or from Replicated Cluster or Archival

If the RMAN catalog is not available, a re-catalog is needed for the restore. The procedure is the same as the one of direct restore from Cohesity for the ZDLRA backups.

SBT Alerts on Backup and Restore Failures

Starting with Cohesity cluster version 7.3 and SBT release 20250626_0548b3bd, the cluster generates alerts for failed SBT backup and restore operations if:

- The catalog view is used, and
- The SBT requests can reach the Backup Manager service through the I/O Operation service when the error occurs.

If the SBT plug-in successfully connects to the Backup Manager service at the start of a backup or restore but later loses the connection due to a network or I/O Operation error, the Backup Manager will raise a timeout alert after the configured threshold (30 minutes by default).

> **Note:** The timeout alert may not be generated if the Backup Manager service is restarted during the timeout period.

Appendix

This section lists the Cohesity ZDLRA installer details, ZDLRA CLI commands, and ZDLRA scripts used for creating ZDLRA views and ZDLRA restore.

- Cohesity ZDLRA Installer Details
- ZDLRA CLI Commands
- ZDLRA Scripts and Supported Arguments

Cohesity ZDLRA Installer Details

The name of the installer package is `cohesity_zdlra_sbt_linux_x86_64_installer`.

To run the installer, use the following command:

```
cohesity_zdlra_sbt_linux_x86_64_installer -- -d <install dir> -u <user> -g
<group>
```

The installer creates the following directory structure:

<install dir>	/opt/cohesity_sbt if no -d option is provided		
	/bin	cohesity_create_view_for_zdlra.sh	Used for creating the Cohesity Views and Cohesity Protection Jobs by Cohesity admin (see details below)
		cohesity_end_restore.sh	Used for cleaning up the cloned views and temp files by DBA after performing the direct restore (see details below)
		cohesity_prepare_restore.sh	Used for cloning the data views and generating the template file with the file list to be cataloged for restore (see details below)
		sbt_list	Used for listing the files that exist in a given View (see details below)
		view_cli	Used for manipulating Views (see details below)
		sbt_report	Used for reporting the restore activities (see details below)
	/config		Used for setting the catalog view name and VIPs in the configuration file `sbt_config.cfg` on ZDLRA hosts.
	/lib	libsbt_linux_x86_64.so	SBT library
	/logs		Used for writing logs to the `sbtio.log` of ZDLRA. You may add the optional parameter `log_dir` to the configuration file to redirect the logs to any directory of your choice.

ZDLRA CLI Commands

- **sbt_list**

  This CLI command is used for listing the files that exist in a given View. It is called internally by `cohesity_prepare_restore.sh`. For example:

  ```
  sbt_list --view=<data view name> --vips=<vips> --db_name=<db name> [--start_time=<yyyy/mm/dd-HH24:MI:SS>] [--end_time=<yyyy/mm/dd-HH24:MI:SS>]
  ```

- **sbt_report**

  This utility is used for printing the report of the SBT read activities. The syntax is:

  ```
  sbt_report --vips=<vips> [--start_time=<yyyy/mm/dd-HH24:MI:SS>] [--end_time=<yyyy/mm/dd-HH24:MI:SS>][--db_names=<db_names>]
  ```

```
[--sbt_certificate_file=<certificate_file_name>]
[--client_ips=<client_ips>]
[--status=[InProgress|Success|Failure|TimeOut]]
[--sbt_use_ipv6=[true|false]] [--log_dir=<dir>]
```

The arguments of the command sbt_report are listed as below. Please note the vips option is mandatory, all other options are optional.

Command	Description	Arguments	Argument Description
sbt_report	Print the report of the SBT reading events on a Cohesity cluster.	--vips <string>	The Cohesity cluster name or VIP
		--start_time <string>	The start time of the reading events to be reported.
		--end_time <string>	The end time of the reading events to be reported.
		--db_names <string>	The comma separated database names of the reading events to be reported.
		--sbt_ certificate_file <string>	The full path of the SBT certificate file if secure gRPC is enabled.
		--client_ips <string>	The comma separated client IPs of the reading events to be reported.
		--status <string>	The comma separated status of the reading events to be reported.
		--sort_by <string>	The column name used to sort the results.
		--show_units <bool>	If displaying the size units such as KB, MB, GB etc.
		--sbt_use_ipv6 <bool>	If using IPv6 to connect to Cohesity cluster.
		--log_dir <string>	The full path of the sbt_report logs.

- **view_cli**

  This CLI command is used for manipulating Views. The currently supported commands are:

Command	Description	Arguments	Argument Description
create	Create a View	--host <string>	The Cohesity cluster name or VIP
		--username <string>	*The username for the Cohesity UI
		--password <string>	**The password for the Cohesity UI
		--view <string>	The name of the view to create
		--viewbox <string>	The name of the Storage Domain. The JPMC viewbox is “DefaultStorageDomain”
		--whitelist <string>	The allowlist in the format of x.x.x.x/x,x.x.x.x/x
update	Update a View allowlist	--host <string>	The Cohesity cluster name or VIP
		--username <string>	**The username for the Cohesity UI
		--password <string>	**The password for the Cohesity UI
		--view <string>	The name of the view to update
		--whitelist <string>	The allowlist in the format of x.x.x.x/x,x.x.x.x/x
		--isDataview <true/false>	True to change the view to a data view; False to change the view to a regular view.
		--isLocked <string>	True to lock the view; False to unlock the view.

Command	Description	Arguments	Argument Description
clone	Clone a View	--host <string>	The Cohesity cluster name or VIP
		--username <string>	*The username for the Cohesity UI
		--password <string>	**The password for the Cohesity UI
		--source <string>	The name of the view to be cloned
		--target <string>	The name of the cloned view
		--whitelist <string>	The allowlist in the format of x.x.x.x/x,x.x.x.x/x
protect	Create a Protection Job	--host <string>	The Cohesity cluster name or VIP
		--username <string>	*The username for the Cohesity UI
		--password <string>	*The password for the Cohesity UI
		--view <string>	The name of the view to be protected
		--policy <string>	The name of the Protection Policy
delete	Delete a View	--host <string>	The Cohesity cluster name or VIP
		--username <string>	*The username for the Cohesity UI
		--password <string>	*The password for the Cohesity UI
		--view <string>	The name of the View to delete
search	Search Views based on DB name	--host <string>	The Cohesity cluster name or VIP
		--username <string>	*The username for the Cohesity UI
		--password <string>	*The password for the Cohesity UI
		--dbname <string>	The DB name

Command	Description	Arguments	Argument Description
generate	Generate API key	--host <string>	The Cohesity cluster name or VIP
		--username <string>	*The username for the Cohesity UI
		--password <string>	*The password for the Cohesity UI
		--apikeyname	The name of the API key to create
		--apikeyusername	**The username for which to create the key
		--apikeydir	***The location in which to create the API Key file

*Username and password are optional if the API Key file is present.

**If not specified, the value from `--username <string>` will be used.

***If not specified, the file will be created in `${HOME}`.

Examples

- **create**

```
./view_cli create --host cluster01.xxx.com --username dsuser --password
abcd1234 --view zdlra_data --viewbox DefaultStorageDomain --whitelist
10.5.68.178,10.5.68.179
```

- **update**

```
./view_cli update -host cluster01.xxx.com -username dsuser -password
abcd1234 -view zdlra_data -whitelist 10.5.68.179,10.5.68.180
```

- **clone**

```
./view_cli clone --host cluster01.xxx.com --source zdlra_data --
whitelist 10.5.68.118,10.5.68.119 --target zdlra_data_clone --username
db_clone --password abcd1234
```

- **protect**

```
./view_cli protect --host cluster01.xxx.com --policy "90_day_policy" --
username cohesity-admin --password admin --view zdlra_data
```

- **generate**

```
./view_cli generate --host cluster01.xxx.com --username cohesity-admin
--password admin --apikeyusername oracle_zdlra --apikeydir /tmp --
apikeyname oracle_zdlra_20200703
```

ZDLRA Scripts and Supported Arguments

This section lists the scripts and arguments used for creating ZDLRA views and preparing to restore directly from the Cohesity cluster.

`cohesity_create_view_for_zdlra.sh`

Arguments that can be used with the `cohesity_create_view_for_zdlra.sh script`:

Argument	Description
-V	View name to create
-I	Cohesity Cluster IP
-P	Cohesity Cluster Policy name
-W	Allowed IP address/netmask bits separate by commas if multiple
-u	Cohesity username (optional - if not provided will use API key)
-p	Cohesity password (optional - if not provided will use API key)
-s	Cohesity Storage Domain name (optional - if not provided will use DefaultStorageDomain)

`cohesity_prepare_restore.sh`

Arguments that can be used with the `cohesity_prepare_restore.sh script`:

Argument	Description
-D	DB name to be restored
-I	Cohesity Cluster IP
-S	Cohesity SBT library path
-W	Allowed IP address/netmask bits separate by commas if multiple
-u	Cohesity username (optional - if not provided will use API key)
-p	Cohesity password (optional - if not provided will use API key)

Argument	Description
-V	The Cohesity data view used for backup the DB (optional - if not provided, the script will search all the views that have a backup for this DB name)
-s	start_time with format yyyy/mm/dd-HI:MM:SS (optional - if not provided, no limit on start time)
-e	end_time with format yyyy/mm/dd-HI:MM:SS (optional - if not provided, no limit on end time)
-A	The archival target if the restore needs to get data from the archival (optional - if not provided, only local snapshots will be searched)
-J	The job name or job UID of the job to be used for the restore (optional - if not provided, will use Yoda search to get the snapshots)
-c	The sbt certificate file on the Oracle host if secure gRPC will be used between the Cohesity cluster and the Oracle host (optional - if not provided, regular gRPC will be used)
-C	The sbt certificate file on the Linux management host if secure gRPC will be used between the Cohesity cluster and the Linux host (optional - if not provided, regular gRPC will be used)
-M	The file contains the list of views to be merged (optional - if provided, the script will merge the cloned views listed in the file instead of searching the snapshots internally)
-K	Keep the views undeleted (optional - if not provided, will delete the temp views generated by the script)
-Z	Indicates the restore will be done through ZDLRA. A catalog view will be created after running the script with this option. (optional - if not provided, only a data view will be created.)
-O	Overwrite the duplicate entries in the catalog view. (optional - if not provided, the script will fail if duplicate files are found.)

`cohesity_end_restore.sh`

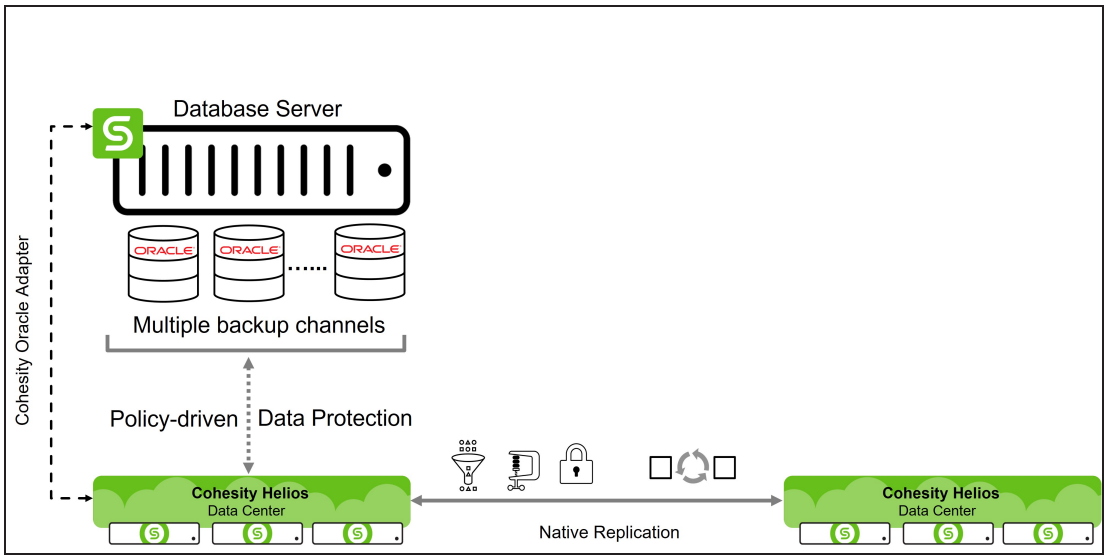
Arguments that can be used with the `cohesity_end_restore.sh` script:

Argument	Description
-d	The temp directory generated by cohesity_prepare_restore.sh
-l	Cohesity Cluster IP
-u	Cohesity username (optional - if not provided will use API key)

Argument	Description
-p	Cohesity password (optional - if not provided will use API key)

Replicate Oracle Database

Oracle application administrators can use Cohesity replication for cost-effective disaster recovery (DR). Cohesity provides a policy-based data replication solution from the core to the cloud or to the edge, from one cluster to another cluster. As part of replication, Cohesity always performs source-side compression and deduplication first, and sends only the changed data over the network.



Replicate Oracle Database

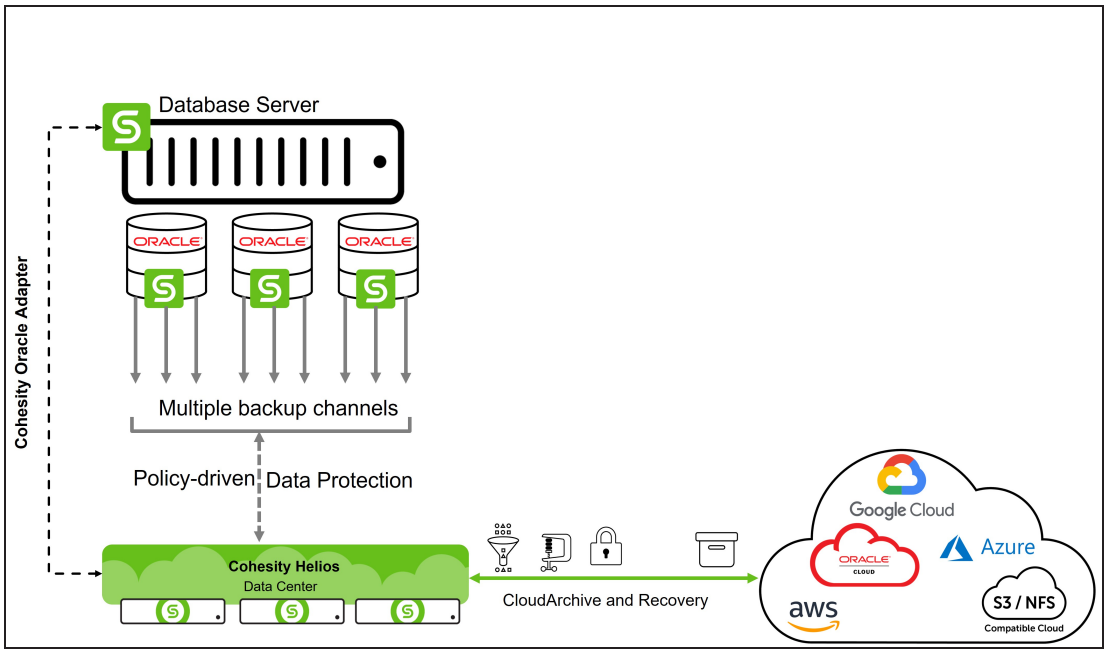
For more information about database replication, see Creating a Connection to the Remote Cluster.

Considerations

1. Overwrite restore is not supported for replication sites.
2. Failover is not supported for the Cohesity Oracle adapter. You have to perform a force re-register of the same sources on the replication cluster and start the backup process all over again.
3. In case of a failover, after the re-registration, a full backup is required before you can perform an incremental or a log backup.

CloudArchive and CloudRetrieve for Oracle Database

Cohesity offers cost-effective, reliable data storage and protection solutions for rapidly growing environments that deploy Oracle Databases. The data in these environments can grow to terabytes and even petabytes in size.



Cohesity provides a policy-based method to archive to public clouds (AWS, Azure, GCP, and Oracle Cloud), to any S3-compatible storage, to tape, and/or to any NFS mount point. Oracle application administrators can use Cohesity CloudArchive to address long-term data retention requirements and can choose to restore an entire database. The archived data is efficiently transferred and stored by sending only deduplicated, compressed incremental backups, thereby reducing network and storage utilization.

Once the data is archived, Oracle application administrators can make use of Cohesity CloudRetrieve features as a cost-effective alternative for disaster recovery and geo-redundancy. If the cluster from which the data is archived becomes unavailable, you can retrieve your data onto a different cluster.

CloudRetrieve for Oracle Database

The CloudRetrieve approach involves the following steps:

1. Register the cloud container (where you archived the Oracle Database) with a new Cohesity cluster.
2. Provide the search parameters, such as cluster name, Protection Group name, and date range.
3. Cohesity retrieves the data that you specify onto the new Cohesity cluster, based on your search of the metadata.

For more information, see CloudRetrieve Searches.

> **Note:** CloudArchive and CloudRetrieve are agnostic of Cohesity Oracle Adapter and Remote Adapter versions.

Oracle Database Troubleshooting

This topic provides the troubleshooting information for the Cohesity Oracle Adapter.

Oracle agent troubleshooting checklist

1. Verify the agent user (cohesityagent by default) is part of the dba and/or the oinstall groups. Use the command ID to check:

   ```
   id cohesityagent
   uid=1002(cohesityagent) gid=1001(dba) groups=1001(dba)
   ```

2. Verify the /etc/sudoers file has the agent configured. For example:

   ```
   cohesityagent        ALL=(ALL)       NOPASSWD:ALL
   Defaults:cohesityagent !requiretty
   ```

   > **Note:** Use spaces and not tabs as tabs may lead to syntax errors.

3. Verify the home of the agent user is configured with the drwxr-xr-x minimum permission. For example:

   ```
   ls -ld /home/cohesityagent
   drwxr-xr-x 6 cohesityagent cohesityagent 198 Jan 17 08:58
   /home/cohesityagent
   ```

   To change the permissions, execute the following command:

   ```
   chmod 755 /home/cohesityagent
   ```

4. Verify `.bashrc` in the home of the agent user has `umask 0002`.
5. Verify the agent is running:

   ```
   /etc/init.d/cohesity-agent status
   ```

6. Verify with the DBA that the database to be backed up is in `/etc/oratab` and has the correct `ORACLE_HOME` path.

   > **Note:** Ensure the third field contains Y or N.

   ```
   CohesityOra:/oracle/app/oracle/product/12.2.0/dbhome_1:Y
   ^database^ ^ORACLE_HOME path                          ^
   ```

7. If database access will use OS authentication, the Cohesity agent user must have sysdba privileges on the database. If database authentication will be used, the database user also requires sysdba privileges. Verify using sqlplus commands:

```
SQL> column sysdba format a10
SQL> select username,sysdba from v$pwfile_users;
USERNAME   SYSDBA
---------- ----------
SYS        TRUE
COHBACKUP  TRUE
```

8. Verify the Linux physical server has been registered as a source.
    a. Navigate to **Protection** > **Sources**.
    b. Click **Register Source** located at the top right of the page.
    c. Click **Physical Server**.
    d. Enter the Oracle server Host Address.
    e. Click **Register Server**.
9. Verify the Oracle Database is registered.
    a. Navigate to **Protection** > **Sources**.
    b. Click **Register Source** located at the top right of the page.
    c. Click **Oracle Source**.
    d. Accept the default Single Instance as the source type.
    e. Enter the Oracle server Host Address or browse the registered sources and select one.
    f. Select the **Authentication Type** to use when connecting to the database.
    g. Click **Register**.

Troubleshooting Agent Issues

The following table provides details about Cohesity Oracle adapter issues that you might encounter:

Issue	Cause	Workaround
Oracle Remote Adapter Job error "Execution of script failed with exit code: 255, error msg: Received disconnect from X.X.X.X port 22: Too many authentication failures for oracle Authentication failed"	This can occur if Public Key (Password less) authentication between Cohesity Nodes and the Oracle server is not working.	• Access the Cohesity bash shell, as described in How to access the bash shell on a Cohesity node and run the below command to confirm password less authentication is working to the Oracle server: `ssh oracle@<oracle_host>` • If the above step prompts for password, it means that the Public Key (Password less) authentication between Cohesity Nodes and the Oracle server is not working. Perform the following to resolve the issue: ◦ Attempt to re-copy the RSA key from the Cohesity Job edit page to the oracle server authorized_keys file for the corresponding user. ◦ Check the permissions on the authorized_keys file is owned by the correct user and file permission allows the same user to read. ◦ Refer to the Cohesity Documentation and search for the section Add or Edit a Remote Adapter Protection Group.

Oracle single instance database is not discovered after registering a Linux Oracle server	There is an incorrect `$ORACLE_HOME` directory path entry in the `/etc/oratab` file for the Oracle SID.	To resolve this error, verify that entries in `/etc/oratab` are following the correct format:
		`$ORACLE_SID:$ORACLE_HOME:<N|Y>`
		Example:
		`ORADB:/u01/app/oracle/product/11.2.0.4:N`

Issue	Cause	Workaround
Cohesity workaround for Oracle RMAN database recovery fails (ORA-01180 and ORA-01110)	This error occurs because of known Oracle issues. Refer to ORA-01180 and ORA-01110.	To workaround this issue, open the Cohesity UI and adjust the Point in Time slider to a later date to include more log files. For example, as shown in the following screen shot, move the Point in Time slider from August 19 to August 22. Oracle Remote Adapter recovery job to an alternate location fails with "RMAN-05501: aborting duplication of target database"	If the RMAN script includes the same file_ path as the original server when recovering in the destination server, Oracle will report an error.	Contact Cohesity support and reference this KB article. As a workaround, the script can be updated to ignore this error by adding NOFILENAMECHECK.

Issue	Cause	Workaround
Oracle protection job fails with the RMAN error "ORA-09925: Unable to create audit trail file"	Cohesity creates a new session and in turn a new Oracle trace file when the database backup progress query is run. This behavior is expected with Oracle. Refer to the Oracle documentation.	Cause Cohesity creates a new session and in turn a new Oracle trace file when the database backup progress query is run. This behavior is expected with Oracle. Refer to the Oracle documentation. Resolution Review the Oracle database settings and determine whether SQL_TRACING is enabled. In addition, kcb / krb tracing might be enabled.
Oracle RMAN protection job configured to use source-side deduplication (SBT) fails in environments without IPv6 enabled	By default, the SBT library uses sun_rpc calls which communicate over IPv6.	To resolve this issue: 1. Enable IPv6 on the Oracle database server(s). 2. Contact Cohesity support to download a new library which forces communication over IPv4. The new library requires that additional SBT parameters be used in the RMAN script.

Issue	Cause	Workaround
Cloning an Oracle database fails with the RMAN error "ORA-65093: multitenant container database not set up properly"	As indicated in the error message, Cohesity does not support cloning Oracle databases when multitenant container database (CDB) is enabled.	To request this capability, refer to Cohesity knowledge base article, How to create and view Request for Enhancements.

Issue	Cause	Workaround
Oracle database protection job fails with "[kTimeout]: RPC call MountOracle NAS timed out"	This error has been seen when the time required to set the Oracle Server permissions for the Cohesity user times out or because of a connectivity issue between the Oracle Server and the Cohesity Cluster. For example, this error has been seen when bi-directional communication over port 2049 is not open across network firewalls or when there is a networking issue.	For details on how to resolve this error, see the KB article.

Issue	Cause	Workaround
Oracle protection job fails with "[kAgentError]: ORA-00312: online log 2 thread 1: ORA-19809: limit exceeded for recovery files"	This failure results from a server-side issue.	Refer to the Oracle documentation on the ORA error codes. **ORA-000312: session marked for kill** **Cause**: The session specified in an ALTER SYSTEM KILL SESSION command cannot be killed immediately (because it is rolling back or blocked on a network operation), but it has been marked for kill. This means it will be killed as soon as possible after its current uninterruptible operation is done. **Action**: No action is required for the session to be killed, but further executions of the ALTER SYSTEM KILL SESSION command on this session may cause the session to be killed sooner. **ORA-19809: limit exceeded for recovery files** **Cause**: The limit for recovery files specified by the db_recovery_file_dest_size was exceeded. **Action**: The error is accompanied by 19804. See message 19804 for further details **ORA-19804: cannot reclaim string bytes disk space from string limit** **Cause**: Oracle cannot reclaim disk space of specified bytes from the `DB_RECOVERY_FILE_DEST_SIZE` limit. **Action**: There are five possible solutions: 1) Take frequent backup of recovery area using RMAN. 2) Consider changing RMAN retention policy. 3) Consider changing RMAN archivelog deletion policy. 4) Add disk space and increase `DB_RECOVERY_FILE_DEST_SIZE`. 5) Delete files from recovery area using RMAN.

Issue	Cause	Workaround
Oracle Remote Adapter protection job fails with the RMAN error " [kIOError]: [kAppError]: Dedup write failed with error: kQuotaExceeded"	These errors have been seen when a quota was set on the View used for the RMAN backup, and the View's quota nearly reached the limit.	To resolve this issue, increase the quota assigned to the View and re-run the job.

CockroachDB

Cohesity natively integrates with CockroachDB to provide backup and recovery for clustered CockroachDB deployments. Using Cohesity Connector Agent, you can backup and restore the CockroachDB database. The Cohesity Connector Agent provides a simple workflow to back up and restore your CockroachDB deployment.

Cohesity provides a CockroachDB connector for backup and restore of enterprise CockroachDB deployments. The CockroachDB connector leverages the backup and restore capabilities provided by CockroachDB.

The CockroachDB connector enables you to back up and restore the following:

- Backup:
  - Full backup of the following with or without revision history:
    - Cluster
    - Database
    - Table
  - Incremental backup of the following with or without revision history:
    - Cluster
    - Database
    - Table

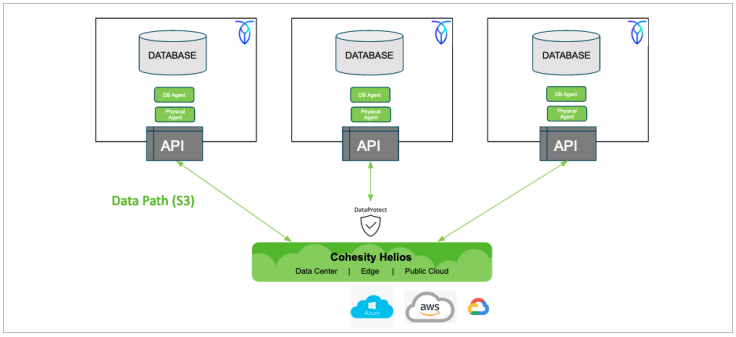
- Restore: Full restore of the following:
  - Cluster
  - Database
  - Table
- Point In Time Restore (PITR) of the following:
  - Cluster
  - Database
  - Table

Core Components

The following are the core components for protecting CockroachDB databases:

- CockroachDB cluster
- Cohesity CockroachDB connector (DB Agent)
- Cohesity Connector Agent (Physical Agent)
- Cohesity S3 View

As illustrated, you can integrate Cohesity with your CockroachDB deployments using the Cohesity CockroachDB connector and Cohesity Connector Agent.



Plan and Prepare for CockroachDB Protection

Before you register your CockroachDB deployment as a source with Cohesity, and protect CockroachDB databases, ensure the following prerequisites:

- Identify the node(s) in your CockroachDB cluster with adequate resources to execute the CockroachDB connector.
- Ensure that the fully qualified domain name (FQDN) of the Cohesity cluster is resolvable from all the nodes in the CockroachDB cluster.
- A database user with database admin user privileges.

- Cohesity CockroachDB connector uses PostgreSQL client (psql) to connect to CockroachDB. Ensure that PostgreSQL client is already installed and available in PATH.
- Download and install the Cohesity Linux Agent on the CockroachDB node.
- Download and install the CockroachDB connector.
- Review and understand the considerations.

Supported Versions

For more information on supported CockroachDB versions, see Supported Software versions.

Port Requirements

Outgoing Traffic

Source	Destination	Port	Protocol	Type of Traffic
Cohesity cluster	CockroachDB Node	50051	TCP/IP	Control path for all workflows

Bidirectional Traffic

Source	Destination	Port	Protocol	Type of Traffic
CockroachDB Local Host	CockroachDB Local Host	59999	TCP/IP	Required only if local-to-local communication (used for self-monitoring and debugging purposes) is blocked by the firewall.

Incoming Traffic

Source	Destination	Port	Protocol	Type of Traffic
CockroachDB Node	Cohesity cluster	11113	TCP/IP	Backup and Recovery
CockroachDB Node	Cohesity cluster	11117	TCP/IP	Backup and Recovery with secure gRPC

Considerations

Review and understand the following considerations before you protect your CockroachDB cluster.

- In a Recovery run, we can restore only one object at a time.
- Backup or restore might fail, if the S3 keys are changed when the backup or restore is in progress.

Download and Install the Cohesity Linux Agent

The Cohesity Linux Agent is available as script-based and RPM-based installers, based on your requirements download the installer and install it accordingly on the node(s) of the CockroachDB cluster . For detailed instructions, see Download and Install the Linux Agent.

> **Note:** Ensure that you install the Cohesity Linux Agent using the RPM-based installer.

Download and install the CockroachDB Connector

Cohesity provides a CockroachDB connector for backup and restore of enterprise CockroachDB deployments. The CockroachDB connector leverages the backup and restore capabilities provided by CockroachDB.

Download the CockroachDB Connector

Cohesity provides a CockroachDB connector to backup and restore CockroachDB databases. The CockroachDB connector is available as a datasource agent on the Cohesity Download portal. Log on to the Cohesity Download portal, download the respective datasource agent for CockroachDB connector, and copy the datasource agent to the CockroachDB host.

Install the CockroachDB Connector

Before you install the CockroachDB Connector, ensure that you have sudo privileges.

To install the CockroachDB connector:

1. Log on to the CockroachDB node where you have copied the CockroachDB connector RPM-based installer, `cohesity-cockroachdb-connector-<version>.x86_64.rpm`.
2. Run the following command to install the CockroachDB connector:

   ```
   sudo rpm -ivh /home/cockroach/cohesity-cockroachdb-connector-
   <version>.x86_64.rpm --prefix <connector_install_directory>
   ```

   Where `<connector_install_directory>` is the CockroachDB node's directory where you want to install the CockroachDB connector. If you do not define the installation directory, then by default, the connector is installed in the `/opt/cohesity/cockroachdb/scripts` directory.

Uninstall the CockroachDB Connector

To uninstall the CockroachDB Connector:

1. Log on to the CockroachDB node where you have installed the CockroachDB connector.
2. Run the following command to uninstall the CockroachDB connector:

```
#sudo rpm -e cohesity-cockroachdb-connector-<version>.x86_64
```

Register and Manage the CockroachDB Source

To protect your CockroachDB databases, you need to register your CockroachDB deployment as a source on Cohesity. After registering your CockroachDB deployment as a source, you can:

- Update the CockroachDB source configuration, such as:
  - Add more node(s) to run the CockroachDB connector. Ensure that you have installed the Cohesity Linux Agent and CockroachDB connector on the node(s).
  - Update the username and password of the database user.
- Refresh the source details.
- Unregister the CockroachDB source from Cohesity.

Register CockroachDB as a source

Before you register CockroachDB as a source, ensure that you:

- Review the requirements and considerations.
- Perform the prerequisite tasks.

For more information, see Plan and Prepare for CockroachDB Protection.

To register CockroachDB as a source:

1. Navigate to **Data Protection > Sources**.
2. Click **Register** at the top-right of the page and then select **Universal Data Adapter**.
3. In the **Register Universal Data Adapter** page, perform the following:
   1. From the Source Type drop-down menu, select **CockroachDB**.
   2. In the **Hostname/IP Addresses** field, enter the hostname or IP address of the node(s) you have identified to run the CockroachDB connector. For more information, see Plan and Prepare for CockroachDB Protection.
   3. In the **Datasource Agent Installation Path** field, enter the directory path on the CockroachDB node, where you have installed the CockroachDB connector. For more information, see Install the CockroachDB Connector.
   4. In the **APP Authentication** section, enter the **Username** and **Password** of the CockroachDB database admin user.

> **Note:** The **Password** field is optional.

5. Enable **Custom Options**, and perform the following:
   1. Ignore the **Mounts View** option. It is not applicable for CockroachDB source registration.

      > **Note:** The **Mount View** option is not applicable, and ensure you do not enable the option.

   2. Optional. In the **Source Registration Options** field, enter the following source registration parameters based on your requirement:

Parameters	Mandatory?	Description
`--cluster-name`	No	(optional) A unique name to identify the CockroachDB cluster.
`--port`	No	The port used to connect to the CockroachDB cluster. Default : 26257
`--certs-dir`	No	If you want the Cohesity to authenticate to the CockroachDB cluster using client certificate and key authentication then provide the path to the certificate directory containing all certificates and keys in the CockroachDB node. The certificate file names must be in following format: • CA certificate: `ca.crt` • Client certificate for the user: `client.<user>.crt`. Example: The root user certificate file must be `client.root.crt`. • Client key for the user: `client.<user>.key` Example: The root user client key file must be `client.root.key`
`--keytab`	No	If you want the Cohesity to authenticate to the CockroachDB cluster using kerberos authentication then provide the path to the Keytab file with client principals.

6. Click **Register**.

Update the CockroachDB Source Configuration

After registering your CockroachDB as a source on Cohesity, you can:

- Add more node(s) to run the CockroachDB connector. Ensure that you have installed the Cohesity Linux Agent and CockroachDB connector on the node(s).
- Update the username and password of the database user.
- Modify the **Global Source Registration Parameters** based on your requirements.
- Update the **Script Directory Path** only if you have uninstalled and reinstalled the CockroachDB connector in a different directory on the CockroachDB node.

> **Note:** Ensure that the CockroachDB connector is installed on all the node(s) in the Cohesity cluster.

To update the CockroachDB source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the CockroachDB source and select **Edit**.
3. On the **Update Universal Data Adapter** page, update the required configurations.
4. Click **Update**.

Refresh the CockroachDB Source Configuration

You can refresh the CockroachDB source and re-verify the source with the available source registration parameters.

To refresh the CockroachDB source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the CockroachDB source and select **Refresh**.

Unregister the CockroachDB Source

If you plan to stop taking the backup of your CockroachDB databases, you can unregister the CockroachDB source from the Cohesity Cluster.

To unregister the CockroachDB source:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the CockroachDB source and select **Unregister**.

Backup CockroachDB Database

Cohesity provides a simple workflow to back up your CockroachDB databases. After registering the CockroachDB source on Cohesity, you can start configuring your backups.

Backup Process

Cohesity provides a CockroachDB connector for backup and restore of enterprise CockroachDB deployments. The CockroachDB connector leverages the backup capabilities provided by CockroachDB.

After registering the CockroachDB source on Cohesity, you can create a Protection Group and specify the objects such as databases and tables that you want to backup. In the Protection Group, you need to define the parameters that enable you to provide additional parameters required by the backup statements provided by CockroachDB.

> **Note:** Cohesity recommends that you configure periodic full backups.

Backup Parameters

In the Protection Group, you can define the following parameters for your CockroachDB backup configuration:

Backup Parameters	Description
`--cluster-backup`	Enables you to create a backup of the CockroachDB cluster. If you define this parameter, then the objects specified in the Protection Group are ignored. For example: `--cluster-backup=true`
`--custom-args`	Allows you to use the backup options provided by CockroachDB. For example: `--custom-args=<backup-options>`

Protect CockroachDB Deployments

CockroachDB deployments are protected using a Protection Group and a Protection Policy. A Protection Group enables you to:

- Specify the objects such as databases and tables that you want to backup.
- Based on your requirement, define the parameters for the backup statements provided by CockroachDB. For more information, see Backup Parameters.

The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select which standard or custom policy to use when creating a Protection Group. For more information, see Manage Protection Policy.

To protect CockroachDB deployments:

1. Do one of the following:
   - Select **Data Protection > Protection**. Click **Protect** on the top-right of the page and then select **Universal Data Adapter**.
   - Select **Data Protection > Sources**. Click the actions menu (⋮) next to the CockroachDB source and then select **Protect**.
2. From the **Source** drop-down list, select the registered CockroachDB source or click **Register Source** to register a CockroachDB source. For more information, see Register CockroachDB as a source.
3. In the **Objects** section, add the objects that you plan to protect. The object can be a database or a table. To back up a database, enter the name of the database. If you want to backup a table, enter the database name and the table name with a dot(**.**). For example, `bank.account`. Where `bank` is the database name and `account` is the table name.
4. Click the plus icon **(+)** to enter multiple objects that you plan to back up. Then, click **Save Selection**.
5. In the **Protection Group** section, do one of the following:
   - Select **New Group** to create a new Protection Group. In the **Protection Name** field, enter a name from the Protection Group.
   - Select **Existing Group** to use the settings of an existing Protection Group. From the **Group** list, select an existing Protection Group and click **Protect**.
6. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, see Protect CockroachDB Deployments.
7. In the Settings section, do the following:
   1. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains.
   2. In the **Start Time** field, define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard.

      Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
   3. In the **Custom Options** section, perform any one of the following:
      - Apart from the `--custom-args` parameters, do not enter any backup parameters in the **Full Backup** and **Incremental Backup** fields if you plan to protect only the specified object(s) in the Protection Group.
      - Enter the Backup Parameters in the **Full Backup** and **Incremental Backup** fields if you plan to back up the entire CockroachDB cluster.

Ensure that you enter the same backup parameters in the **Full Backup** and **Incremental Backup** fields.

For example:

Use Cases	Sample Parameters
Create a full or incremental backup of the CockroachDB cluster. **Note:** In the case of the CockroachDB cluster backup, the objects you have defined in the Protection Group is ignored.	`--cluster-backup=true`
Create a full or incremental backup of the CockroachDB cluster with full revision history **Note:** Based on your requirements you can also use various backup options provided by CockroachDB. You can use all backup options provided by CockroachDB, except the `detached` option.	`--cluster-backup=true --custom-args=revision_history`

- Ignore the **Mounts** field. It is not applicable for CockroachDB data protection.

8. After you have completed the **Settings**, if you need to change any additional settings on the **New Universal Data Adapter Protection Group** page, scroll down and click Edit on the right. For more information, see Additional Settings.
9. Click **Protect**.

Additional Settings

Additional Settings	Description
Pause Future Run	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.

Additional Settings	Description
End Time	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup Target HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup Target SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Concurrency	Maximum number of backup streams that will be created to exchange data with the cluster. By default, maximum scaling is capped at 16. > **Note:** Not applicable for CockroachDB data protection.
Alerts	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.

Additional Settings	Description
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).
Description	**Optional**. Enter a brief description about the Protection Group.

Manage the CockroachDB Backup Configuration

A backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Object(s) to the Protection Group

You can add new databases or tables to the existing Protection Group for backup. The newly added object is backed up from the next protection run, and it will be a full backup for the newly added object.

To add object(s) to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for CockroachDB.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ in the **Objects** section.
5. In the **Objects** section, Click the plus icon (**+**) to enter multiple objects that you plan

to back up. click **Save Selection**.

6. Click **Save**.

Remove Object(s) from the Protection Group

You can remove object(s) from the Protection Group that you do not want to back up in the next protection run. When you remove an object from the protection group, incremental backup of the object is not performed from the next protection run. The existing backup for the object is preserved until the snapshot expires.

To remove object(s) from the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for CockroachDB.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ on the **Objects** section.
5. In the **Objects** section, Click the minus icon (**-**) next to the objects to remove them from the backup. click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for CockroachDB.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ on the **Objects** section.
5. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
6. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to

execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for CockroachDB.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

When you cancel a protection run, the CockroachDB connector leverages the Cancel Job capabilities provided by CockroachDB.

To cancel a recovery run:

1. Navigate to **Data Protection > Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity.

To delete the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for CockroachDB.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Delete Protection Group Only
    - Delete Protection Group and Snapshots

Recover CockroachDB Database

You can restore the CockroachDB cluster or object(s) such as databases and tables in CockroachDB. You can restore to the same CockroachDB cluster or to a different CockroachDB cluster.

The CockroachDB connector leverages the restore statements provided by CockroachDB. You can create a Recovery configuration and specify the objects such as databases and tables backed up using the Protection Group.

In the Recovery configuration, you need to specify the object you plan to restore and define the script parameters required by the restore statements provided by CockroachDB.

Recovery Parameters

In the Recovery configuration, you can define the following script parameters for your CockroachDB recovery:

Recovery Parameters	Description
`--cluster-restore`	Enables you to restore the CockroachDB cluster. If you define this parameter, then the object you have specified for recovery is ignored. For example: `--cluster-restore=true`

Recovery Parameters	Description
`--custom-args`	Allows you to use the restore options provided by the CockroachDB. For example: `--custom-args=<restore-options>` **Note:** The `detached` and `into_db` options from the restore options are not supported.
`--pitr-epoch`	Allows you to perform Point In Time Restore (PITR). You need to provide the restore point in the epoch format. For example, on a Linux machine, you can find the epoch for a required time using the following command: `# date "+%s" -d "02/28/2021 15:41:15"` For example: `--pitr-epoch=1632125909` **Note:** You can perform PITR only if the corresponding backup is taken with revision history.

Recover CockroachDB Databases

To recover CockroachDB:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** at the top right of the page and then select **Universal Data Adapter**.
3. Search for the Protection Group that contains the snapshots to recover from by entering characters of the Protection Group name, or by specifying the wildcard character *.
4. From the list of search results, select the Protection Group that contains the snapshots to recover.
5. In the **Object** field, enter the name of the database or table that you had backed up using the selected Protection Group. By default, the latest snapshot is selected for recovery.
6. Click **Next: Recover Options**.
7. In the **Recover As** section, based on your requirements, select any one of the following options:

Options	Description
Replace Original	To restore to the same CockroachDB cluster.
New Object	To restore to a different CockroachDB cluster. Select the **Target** CockroachDB cluster to which the data needs to be restored. Also, enable **Overwrite existing object with the same name** and type **Yes**, if you want to overwrite the existing object with the same name.

8. In the **Recovery Options** section, configure the following options:

Options	Description
Mounts	Not applicable for CockroachDB recovery.
Concurrency	Not applicable for CockroachDB recovery.
Custom Options	Specify the Recovery Parameters based on your requirements. For examples, see Sample Recovery Use Cases
Rename	Provide the new name for the object, if you want to restore the object with a new name.
Task Name	Change the default name of the recovery task.

9. Click **Start Recovery**.

Sample Recovery Use Cases

Use Case	Sample Recovery Parameters
Restore the CockroachDB cluster	`--cluster-restore=true` **Note:** If you have specified this parameter then the object defined in the Recovery configuration is ignored.

Use Case	Sample Recovery Parameters
Restore a database	Do not specify the parameter: `--cluster-restore=true` **Note:** You can use other parameters such as `--custom-args=<restore-options>` based on your requirements. For example, If you plan to restore a database and want to ignore sequence dependencies during the restore process. You can specify the parameter as follows: `--custom-args=skip_missing_sequences`
Restore a table	Do not specify the parameter: `--cluster-restore=true` **Note:** You can use other parameters such as, `--custom-args=<restore-options>` based on your requirements. For example, if you plan to restore either a table that was previously a sequence owner or a sequence that was previously owned by a table. You can specify the parameter as follows: `--custom-args=skip_missing_sequence_owners`
Point In Time Restore (PITR)	You need to provide the restore point in the epoch format. For example, on a Linux machine, you can find the epoch for a required time using the following command: `# date "+%s" -d "02/28/2021 15:41:15"` To perform PITR, specify the parameter as follows: `--pitr-epoch=value` For example: `--pitr-epoch=1632125909`

Cancel a Recovery Run

When you cancel a recovery run, the CockroachDB connector leverages the Cancel Job capabilities provided by CockroachDB.

To cancel a recovery run:

1. Navigate to **Data Protection > Recoveries**.
2. Click the action icon (⋮) next to the recovery run and click **Cancel Run**.
3. In the Cancel Recovery dialog box, select any one of the following:
   - Click **Continue Recovery** if you want to continue to recovery run
   - Click **Cancel Recovery** if you want to cancel the recovery run.

Epic Database Protection using Cohesity Physical Agents

Epic database administrators face the challenges of prolonged backup durations, rapid data growth, escalating storage costs, and the need for enhanced flexibility and storage management tools within Epic.

In addition to these challenges, today's database protection must encompass more than obtaining a clean copy; it must also include factors such as security, storage efficiency, minimizing impact on production systems, automation, and scalability.

Cohesity protection for Epic provides a solution to these challenges. It simplifies database backups and restores through secure, streamlined workflows. You can protect and manage your workloads and execute available protection and recovery workflows with a few steps. The Cohesity Physical Agents provide flexible deployment options to make Epic backup and restores simple and secure.

The backup and recovery of the Epic Caché database involves snapshotting the LUNs on the storage array. This method is agnostic of the OS on which Epic is hosted. Also, this method doesn't need the mount host but still requires a Proxy server to host the Epic freeze- thaw script.

Plan and Prepare for Epic Database Protection

This topic provides information on minimum permissions, prerequisites, and considerations to protect physical servers with a Cohesity cluster.

Support Matrix

Before you register your physical servers with the Cohesity cluster, ensure that Cohesity supports the physical server versions. For more information, see Supported Software.

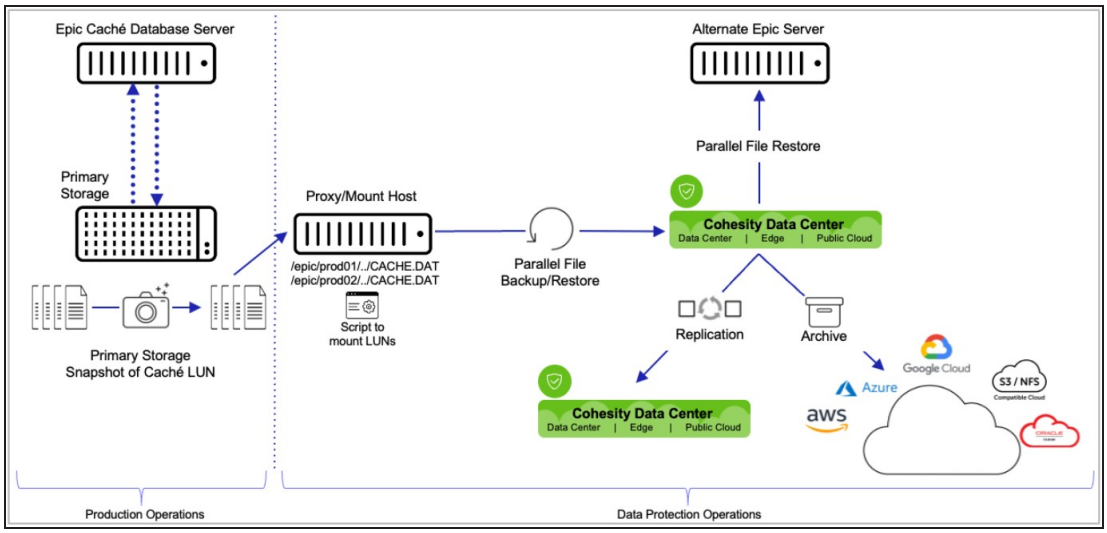
Minimum Agent Requirements

For details on hardware and software agent requirements, see Minimum Agent Requirements.

How Cohesity Works with Epic Databases

Using the Mount host method for backing up the Epic database involves utilizing the Cohesity Linux or AIX agents on an independent mount host. The mount host has the Epic LUNs mounted to it from a previous Snap of the primary storage.

Cohesity's Linux or AIX agent integrates with the mount point host to provide a file-based backup and recovery solution for Epic deployments.

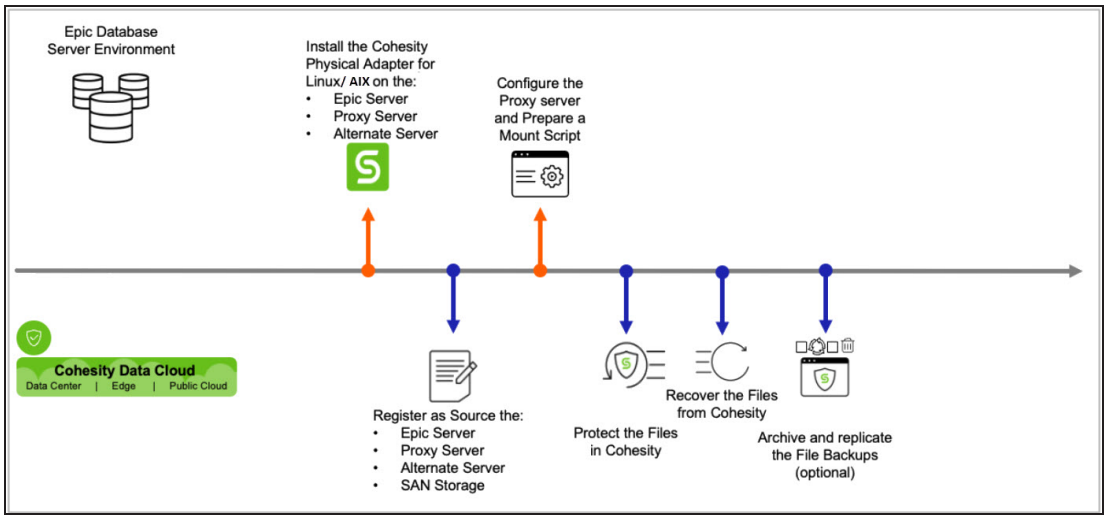


The following steps illustrate the steps that the script handles, and it can be modified to meet your requirements.

1. Script (executed by Cohesity Pre-Script option)
    a. Freeze Caché in production.
    b. Take a SAN/LUN Snapshot on primary storage.
    c. Unfreeze Caché.
    d. Present the snapshot from primary storage to the proxy host.
    e. Mount the File System on the proxy host.
2. Initiate a Cohesity file-based backup of the filesystem
3. Script (continues from Cohesity Pre-Script option)
    a. Unmount the file system from the proxy host.
    b. Delete snapshot in primary storage.

Deployment Steps

Install the Cohesity Physical Agents for Linux or AIX on the mount point host you plan to use.



Once you complete the installation of the Physical Agents on each host, you are ready to register them as a source.

You must complete the following steps to configure the Epic environment for protection:

1. Register Epic Database Source
2. Mount Host Server Script Setup for Epic Database

Register Epic Database Source

Downloading and installing the Physical Agents for Linux or AIX on the mount point server allows you to register it as a source with the Cohesity cluster. The Cohesity cluster can then use a file-based Protection Group for backups.

Before you install the Physical Agents, ensure the following prerequisites are met. For details, see Port Requirements and Firewall Settings.

Note: Install the Cohesity Linux or AIX Physical Agents on each host that is potentially a restore target.

Install the Linux or AIX Agent on Selected Hosts

Cohesity recommends the RPM installer for Linux installations. For details on installing the Cohesity Physical Agents for Linux or AIX, refer to the **Linux** or **AIX** sections in Download and Install Agent for Physical Servers.

> **Note:** The Cohesity cluster can be tuned using cluster and agent gflag values to achieve its performance. Your Cohesity team needs to determine recommended flag values based on the size of your cluster. Contact the Cohesity Account team for cluster configuration.

Mount Host Server Script Setup for Epic Database

The mount host is used as the target location where the script mounts the newly snapped LUNs. These LUNs are then backed up by Cohesity, and it is also the location for the existing script.

All Epic customers generally have the Epic freeze and thaw script that snapshots the Epic database and mounts it on a mount host.

This script can also live on a script server (the most common method) or be part of Cohesity agent pre- and post-script (uncommon, but wholly supported).

The examples in the following sections will show you how to incorporate your existing script into the Cohesity agent pre- and post-script options in the protection group.

Your existing script must perform these major tasks:

1. Freeze the Epic database.
2. Execute a snap of the storage LUNs.
3. Unfreeze the Epic database.
4. Mount the newly snapped LUNs on the mount host.

Use the mount host method:

- If granular file folder recovery is required.
- If zero impact to the production server is required.

Existing Script Location and Modification

1. Cohesity will execute your script as part of the protection job. Copy the script to the user_scripts directory on the mount host, located in `/opt/cohesity/agent/software/crux/bin/user_scripts`.
2. Where the script calls out to the existing backup software, comment that step out of the script.

Register Mount Host as a Server Source

The mount point method protects the Epic database at the primary storage level by taking a snap of the LUNs via script execution. To register your mount point host as a Source on a Cohesity cluster, see Register a Physical Server with Cohesity Cluster.

By registering the mount point host, you prepare the server for script execution and Epic file protection by Cohesity.

Protect Epic Database (File-Based)

After registering your mount point host on the Cohesity cluster, you can start configuring your Cohesity Protection Group. For more information, see Protect Physical Server (File-

Based).

When creating a Protection Group for the Epic Databases, configure the **Pre & Postscripts Settings** using the settings listed below:

Cohesity provides you the option to run user-defined scripts as a part of the Protection Group. When creating a Protection Group, you can configure:

- Pre-Scripts: Scripts that will be executed before the protection run.
- Script Path: A path to the script is not needed if the script is located in the directory: `/opt/cohesity/agent/software/crux/bin/user_scripts` on the mount host.
- Script Params: Parameters entered here are appended to the script at runtime and are subject to PowerShell parsing rules.
- Continue Backup if script fails: Disable this option. By default, this option is enabled.

  > **Note:** Cohesity recommends disabling this option so that the protection job can accurately report the success or failure of the run. Additionally the script must have zero exit code to properly report success.

- Postscripts: Scripts that will be executed after the protection run.
- Post Snapshot Scripts: Scripts that will be executed after the snapshot has been created on the source.

  > **Important:** Cohesity does not validate the content of the script and is not responsible for the content of the script or any actions done by the script. You must verify the script actions before a script or executable is run.

You can find a more in-depth discussion of Pre & Post Script in Configure Pre & Post Scripts.

Restore Epic Database

Cohesity provides the ability to restore individual database files. You can restore them to their original location or an alternate location. For more information, see Recover Physical Server Files or Folders.

Once the Epic files are recovered, you must restart the Epic server.

IBM DB2

Cohesity natively integrates with IBM DB2 to provide backup and recovery for IBM DB2 deployments on Linux x86_64 platform. Using Cohesity Connector Agent, you can backup and restore the IBM DB2 databases.

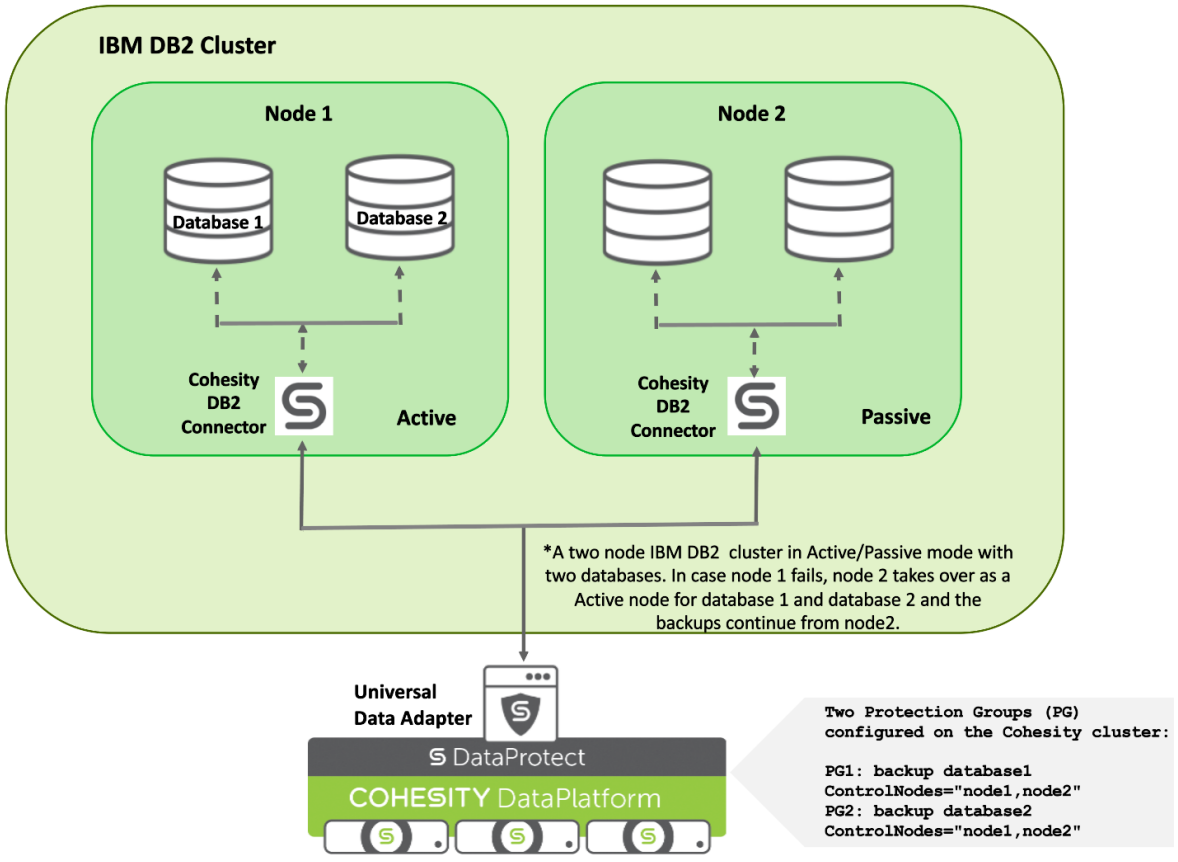
Cohesity provides a DB2 connector that enables you to perform a full backup, incremental backup, log backup, restore, and point in time restore at the database level.

Core Components

The following are the core components for protecting IBM DB2 databases:

- IBM DB2 cluster
- Cohesity IBM DB2 connector
- Cohesity Connector Agent

As illustrated, you can integrate the Cohesity with your IBM DB2 deployments using the Cohesity IBM DB2 connector and Cohesity Connector Agent.



Plan and Prepare for IBM DB2 Protection

Before you register your IBM DB2 deployment as a source with Cohesity Platform, ensure the following prerequisites:

- The user account of the DB2 instance must have SYSADM, SYSCTRL, or SYSMAINT privilege.
- Download and install the Cohesity Linux Agent on the IBM DB2 nodes.
- Download and install the Cohesity DB2 connector.
- Review and understand the prerequisites.

Supported Versions

For more information on supported IBM DB2 versions, see Supported Software versions.

Port Requirements

Outgoing Traffic

Source	Destination	Port	Protocol	Type of Traffic
Cohesity cluster	IBM DB2 Node	50051	TCP/IP	Control path for all workflows

Bidirectional Traffic

Source	Destination	Port	Protocol	Type of Traffic
IBM DB2 Local Host	IBM DB2 Local Host	59999	TCP/IP	Required only if local-to-local communication (used for self-monitoring and debugging purposes) is blocked by the firewall.
IBM DB2 Local Host	IBM DB2 Local Host	58881	TCP/IP	Local data transfer
IBM DB2 Local Host	IBM DB2 Local Host	58882	TCP/IP	Local data transfer

Incoming Traffic

Source	Destination	Port	Protocol	Type of Traffic
IBM DB2 Node	Cohesity cluster	11113	TCP/IP	Backup and Recovery
IBM DB2 Node	Cohesity cluster	11117	TCP/IP	Backup and Recovery with secure gRPC

Considerations

Review and understand the following before you protect your IBM DB2 cluster:

- Only database-level backup is supported.
- Once a database is configured to be protected using Cohesity, users should not initiate a manual backup on the same database outside of the Cohesity cluster.
- The same database should not be part of multiple Protection Groups.
- Backup with compression and encryption options are not supported.
- Using the Cohesity DB2 Connector, you can protect an IBM DB2 HADR active/standby cluster. But, you can backup or restore from the active node only.
- Protection of DB2 databases with Purescale is not supported.
- If the hole is introduced in the backup timeline, then point-in-time recovery (PITR) is possible only after the subsequent successful full or incremental backup is completed.
- Source side deduplication is not supported.
- Log archival method configured for a source during source registration can not be changed. Any change in the log archival method needs re-registration of the source with different archival method.
- Cohesity supports backup and restore of DB2 databases running on dual-stack (IPv4 and IPv6) mode or single-stack (only IPv6) mode.
- The Cohesity DB2 connector is only compatible with the bash shell and cannot be used with any other shells.
- If you have set a limit on Java heap memory usage, ensure that at least 512 MB is allocated per VIP. For example, if you are using 4 VIPs, the total Java heap memory usage limit should be at least 2 GB.
- Cohesity supports data protection for IBM DB2 deployments with SSL-encrypted communication between the IBM DB2 client and server.

Prerequisites

Ensure that:

- You use a root user or non-root user to install the Cohesity Linux agent and IBM DB2 Connector. If you choose to use a non-root user, you must add the `sudo` privileges for the non-root user using the syntax given below:

  ```
  <user_name> ALL=(ALL) NOPASSWD:SETENV: /path/to/command1,
  /path/to/command2, /path/to/command3
  ```

  The following are the `sudo` commands for IBM DB2 Connector:

  ```
  cohesityagent ALL=NOPASSWD:SETENV:/usr/bin/rpm, /usr/bin/find,
  /usr/bin/stat,/usr/bin/test, /usr/bin/mv, /usr/bin/cat, /usr/bin/mkdir,
  /usr/bin/rm, /usr/bin/cp, /usr/bin/chown, /usr/bin/chmod,
  /usr/bin/kinit, /opt/cohesity/db2/bin/named_pipe_snap_fs_util,
  /usr/bin/su, /usr/bin/java, /usr/bin/netstat, /usr/bin/sed,
  /usr/bin/cmp, /usr/bin/tee,
  ```

```
/usr/bin/wc,/usr/bin/truncate,/usr/sbin/runuser, /usr/bin/ps,
/usr/bin/cat, /usr/bin/true
```

Where, `/opt/cohesity/db2` is the IBM DB2 connector installation directory.

> **Note:**
> - If the **cohesityagent** user entry is already present in **/etc/sudoers**, append the list of commands to the existing entry.
> - The actual paths for each command might vary depending on the Platform and OS distribution. For more information, see Download and Install the Linux Agent.

- Ensure that the user account of the DB2 instance is assigned the required system authorities to perform backup or restore operations on a DB2 instance.
- For Kerberos authentication, the **keytab** file must be available on all nodes at the given location and must be accessible by the DB2 instance and the protection (backup/restore) user.
- Install Java 1.8.0_382 or higher version on all the IBM DB2 nodes.
- The Cohesity DB2 connector is only compatible with the bash shell and cannot be used with any other shells.
- For incremental backup, set "`TRACKMOD`" to "`YES`" in the database configuration.
- If you are using the Dump and Sweep based log archival (log backup) method, set "`LOGARCHMETH1`" to a specific path.

  For more information, see the BACKUP DATABASE command reference. If you have not performed the mentioned database configurations then you must manually configure the database configuration on each database in the cluster and requires database downtime. The following is the sample steps for the database configuration:

```
db2 connect to <database>
db2 update database configuration using LOGARCHMETH1 'DISK:<log_
archive_path>'
db2 "update db cfg using TRACKMOD YES"
db2 terminate
db2 deactivate database <database>
db2 backup database <database> to /dev/null
db2 activate database <database>
```

> **Note:** The database goes into the BACKUP PENDING state after applying the required configurations. As shown in the sample steps, ensure that you take an offline backup of the database to prevent the BACKUP PENDING state. For more information, see the IBM Support article on BACKUP PENDING state.

- To securely connect to the Cohesity cluster while reading or writing data, you can use secure gRPC.

  > **Note:**
  > - It is **mandatory** to connect to the Cohesity cluster securely using secure gRPC when writing or reading data.
  > - Using non-secure gRPC for data transfer between Cohesity and database hosts will result in unsecured communication.
  > - Enabling secure gRPC will increase data transfer time between Cohesity and database hosts compared to non-secure communication.

  To use secure gRPC, perform the following:

  1. Generate the certificate config file on the Cohesity node using the following command:

     ```
     ~/<release-version>/crux/bin/client_tls_cert_generator_exec -cert_name <clustername> -output_file /home/cohesity/<clustername>.cfg
     ```

  2. Copy `/home/cohesity/<clustername>.cfg` from the Cohesity node to all IBM DB2 nodes at the same location. For example, `/opt/certs/<clustername>.cfg`.

     > **Note:** Ensure that the `root` or `non-root` user used to install the Cohesity Linux agent and IBM DB2 Connector has read access to the copied certificate config file.

  3. While registering the IBM DB2 source, provide the path of the certificate config file in the **Cohesity SSL Settings** field.

Required System Authorities

To perform backup or restore operations on a DB2 instance, the protection user account of the DB2 instance must have one of the following levels of authority:

- **SYSADM**
- **SYSCTRL**
- **SYSMAINT**

When restoring to a new database server, either **SYSADM** or **SYSCTRL** authority is required.

System authorities (**SYSADM**, **SYSCTRL**, and **SYSMAINT**) are determined by group membership and are defined in the database manager configuration file for a given instance:

- **SYSADM Authority**
  - Assigned to the group specified by the `sysadm_group` configuration parameter.
  - Users with **SYSADM** authority can also perform the functions of users with **SYSCTRL** and **SYSMAINT** authorities.
- **SYSCTRL Authority**
  - Assigned to the group specified by the `sysctrl_group` configuration parameter.
  - Users with **SYSCTRL** authority can also perform the functions of users with **SYSMAINT** authority.
- **SYSMAINT Authority**
  - Assigned to the group specified by the `sysmaint_group` configuration parameter.

Download and install the Cohesity Linux Agent

The Cohesity Linux Agent is available as an RPM-based installer. Based on your requirements, download the installer and install it accordingly on the node(s) of the IBM DB2 cluster. For detailed instructions, see Download and Install the Linux Agent.

> **Note:** Ensure that you install the Cohesity Linux Agent using the RPM-based installer.

Download and install the IBM DB2 Connector

Cohesity Platform provides IBM DB2 connector RPM for backup and restore of IBM DB2 deployments.

Download the IBM DB2 Connector

Cohesity Platform provides a IBM DB2 Connector to backup and restore IBM DB2 databases. The IBM DB2 Connector is available as a datasource agent on the Cohesity Download portal. Log on to the Cohesity Download portal, download the respective datasource agent for IBM DB2 Connector, and copy the datasource agent to the IBM DB2 node.

Install the Cohesity DB2 Connector RPM

Before you install the Cohesity DB2 connector, ensure that you have `sudo` privileges.

To install the Cohesity DB2 connector:

1. Log on to the IBM DB2 node where you have copied the Cohesity DB2 connector RPM-based installer, `cohesity-db2-connector-<version>.x86_64.rpm`.
2. Run the following command to install the Cohesity DB2 connector:

   Using `yum`:

   ```
   sudo sh -c 'yum localinstall /tmp/cohesity/cohesity-db2-connector-<version>.x86_64.rpm'
   ```

   Using `rpm -ivh`:

   ```
   sudo rpm -ivh cohesity-db2-connector-<version>.x86_64.rpm
   ```

Uninstall the Cohesity DB2 Connector

To uninstall the Cohesity DB2 connector, log on to the IBM DB2 node where you have installed the Cohesity DB2 connector and run the following command:

Using `yum`:

```
sudo yum remove cohesity-db2-connector-<version>.x86_64.rpm
```

Using `rpm`:

```
sudo rpm -e cohesity-db2-connector-<version>.x86_64.rpm
```

Upgrade the Cohesity DB2 Connector

To upgrade the Cohesity DB2 connector, run the following command on IBM DB2 node:

```
sudo rpm -U cohesity-db2-connector-<version>.x86_64.rpm
```

Register and Manage the IBM DB2 Source

To protect your IBM DB2 databases, you need to register your IBM DB2 deployment as a source on the Cohesity cluster. After registering your IBM DB2 deployment as a source, you can:

- Update the IBM DB2 source configuration.
- Unregister the IBM DB2 source from the Cohesity cluster.

Register IBM DB2 as a Source

Before you register IBM DB2 as a source, ensure that you:

- Read and understand the log backup methods provided by Cohesity
- Review the considerations.

- Perform the prerequisite tasks.

For more information, see Plan and Prepare for IBM DB2 Protection.

To register IBM DB2 as a source:

1. In the Cohesity Dashboard, select **Data Protection** > **Sources**.
2. Click **Register** on the top-right of the page and then select **Universal Data Adapter**.
3. In the **Register Universal Data Adapter** page, perform the following:
   a. From the **Source Type** drop-down menu, select **IBM DB2**.
   b. From the **Host OS Type** drop-down menu, select **Linux**.
   c. In the **Hostname/IP Addresses** field, enter the hostname or IP address of the node(s) that you have identified to run the Cohesity DB2 connector. For more information, see Plan and Prepare for IBM DB2 Protection.

      > **Note:** Cohesity supports backup and restore of DB2 databases running on dual-stack (IPv4 and IPv6) mode or single-stack (only IPv6) mode.

   d. In the **Datasource Agent Installation Path** field, update the directory path if you have installed the Cohesity DB2 connector at the non-default location. For more information, see Install the Cohesity DB2 Connector RPM.
   e. Optional. Enable **Kerberos Authentication** Settings, if you want to connect to the IBM DB2 database using Kerberos-based authentication. Enter the following details:

Field	Mandatory?	Description
Kerberos Principal	No	The Kerberos principal that is required to connect to the database.
Keytab File Path	No	The absolute path of the keytab file for the given Kerberos principal. **Note:** The path must be accessible by the protection(backup/restore) user.

Field	Mandatory?	Description
Kerberos credential cache path	No	The absolute path of the Kerberos ticket cache. **Note:** The path must be accessible by the protection(backup/restore) user.

> **Note:** At a time, you can use either Keytab OR Kerberos cache-based authentication.

f. Enable **Cohesity SSL Settings** to enable a secure connection to the Cohesity cluster while reading or writing data. Enter the path to the SSL certificate used to securely connect to the Cohesity cluster.

> **Note:**
> - It is **mandatory** to connect to the Cohesity cluster securely using secure gRPC when writing or reading data.
> - Ensure that you generate and copy the certificate config file from the Cohesity node to all the IBM DB2 nodes. For more information, see Prerequisites.
> - Using non-secure gRPC for data transfer between Cohesity and database hosts will result in unsecured communication.
> - Enabling secure gRPC will increase data transfer time between Cohesity and database hosts compared to non-secure communication.

g. Under **Source Settings**, enter the details of the IBM DB2 source:

Field	Mandatory?	Description
Datasource Name	Yes	A unique name to identify your IBM DB2 cluster. > **Note:** After the source registration, you cannot change the Datasource name.
Protection Username	Yes	The username of the user account in the IBM DB2 server that has required privileges to perform backup or restore of DB2 databases. > **Note:** The protection user must have SYSADM, SYSCTRL, or SYSMAINT privileges.
Instance Name	Yes	The name of your IBM DB2 instance.
Environment Variables	No	Provide the environment variables if you want to override the environment's default value. For example, `PATH=/sbin:/bin:/usr/bin`
Use Cohesity storage for log archival using LOGARCHMETH2	No	Enable to use Cohesity storage for log archival using LOGARCHMETH2. For more information, see Log Backup Methods. > **Note:** By default the option is disabled and the dump and sweep log backup method is used. For more information, see Log Backup Methods.
Profile Path	Yes	The path to the DB2 Profile of the instance. For example: `/home/db2inst1/sqllib/db2profile`

h. Click **Register**.

Update the IBM DB2 Source Configuration

After registering your IBM DB2 as a source on the Cohesity cluster, you can update the IBM DB2 source configuration.

> **Note:**
> - Ensure that the Cohesity DB2 connector is installed on all the node(s) in the IBM DB2 cluster.
> - You cannot modify the source name.

To update the IBM DB2 source configuration:

1. In the Cohesity Dashboard, select **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the IBM DB2 source and select **Edit**.
3. On the **Update Universal Data Adapter** page, update the required configurations.
4. Click **Update**.

Unregister the IBM DB2 Source

If you plan to stop protecting your IBM DB2 databases, you can unregister the IBM DB2 source from the Cohesity cluster.

To unregister the IBM DB2 source:

1. In the Cohesity Dashboard, select **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the IBM DB2 source and select **Unregister**.

Backup IBM DB2 Database

Cohesity Platform provides a simple workflow to back up your IBM DB2 databases. After registering the IBM DB2 as a source on the Cohesity Platform, you can start configuring your backups.

Backup Process

Cohesity Platform provides a DB2 Connector for backup and restore of IBM DB2 deployments. The IBM DB2 Connector leverages the native backup capabilities provided by IBM DB2.

After registering the IBM DB2 source on the Cohesity Platform, you can create a Protection Group and specify the objects such as databases you want to backup.

Log Backup Methods

Cohesity provides the following two log backup methods:

- **Dump and sweep** - In this backup method:
  - IBM DB2 archives log files to local archive locations configured in the LOGARCHMETH1 option in the database configuration.

    - The Cohesity IBM DB2 connector copies log files from the local archive location to Cohesity storage during scheduled log backup execution.
    - Log files that are copied to Cohesity storage and older than "X" hours are pruned from the local archive location as a part of the scheduled log backup workflow. Where "X" is the prune hours value configured in the Protection Group.
- **Log Archival to Cohesity View using Vendor Library** - In this backup method,
    - The IBM DB2 Vendor library approach is used for log archival.
    - In the DB2 database configuration, the LOGARCHMETH2 option is configured to use the Cohesity DB2 vendor library to archive log files directly to Cohesity storage instead of the local archive location on DB2 nodes.
    - Logs from the Cohesity storage are pruned or deleted based on the retention period configured in the Protection Policy.

Considerations for Using the Log Backup Methods

Review and understand the following before you use the vendor library-based approach for direct log archival to Cohesity storage:

- The `LOGARCHMETH2` option in the database configuration is used to archive logs directly to the Cohesity view.
- During the first full backup for a database, Cohesity IBM DB2 Connector performs the following:
    - Configures `LOGARCHMETH2` and `LOGARCHOPT2` to utilize the Cohesity DB2 log archival library and Cohesity storage configurations.
    - Deactivates the database, performs an offline backup on the database, and then activates the database to change the `LOGATHMETH` option. This results in database downtime, as required by IBM DB2. For more information, see https://www.ibm.com/docs/en/db2/11.5?topic=parameters-logarchmeth2-secondary-log-archive-method.
    - The first full database backup will take extra time because of additional offline backup.

> **Note:** If you want to use only `LOGARCHMETH2` for log archival, make sure to manually turn off `LOGARCHMETH1`-based archival (if configured). The Cohesity IBM DB2 connector will not turn off `LOGARCHMETH1`-based archival.

Review and understand the following before you use `LOGARCHMETH1` and `LOGARCHMETH2` both on a database:

- In IBM DB2 nodes, you can configure `LOGARCHMETH1` and `LOGARCHMETH2` options in the database configuration to backup logs. If there is an archival failure in one of the

archive methods, IBM DB2 will continue to retry the log archival for failed files until the log files are successfully archived using both the methods.

- Using both archival methods on a DB2 database will impact Cohesity log backup or archival performance.

> **Important:**
> - Log Archival to Cohesity View using the vendor library backup method cannot be enabled on a registered source.
> - The backup jobs added before the release of version 7.1.1 will continue to utilize dump and sweep-based log backups.
> - To use the Log Archival to Cohesity View using the vendor library backup method, you must register a new source and enable the backup method during registration.

Offline Backup Best Practices

If you want to periodically perform an online and offline backup on the same database, then the following is the best practice workflow:

1. Create a Protection Group for online backup, for example, **DB1_online_backup**.
2. Create a different Protection Group for offline backup, for example, **DB1_offline_backup**.
3. Always keep the Protection Group, **DB1_offline_backup**, in the **Paused** state.
4. Run the Protection Group, **DB1_offline_backup**, as per the defined schedule in the protection policy.
5. When you want to perform an offline backup, pause the Protection Group for online backup, **DB1_online_backup**, and wait for the current protection run to finish before triggering the offline backup.
6. Perform the offline backup using the **RunNow** option, and bring the database online.
7. Unpause the Protection Group for online backup, **DB1_online_backup**.

Protect IBM DB2 deployments

In Cohesity Platform, IBM DB2 deployments are protected using a Protection Group and a Protection Policy. A Protection Group enables you to specify the objects such as databases that you want to backup.

The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select which standard or custom policy to use when

creating a Protection Group. For more information, see About Policies and Protection Groups.

To protect IBM DB2 deployments:

1. In the Cohesity Dashboard, do one of the following:
   - Select **Data Protection > Protection**. Click **Protect** on the top-right of the page and then select **Universal Data Adapter**.
   - Select **Data Protection > Sources**. Click the actions menu (⋮) next to the IBM DB2 source and then select **Protect**.
2. From the **Source** drop-down list, select the registered IBM DB2 source or click **Register Source** to register an IBM DB2 source. Click **+** to add multiple objects. For more information, see Register IBM DB2 as a Source.
3. In the **Objects** section, add the object that you plan to protect. The object should be a database name. To back up a database, enter the name of the database. For example, `DEMODB`. Then, click **Save Selection**.
4. In the **Protection Group** section, do one of the following:
   - Select **New Group** to create a new Protection Group. In the **Protection Name** field, enter a name from the Protection Group.
   - Select **Existing Group** to use the settings of an existing Protection Group. From the **Group** list, select an existing Protection Group and click **Protect**.
5. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy.
6. In the **Backup Settings** section, select **Online Backup** or **Offline Backup** as per your requirements.

- If you have selected **Online Backup**, configure the following:

Field	Mandatory?	Default	Description
Convert Incremental Backup To Full Backup On failure	No	Disabled	Enable if you want to convert the incremental backup to full backup in case of an error. **Note:** Any failure of an incremental backup will trigger a full backup, increasing the total backup time.
Prune Logs	No	Disabled	Prune the backup history up to the last successful full backup to delete unnecessary entries from the history table. **Note:** Applicable to both the Log Backup Methods.
Prune Logs hour	No	N/A	Enter the number of hours. DB2 log files older than the provided hour will be deleted or pruned from the local archive location on DB2 nodes as a part of the scheduled log backup. **Note:** Applicable only to dump and sweep backup method. For more information, see Log Backup Methods.

- If you have selected **Offline Backup**, perform the following:

Field	Mandatory?	Default	Description
Convert Incremental Backup To Full Backup On failure	No	Disabled	Enable if you want to convert the incremental backup to full backup in case of an error.

Field	Mandatory?	Default	Description
Deactivate database	No	Disabled	Enable to deactivate the database before performing the offline backup.
Activate database	No	Disabled	Enable to activate the database after the backup is completed.

7. Optional. Enable **Advanced Options** to configure advanced settings:

Field	Mandatory?	Default	Description
Number of objects to backup in parallel	No	6	The number of objects you want to backup simultaneously.
RPC Timeout In Seconds	No	120 seconds	The request timeout between the IBM DB2 source and the Cohesity cluster.
Max IO Write Size To Cohesity	No	4194304 bytes	The maximum size of the data packet that can be sent to the Cohesity cluster.
Environment Variables	No	N/A	Provide the environment variables if you want to override the environment's default value. `For example, PATH=/sbin:/bin:/usr/bin`

8. In the **Settings** section, do the following:
   a. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains.
   b. In the **Start Time** field, define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard.

      Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
   c. In the **Mounts** field, enter the number of VIPs you want to use while writing data to the Cohesity storage.

9. After you have completed the **Settings**, if you need to change any additional settings on the **New Universal Data Adapter Protection Group** page, scroll down and click **Edit** on the right. For more information, see Additional Settings.
10. Click **Protect**.

Additional Settings

Additional Settings	Description
Pause Future Run	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
End Time	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup Target HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup Target SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Concurrency	Maximum number of backup streams that will be created to exchange data with the cluster. By default, maximum scaling is capped at 16.

Additional Settings	Description
Alerts	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.
Priority	Select a priority for the Protection Group execution. Cohesity Platform supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).
Description	**Optional**. Enter a brief description about the Protection Group.

Manage the IBM DB2 Backup Configuration

In the Cohesity Platform, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for IBM DB2.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ on the **Objects** section.
5. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
6. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for IBM DB2.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a recovery run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for IBM DB2.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
   - Delete Protection Group Only
   - Delete Protection Group and Snapshots

Recover IBM DB2 Database

You can restore the IBM DB2 object such as databases in IBM DB2. You can restore to the same IBM DB2 cluster or a different IBM DB2 cluster.

The Cohesity DB2 connector leverages the restore tool provided by IBM DB2. You can create a Recovery configuration and specify the objects such as databases backed up using the Protection Group.

> **Note:**
>
> If you plan to restore the backup to a different IBM DB2 cluster, ensure that you add the following registry variable to the environment variables of the target IBM DB2 instance using the following commands:

```
>db2stop
>db2set DB2_RESTORE_GRANT_ADMIN_AUTHORITIES=ON
>db2start
```

Redirected Restore

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

Cohesity Platform supports redirected restore operation provided by IBM DB2. Using the redirected restore operation, you can perform the following while restoring the IBM DB2 backup:

- Replace the same IBM DB2 cluster using the existing storage groups and tablespace locations
- Redirect all tablespaces to new locations
- Redirect the subset of tablespaces to new locations
- Redirect all storage groups to new locations
- Redirect the subset of storage groups to new locations

Before performing the redirected restore operation using the Cohesity Platform, you must create a script with the redirection statements and provide the path of the script in the **Redirection script path** field in the IBM DB2 restore configuration. The script is replayed at the time of redirection for storage group and tablespaces containers.

> **Note:** The script should only contain redirection statements, and the restore statements must not be part of the script.

The following is a sample of the script:

```
set stogroup paths for DATA_SG on '/var/ibmdb2/DATABASE1/db1.DMSFILETSP' ,
'/var/ibmdb2/DATABASE1/db1.DMSFILETSP2' , '/var/ib-
mdb2/DATABASE1/db1.DMSFILETSP3';
set stogroup paths for TEMP_SG on '/var/ibmdb2/DB1/db1.TMPFILETSP' ;
set tablespace containers for 0 using ( path
```

```
'/var/ibmdb2/DATABASE1/NODE0000/BACKTST2/SYSCATSPACE' );
set tablespace containers for 3 using automatic storage;
```

Recover IBM DB2 Databases

To restore IBM DB2 databases:

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Click **Recover** at the top right of the page and then select **Universal Data Adapter**.
3. Search for the Protection Group that contains the snapshots to recover from by entering characters of the Protection Group name, or by specifying the wildcard character *****.
4. From the list of search results, select the Protection Group that contains the snapshots to recover. By default, the latest recovery point is selected. To select a different recovery point, from the selected lists, mouse over the recovery point, and then click the **edit** icon.

   By default, the option to select the recovery point is displayed in **Timeline** mode. You can also choose to view the option in List mode by clicking the **List** tab in the top-right corner of the page. The **Timeline** mode displays the full backups (recovery points) captured at the scheduled time and the CDP-based data available for point-in-time restore. The **List** tab displays only the full backups captured at a scheduled time.

   - To select a recovery point from the Timeline mode:
     a. From the **Choose a date** drop-down, select a date.

        The recovery points available on the selected date are displayed in blue dots on the timeline bar and the point-in-time for restore is displayed in a solid green line on the timeline bar.

     b. To recover from a full backup, click the corresponding blue dot. For point-in-time restore, specify the exact point-in-time recovery by sliding the timeline bar.

     c. Click **Select Recovery Point** and then go to **step 5**.
   - To select a recovery point from the List mode:
     a. Select the **List** tab from the top-right corner of the *Edit recovery point for <database_name>* page.

        By default, the page displays the recovery points available for the last 30 days.

     b. You can also select a recovery point from a different date range by selecting the date range from the Date drop-down list. The page displays the available recovery points in the specified range.

     c. Select the recovery points to be recovered.

     d. Click **Select Recovery Point** and then go to **step 5**.

5. In the **Object** field, enter the name of the database or table that you had backed up using the selected Protection Group. Click **+** to add multiple objects.
6. Click **Next: Recover Options**.
7. In the **Recover As** section, based on your requirements, select any one of the following options:

Options	Description
Replace Original	To restore to the same IBM DB2 cluster.
New Object	To restore to a different IBM DB2 cluster. Select the **Target** IBM DB2 cluster to which the data needs to be restored. Also, enable **Overwrite existing object with the same name** and type **Yes**, if you want to overwrite the existing object with the same name. > **Note:** Ensure that the **Target** IBM DB2 cluster is registered as a source on the Cohesity cluster.

8. In the **Restore Settings** section, select **Regular Restore** or **Redirected Restore** based on your requirements.

- If you have selected **Regular Restore**, configure the following:

Field	Mandatory?	Default	Description
New Data Path	No	N/A	Enter the path on the target IBM DB2 instance to restore the data directory from the database. You can specify the path(s) as a comma-separated list of directories. **Note:** If the path is not specified, the data is restored to the default database path, DFTDBPATH. You can view the default database path, DFTDBPATH, using the following command: `db2 get dbm cfg | grep DFTDBPATH`
New Log Path	No	N/A	Enter the path on the target IBM DB2 instance to restore the active logs from the restored database.
Local Database Directory	No	N/A	Enter the path of the local database directory.
Rollforward Database	No	Enabled	Roll forward the database to recover the database by applying transaction logs after restore.

- If you have selected **Redirected Restore**, configure the following:

Field	Mandatory?	Default	Description
New Data Path	No	N/A	Enter the path on the target IBM DB2 instance to restore the data directory from the database. You can specify the path(s) as a comma-separated list of directories. **Note:** If the path is not specified, the data is restored to the default database path, DFTDBPATH. You can view the default database path, DFTDBPATH, using the following command: `db2 get dbm cfg | grep DFTDBPATH`
Redirection Script Path	Yes	N/A	Enter the path of the script with the redirection statements. For more information, see Redirected Restore.
New Log Path	Yes	N/A	Enter the path on the target IBM DB2 instance to restore the active logs from the restored database.
Local Database Directory	No	N/A	Enter the path of the local database directory.
Rollforward Database	No	Enabled	Roll forward the database to recover the database by applying transaction logs after restore.

9. Optional. Enable **Advanced Options** to configure advanced settings:

Field	Mandatory?	Default	Description
RPC Timeout In Seconds	No	120 seconds	The request timeout between the IBM DB2 source and the Cohesity cluster.

Field	Mandatory?	Default	Description
Max IO Read Size To Cohesity	No	4194304 bytes	The maximum size of the data packet that can be transferred to the Cohesity cluster.
Environment Variables	No	N/A	Provide the environment variables if you want to override the environment's default value. For example, `PATH=/sbin:/bin:/usr/bin`

10. In the **Recovery Options** section, based on your requirements, select any one of the following options:

Options	Description
Mounts	Enter the number of VIPs you want to use while reading data from the Cohesity storage.
Concurrency	Not applicable for IBM DB2 cluster database recovery.
Rename	Allows you to rename the object, if you are recovering the object to **New Location**. **Note:** If you are overwriting the existing object, do not rename the object using the database alias name.
Task Name	Change the default name of the recovery task.

11. Click **Recover**.

Cancel a Recovery Run

When you cancel a recovery run, the IBM DB2 connector cancels the job by terminating the recovery processes.

To cancel a recovery run:

1. In the Cohesity Dashboard, select **Data Protection** > **Recoveries**.
2. Click the action icon (⋮) next to the recovery run and click **Cancel Run**.
3. In the **Cancel Recovery** dialog box, select any one of the following:
   - **Continue Recovery** if you want to continue to recovery run
   - **Cancel Recovery** if you want to cancel the recovery run.

MySQL EE

Cohesity natively integrates with MySQL to provide backup and recovery for MySQL deployments. Using Cohesity Connector Agent, you can backup and restore the MySQL database. The Cohesity Connector Agent provides a simple workflow to back up and restore your MySQL deployment.

The MySQL Connector enables you to back up and restore the following:

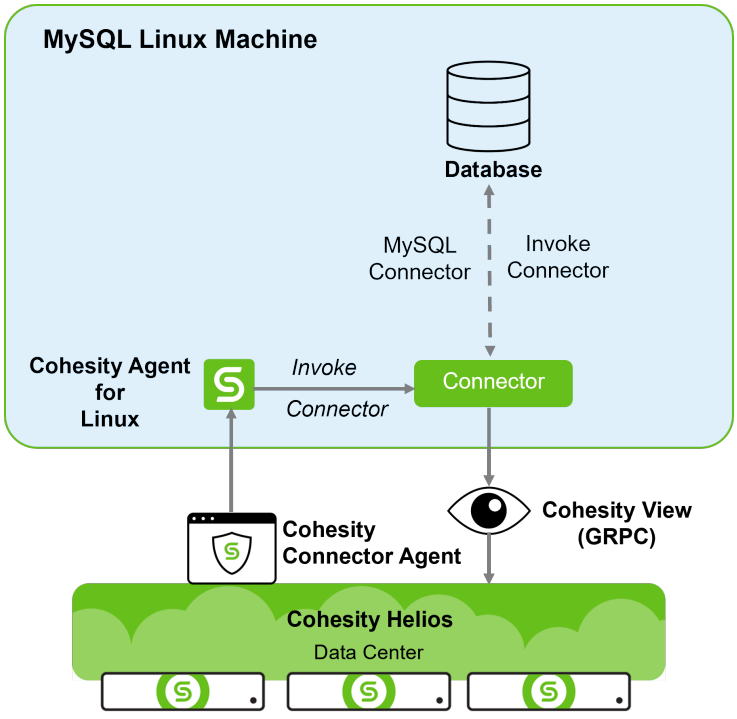
- Full and incremental backup of a MySQL database.
- Physical level restore (No option to restore on a per-database level).

Core Components

The following are the core components for protecting MySQL databases:

- MySQL Linux machine
- MySQL Connector
- Cohesity Connector Agent
- Cohesity View

As illustrated, you can integrate Cohesity with your MySQL deployments using the MySQL Connector and Cohesity Connector Agent.



Plan and Prepare for MySQL EE Protection

Before you register your MySQL deployment as a source with Cohesity and protect MySQL instances, ensure the following prerequisites:

- Ensure that the fully qualified domain name (FQDN) of the Cohesity cluster is resolvable from the MySQL host.
- A database user with database admin user privileges. (Only MySQL Enterprise Edition is supported. Ensure mysqlbackup is installed along with the MySQL database.)
- Download and install the Cohesity Linux Agent on the MySQL host.
- Download and install the MySQL Connector.

Supported Versions

For more information on supported MySQL versions, see Supported Software versions.

Port Requirements

Outgoing Traffic

Source	Destination	Port	Protocol	Type of Traffic
Cohesity cluster	MySQL Node	50051	TCP/IP	Control path for all workflows

Bidirectional Traffic

Source	Destination	Port	Protocol	Type of Traffic
MySQL Local Host	MySQL Local Host	59999	TCP/IP	Required only if local-to-local communication (used for self-monitoring and debugging purposes) is blocked by the firewall.

Incoming Traffic

Source	Destination	Port	Protocol	Type of Traffic
MySQL Node	Cohesity cluster	11113	TCP/IP	Backup and Recovery
MySQL Node	Cohesity cluster	11117	TCP/IP	Backup and Recovery with secure gRPC

Considerations

Review and understand the following before you protect your MySQL database.

- Only RHEL is supported.
- Database instance auto-discovery and object search are not supported.
- You cannot protect multiple hosts using a single Protection Group.
- Multiple object restore is not supported.
- MySQL Connector upgrade is not supported. To use the latest version of the MySQL Connector, uninstall the existing MySQL Connector and install the latest version.
- Only instance-level backup and restore are supported. Granular-level use cases such as database-level backup and restore are not supported.
- Log backups and PITR recovery are supported.
- Recovery is performed only at the instance level; hence, you cannot rename the database after recovery.
- Only single-stream backup and restore are supported.
- Only backup and restore of a single MySQL database on the source machine is supported. If the source machine has multiple database instances, you cannot backup and restore the database.
- Recovery from a replication copy of the database is not supported.

Download and install the Cohesity Linux Agent

The Cohesity Linux Agent is available as script-based and RPM-based installers, based on your requirements download the installer and install it accordingly on the MySQL host. For detailed instructions, see Download and Install the Linux Agent.

> **Note:** Ensure you meet the following prerequisites below before you install the Cohesity Linux agent.

Prerequisites

- For Cohesity clusters to be able to interact with the Linux agent, ports 50051 and 59999 need to be opened up on the agent host.
- On the Cohesity cluster, enable UDA on the Linux agent (if agent older than 6.6.0) and restart the agent from the cluster.

Download the MySQL Connector

Cohesity provides a MySQL Connector to backup and restore MySQL databases. The MySQL Connector is available as a datasource agent on the Cohesity Download portal. Log on to the Cohesity Download portal, download the respective datasource agent for MySQL Connector, and copy the datasource agent to the MySQL host.

Install the MySQL Connector

Before you install the MySQL Connector, ensure that you have sudo privileges.

To install the MySQL Connector:

1. Log on to the MySQL EE host where you have copied the MySQL Connector installer, `cohesity-mysql-java-agent-<version>.x86_64.rpm`.
2. To set the service user to run the installer, run the following command. If not set, the default value will be `cohesityagent`.

   ```
   export SERVICE_USER=user1
   ```

3. Run the following command to install the MySQL Connector:

   ```
   rpm -ivh cohesity-mysql-java-agent-<version> .x86_64.rpm
   ```

After the MySQL Connector is installed, the agent is available at: `/opt/cohesity/agent/uda_scripts`

Uninstall the MySQL Connector

To uninstall the MySQL Connector:

Log on to the MySQL host where you have installed the MySQL Connector. Run the following command to uninstall the MySQL Connector:

```
rpm -e cohesity-mysql-java-agent-<verions>. x86_64
```

Register and Manage the MySQL Source

To protect your MySQL databases, you need to register your MySQL deployment as a source on Cohesity.

After registering your MySQL deployment as a source, you can:

- Update the username and password of the database user.
- Refresh the source details.
- Unregister the MySQL source from Cohesity.

Register MySQL as a Source

Before you register MySQL as a source, ensure that you:

- Review the requirements and limitations.
- Perform the prerequisite tasks.

For more information, see Plan and Prepare for MySQL EE Protection.

To register MySQL as a source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the **Register** on the top-right of the page and then select **Universal Data Adapter**.
3. In the **Register Universal Data Adapter** page, perform the following:

1. From the **Source Type** drop-down menu, select **MySQL**.
2. In the **Hostname/IP Addresses** field, enter the hostname or IP address of the MySQL host you have identified to run the MySQL Connector. For more information, see Plan and Prepare for MySQL EE Protection.
3. In the **Datasource Agent Installation Path**, enter the directory path on the MySQL host, where you have installed the MySQL Connector. For more information, see Install the MySQL Connector.
4. In the **APP Authentication** section, provide the MySQL database's **Username** and **Password**.
5. Enable **Custom Options**, and perform the following:
    1. Ignore the **Mounts View** option. It is not applicable for MySQL source registration.
    2. In the **Source Registration Options** field, enter the following source registration arguments based on your requirement:

Arguments	Mandatory ?	Description
`source_name`	Yes	A unique name to identify the MySQL source.

Arguments	Mandatory ?	Description
`defaults_file`	Yes	The MySQL's configuration file path (typically `/etc/my.cnf`).

Arguments	Mandatory ?	Description

		Note: Ensure that the `[client]` section is present in the `my.cnf` file and includes the same socket path as defined in the `[mysqld]` section. This is required for proper socket-based communication between the MySQL client and server.
		Example:
		`[mysqld]`
		`datadir=/data/mysql/mysql-8.4`
		`socket=/data/mysql/mysql-8.4/mysql.sock`

```
source_name=<SOURCE_NAME>, defaults_file=/etc/my.cnf
```

6. Click **Register**.

Update the MySQL Source Configuration

After registering your MySQL as a source on Cohesity, you can:

- Update the username and password of the database user.
- Update the **Datasource Agent Installation Path** only if you have uninstalled and reinstalled the MySQL Connector in a different directory on the MySQL host.

To update the MySQL source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the MySQL source and select **Edit**.

> **Note:** When you edit the source, the username and password fields are reset. Ensure that you re-enter the credentials before clicking **Update**.

3. In the **Update Universal Data Adapter** page, update the required configurations.
4. Click **Update**.

Refresh the MySQL Source Configuration

You can refresh the MySQL source and re-verify the source with the available source registration parameters.

To refresh the MySQL Source Configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the MySQL source and select **Refresh**.

Unregister the MySQL Source

If you plan to stop taking the backup of your MySQL databases, you can unregister the MySQL source from Cohesity.

> **Note:** To unregister a source, ensure that no protection jobs are associated with it. The unregistration will fail if active protection jobs exist for the source.

To unregister the MySQL source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the MySQL source and select **Unregister**.

Backup MySQL Database

Cohesity provides a simple workflow to back up your MySQL databases. After registering MySQL as a source on Cohesity, you can start configuring your backups.

Backup Process

Cohesity provides a MySQL EE connector for backup and restores of enterprise MySQL deployments. The MySQL EE connector leverages the backup capabilities provided by MySQL.

After registering the MySQL source on Cohesity, you can create a Protection Group and specify the MySQL instances that you want to back up. In the Protection Group, you need to define the script parameters that enable you to provide additional parameters required by the backup statements provided by MySQL.

> **Note:** Cohesity recommends that you configure periodic full backups.

Backup Parameters

In the Protection Group, you can define the following parameters for your MySQL backup configuration: (parameters are to be passed comma(,) separated)

Backup Parameters	Description
`number-of-buffers`	Optional. Specify the number of buffers to use during multithreaded operations. you can use a high number of buffers for CPU-intensive processing such as backup, particularly when using compression, and use a low number of buffers for disk-intensive processing such as restoring a backup. This value should be at least as high as the number of read threads or write threads, depending on the type of operation. For more information, see MySQL Enterprise Backup 8.0 User's Guide :: 20.10 Performance / Scalability / Capacity Options.
`read-thread`	Optional. Specify the number of threads to use for reading data from the disk. For more information, see MySQL Enterprise Backup 8.0 User's Guide :: 20.10 Performance / Scalability / Capacity Options.

Backup Parameters	Description
`process-threads`	Optional. Specify the number of threads to use for processing data. This includes compression and uncompression, encryption and decryption, apply-log operations, and packing and extracting backup images. For more information, see MySQL Enterprise Backup 8.0 User's Guide :: 20.10 Performance / Scalability / Capacity Options.
`write-threads`	Optional. Specify the number of threads to use for writing data to disk. For more information, see MySQL Enterprise Backup 8.0 User's Guide :: 20.10 Performance / Scalability / Capacity Options.
`limit-memory`	Optional. Specify maximum memory in megabytes that can be used by mysqlbackup. **Note:** Do not include any suffixes such as MB or KB in the option value. For more information, see MySQL Enterprise Backup 8.0 User's Guide :: 20.10 Performance / Scalability / Capacity Options.

Example

```
number-of-buffers=10, read-threads=5, process-threads=5, write-threads=5,
limit-memory=500
```

Protect MySQL EE Deployments

MySQL deployments are protected using a Protection Group and a Protection Policy. A Protection Group enables you to:

- Specify the MySQL instance that you want to backup.
- Based on your requirement, define the parameters for the backup statements provided by MySQL. For more information, see Backup Parameters.

The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select which standard or custom policy to use when creating a Protection Group. For more information, see About Policies and Protection Groups.

To protect MySQL deployments:

1. Do one of the following:
    1. Select **Data Protection** > **Protection**. Click **Protect** on the top-right of the page and then select **Universal Data Adapter**.
    2. Select **Data Protection** > **Source**. Click the actions menu (⋮) next to the MySQL source and then select **Protect**.
2. From the **Source** drop-down list, select the registered MySQL source or click **Register Source** to register a MySQL source. For more information, see Register and Manage the MySQL Source.
3. In the **Objects** section, specify the object you want to protect.

    > **Note:** Only instance-level backup and restore are currently supported. Granular-level operations, such as backing up or restoring individual databases or tables, are not supported. As a result, you need to enter a placeholder value in the **Objects** field to continue.

    Then, click **Save Selection**.
4. In the **Protection Group** section, do one of the following:
    1. Select **New Group** to create a new Protection Group. In the Protection Name field, enter a name from the Protection Group.
    2. Select **Existing Group** to use the settings of an existing Protection Group. From the **Group** list, select an existing Protection Group and click Protect.
5. In the **Settings** section, do the following:
    1. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains.
    2. In the **Start Time** field, define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard.

        Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
6. After you have completed the **Settings** configuration, if you need to change any additional settings on the **New Universal Data Adapter Protection Group** page, scroll down and click **Edit** on the right. For more information, see **Additional Settings** below.
7. Click **Protect**.

Additional Settings

Additional Settings	Description
Pause Future Run	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
End Time	Optional. Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts before this date runs until completion even if it completes after this date.
QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup Target HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup Target SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Alerts	Optional. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.

Additional Settings	Description
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection groups exceeds the ability to process protection groups, this will be the priority of implementation of the protection groups: • High-priority protection groups • Medium-priority protection groups • Low-priority protection groups.
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).
Description	Optional. Enter a brief description of the Protection Group.

Manage the MySQL Backup Deployments

A backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group in the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the Protection page, select the Protection Group that you had created for MySQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for MySQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a recovery run:

1. Navigate to **Data Protection** > **Protection**.
2. Click the action menu (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups, local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group, the reclaimed storage space details will not be displayed immediately. It will take some time to reflect on Cohesity.

To delete the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for MySQL.
3. Click the actions menu (⋮) next to the Protection Group and select Delete.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    1. Delete Protection Group Only
    2. Delete Protection Group and Snapshots.

Recover MySQL Database

You can restore the MySQL host or object(s) such as databases in MySQL. You can restore to the same MySQL host or a different MySQL host.

The MySQL EE connector leverages the restore statements provided by MySQL. You can create a Recovery configuration and specify the objects such as databases backed up using the Protection Group.

In the Recovery configuration, you need to specify the object you plan to restore and define the script parameters required by the restore statements provided by MySQL.

Recovery Parameters

In the Recovery configuration, you can define the following script parameters for your MySQL recovery:

> **Note:** You can use the optional recovery parameters based on your requirements.

Recovery Parameters	Mandatory?	Description
`data_dir`	Yes	Specify the path where the MySQL data directory will be restored. The data directory contains all information managed by the MySQL server. **Note:** Ensure that the specified directory is empty. If it is not empty, Cohesity will automatically delete its contents during the restore operation.
`restart_instance`	No	Specifies whether the recovered instance automatically starts after the recovery completes. • If set to `true`, the instance restarts once recovery completes. • If set to `false`, the instance remains powered off. Default value: `true`.
`number-of-buffers`	No	Specify the number of buffers to use during multithreaded operations. you can use a high number of buffers for CPU-intensive processing such as backup, particularly when using compression, and use a low number of buffers for disk-intensive processing such as restoring a backup. This value should be at least as high as the number of read threads or write threads, depending on the type of operation. For more information, see MySQL Enterprise Backup 8.0 User's Guide :: 20.10 Performance / Scalability / Capacity Options.

Recovery Parameters	Mandatory?	Description
`read-thread`	No	Specify the number of threads to use for reading data from the disk. For more information, see MySQL Enterprise Backup 8.0 User's Guide :: 20.10 Performance / Scalability / Capacity Options.
`process-threads`	No	Specify the number of threads to use for processing data. This includes compression and uncompression, encryption and decryption, apply-log operations, and packing and extracting backup images. For more information, see MySQL Enterprise Backup 8.0 User's Guide :: 20.10 Performance / Scalability / Capacity Options.
`write-threads`	No	Specify the number of threads to use for writing data to disk. For more information, see MySQL Enterprise Backup 8.0 User's Guide :: 20.10 Performance / Scalability / Capacity Options.
`limit-memory`	No	Specify maximum memory in megabytes that can be used by mysqlbackup. **Note:** Do not include any suffixes such as MB or KB in the option value. For more information, see MySQL Enterprise Backup 8.0 User's Guide :: 20.10 Performance / Scalability / Capacity Options.

Example

```
data_dir=/var/lib/mysql_restore, restart_instance=false, number-of-buf-
fers=10, read-threads=5, process-threads=5, write-threads=5, limit-memory-
y=500
```

Recover MySQL

To recover a MySQL source:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **Universal Data Adapter**.
3. Search for the Protection Group that contains the snapshots to recover from by entering characters of the Protection Group name, or by specifying the wildcard character *.
4. From the list of search results, select the Protection Group that contains the snapshots to recover.
5. In the **Object** field, enter the name of the database or table that you had backed up using the selected Protection Group. By default, the latest snapshot is selected for recovery.
6. Click **Next: Recover Options**.
7. In the **Recover As** section, select **Replace Original**.

Options	Description
Replace Original	To restore to the same MySQL host.
New Object	To restore to a different MySQL host. Select the **Target** MySQL host to which the data needs to be restored. Also, ignore **Overwrite existing object with the same name toggle** option. It is not applicable for MySQL.

8. In the **Recovery Options** section, based on your requirements, select any one of the following options:

Options	Description
Mounts	Not applicable for MySQL host recovery.
Custom Options	Specify the Recovery Parameters based on your requirements. See Sample Recovery Use Cases for examples.
Rename	Provide the new name for the database, if you want to restore the database with a new name.
Task Name	Change the default name of the recovery task.

9. Click **Recover**.

Sample Recovery Use Cases

Use Case	Instructions with Sample Recovery Parameters
Restore the MySQL host to Same Location	`data_dir=/var/lib/mysql_restore, restart_instance=true` **Note:** Provide an empty directory as an parameter in the `data_dir` parameter when restoring data to the same location to avoid overwriting of data in the restore data directory.

Cancel a Recovery Run

To cancel a recovery run follow the steps below:

1. Navigate to **Data Protection > Recoveries.**
2. Click the action menu (⋮) next to the recovery run and click **Cancel Run**.
3. In the Cancel Recovery dialog box, select any one of the following:
    1. Click **Continue Recovery** if you want to continue a recovery run
    2. Click **Cancel Recovery** if you want to cancel the recovery run.

Percona MySQL on Linux

Cohesity natively integrates with Percona MySQL to provide backup and recovery for Percona MySQL deployments. Using Cohesity Connector Agent, you can backup and restore the Percona MySQL databases.

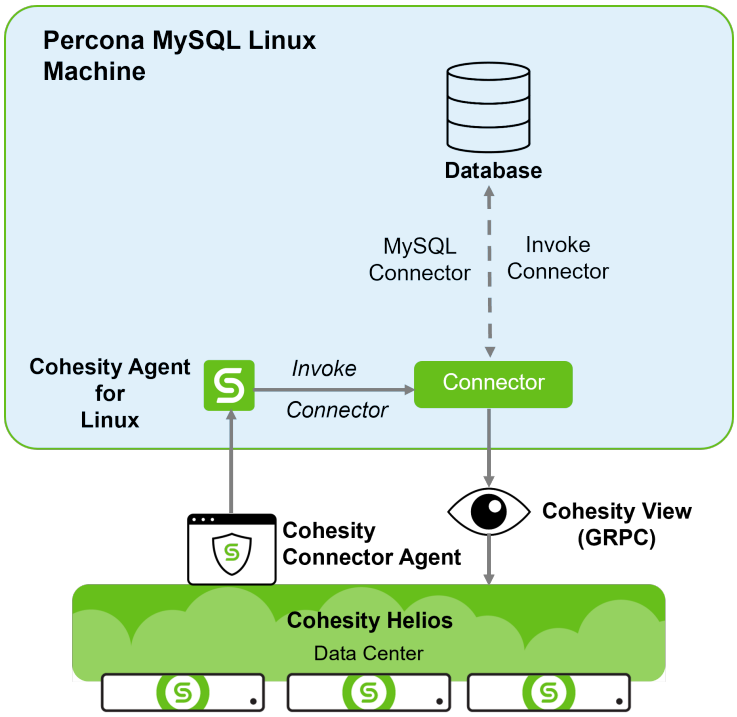
Cohesity Platform provides a MySQL connector that enables you to perform full backup, incremental backup, log backup, restore and point in time restore at the instance level.

Core Components

The following are the core components for protecting Percona MySQL databases:

- Percona MySQL Linux machine
- MySQL Connector
- Cohesity Connector Agent
- Cohesity View

As illustrated, you can integrate Cohesity with your Percona MySQL deployments using the MySQL Connector and Cohesity Connector Agent.



Plan and Prepare for Percona MySQL Protection

Before you register your Percona MySQL deployment as a source with Cohesity and protect Percona MySQL instances, ensure the following prerequisites:

- Ensure that the fully qualified domain name (FQDN) of the Cohesity cluster is resolvable from the MySQL host.
- A database user with database admin user privileges.
- Ensure that the `xtrabackup` and `mysqlbinlog` utilities are installed on the host along with the MySQL database.
- Download and install the Cohesity Linux Agent on the MySQL host.
- Download and install the MySQL connector.

Supported Versions

For more information on supported Percona MySQL versions, see Percona MySQL versions.

Port Requirements

Outgoing Traffic

Source	Destination	Port	Protocol	Type of Traffic
Cohesity cluster	Percona MySQL Node	50051	TCP/IP	Control path for all workflows

Bidirectional Traffic

Source	Destination	Port	Protocol	Type of Traffic
Percona MySQL Local Host	Percona MySQL Local Host	59999	TCP/IP	Required only if local-to-local communication (used for self-monitoring and debugging purposes) is blocked by the firewall.

Incoming Traffic

Source	Destination	Port	Protocol	Type of Traffic
Percona MySQL Node	Cohesity cluster	11113	TCP/IP	Backup and Recovery
Percona MySQL Node	Cohesity cluster	11117	TCP/IP	Backup and Recovery with secure gRPC

Considerations

Review and understand the following before you protect your Percona MySQL database.

- Only RHEL is supported.
- Database instance auto-discovery and object search are not supported.
- You cannot protect multiple hosts using a single Protection Group.
- Multiple object restore is not supported.
- MySQL Connector upgrade is not supported. To use the latest version of the MySQL Connector, uninstall the existing MySQL Connector and install the latest version.
- Only instance-level backup and restore are supported. Granular-level use cases such as database-level backup and restore are not supported.
- Log backups and PITR recovery are supported.
- Recovery is performed only at the instance level; hence, you cannot rename the database after recovery.
- Only backup and restore of a single Percona MySQL database on the source machine is supported. If the source machine has multiple database instances, you cannot backup and restore the database.
- Recovery from a replication copy of the database is not supported.

Download and install the Cohesity Linux Agent

The Cohesity Linux Agent is available as script-based and RPM-based installers, based on your requirements download the installer and install it accordingly on the Percona MySQL host. For detailed instructions, see Download and Install the Linux Agent.

> **Note:** Ensure you meet the following prerequisites below before you install the Cohesity Linux agent.

Prerequisites

- For Cohesity clusters to be able to interact with the Linux agent, ports 50051 and 59999 need to be opened up on the agent host.
- On the Cohesity cluster, enable UDA on the Linux agent (if agent older than 6.6.0) and restart the agent from the cluster.

Download the MySQL Connector

Cohesity provides a MySQL Connector to backup and restore Percona MySQL databases. The MySQL Connector is available as a datasource agent on the Cohesity Download portal. Log on to the Cohesity Download portal, download the respective datasource agent for MySQL Connector, and copy the datasource agent to the Percona MySQL host.

Install the MySQL Connector

Before you install the MySQL Connector, ensure that you have sudo privileges.

To install the MySQL Connector:

1. Log on to the Percona MySQL host where you have copied the MySQL Connector installer, `cohesity-mysql-java-agent-<version>.x86_64.rpm`.
2. To set the service user to run the installer, run the following command. If not set, the default value will be `cohesityagent`.

   ```
   export SERVICE_USER=user1
   ```

3. Run the following command to install the MySQL Connector:

   ```
   rpm -ivh cohesity-mysql-java-agent-<version> .x86_64.rpm
   ```

After the MySQL Connector is installed, the agent is available at:
`/opt/cohesity/agent/uda_scripts`

Uninstall the MySQL Connector

To uninstall the MySQL Connector:

Log on to the Percona MySQL host where you have installed the MySQL Connector. Run the following command to uninstall the MySQL Connector:

```
rpm -e cohesity-mysql-java-agent-<verions>. x86_64
```

Register and Manage the Percona MySQL Source

To protect your Percona MySQL databases, you need to register your Percona MySQL deployment as a source on Cohesity.

After registering your Percona MySQL deployment as a source, you can:

- Update the username and password of the database user.
- Refresh the source details.
- Unregister the Percona MySQL source from Cohesity.

Register Percona MySQL as a Source

Before you register Percona MySQL as a source, ensure that you:

- Review the requirements and limitations.
- Perform the prerequisite tasks.

For more information, see Plan and Prepare for Percona MySQL Protection.

To register Percona MySQL as a source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the **Register** on the top-right of the page and then select **Universal Data Adapter**.
3. In the **Register Universal Data Adapter** page, perform the following:
    a. From the **Source Type** drop-down menu, select **MySQL**.
    b. In the **Hostname/IP Addresses** field, enter the hostname or IP address of the Percona MySQL host you have identified to run the MySQL Connector. For more information, see Plan and Prepare for Percona MySQL Protection.
    c. In the **Datasource Agent Installation Path**, enter the directory path on the Percona MySQL host, where you have installed the MySQL Connector. For more information, see Install the MySQL Connector.
    d. In the **APP Authentication** section, provide the Percona MySQL database's **Username** and **Password**.
    e. Enable **Custom Options**, and perform the following:
        1. Ignore the **Mounts View** option. It is not applicable for Percona MySQL source registration.
        2. In the **Source Registration Options** field, enter the following source registration arguments based on your requirement:

Arguments	Mandatory ?	Description
`--source-name`	Yes	A unique name to identify the Percona MySQL source.

Arguments	Mandatory ?	Description
`--defaults-file`	Yes	The Percona MySQL's configuration file path (typically `/etc/my.cnf`).

Arguments	Mandatory ?	Description

		Note: Ensure that the `[client]` section is present in the `my.cnf` file and includes the same socket path as defined in the `[mysqld]` section. This is required for proper socket-based communication between the MySQL client and server.
		Example:
		`[mysqld]`
		`datadir=/data/mysql/mysql-8.4`
		`socket=/data/mysql/mysql-8.4/mysql.sock`

Arguments	Mandatory ?	Description
`--port`	No	The port used to connect to the Percona MySQL source. If not specified, the default port **3306** is used.

Sample:

```
--source-name=test_source --defaults-file=/etc/my.cnf --
port=3306
```

f. Click **Register**.

Update the Percona MySQL Source Configuration

After registering your Percona MySQL as a source on Cohesity, you can:

- Update the username and password of the database user.
- Update the **Datasource Agent Installation Path** only if you have uninstalled and reinstalled the MySQL Connector in a different directory on the Percona MySQL host.

To update the Percona MySQL source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Percona MySQL source and select **Edit**.

> **Note:** When you edit the source, the username and password fields are reset. Ensure that you re-enter the credentials before clicking **Update**.

3. In the **Update Universal Data Adapter** page, update the required configurations.
4. Click **Update**.

Refresh the Percona MySQL Source Configuration

You can refresh the Percona MySQL source and re-verify the source with the available source registration parameters.

To refresh the Percona MySQL Source Configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Percona MySQL source and select **Refresh**.

Unregister the Percona MySQL Source

If you plan to stop taking the backup of your Percona MySQL databases, you can unregister the Percona MySQL source from Cohesity.

> **Note:** To unregister a source, ensure that no protection jobs are associated with it. The unregistration will fail if active protection jobs exist for the source.

To unregister the Percona MySQL source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Percona MySQL source and select **Unregister**.

Backup Percona MySQL Database

Cohesity provides a simple workflow to back up your Percona MySQL deployment. After registering the Percona MySQL as a source on Cohesity, you can start configuring your backups.

Backup Process

Cohesity provides a MySQL connector to protect Percona MySQL deployments. The MySQL Connector uses the XtraBackup FIFO data sink method from Percona to stream data efficiently during backup.

When a protection job runs, multiple parallel threads write database data into a set of FIFO (First-In-First-Out) pipes on the source system. These FIFO pipes act as streaming interfaces. The Cohesity cluster then reads the data from the pipes and transfers it directly to the Cohesity cluster for protection.

Backup Scope

- Backups are supported at the instance level.
- If the instance contains multiple databases, all databases are included in a single backup workflow.
- Selective database-level backups are not supported.

Backup Types Supported

Cohesity supports the following types of backups:

- **Full Backup**

  Captures a complete copy of the entire MySQL instance, including all databases, tables, indexes, tablespaces, and logs.
- **Incremental Backup**

Captures only the changes made since the last successful full or incremental backup on the Cohesity cluster. **XtraBackup** performs incremental backups based on the last redo log position of the previous backup.

- **Log Backup**

  Captures the binary logs (`binlogs`), which contain all database changes (`INSERT`, `UPDATE`, `DELETE`) with associated timestamps. Log backups enable point-in-time recovery by replaying changes after a full or incremental backup.

Backup Parameters

In the Protection Group, you can define the following parameters for your Percona MySQL backup configuration: (parameters are to be passed space (" ") separated)

> **Note:** The backup parameters are not applicable for log backups.

Backup Parameters	Mandatory?	Description
`--fifo-streams`	No	Number of FIFO streams used for backup. Default: **6**.
`--parallel-threads`	No	Number of parallel threads writing to the FIFO streams. Default: **18**.

Example

```
--fifo-streams=8 --parallel-threads=24
```

Protect Percona MySQL Deployments

In Cohesity Platform, Percona MySQL deployments are protected using a Protection Group and a Protection Policy. A Protection Group enables you to:

- Specify the MySQL instance that you want to backup.
- Based on your requirement, define the parameters for the backup statements provided by MySQL. For more information, see Backup Parameters.

The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select which standard or custom policy to use when creating a Protection Group. For more information, see About Policies and Protection Groups.

To protect Percona MySQL deployments:

1. Do one of the following:
   a. Select **Data Protection** > **Protection**. Click **Protect** on the top-right of the page and then select **Universal Data Adapter**.
   b. Select **Data Protection** > **Source**. Click the actions menu (⋮) next to the Percona MySQL source and then select **Protect**.
2. From the **Source** drop-down list, select the registered Percona MySQL source or click **Register Source** to register a Percona MySQL source. For more information, see Register and Manage the Percona MySQL Source.
3. In the **Objects** section, specify the object you want to protect.

   > **Note:** Only instance-level backup and restore are supported. Granular operations, such as backing up or restoring individual databases or tables, are not available. To proceed, you must enter a placeholder value in the **Objects** field.

   Then, click **Save Selection**.
4. In the **Protection Group** section, do one of the following:
   a. Select **New Group** to create a new Protection Group. In the **Protection Name** field, enter a name from the Protection Group.
   b. Select **Existing Group** to use the settings of an existing Protection Group. From the **Group** list, select an existing Protection Group and click **Protect**.
5. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy.
6. In the **Settings** section, do the following:
   a. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains.
   b. In the **Start Time** field, define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard.

      Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
   c. In the **Custom Options** sections, perform the following:

      Provide the backup parameters in the **Full Backup** and **Incremental Backup** fields if you plan to back up the entire Percona MySQL host. The parameters for

full and incremental backups can differ, but ensure that the value of `--fifo-streams` is always less than the value of `--parallel-threads`.

> **Note:** The **Log Backup** field is optional. Although log backups are supported, any value entered in this field is not used during backup operations.

For example,

Use Cases	Sample Parameters
Create a full backup of the Percona MySQL host	`--fifo-streams=8 --parallel-threads=24`
Create an incremental backup of the Percona MySQL host	`--fifo-streams=4 --parallel-threads=12`

Ignore the **Mounts** field. It is not applicable for Percona MySQL data protection.

7. After you have completed the **Settings** configuration, if you need to change any additional settings on the **New Universal Data Adapter Protection Group** page, scroll down and click **Edit** on the right. For more information, see Additional Settings below.
8. Click **Protect**.

Additional Settings

Additional Settings	Description
Pause Future Run	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
End Time	Optional. Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts before this date runs until completion even if it completes after this date.

Additional Settings	Description
QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup Target HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup Target SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Alerts	Optional. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection groups exceeds the ability to process protection groups, this will be the priority of implementation of the protection groups: • High-priority protection groups • Medium-priority protection groups • Low-priority protection groups.

Additional Settings	Description
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).
Description	Optional. Enter a brief description of the Protection Group.

Manage the Percona MySQL Backup Configuration

A backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group in the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the Protection page, select the Protection Group that you had created for Percona MySQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Percona MySQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a recovery run:

1. Navigate to **Data Protection** > **Protection**.
2. Click the action menu (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups, local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group, the reclaimed storage space details will not be displayed immediately. It will take some time to reflect on Cohesity.

To delete the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Percona MySQL.
3. Click the actions menu (⋮) next to the Protection Group and select Delete.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    1. Delete Protection Group Only
    2. Delete Protection Group and Snapshots.

Recover Percona MySQL Database

You can restore the protected Percona MySQL data to the same Percona MySQL deployment or to a different Percona MySQL deployment.

Recovery Process

Cohesity Platform supports instance-level recovery for Percona MySQL using the MySQL connector. If multiple databases were included in the backup, all databases are restored together within the same recovery workflow.

Recovery Options

Cohesity provides the following restore options:

- **Full or Incremental Image Restore**

  Restores the database instance using a full backup or a combination of full and incremental backups. Recovery is performed to the state captured in the selected backup image(s).

- **Point-in-Time Restore (PITR)**

  Restores the database instance to an exact point in time defined by the user. PITR combines full backups, incremental backups, and binary logs (binlogs) to replay changes up to the requested timestamp, providing granular recovery.

Recovery Parameters

In the Recovery configuration, you can define the following script parameters for your Percona MySQL recovery:

> **Note:** You can use the optional recovery parameters based on your requirements.

Recovery Parameters	Mandatory?	Description
`--target-dir`	Yes	Specifies the path where the MySQL data directory will be restored. The data directory contains all information managed by the Percona MySQL server. **Note:** Ensure that the directory path provided in the **target-dir** parameter already exists and is empty. The restore workflow will fail if the directory does not exist or contains data.
`--restart-instance`	No	Set to **false** if you do not want the Percona MySQL instance to restart automatically after recovery. The default value is **true**.

Example

```
--target-dir=/var/lib/mysql_restore --restart-instance=true
```

Recover Percona MySQL

To recover a Percona MySQL source:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **Universal Data Adapter**.
3. Search for the Protection Group that contains the snapshots to recover from by entering characters of the Protection Group name, or by specifying the wildcard character *.
4. From the list of search results, select the Protection Group that contains the snapshots to recover.
5. In the **Object** field, enter the name of the database or table that you had backed up using the selected Protection Group. By default, the latest snapshot is selected for recovery.
6. Click **Next: Recover Options**.
7. In the **Recover As** section, select **Replace Original**.

Options	Description
Replace Original	To restore to the same Percona MySQL host.
New Object	Select this option to restore data to a different MySQL host. Choose the **Target MySQL** host where you want to restore the data. > **Note:** The **Overwrite existing object with the same name** toggle is not applicable for MySQL and can be ignored.

8. In the **Recovery Options** section, based on your requirements, select any one of the following options:

Options	Description
Mounts	Not applicable for Percona MySQL host recovery.
Custom Options	Specify the Recovery Parameters based on your requirements. See Sample Recovery Use Cases for examples.
Rename	Not applicable for Percona MySQL. This field can be ignored.
Task Name	Change the default name of the recovery task.

9. Click **Recover**.

Sample Recovery Use Cases

Use Case	Instructions with Sample Recovery Parameters
Restore the Percona MySQL host to Same Location	`--target-dir=/var/lib/mysql_restore --restart-instance=true` > **Note:** Ensure that the directory path provided in the **target-dir** parameter already exists and is empty. The restore workflow will fail if the directory does not exist or contains data.

Cancel a Recovery Run

To cancel a recovery run follow the steps below:

1. Navigate to **Data Protection > Recoveries.**
2. Click the action menu (⋮) next to the recovery run and click **Cancel Run**.
3. In the Cancel Recovery dialog box, select any one of the following:
    1. Click **Continue Recovery** if you want to continue a recovery run
    2. Click **Cancel Recovery** if you want to cancel the recovery run.

SAP HANA

Cohesity natively integrates with SAP HANA to provide backup and recovery for clustered SAP HANA deployments. Using Cohesity Connector Agent, you can backup and restore the SAP HANA database. The Cohesity Connector Agent provides a simple workflow to back up and restore your SAP HANA deployment.

> **Tip:** To protect SAP HANA database using the Cohesity BACKINT plug-in Remote Adapter Jobs, see About SAP HANA Database Backups.

Cohesity provides a SAP HANA Connector for backup and restore of enterprise SAP HANA deployments. The SAP HANA Connector leverages the backup and restore capabilities provided by SAP HANA.

The SAP HANA Connector enables you to back up and restore both TenantDB and SystemDB. It provides:

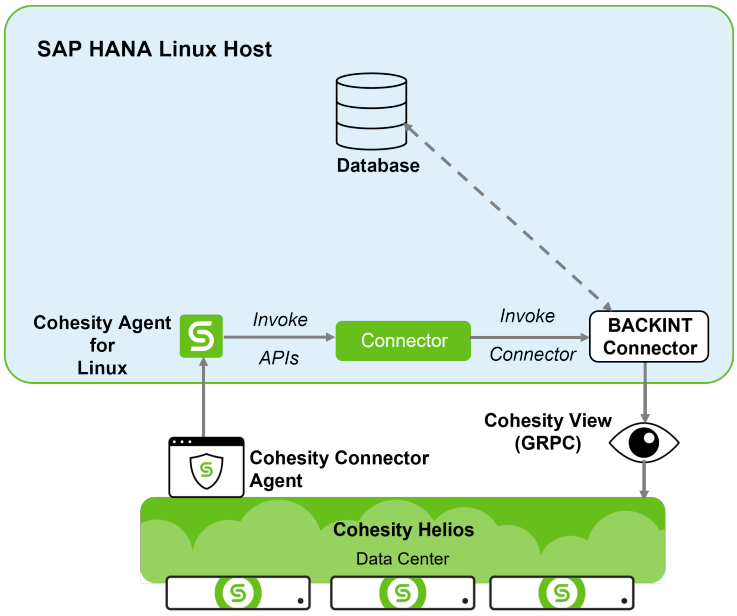
- Backup:
    - Full backup
    - Incremental backup
    - Differential backup
    - Automatic Log backup
- Restore:
    - Restore the database to its most recent state.
    - Restore the database to the point in time.
    - Restore the database to a specific data backup.
    - Alternate restore of SAP HANA database
        - Alternate restore to new database or active database on the same SAP HANA system.
        - Alternate restore to a new or active database on a different SAP HANA system.

Core Components

The following are the core components for protecting SAP HANA databases:

- SAP HANA Linux machine
- SAP HANA Connector
- Cohesity Connector Agent
- Cohesity View

As illustrated, you can integrate the Cohesity cluster with your SAP HANA deployments using the SAP HANA Connector and Cohesity Connector Agent.



Plan and Prepare for SAP HANA Protection

Before you register your SAP HANA deployment as a source with Cohesity and protect SAP HANA databases, ensure the following prerequisites:

- Identify the node(s) in your SAP HANA cluster with adequate resources to execute the SAP HANA connector.
- Ensure that the fully qualified domain name (FQDN) of the Cohesity cluster is resolvable from all the nodes in the SAP HANA cluster.
- Synchronize the SAP HANA Linux machine time with a Network Time Protocol (NTP) server. For detailed instructions, see How to Sync Linux Server Time with an NTP Server.
- Ensure that the NTP time is in sync between the client and the Cohesity cluster. Perform the following on the client:

- Verify if NTP is enabled and synchronized in the client using the following command:

```
timedatectl
```

- If the NTP time is not synchronized, use the following command to synchronize the NTP time

```
timedatectl set-ntp true
```

- Use "bash" shell to install the SAP HANA Connector and to run backups and restore workflows of SAP HANA databases.
- A database user with database admin user privileges.
- Download and install the Cohesity Linux Agent on the SAP HANA node.
- Download and install the SAP HANA connector.

Supported Versions

For more information on supported SAP HANA versions, see Supported Software versions.

Port Requirements

Outgoing Traffic

Source	Destination	Port	Protocol	Type of Traffic
Cohesity cluster	SAP HANA Node	50051	TCP/IP	Control path for all workflows

Bidirectional Traffic

Source	Destination	Port	Protocol	Type of Traffic
SAP HANA Local Host	SAP HANA Local Host	59999	TCP/IP	Required only if local-to-local communication (used for self-monitoring and debugging purposes) is blocked by the firewall.

Incoming Traffic

Source	Destination	Port	Protocol	Type of Traffic
SAP HANA Node	Cohesity cluster	11113	TCP/IP	Backup and Recovery
SAP HANA Node	Cohesity cluster	11117	TCP/IP	Backup and Recovery with secure gRPC

Considerations

Review and understand the following before you protect your SAP HANA database:

- SAP HANA 1.0 is not supported.
- Source-side deduplication is not supported for SAP HANA on PowerPC platform.
- You cannot protect multiple hosts using a single Protection Group.
- You cannot restore multiple objects, search and recover an object.
- Scheduling log backups in the Cohesity cluster is not supported, as SAP HANA automatically performs log backups.
- Cohesity supports backup and restore of SAP HANA(x86) databases running on dual-stack (IPv4 and IPv6) mode or single-stack (only IPv6) mode.
- Cohesity supports the recovery of SAP HANA 2.0 backups across both Intel x86-64 and Power PC platforms, allowing you to restore your critical SAP HANA data regardless of the underlying hardware architecture.
- Restoring backups from a higher version of SAP HANA to a lower version is not supported.
- Cohesity supports SAP HANA scale-out deployments that use independent disks for each node.
- Only Pacemaker-based cluster stacks provided by RHEL and SLES are supported for SAP HANA HA cluster data protection.

  > **Note:** The Pacemaker version 0.9.167 is supported.

- It is **mandatory** to connect to the Cohesity cluster securely using secure gRPC when writing or reading data.
- For a secure connection between the Cohesity cluster and the SAP HANA database, you need to generate an SAP HANA certificate for authentication.
- Cohesity supports native SAP HANA backup encryption. When encryption is enabled, backup data is encrypted and transferred to the Cohesity cluster for backups created using the Cohesity SAP HANA Connector Agent.
  - Supported encryption methods include:
  - SAP HANA Backup Encryption
  - System PKI SSFS (for internal communication encryption)
  - Data and Log Volume Encryption

  Supported secure stores:
  - SSFS (Secure Store and File System)
  - LSS (Local Secure Store)

Create the Secure User Store (hdbuserstore) Key

Create the SAP HANA hdbuserstore key to connect to SYSTEMDB. For detailed instructions, see Secure User Store (hdbuserstore). Use the following command to create the hdbuserstore key:

```
hdbuserstore SET <KEY> <host:port> <USERNAME> <PASSWORD>
```

> **Note:** Ensure that the user account of the secure user store has the following administrator privileges:
> - BACKUP ADMIN
> - DATABASE ADMIN
> - DATABASE START
> - CATALOG READ
> - MONITORING

Sample:

```
hdbuserstore SET SYS_KEY test-FI:30013 SYSTEM testpassword
```

After you have created the hdbuserstore key, verify if the key has the required SAP HANA connection information, such as hostname or login credentials. Verify the key using the following command:

```
tecadm@test-FI:/usr/sap/TEC/home> hdbsql -AU SYS_KEY
"select DATABASE_NAME,ACTIVE_STATUS from m_databases"
| DATABASE | ACT |
| -------- | --- |
| SYSTEMDB | YES |
| TEC | YES |
| SRC | YES |
| DST | YES |
4 rows selected (overall time 28.150 msec; server time 659 usec)
tecadm@test-FI:/usr/sap/TEC/home>
```

Download and Install the Cohesity Linux Agent

The Cohesity Linux Agent is available as script-based and RPM-based installers, based on your requirements download the installer and install it accordingly on the SAP HANA node (s). For detailed instructions, see Download and Install the Linux Agent.

> **Note:**
> - Use the `root` user account to install the Cohesity Linux Agent.
> - For multi-node SAP HANA deployments, install the Cohesity Linux Agent on the master node.

Download the SAP HANA Connector Installer

Cohesity provides a SAP HANA connector for SAP HANA to backup and restore SAP HANA databases. The SAP HANA connector for SAP HANA is available as a script or RPM-based installer on the Cohesity Download portal. Log on to the Cohesity Download portal, download the respective SAP HANA Connector installer for the Cohesity SAP HANA BACKINT plug-in, and the SAP HANA Connector installer to the SAP HANA host.

Install and Manage the SAP HANA Connector on x86-64 Platform

This topic covers instructions on how to install the SAP HANA Connector on x86-64 Platform.

Prerequisites

Before you register your SAP HANA deployment as a source with Cohesity and protect SAP HANA databases, ensure the following prerequisites:

- Identify the node(s) in your SAP HANA cluster with adequate resources to execute the SAP HANA connector.
- Ensure that the fully qualified domain name (FQDN) of the Cohesity cluster is resolvable from all the nodes in the SAP HANA cluster.
- Synchronize the SAP HANA Linux machine time with a Network Time Protocol (NTP) server. For detailed instructions, see How to Sync Linux Server Time with an NTP Server.
- Ensure that the NTP time is in sync between the client and the Cohesity cluster. Perform the following on the client:
  - Verify if NTP is enabled and synchronized in the client using the following command:

    ```
    timedatectl
    ```

  - If the NTP time is not synchronized, use the following command to synchronize the NTP time

    ```
    timedatectl set-ntp true
    ```

- "bash" shell is required for SAP HANA connector installation, backup, and restore workflows.
- A database user with database admin user privileges.

- Download and install the Cohesity Linux Agent on the SAP HANA node.
- Download the SAP HANA connector for the x86-64 platform.

Install the SAP HANA Connector

On the SAP HANA node where you have copied the SAP HANA connector installer, perform the following to install the SAP HANA connector.

> **Note:**
> For multi-node SAP HANA deployments with shared storage, ensure that:
>
> - You install the SAP HANA connector on the machine where you have installed Cohesity Linux Agent.
> - The SAP HANA Connector is installed on the shared NFS path, to which all the SAP HANA nodes have access.
>
> For multi-node SAP HANA deployments with non-shared storage, ensure that the Cohesity Linux Agent and the SAP HANA connector are installed on all the nodes in the SAP HANA HA cluster in the same installation directory.

Install the SAP HANA Connector Using Script Based Installer

To install the SAP HANA connector using script-based installer:

1. Log on to the SAP HANA node's bash CLI using `<SID>adm` user.
2. Make the SAP HANA connector installer (`cohesity_secure_connector_service_<version>_sap_hana_installer`) executable using the following command:

   ```
   SAP_HANA_SERVER:/home/adminse # chmod +x cohesity_secure_connector_service_<version>_sap_hana_installer
   ```

   > **Note:** During the SAP HANA connector installation, by default, the script installer extracts the files to the `/tmp` directory. If you plan to extract the files to a different directory, you can define the directory path in the `TMPDIR` environment variable as follows: `export TMPDIR=<directory_path>`.

3. Install the SAP HANA connector using the following command:

   ```
   ./cohesity_secure_connector_service_<version>_sap_hana_installer -- --install --install-dir=<backint install directory> --sid=<SID> --systemdb-key=<systemdb_key> --workflow=<workflow>
   ```

> **Note:** You can view the details of SAP HANA Connector installer options using the `--help` option. For example: `./cohesity_secure_connector_service_sap_hana_installer --help`

Where:

Options	Mandatory?	Description
`--install-dir`	No	The directory on the SAP HANA node on which you want to install the SAP HANA connector. **Note:** If `--install-dir` is not specified, the SAP HANA connector is installed in the `/usr/sap/${SAPSYSTEMNAME}/home` directory.
`--systemdb-key`	NO	The SAP HANA HDBUSERSTORE key to connect to the SYSTEM DB. • Use the option `--systemdb-key-k <user_store_key>` only if you want to edit the global.ini file and create a symbolic link from `HDBBACKINT` to the SAP HANA connector. • If you plan to backup your SAP HANA databases using the SAP HANA connector, ensure that you use the option `--systemdb-key <user_store_key>`. • If you have not used the option `--systemdb-key <user_store_key>` while installing the SAP HANA connector, specify the option `--systemdb-key <user_store_key>` while upgrading the SAP HANA connector.
`--cluster-port`	No	The ports in the firewall to allow the Cohesity cluster to transmit and receive data. The supported values are 11111 or 11113. By default the port is set as `11117`.

Options	Mandatory?	Description
`--workflow`	No	The type of workflow you intend to install the SAP HANA connector. The supported values are `uda` or `ra`. The `uda` value is for Universal Data Adapter workflow and `ra` is for Remote Adapter workflow.
`--multi-tenancy`	No	The type of deployment. The supported values are `vlan` or `hyx`. Specify `vlan` for 'VLAN' and `hyx` for 'Single Homed NAT' deployments.
`--standby`	No	Specify if you are installing the SAP HANA connector on a standby node.
`--hana-version`	No	The SAP HANA version. Supported values are 1 or 2. By default, the value is set to 1.
`--debug`	No	Option to enable installer debug.

After the SAP HANA connector is installed, the SAP HANA connector agent are available at: `<backint_install_directory>/cohesity_backint_plugin/uda_scripts`

For example:

```
/usr/sap/SID/home/cohesity/cohesity_backint_plugin/uda_scripts
```

4. Log on to the SAP HANA node as root user and create a soft link of `<backint_install_directory>/cohesity_backint_plugin/uda_scripts` folder to `/opt/cohesity/agent/uda_scripts` using the following command:

```
ln -s /usr/sap/SID/home/cohesity/cohesity_backint_plugin/uda_scripts
/opt/cohesity/agent/uda_scripts
```

> **Note:** Before creating the soft link, make sure to remove any existing soft link to the `<backint_install_directory>/cohesity_backint_plugin/uda_scripts` folder.

Enable Displaying Log Backups in the Cohesity Cluster

SAP HANA automatically triggers log backups, you can view these log backups on the Cohesity cluster. For viewing the SAP HANA log backups on the Cohesity cluster, you need to authenticate to the Cohesity cluster using the following java binary available in the SAP HANA connector installation directory: `<backint_install_directory>/cohesity_backint_plugin/et_log_backup_tool.jar`

> **Note:** Ensure that you have JDK installed on the SAP HANA node.

After you have successfully installed the SAP HANA connector, run the following command:

```
java -jar <backint_install_directory>/cohesity_backint_plugin/et_log_backup_tool.jar --authenticate
```

Example:

```
java -jar /opt/cohesity/cohesity_backint_plugin/bin/et_log_backup_tool.jar --authenticate
```

> **Note:**
> - When prompted, authenticate using the **Cohesity cluster's local admin user credentials**. If the password has been changed, make sure to reauthenticate using the updated password.
> - After you authenticate to the Cohesity cluster using the `et_log_backup_tool.jar` java binary, ensure that you set the `-et-log-backup` source registration parameter to `true` while registering the SAP HANA source. For more information, see Register and Manage the SAP HANA Source.
> - After registering the source with Cohesity (with`-et-log-backup=true`), a full backup is mandatory. The initial full backup must be completed before any log backups appear on the Cohesity user interface.
> - If you upgrade to version 7.3.1, you need to modify the existing registered source and set the `et-log-backup` source registration parameter to `true` in order to enable the display of log backups in the Cohesity cluster. Only the log backups triggered after enabling `et-log-backup` will be shown on the Cohesity cluster.

Install the SAP HANA Connector Using RPM Based Installer

Before you install the SAP HANA Connector Using RPM-based installer, ensure that you configure the following environment variables on the SAP HANA machine:

Environment Variable	Description	Mandatory?	Command
SID	The <SID>adm user account that must own the backup files on the Cohesity view. If you have not created the user account, then create an Operating System (OS) user account in the following format: <SID>adm. Where <SID> is a unique three-character code called SAP System Identification (SID). It is available for every R/3 installation (SAP system) that consists of a database server and several application servers.	Yes	export SID=<VALUE>
SYSTEMDB_KEY	The SAP HANA HDBUSERSTORE key to connect to the SYSTEM DB.	No	export SYSTEMDB_KEY=<HDBUSERSTORE key>
CLUSTER_PORT	The ports in the firewall to allow the Cohesity cluster to transmit and receive data. The supported values are 11111 or 11113. By default the port is set as 11117.	No	export CLUSTER_PORT=<Port_number>
WORKFLOW	The type of workflow you intend to install the SAP HANA connector. The supported values are uda or ra. The uda value is for Universal Data Adapter workflow and ra is for Remote Adapter workflow. Default is uda.	No	export WORKFLOW=ra
MULTI_TENANCY	The type of deployment. The supported values are vlan or hyx. Specify vlan for 'VLAN' and hyx for 'Single Homed NAT' deployments.	No	export MULTI_TENANCY=<VALUE>
STANDBY	Specify if you are installing the SAP HANA connector on a standby node. Supported values are 1 or 0.	No	export STANDBY=<VALUE>
HANA_VERSION	The SAP HANA version. Supported values are 1 or 2.	No	export HANA_VERSION=<VALUE>
DEBUG	Option to enable installer debug. Supported values are 1 or 0.	No	export DEBUG=<VALUE>

To install the SAP HANA connector using rpm-based installer:

1. Log on to the SAP HANA node's bash CLI using root or user with sudo access.
2. Make the SAP HANA connector installer (`cohesity-hana-backint-<version>.x86_64.rpm`) executable using the following command:

   ```
   > chmod +x cohesity-hana-backint-<version>.x86_64.rpm
   ```

3. Install the SAP HANA connector using the following command:

   ```
   > sudo -E rpm -ivh cohesity-hana-backint-<version>.x86_64.rpm
   ```

Uninstall the SAP HANA Connector

To uninstall the SAP HANA connector, run the following command with appropriate parameters on SAP HANA node's bash CLI.

Using the Script installer:

```
./cohesity_secure_connector_service_sap_hana_installer -- --uninstall --
install-dir=<backint_install_directory> --sid=<sid> --workflow=<workflow>
```

> **Note:** Specify the `--standby` option, if you are uninstalling the SAP HANA connector on a standby node.

Using the RPM installer:

```
> sudo -E rpm -evh cohesity-hana-backint-<version>.x86_64.rpm
```

After you have successfully uninstalled the SAP HANA connector, log on to the SAP HANA node as root user and unlink the soft link from `/opt/cohesity/agent/uda_scripts`.

Upgrade the SAP HANA Connector

To upgrade the SAP HANA connector, run the following command on all SAP HANA nodes.

Using the Script installer:

```
./cohesity_secure_connector_service_sap_hana_installer -- --upgrade --
install-dir=<backint_install_directory> --sid=<sid> --systemdb-key=<user_
store_key> --workflow=<workflow>
```

Using the RPM installer:

```
> sudo -E rpm -Uvh cohesity-hana-backint-<version>.x86_64.rpm
```

After you have upgraded the SAP HANA connector, log on to the SAP HANA node as root user and create a soft link of `<backint_install_directory>/cohesity_backint_plugin/uda_scripts` folder to `/opt/cohesity/agent/uda_scripts` using the following command:

```
ln -s /usr/sap/SID/home/cohesity/cohesity_backint_plugin/uda_scripts /op-
t/cohesity/agent/uda_scripts
```

Install and Manage the SAP HANA Connector on IBM PowerPC Platform

This topic covers instructions on how to install the SAP HANA Connector on IBM PowerPC Platform.

Prerequisites

Before you register your SAP HANA deployment as a source with Cohesity and protect SAP HANA databases, ensure the following prerequisites:

- Identify the node(s) in your SAP HANA cluster with adequate resources to execute the SAP HANA connector.
- SAP HANA node(s) must be using JDK version 1.8 or higher.
- Ensure that the fully qualified domain name (FQDN) of the Cohesity cluster is resolvable from all the nodes in the SAP HANA cluster.
- Synchronize the SAP HANA Linux machine time with a Network Time Protocol (NTP) server. For detailed instructions, see How to Sync Linux Server Time with an NTP Server.
- Ensure that the NTP time is in sync between the client and the Cohesity cluster. Perform the following on the client:
  - Verify if NTP is enabled and synchronized in the client using the following command:

    ```
    timedatectl
    ```

  - If the NTP time is not synchronized, use the following command to synchronize the NTP time

    ```
    timedatectl set-ntp true
    ```

- "bash" shell is required for SAP HANA connector installation, backup, and restore workflows.
- A database user with database admin user privileges.
- Download and install the Cohesity Linux Agent on the SAP HANA node.
- Download the SAP HANA connector Installer for the IBM PowerPC Platform.

Install the SAP HANA Connector

On the SAP HANA node where you have copied the SAP HANA connector, perform the following to install the SAP HANA connector.

> **Note:**
> For multi-node SAP HANA deployments, ensure that:
>
> - You install the SAP HANA connector on the machine where you have installed Cohesity Linux Agent.
> - The SAP HANA Connector is installed on the shared NFS path, to which all the SAP HANA nodes have access.

Install the SAP HANA Connector Using Script Based Installer

To install the SAP HANA connector using script-based installer:

1. Log on to the SAP HANA node's bash CLI using `<SID>adm` user.
2. Make the SAP HANA connector installer (`cohesity_secure_connector_service_<version>_sap_hana_java_installer`) executable using the following command:

   ```
   SAP_HANA_SERVER:/home/adminse # chmod +x cohesity_secure_connector_service_<version>_sap_hana_java_installer
   ```

3. Install the SAP HANA connector using the following command:

   ```
   ./cohesity_secure_connector_service_<version>_sap_hana_java_installer -- --install=<backint install directory> --sid=<SID> --systemdb-key=<systemdb_key> --workflow=<workflow>
   ```

   > **Note:** You can view the details of SAP HANA Connector installer options using the `--help` option. For example: `./cohesity_secure_connector_service_sap_hana_installer --help`After the SAP HANA connector is installed, the SAP HANA connector agent is available at: `<backint_install_directory>/cohesity_backint_plugin/uda_scripts`

   Where:

Options	Mandatory?	Description
`--install-dir`	No	The directory on the SAP HANA node on which you want to install the SAP HANA connector. **Note:** If `--install-dir` is not specified, the SAP HANA connector is installed in the `/usr/sap/${SAPSYSTEMNAME}/home` directory.
`--systemdb-key`	NO	The SAP HANA HDBUSERSTORE key to connect to the SYSTEM DB. • Use the option `--systemdb-key-k <user_store_key>` only if you want to edit the global.ini file and create a symbolic link from `HDBBACKINT` to the SAP HANA connector. • If you plan to backup your SAP HANA databases using the SAP HANA connector, ensure that you use the option `--systemdb-key <user_store_key>`. • If you have not used the option `--systemdb-key <user_store_key>` while installing the SAP HANA connector, specify the option `--systemdb-key <user_store_key>` while upgrading the SAP HANA connector.
`--cluster-port`	No	The ports in the firewall to allow the Cohesity cluster to transmit and receive data. The supported values are 11111 or 11113. By default the port is set as `11117`.
`--workflow`	No	The type of workflow you intend to install the SAP HANA connector. The supported values are `uda` or `ra`. The `uda` value is for Universal Data Adapter workflow and `ra` is for Remote Adapter workflow.
`--multi-tenancy`	No	The type of deployment. The supported values are `vlan` or `hyx`. Specify `vlan` for 'VLAN' and `hyx` for 'Single Homed NAT' deployments.

Options	Mandatory?	Description
`--standby`	No	Specify if you are installing the SAP HANA connector on a standby node.
`--hana-version`	No	The SAP HANA version. Supported values are 1 or 2. By default, the value is set to 1.
`--debug`	No	Option to enable installer debug.
`--catalog-view`	No	The name of the catalog view where the backup metadata resides. **Note:** The catalog view name should not include the view path or cluster name or IP address.

After the SAP HANA connector is installed, the SAP HANA connector agent is available at: `<backint_install_directory>/cohesity_backint_plugin/uda_scripts`

For example:

```
/usr/sap/SID/home/cohesity/cohesity_backint_plugin/uda_scripts
```

4. Log on to the SAP HANA node as root user and create a soft link of `<backint_install_directory>/cohesity_backint_plugin/uda_scripts` folder to `/opt/cohesity/agent/uda_scripts` using the following command:

```
ln -s /usr/sap/SID/home/cohesity/cohesity_backint_plugin/uda_scripts
/opt/cohesity/agent/uda_scripts
```

> **Note:** Before creating the soft link, make sure to remove any existing soft link to the `<backint_install_directory>/cohesity_backint_plugin/uda_scripts` folder.

Install the SAP HANA Connector Using RPM Based Installer

Before you install the SAP HANA Connector Using an RPM-based installer, ensure that you configure the following environment variables on the SAP HANA machine:

Environment Variable	Description	Mandatory?	Command
SID	The <SID>adm user account that must own the backup files on the Cohesity view. If you have not created the user account, then create an Operating System (OS) user account in the following format: <SID>adm. Where <SID> is a unique three-character code called SAP System Identification (SID). It is available for every R/3 installation (SAP system) that consists of a database server and several application servers.	Yes	export SID=<VALUE>
SYSTEMDB_KEY	The SAP HANA HDBUSERSTORE key to connect to the SYSTEM DB.	No	export SYSTEMDB_KEY=<HDBUSERSTORE key>
CLUSTER_PORT	The ports in the firewall to allow the Cohesity cluster to transmit and receive data. The supported values are 11111 or 11113. By default the port is set as 11117.	No	export CLUSTER_PORT=<Port_number>
WORKFLOW	The type of workflow you intend to install the SAP HANA connector. The supported values are uda or ra. The uda value is for Universal Data Adapter workflow and ra is for Remote Adapter workflow. Default is uda.	No	export WORKFLOW=ra
MULTI_TENANCY	The type of deployment. The supported values are vlan or hyx. Specify vlan for 'VLAN' and hyx for 'Single Homed NAT' deployments.	No	export MULTI_TENANCY=<VALUE>
STANDBY	Specify if you are installing the SAP HANA connector on a standby node. Supported values are 1 or 0.	No	export STANDBY=<VALUE>
HANA_VERSION	The SAP HANA version. Supported values are 1 or 2.	No	export HANA_VERSION=<VALUE>
DEBUG	Option to enable installer debug. Supported values are 1 or 0.	No	export DEBUG=<VALUE>

Environment Variable	Description	Mandatory?	Command
CATALOG_VIEW	The name of the catalog view where the backup metadata resides. **Note:** The catalog view name should not include the view path or cluster name or IP address.	No	`export CATALOG_VIEW=<VALUE>`

To install the SAP HANA connector using rpm-based installer:

1. Log on to the SAP HANA node's bash CLI using <SID>adm user.
2. Make the SAP HANA connector installer (`cohesity-hana-java-backint-<version>.noarch.rpm`) executable using the following command:

```
> chmod +x cohesity-hana-java-backint-<version>.noarch.rpm
```

3. Install the SAP HANA connector using the following command:

```
> sudo -E rpm -ivh cohesity-hana-java-backint-<version>.noarch.rpm
```

Enable Displaying Log Backups in the Cohesity Cluster

SAP HANA automatically triggers log backups, you can view these log backups on the Cohesity cluster. For viewing the SAP HANA log backups on the Cohesity cluster, you need to authenticate to the Cohesity cluster using the following java binary available in the SAP HANA connector installation directory: `<backint_install_directory>/cohesity_backint_plugin/et_log_backup_tool.jar`

> **Note:** Ensure that you have JDK installed on the SAP HANA node.

After you have successfully installed the SAP HANA connector, run the following command:

```
java -jar <backint_install_directory>/cohesity_backint_plugin/et_log_backup_tool.jar --authenticate
```

Example:

```
java -jar /opt/cohesity/cohesity_backint_plugin/bin/et_log_backup_tool.jar --authenticate
```

Note:

- When prompted, authenticate using the **Cohesity cluster's local admin user credentials**. If the password has been changed, make sure to reauthenticate using the updated password.
- After you authenticate to the Cohesity cluster using the `et_log_backup_tool.jar` java binary, ensure that you set the `-et-log-backup` source registration parameter to `true` while registering the SAP HANA source. For more information, see Register and Manage the SAP HANA Source.
- After registering the source with Cohesity (with`-et-log-backup=true`), a full backup is mandatory. The initial full backup must be completed before any log backups appear on the Cohesity user interface.
- If you upgrade to version 7.3.1, you need to modify the existing registered source and set the `et-log-backup` source registration parameter to `true` in order to enable the display of log backups in the Cohesity cluster. Only the log backups triggered after enabling `et-log-backup` will be shown on the Cohesity cluster.

Uninstall the SAP HANA Connector

To uninstall the SAP HANA Connector using the root user account, use the following command:

Using the Script installer:

```
./cohesity_secure_connector_service_<version>_sap_hana_java_installer -- --
uninstall --install-dir=<backint_install_directory> --workflow=<workflow>
```

Using the RPM installer:

```
> sudo -E rpm -evh cohesity-hana-java-backint-<version>.noarch.rpm
```

Upgrade the SAP HANA Connector

To upgrade the SAP HANA connector, run the following command on all SAP HANA nodes.

Using the Script installer:

```
./cohesity_secure_connector_service_<version>_sap_hana_java_installer -- --
upgrade --install-dir=<backint_install_directory> --workflow=<workflow>
```

Using the RPM installer:

```
sudo -E rpm -Uvh cohesity-hana-java-backint-<version>.noarch.rpm
```

Register and Manage the SAP HANA Source

To protect your SAP HANA databases, you need to register your SAP HANA deployment as a source on Cohesity. After registering your SAP HANA deployment as a source, you can:

- Add more SAP HANA node(s) to run the SAP HANA database agent. Ensure that you have installed the Cohesity Linux Agent and SAP HANA database agent on the node (s).
- Refresh the source details.
- Unregister the SAP HANA source from Cohesity.

Register SAP HANA as a Source

Before you register SAP HANA as a source, ensure that you:

- Review the requirements and limitations.
- Perform the prerequisite tasks.

For more information, see Plan and Prepare for SAP HANA Protection.

To register SAP HANA as a source:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Register** on the top-right of the page and then select **Universal Data Adapter**.
3. In the **Register Universal Data Adapter** page, perform the following:
   a. From the **Source Type** drop-down menu, select **SAP HANA**.
   b. From the **Host OS Type** drop-down menu, select **Linux**.
   c. In the **Hostname/IP Addresses** field, enter the hostname or IP address (IPv4 or IPv6) of the node(s) you have identified to run the SAP HANA database agent. For more information, see Plan and Prepare for SAP HANA Protection.

      > **Note:** Cohesity supports backup and restore of SAP HANA(x86) databases running on dual-stack (IPv4 and IPv6) mode or single-stack (only IPv6) mode.

   d. In the **Datasource Agent Installation Path** field, enter the directory path on the SAP HANA node, where you have installed the SAP HANA database agent. For more information, see Plan and Prepare for SAP HANA Protection.
   e. Ignore the In the **APP Authentication** section. It is not applicable to SAP HANA source registration.
   f. Enable **Custom Options**, perform the following:

i. Ignore the **Mounts View** option. It is not applicable for SAP HANA source registration.

ii. Optional. In the **Source Registration Options** field, enter the following source registration parameters based on your requirements:

The parameters are optional. If you do not explicitly specify the values then the values you had provided while installing the SAP HANA database agent are applied.

Parameters	Description
`--sourcename`	A unique name to identify the SAP HANA source. Using this parameter, you can override the unique name that you provided while installing the SAP HANA database agent. For more information, see Plan and Prepare for SAP HANA Protection. For example: `--sourcename=SAPSalesProd`
`--hana-ha-vips`	Optional. Provide the IP address configured for "**Virtual IP address resource**" on the SAP HANA HA cluster. For example: `--hana-ha-vips=10.11.23.112`
`--backint-protocol-version`	Optional. The BACKINT protocol version 1.5 is supported by default from SAP HANA 2.0 SPS 05 or later versions on the IBM PowerPC Platform. By default, the SAP HANA Connector agent supports BACKINT protocol version 1.0. Using this parameter, you can specify the SAP HANA Connector agent to use the BACKINT protocol version 1.5 based on your requirement. For example: `--backint-protocol-version=1.5`
`--et-log-backup`	Set the value to `true`, if you want to view the SAP HANA log backups on the Cohesity cluster. **Note:** Before registering the source, ensure that you authenticate to the Cohesity cluster using the `et_log_backup_tool.jar` java binary available in the SAP HANA connector installation directory. For more information, see Enable Log Backups Replication.

Parameters	Description
`--entity-hierarchy`	Optional. Set the value to `true` to enable auto-discovery and entity hierarchy that lets you browse or search and select SAP HANA objects for backup and restore. **Note:** If you are upgrading to version 7.2 or later, you need to update the existing SAP HANA source configuration to enable auto-discovery and entity hierarchy. Set the `--entity-hierarchy` source registration parameter to "`true`." After updating the source configuration (with `--entity-hierarchy=true`), a full backup is mandatory.
`--tcp-streams`	Optional. Specify the number of TCP connections you want to make with Cohesity Cluster. **Note:** This parameter is primarily useful when your source machine is behind a Hybrid Extender.

g. Click **Register**.

Update the SAP HANA Source Configuration

After registering your SAP HANA as a source on Cohesity, you can:

- Add more node(s) to run the SAP HANA database agent. Ensure that you have installed the Cohesity Linux Agent and SAP HANA database agent on the node(s).
- Modify the **Source Registration Options** based on your requirements.
- Update the **Datasource Agent Installation Path** only if you have uninstalled and reinstalled the SAP HANA database agent in a different directory on the SAP HANA node.

> **Note:** Ensure that the SAP HANA database agent is installed on all the node(s) in the SAP HANA cluster.

To update the SAP HANA source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the SAP HANA source and select **Edit**.

3. In the **Update Universal Data Adapter** page, update the required configurations.
4. Click **Update**.

Refresh the SAP HANA Source Configuration

You can refresh the SAP HANA Source and re-verify the source with the available source registration parameters.

To refresh the SAP HANA Source Configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the SAP HANA Source and select **Refresh**.

Unregister the SAP HANA Source

If you plan to stop taking the backup of your SAP HANA databases, you can unregister the SAP HANA source from the Cohesity.

To unregister the SAP HANA source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the SAP HANA source and select **Unregister**.

Backup SAP HANA Database

Cohesity provides a simple workflow to back up your SAP HANA databases. After registering the SAP HANA as a source on Cohesity, you can start configuring your backups.

Backup Process

Cohesity provides a SAP HANA database agent for the backup and restore of enterprise SAP HANA deployments. The SAP HANA database agent leverages the backup capabilities provided by SAP HANA.

After registering the SAP HANA source on Cohesity, you can create a Protection Group and specify the objects such as databases and tables that you want to backup. In the Protection Group, you need to define the parameters that enable you to provide additional parameters required by the backup statements provided by SAP HANA.

> **Note:** Cohesity recommends that you configure periodic full backups.

Backup Parameters

In the Protection Group, you can define the following parameters for your SAP HANA backup configuration:

Backup Parameters	Mandatory?	Description
`--user-store-key`	No	The hdbuserstore key to connect to the SAP HANA SYSTEMDB. For example: `--user-store-key=H00_KEY`
`--backup-delta`	No	The parameter is only applicable for Incremental or Differential backups. The supported values are INCREMENTAL or DIFFERENTIAL. If you do not explicitly specify a value, by default, incremental backup is considered. For example: `--backup-delta=DIFFERENTIAL`
`--use-secure-grpc=<true/false>`	No	Set the parameter to true, if you want to use secure gRPC communication during backup. For example: `--use-secure-grpc=true` **Note:** It is **mandatory** to connect to the Cohesity cluster securely using secure gRPC when writing or reading data.
`--sap-certificate-path=<cert_file_path>`	No	Specify the path of the self-signed certificate if you want to use it for secure gRPC communication during backups. For example: `--sap-certificate-path=/tmp/certs/sap_cert1837348343.cfg`
`-r, --retention-days`	Yes	Specify the number of days to retain full or incremental backups. This argument helps manage storage by automatically removing backups older than the defined retention period. **Note:** Ensure that the number of days specified in the argument matches the days defined in the backup policy.

Log Backups

SAP HANA automatically triggers log backups, you can view these log backups on the Cohesity cluster and perform the following:

- View the SAP HANA log backups on the Cohesity clusters.
- Replicate the SAP HANA log backups across the Cohesity clusters in your deployment.
- Archive the SAP HANA log backups.

To view SAP HANA log backups on the Cohesity cluster, perform the following:

1. After you have installed or upgraded the SAP HANA Connector, enable SAP HANA log backup replication. For more information, see Enable Log Backups Replication.
2. While registering or updating the SAP HANA source to the Cohesity cluster, set the `–et-log-backup source` registration parameter to `true`. For more information, see Register SAP HANA as a Source.
3. Create a new Protection Group and select a Protection Policy with log backups job in the Protection Group for SAP HANA backups. For more information, see Protect SAP HANA Deployments.

   > **Note:**
   > - To replicate jobs, select the replication option, while creating the Protection Group.
   > - In the source, after setting the source parameter `–et-log-backup` to `true`, the log backups will not be displayed on the Cohesity UI or be replicated for older Protection Groups. You must create a new Protection Group with the updated source.

4. Create a Full Backup for the first time.

Replication to the secondary Cohesity cluster will be enabled after the first successful full backup, and log backups will be displayed on the Cohesity UI.

> **Note:** Catalog backups are not displayed on the Cohesity UI.

Protect SAP HANA Deployments

SAP HANA deployments are protected using a Protection Group and a Protection Policy. A Protection Group enables you to:

- Specify the objects such as databases and tables that you want to backup.
- Based on your requirement, define the parameters for the backup statements provided by SAP HANA. For more information, see Backup Parameters.

The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select which standard or custom policy to use when creating a Protection Group. For more information, see About Policies and Protection Groups.

To protect SAP HANA deployments:

1. Do one of the following:
   - Select **Data Protection > Protection**. Click **Protect** on the top-right of the page and then select **Universal Data Adapter**.
   - Select **Data Protection > Sources**. Click the actions menu (⋮) next to the SAP HANA source and then select **Protect**.
2. From the **Source** drop-down list, select the registered SAP HANA source or click **Register Source** to register a SAP HANA source. For more information, see Register SAP HANA as a Source.
3. In the **Objects** section, select the database or databases that you plan to backup. Then, click **Save Selection**.

   Important:
   - To select the database or databases from the entity hierarchy, make sure to enable entity hierarchy (`--entity-hierarchy`) during source registration. If it is not enabled, you must manually enter the object name for backup.
   - If you are upgrading to version 7.2 or later, you need to update the existing SAP HANA source configuration to enable auto-discovery and entity hierarchy. Set the `--entity-hierarchy` source registration parameter to "`true`." After updating the source configuration (with `--entity-hierarchy=true`), a full backup is necessary.
4. In the **Protection Group** section, do one of the following:
   - Select **New Group** to create a new Protection Group. In the **Protection Name** field, enter a name from the Protection Group.
   - Select **Existing Group** to use the settings of an existing Protection Group. From the **Group** list, select an existing Protection Group and click **Protect**.
5. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy.

   Note: SAP HANA automatically schedules log backups, and you can view these log backups on the Cohesity cluster. Ensure that you add a log backup job in the Protection Policy. The Protection Policy with log backup job retains the SAP HANA log backups and is not used for scheduling SAP HANA log backups.

6. In the **Settings** section, do the following:
    1. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains.
    2. In the **Start Time** field, define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard.

       Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
    3. In the **Custom Options** section, perform any one of the following:
        - Do not enter any backup parameters in the **Full Backup** and **Incremental Backup** fields if you plan to perform full backup or incremental backup respectively.
        - Enter the Backup Parameters in the **Full Backup** and **Incremental Backup** fields based on your requirements.

          For example:

Use Cases	Sample Parameters
Create a full backup of the SAP HANA cluster by overriding the user store key. **Note:** In the case of SAP HANA cluster backup, it takes the user store key as `H00_KEY` which is overridden with the backup parameter.	In the **Full Backup** field, specify the following parameter: `--user-store-key=H00_KEY`
Create an incremental backup of the SAP HANA cluster by overriding the user store key. **Note:** In the case of SAP HANA cluster backup, it takes the user store key as `H00_KEY` which is overridden with the backup parameter.	In the **Incremental Backup** field, specify the following parameter: `--user-store-key=H00_KEY`

Use Cases	Sample Parameters
Create a differential backup of the SAP HANA cluster. **Note:** In the case of SAP HANA cluster backup, it takes the backup delta as DIFFERENTIAL which is overridden with the backup parameter.	In the **Incremental Backup** field, specify the following parameter: `--backup-delta=DIFFERENTIAL`

- In the **Mounts** field, enter the number of VIPs you want to use while writing data to the Cohesity storage.

  Note: Cohesity recommends that the number of mounts is equal to the number of nodes or Hybrid Extenders.

7. After you have completed the **Settings**, if you need to change any additional settings on the **New Universal Data Adapter Protection Group** page, scroll down and click Edit on the right. For more information, see Additional Settings.
8. Click **Protect**.

Additional Settings

Additional Settings	Description
Pause Future Run	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
End Time	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.

Additional Settings	Description
QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup Target HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup Target SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Concurrency	The maximum number of restore streams that is created to exchange data with the cluster. By default, maximum scaling is set to empty. > **Note:** The same value is set to the `parallel_data_backup_backint_channels` parameter in the **global.ini** file for the protected database. Also, the same value is set for the `max_restore_streams` parameter in the SAP HANA parameter file of the database selected for protection.
Alerts	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.

Additional Settings	Description
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).
Description	**Optional**. Enter a brief description about the Protection Group.

Manage the SAP HANA Backup Configuration

A backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for SAP HANA.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ in the **Objects** section.

5. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
6. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for SAP HANA.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a recovery run:

1. Navigate to **Data Protection > Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity Platform provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.

- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity.

To delete the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for SAP HANA.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
   - Delete Protection Group Only
   - Delete Protection Group and Snapshots

Recover SAP HANA Database

You can restore the SAP HANA cluster or object(s) such as databases in SAP HANA. You can restore to the same SAP HANA cluster or a different SAP HANA cluster.

The SAP HANA database agent leverages the restore statements provided by SAP HANA. You can create a Recovery configuration and specify the objects such as databases backed up using the Protection Group.

In the Recovery configuration, you need to specify the object you plan to restore and define the script parameters required by the restore statements provided by SAP HANA.

Recovery Parameters

In the Recovery configuration, you can define the following script parameters for your SAP HANA recovery:

> **Note:** The recovery parameters are optional parameters, you can use these parameters based on your requirements.

Recovery Parameters	Mandatory ?	Description

`--source-sid`	Mandatory for alternate restore use cases.	Provide the SAP HANA source system SID for the SAP HANA host used for the alternate restore use case.
		For example:
		`--source-sid=<sid>`
		`--source-sid=H00`
		Note:
		• The `--source-sid` parameter is applicable only for alternate restore use cases.
		• Ignore the `--source-sid` parameter, if you have enabled entity hierarchy (`--entity-hierarchy`) during source registration.

`--user-store-key`	Optional	The hdbuserstore key to connect to the SAP HANA SYSTEMDB. For example: `--user-store-key=H00_KEY`
`--start-database`	Optional	Set the value to `true` if you want to activate the database after the recovery is completed. Supported values are `true` or `false`. By default the value is set to `true`.
`--use-secure-grpc=<true/false>`	Optional	Set the parameter to true, if you want to use secure gRPC communication during restore. For example: `--use-secure-grpc=true`
`--sap-certificate-path=<cert_file_path>`	Optional	Specify the path of the self-signed certificate if you want to use it for secure gRPC communication during restore. For example: `--sap-certificate-path=/tmp/certs/sap_cert1837348343.cfg`

Prerequisites

Ensure that:

- The Protection Group associated with the object that you plan to restore is paused or in not running state.
- The target database exists, or you manually create the target database before you start the restore process.

- The SAP HANA version used for recovery must always be the same or newer than the version used for backup of data and logs.
- If any of the selected snapshots were backed up with SAP HANA backup encryption enabled, ensure that the encryption keys are recovered to the SAP HANA source system before starting the recovery process.
- All the required SAP HANA services are up and running. You can use the following sample command to verify the required services:

```
sap-hana-2:cohadm> sapcontrol -nr ${TINSTANCE} -function GetProcessList
03.09.2024 14:58:23
GetProcessList
OK
name, description, dispstatus, textstatus, starttime, elapsedtime, pid
hdbdaemon, HDB Daemon, GREEN, Running, 2024 09 02 16:49:20, 22:09:03,
14346
hdbcompileserver, HDB Compileserver, GREEN, Running, 2024 09 02
16:49:26, 22:08:57, 14488
hdbindexserver, HDB Indexserver-COH, GREEN, Running, 2024 09 03

1:27:20, 31567
```

To stop and start the required services, use the following command:

```
sap-hana-2:cohadm> HDB stop
sap-hana-2:cohadm> HDB start
```

Recover SAP HANA Databases

To restore SAP HANA:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** at the top right of the page and then select **Universal Data Adapter**.
3. Search for the Protection Group that contains the snapshots to recover from by entering characters of the Protection Group name, or by specifying the wildcard character *.

4. From the list of search results, select the Protection Group that contains the snapshots to recover.
5. In the **Object** field, select the database that you had backed up using the selected Protection Group.

   > **Note:** Using a recovery job, you can recover only a single database.

   By default, the latest snapshot is selected for recovery. You can also select a point-in-time snapshot or specific data backup that you want to recover. Click the pencil icon and perform the following:

   - For point-in-time snapshots, in the **Edit recovery point for <Protection_Group_Name>** dialog, click the **Timeline** tab, choose the **Date** and select the **point-in-time** from the **timeline** slider and click **Select Recovery Point**.
   - For specific data backup snapshots, in the **Edit recovery point for <Protection_Group_Name>** dialog, click the **list** tab and select the specific **Snapshot Time** that you want and click **Select Recovery Point**.
6. Click **Next: Recover Options**.
7. In the **Recover As** section, based on your requirements, select any one of the following options:

Options	Description
Replace Original	To restore to the same SAP HANA database.
New Object	To restore to a different database on the same SAP HANA cluster or a different SAP HANA cluster. Select the **Target** SAP HANA cluster to which the data needs to be restored. Also, ignore **Overwrite existing object with the same name** toggle option. It is not applicable for SAP HANA.

8. In the **Recovery Options** section, based on your requirements, select any one of the following options:

Options	Description
Mounts	Enter the number of VIPs you want to use while reading data from the Cohesity storage.

Options	Description
Concurrency	The maximum number of restore streams that is created to exchange data with the cluster. By default, maximum scaling is set to empty. **Note:** The same value is set to the `parallel_data_backup_backint_channels` parameter in the **global.ini** file for the protected database. Also, the same value is set for the `max_restore_streams` parameter in the SAP HANA parameter file of the database selected for protection.
Custom Options	Specify the Recovery Parameters based on your requirements. For examples, see Sample Recovery Use Cases.
Rename	Provide the new name for the object, if you want to restore the object with a new name.
Task Name	Change the default name of the recovery task.

9. Click **Start Recovery**.

Sample Recovery Use Cases

Use Case	Sample Recovery Parameters
Overwrite Point In Time Restore (PITR) to the same SAP HANA database.	In the **Recover As** section, select **Replace Original**. Under the **Recovery Options** section, do not specify any parameters in the **Custom Options** field.
Overwrite Point In Time Restore (PITR) the same SAP HANA database overriding the user store key.	In the **Recover As** section, select **Replace Original**. Under the **Recovery Options** section, specify `--user-store-key=H00_KEY` in the **Custom Options** field.

Use Case	Sample Recovery Parameters
Restore specific data backup from the snapshot to the same SAP HANA database.	In the **Recover As** section, select **Replace Original**. Under the **Recovery Options** section, specify `--user-store-key=H00_KEY --is-specific-data-backup-restore=true` in the **Custom Options** field.
Point In Time Restore (PITR) to a different database on the same SAP HANA system.	Perform the following: 1. In the **Recover As** section, select **New Object** and choose the same source name in the **Target** drop-down. 2. Under the **Recovery Options** section, specify `--user-store-key=H00_KEY --source-sid=H00` in the **Custom Options** field and specify the name for the new database in the **Rename** field.
Point In Time Restore (PITR) to a different database on a different SAP HANA system	Perform the following: 1. In the **Recover As** section, select **New Object** and choose the target source name in the **Target** drop-down. 2. Under the **Recovery Options** section, specify `--user-store-key=H00_KEY --source-sid=H00` in the **Custom Options** field and specify the name for the new database in the **Rename** field.

Use Case	Sample Recovery Parameters

Restore specific data backup from the snapshot to a new database on the same SAP HANA system.	Perform the following:
	1. In the **Recover As** section, select **New Object** and choose the same source name in the **Target** drop-down.
	2. Under the **Recovery Options** section, specify the following in the **Custom Options** field and specify the name for the new database in the **Rename** field:
	`--user-store-key=H00_KEY`
	`--source-sid=H00`
	`--is-specific-data-backup-restore=true`

Cancel a Recovery Run

When you cancel a recovery run, the recovery process is terminated. If the recovery run is canceled during an ongoing restore operation, the SAP HANA database may enter an offline or inconsistent state. To bring the SAP HANA database back online, you must initiate a new recovery run.

To cancel a recovery run:

1. In the Cohesity Dashboard, select **Data Protection** > **Recoveries**.
2. Click the action icon (⋮) next to the recovery run and click **Cancel Run**.
3. In the **Cancel Recovery** dialog box, select any one of the following:
   - **Continue Recovery**. if you want to continue to recovery run
   - **Cancel Recovery**. if you want to cancel the recovery run.

SAP HANA Certificate Authentication

The SAP HANA Certification provides the necessary authentication and also verifies whether the SAP HANA database, which performs backups to the Cohesity cluster, is a trusted entity. This certification provides the capability to set verification which allows only trusted sources to write to the Cohesity cluster through the SpanFS.

Create an SAP HANA Authentication Certificate

This section lists the steps for creating an SAP HANA authentication certificate.

1. Start the Cohesity CLI locally and log in to the Cohesity cluster using the ssh command with the `support` user account and specify the IP address. For more information, see Using the Cohesity CLI and List of Cohesity CLI Commands.

```
ssh support@198.51.100.12
```

2. If prompted, enter the password.

```
[support@198.51.100.12's password:
```

The cohesity_shell prompt is displayed.

3. Log in to the CLI:

```
cohesity shell# iris_cli
```

The admin prompt is displayed.

4. Optionally, run the help command for a list of CLI commands.

```
admin@198.51.100.12> help
```

5. Run the cluster gen-src-cert command to generate a new SAP HANA certificate.

```
admin@198.51.100.12 cluster gen-src-cert cert-name="newdemocert" cert-
validity=100 host-name="10.2.146.175" host-target="/tmp"
Success: Certificate "newdemocert" generation and deployment
successful.
```

Parameter Name	Description
cert-name	Name of the certificate file. Its naming format is ${cert-name}_<random_number>.cfg.
cert-validity	The validity of the source certificate generated. The time is displayed in days.
host-name	The IP address/host name of the target system where you want to move the certificate. This is a mandatory parameter because the certificate generation process needs details of the host machine to generate public and private keys.
host-target	The file directory path on the Cohesity cluster where the certificate is generated.

> **Note:** After the SAP HANA certificate is generated on the Cohesity cluster, manually copy the certificate to your SAP HANA machine.

6. Update the following parameters in the parameter file.

Parameter Name	Description
cluster_port	Port number on Cohesity cluster nodes to which the BACKINT executable connects. Use the port 11117 for secure connection (certificate config path should be a valid path). Use the port 11111 for an insecure connection (certificate config path should be an empty string). Contact Cohesity Support to enable these ports.
certificate_ config_path	The path to which the certificate is generated and deployed from the Cohesity Dashboard to the SAP HANA Node. You can use this path as the default config path: `/usr/sap/ORC/home/install/newdemocert.cfg`

7. Run the `list-source-certificates` command to check all the global certificates deployed from the cluster.

Deploy an SAP HANA Certificate in a Multi-node Setup

This section lists the steps to deploy an SAP HANA authentication certificate in a multi-node SAP HANA setup.

1. Generate and deploy the SAP HANA authentication certificate to any one of the nodes in a multi-node SAP HANA system using the instructions provided in the previous section.
2. Use SCP to securely transfer the certificate to a target location on all the remaining (N-1) nodes.

   ```
   scp <certificate_config_path> ip_address:<certificate_config_path>
   ```

   Example

   ```
   scp /usr/sap/ORC/home/install/cert.cfg 10.2.146.72:
   /usr/sap/ORC/home/install/cert.cfg
   ```

3. Change the `cluster_port parameter` value to 11117 and update the `certificate_ config_path` parameter value to the correct path of the certificate in the respective paramfile of each of the N nodes.

SAP Sybase IQ

Cohesity Platform natively integrates with SAP Sybase IQ to provide backup and recovery for clustered SAP Sybase IQ deployments. Using Cohesity Connector Agent, you can backup and restore the SAP Sybase IQ database. The Cohesity Connector Agent provides a simple workflow to back up and restore your SAP Sybase IQ deployment.

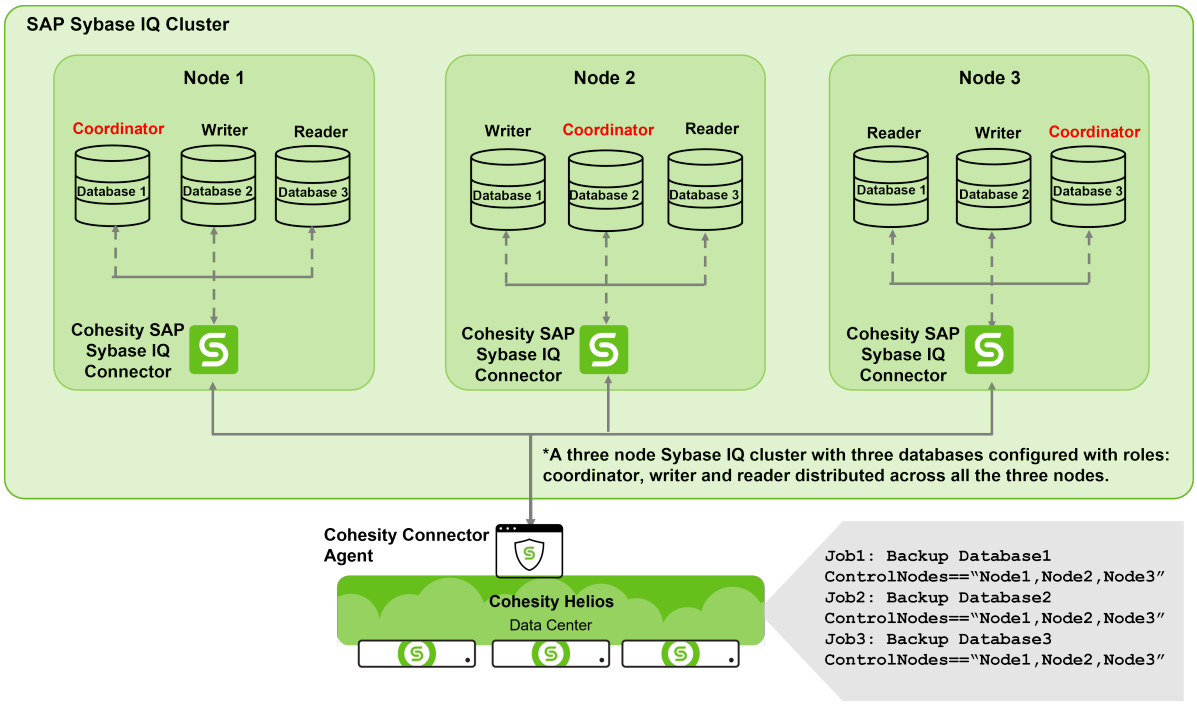
Cohesity Platform provides an SAP Sybase IQ Plug-in for backup and restore of the SAP Sybase IQ database. The SAP Sybase IQ plug-in leverages the third-party dynamic link library (DLL) based capabilities provided by SAP Sybase IQ.

Core Components

The following are the core components for protecting SAP Sybase IQ databases:

- SAP Sybase IQ cluster
- Cohesity SAP Sybase IQ plug-in
- Cohesity Connector Agent

As illustrated, you can integrate the Cohesity Platform with your SAP Sybase IQ deployments using the SAP Sybase IQ Plug-in and Cohesity Connector Agent.



Plan and Prepare for SAP Sybase IQ Protection

Before you register your SAP Sybase IQ deployment as a source with Cohesity Platform, ensure the following prerequisites:

- Identify the Coordinator Node of the database that you plan to protect. The backup or restore scripts run on the coordinator node. If you have a multiplex cluster with failover capability for the coordinator node, choose all those nodes where the coordinator node can failover. To identify the failover node for the coordinator, use

the following DB command:

```
select connection_info ,coordinator_failover from sp_iqmpxinfo() where
coordinator_failover=server_name;
```

- A database user with database admin user privileges.
- Download and install the Cohesity Linux Agent on the SAP Sybase IQ nodes.
- Download and install the SAP Sybase IQ connector RPM-based installer.
- Review and understand the prerequisites.

Supported Versions

For more information on supported SAP Sybase IQ versions, see Supported Software versions.

Port Requirements

Outgoing Traffic

Source	Destination	Port	Protocol	Type of Traffic
Cohesity cluster	SAP Sybase IQ Node	50051	TCP/IP	Control path for all workflows

Bidirectional Traffic

Source	Destination	Port	Protocol	Type of Traffic
SAP Sybase IQ Local Host	SAP Sybase IQ Local Host	59999	TCP/IP	Required only if local-to-local communication (used for self-monitoring and debugging purposes) is blocked by the firewall.

Incoming Traffic

Source	Destination	Port	Protocol	Type of Traffic
SAP Sybase IQ Node	Cohesity cluster	11113	TCP/IP	Backup and Recovery
SAP Sybase IQ Node	Cohesity cluster	11117	TCP/IP	Backup and Recovery with secure gRPC

Supported Backup and Restore Matrix

The following table provides the support matrix for backup and restore operations:

		Supported SAP Sybase IQ Database Restore Versions			
		16.0 SP11 PL28	**16.1 SP03 PL9**	**16.1 SP04 PL01**	**16.1 SP04 PL09**
SAP Sybase IQ Database Backup Version	**16.0 SP11 PL28**	Supported	Supported	Supported	Supported
	16.1 SP03 PL9	Not Supported	Supported	Supported	Supported
	16.1 SP04 PL01	Not Supported	Not Supported	Supported	Supported
	16.1 SP04 PL09	Not Supported	Not Supported	Supported	Supported

Considerations

Review and understand the following before you protect your SAP Sybase IQ database:

- You can back up only one database per Protection Group.
- Currently only online backup of databases is supported.
- The same database should not be part of multiple Protection Groups.
- Log backups are not supported.
- SAP Sybase IQ does not support Point in time recovery (PITR) from backups taken using a third-party dynamic link library (DLL).
- In the case of multiplex database restore, data is restored to only one node (coordinator). You need to set the multiplex roles and start the multiplex database manually.
- Cohesity supports backup and restore of SAP Sybase IQ databases running on dual-stack (IPv4 and IPv6) mode or single-stack (only IPv6) mode.

Prerequisites

- For backups, the database server must be up and running.
- For Kerberos authentication, the keytab file must be available on all nodes at the given location and accessible by the user used to run the Cohesity Linux Agent.
- SSL certificates must be used for connecting to the database servers. The SSL certificates must be available in the same path on all servers and accessible by the user used to run the Cohesity Linux Agent.

- To securely connect to the Cohesity cluster while reading or writing data, you can use secure gRPC.

  > **Note:**
  > - From 7.2.2 version onwards, it is **mandatory** to connect to the Cohesity cluster securely using secure gRPC when writing or reading data.
  > - Using non-secure gRPC for data transfer between Cohesity and database hosts will result in unsecured communication.
  > - Enabling secure gRPC will increase data transfer time between Cohesity and database hosts compared to non-secure communication.

  To use secure gRPC, perform the following:

  1. Generate the certificate config file on the Cohesity node using the following command:

     ```
     ~/<release-version>/crux/bin/client_tls_cert_generator_exec -cert_name <clustername> -output_file /home/cohesity/<clustername>.cfg
     ```

  2. Copy `/home/cohesity/<clustername>.cfg` from the Cohesity node to all your SAP Sybase IQ nodes at the same location. For example, `/opt/certs/<clustername>.cfg`.

     > **Note:** Ensure that the `root` or `non-root` user used to install the Cohesity Linux agent and your SAP Sybase IQ Connector has read access to the generated certificate config file.

  3. While registering the your SAP Sybase IQ source, provide the following as a part of **Source Registration Options**:

     ```
     --certificate-config-path=opt/certs/<clustername>.cfg
     ```

Download and install the Cohesity Linux Agent

The Cohesity Linux Agent is available as script-based and RPM-based installers. Based on your requirements, download the installer and install it accordingly on the node(s) of the SAP Sybase IQ cluster. For detailed instructions, see Download and Install the Linux Agent.

> **Note:** Ensure that you install the Cohesity Linux Agent using the RPM-based installer.

Download and Install the SAP Sybase IQ Connector Installer

Cohesity Platform provides an SAP Sybase IQ connector for the backup and restore of SAP Sybase IQ deployments. Sybase IQ supports backup and restore operations with third-party products using a dynamic link library loaded at run time(.dll or .so).

Download the SAP Sybase IQ Connector

Cohesity Platform provides a SAP Sybase IQ Connector to backup and restore SAP Sybase IQ databases. The SAP Sybase IQ Connector is available as a datasource agent on the Cohesity Download portal. Log on to the Cohesity Download portal, download the respective datasource agent for SAP Sybase IQ Connector, and copy the datasource agent to the SAP Sybase IQ host.

Install the SAP Sybase IQ Connector

Before you install the SAP Sybase IQ Connector, ensure that you have `sudo` privileges.

To install the SAP Sybase IQ connector:

1. Log on to the SAP Sybase IQ node where you have copied the SAP Sybase IQ connector RPM-based installer, `cohesity-sybaseiq-connector-<version>.x86_64.rpm`.
2. Run the following command to install the SAP Sybase IQ connector:

   ```
   sudo sh -c 'export SYBASEIQ_ENV_PATH=/path/to/SAP Sybase IQ/IQ-16_0/IQ-16_0.sh ; yum localinstall /home/cohesity/cohesity-sybaseiq-connector-<version>.x86_64.rpm'
   ```

   Where `/path/to/SAP Sybase IQ/` is the directory where the SAP Sybase IQ connector is installed.

   > **Note:** If you do not explicitly specify the details, the hostname is applied as the value for control nodes and source name. Also, a unique hash value is applied for the source UUID.

Upgrade the SAP Sybase IQ Connector

To upgrade the SAP Sybase IQ Connector, run the following command with appropriate parameters on SAP Sybase IQ node's CLI:

```
$ sudo sh -c 'export SYBASEIQ_ENV_PATH=/opt/sybase/iq16/IQ-16_1/IQ-16_1.sh ; yum update cohesity-sybaseiq-connector-<version>-1.x86_64.rpm'
```

Uninstall the SAP Sybase IQ Connector

To uninstall the SAP Sybase IQ Connector, run the following command with appropriate parameters on SAP Sybase IQ node's CLI:

Using `yum`:

```
sudo yum remove cohesity-sybaseiq-connector-<version>.x86_64
```

Using `rpm`:

```
sudo rpm -e cohesity-sybaseiq-connector-<version>.x86_64.rpm
```

Register and Manage the SAP Sybase IQ Source

To protect your SAP Sybase IQ databases, you need to register your SAP Sybase IQ deployment as a source on the Cohesity Platform. After registering your SAP Sybase IQ deployment as a source, you can:

- Update the SAP Sybase IQ source configuration, such as:
  - Add more coordinator node(s) to run the SAP Sybase IQ Connector. Ensure that you have installed the Cohesity Linux Agent and SAP Sybase IQ Connector on the node(s).
  - If you connect to the database using password-based authentication then you can modify the username and password of the database user.
- Unregister the SAP Sybase IQ source from the Cohesity Platform.

Register SAP Sybase IQ as a Source

Before you register SAP Sybase IQ as a source, ensure that you:

- Review the requirements and limitations.
- Perform the prerequisite tasks.

For more information, see Plan and Prepare for SAP Sybase IQ Protection.

To register SAP Sybase IQ as a source:

1. In the Cohesity Dashboard, select **Data Protection** > **Sources**.
2. Click **Register** on the top-right of the page and then select **Universal Data Adapter**.
3. In the **Register Universal Data Adapter** page, perform the following:
   a. From the **Source Type** drop-down menu, select **SAP Sybase IQ**.
   b. From the **Host OS Type** drop-down menu, select **Linux**.
   c. In the **Hostname/IP Addresses** field, enter the hostname or IP address of the coordinator node for a given database that you have identified to run the SAP Sybase IQ connector. For more information, see Plan and Prepare for SAP Sybase IQ Protection.

> **Note:** Cohesity supports backup and restore of SAP Sybase IQ databases running on dual-stack (IPv4 and IPv6) mode or single-stack (only IPv6) mode.

d. In the **Datasource Agent Installation Path** field, enter the directory path on the SAP Sybase IQ Linux machine, where you have installed the SAP Sybase IQ Connector. For more information, see Install the SAP Sybase IQ Connector.

e. In the **APP Authentication** section, enter the **Username** and **Password** of the SAP Sybase IQ database admin user to connect to the database using password-based authentication.

> **Note:** If you do not want to use password-based authentication, ignore the **OS APP Authentication** section.

f. Enable **Custom Options**, and perform the following:

   a. Ignore the **Mounts View** option. It is not applicable for SAP Sybase IQ source registration.

   > **Note:** The **Mount View** option is not applicable, and ensure you do not enable the option.

   b. In the **Source Registration Options** field, enter the following source registration parameters based on your requirements:

   For example:

```
--source-name=sybaseDBCluster1
```

Parameters	Mandatory?	Default	Description
`--source-name`	Yes	N/A	A unique name to identify the SAP Sybase IQ source. For example: `--sourcename=SalesProd` **Note:** Once you configure the source name, you cannot change it later.
`--use-secure-grpc`	No	False	Set the parameter to `true`, to enable secure connection to the Cohesity cluster while reading or writing data.

Parameters	Mandatory?	Default	Description
`--certificate-config-path`	No	N/A	The path to the certificate used to securely connect to the Cohesity cluster.

Parameters	Mandatory?	Default	Description
			Note: • It is **mandatory** to connect to the Cohesity cluster securely using secure gRPC when writing or reading data. • Ensure that you generate and copy the certificate config file from the Cohesity node to all the SAP Sybase IQ nodes. For more information, see Prerequisites. • Using non-secure gRPC for data transfer between Cohesity and database hosts will result in unsecured communicatio n. • Enabling secure gRPC will increase data transfer time between Cohesity and database hosts compared to non-secure

g. Click **Register**.

Update the SAP Sybase IQ Source Configuration

After registering your SAP Sybase IQ as a source on the Cohesity Platform, you can:

- Add more coordinator node(s) to run the SAP Sybase IQ Connector. Ensure that you have installed the Cohesity Linux Agent and SAP Sybase IQ Connector on the node(s).
- If you connect to the database using password-based authentication then you can modify the username and password of the database user.
- Modify the **Source Registration Options** based on your requirements.
- Update the **Datasource Agent Installation Path** only if you have uninstalled and reinstalled the SAP Sybase IQ Connector in a different directory on the SAP Sybase IQ node.

> **Note:** Ensure that the SAP Sybase IQ Connector is installed on all the node(s) in the SAP Sybase IQ cluster.

To update the SAP Sybase IQ source configuration:

1. In the Cohesity Dashboard, select **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the SAP Sybase IQ source and select **Edit**.
3. In the **Update Universal Data Adapter** page, update the required configurations.
4. Click **Update**.

Unregister the SAP Sybase IQ Source

If you plan to stop taking the backup of your SAP Sybase IQ databases, you can unregister the SAP Sybase IQ source from the Cohesity Platform.

To unregister the SAP Sybase IQ source:

1. In the Cohesity Dashboard, select **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the SAP Sybase IQ source and select **Unregister**.

Backup SAP Sybase IQ Database

Cohesity Platform provides a simple workflow to back up your SAP Sybase IQ databases. After registering the SAP Sybase IQ as a source on the Cohesity Platform, you can start configuring your backups.

Backup Process

Cohesity Platform provides an SAP Sybase IQ connector for the backup and restore of SAP Sybase IQ deployments. The SAP Sybase IQ connector leverages the third-party dynamic link library (DLL) based capabilities provided by SAP Sybase IQ.

After registering the SAP Sybase IQ source on the Cohesity Platform, you can create a Protection Group and specify the objects such as databases you want to backup. In the Protection Group, you need to define the parameters that enable you to provide additional parameters required by the backup statements provided by SAP Sybase IQ.

> **Note:** Cohesity recommends that you configure periodic full backups.

Backup Parameters

In the Protection Group, you can define the following parameters for your SAP Sybase IQ backup configuration:

Backup Parameters	Default Value	Mandatory?	Description
`--database-server`	N/A	Yes	The database server name that is used to connect to the database. You can retrieve the database server name using the following command: `dblocate -dn <dbname>`
`--database-port`	N/A	No	If database broadcast is disabled, specify the database port.
`--database-host`	N/A	No	If database broadcast is disabled, specify the database host.
`--database-config-path`	N/A	No	The path of the database configuration file that is used to start the database. Cohesity SAP SybaseIQ Connector checks database configuration file at location `<.db path>/params.cfg` or `<.db path>/dbname.cfg`. If the file is not present, you have to explicitly provide the absolute path of the database configuration file or the parameters file.
`--sybase-block-factor`	25	No	Specifies the number of blocks to write to the archive device at a time.

Backup Parameters	Default Value	Mandatory?	Description
`--check-crc`	true	No	Allows you to verify the checksums computed on the backup during any subsequent restore operation.
`--user-principal`		Yes (If you are using Kerberos authentication)	The Kerberos principal required to connect to the database.
`--keytab-path`			The absolute path of the keytab file for a given Kerberos principal. **Note:** The path must be accessible by the Cohesity Agent user.

Protect SAP Sybase IQ Deployments

In Cohesity, SAP Sybase IQ deployments are protected using a Protection Group and a Protection Policy. A Protection Group enables you to:

- Specify the objects such as databases and tables that you want to backup.
- Based on your requirement, define the parameters for the backup statements provided by SAP Sybase IQ. For more information, see Backup Parameters.

The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select which standard or custom policy to use when creating a Protection Group. For more information, see About Policies and Protection Groups.

To protect SAP Sybase IQ deployments:

1. In the Cohesity Dashboard, do one of the following:
   - Select **Data Protection > Protection**. Click **Protect** on the top-right of the page and then select **Universal Data Adapter**.
   - Select **Data Protection > Sources**. Click the actions menu (⋮) next to the Sybase IQ and then select **Protect**.
2. From the **Source** drop-down list, select the registered SAP Sybase IQ source or click **Register Source** to register a SAP Sybase IQ source. For more information, see Register SAP Sybase IQ as a Source.

3. In the **Objects** section, add the object that you plan to protect. The object should be a database name. To back up a database, enter the name of the database. For example, `DEMODB`. Click the plus icon (+) to enter multiple objects that you plan to back up. Then, click **Save Selection**.
4. In the **Protection Group** section, do one of the following:
   - Select **New Group** to create a new Protection Group. In the **Protection Name** field, enter a name from the Protection Group.
   - Select **Existing Group** to use the settings of an existing Protection Group. From the **Group** list, select an existing Protection Group and click **Protect**.
5. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy.
6. In the Settings section, do the following:
   1. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains.
   2. In the **Start Time** field, define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard.

      Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
   3. In the **Custom Options** section, enter the backup parameters in the **Full Backup**, **Incremental Backup** and **Log Backup** fields based on your requirements. For more information, see Backup Parameters.

      > **Note:** Ensure that you enter the same backup parameters in the **Full Backup** and **Incremental Backup** fields.

      For example: To perform backup of an SSL-enabled database with Kerberos authentication. In the Full Backup and Incremental Backup fields, enter the following parameters:

      ```
      --database-server=bankdb_server --user-principal=username@REALM_
      NAME --keytab-path=/data/bankdb/username.keytab --cert-
      path=/data/bankdb/certs/CA.crt
      ```
   4. In the **Mounts** field, enter the number of VIPs you want to use while writing data to the Cohesity storage.

> **Note:** Cohesity recommends that the number of mounts is equal to the number of nodes or Hybrid Extenders.

7. After you have completed the **Settings**, if you need to change any additional settings on the **New Universal Data Adapter Protection Group** page, scroll down and click **Edit** on the right. For more information, see Additional Settings.
8. Click **Protect**.

Additional Settings

Additional Settings	Description
Pause Future Run	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
End Time	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup Target HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup Target SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Concurrency	Maximum number of backup streams that will be created to exchange data with the cluster. By default, maximum scaling is capped at 16.

Additional Settings	Description
Alerts	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).
Description	**Optional**. Enter a brief description about the Protection Group.

Manage the SAP Sybase IQ Backup Configuration

In the Cohesity Platform, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for SAP Sybase IQ.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ on the **Objects** section.
5. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
6. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for SAP Sybase IQ.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a recovery run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for SAP Sybase IQ.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Delete Protection Group Only
    - Delete Protection Group and Snapshots

Recover SAP Sybase IQ Database

You can restore the SAP Sybase IQ object(s) such as databases in SAP Sybase IQ. You can restore to the same SAP Sybase IQ cluster or a different SAP Sybase IQ cluster.

The SAP Sybase IQ connector leverages the restore statements provided by SAP Sybase IQ. You can create a Recovery configuration and specify the objects such as databases backed up using the Protection Group.

In the Recovery configuration, you need to specify the object you plan to restore and define the parameters required by the restore statements provided by SAP Sybase IQ.

> **Note:** In the case of multiplex database restore, data is restored to only one node (coordinator). Therefore, you must set the multiplex roles and start the multiplex database manually. For details on how to setup multiplex roles, see SAP IQ Administration Guide,

Recovery Parameters

In the Recovery configuration, you can define the following parameters for your SAP Sybase IQ recovery:

> **Note:** The recovery parameters are optional parameters, you can use these parameters based on your requirements.

Recovery Parameters	Default Value	Mandatory?	Description
`--catalog-store-path`	N/A	Yes	The absolute path of the directory to which the catalog store must be restored. **Note:** The directory must already exist.
`--main-store-path`	The path provided in `--catalog-store-path`	No	The absolute path of the directory to which the IQ main store must be restored. If you do not define the directory path, the IQ main store is restored to the directory provided in the "`--catalog-store-path`" parameter. **Note:** The directory must already exist.
`--temp-store-path`	N/A	No	The absolute path of the directory to which the temp store must be restored. **Note:** The directory must already exist.

Recovery Parameters	Default Value	Mandatory?	Description
`--shared-temp-store-path`	N/A	No	The absolute path of the directory to which the IQ shared temp store must be restored. If you do not define the directory path, the IQ shared temp store is restored to the directory provided in the "`--catalog-store-path`" parameter. **Note:** The directory must already exist.
`--coordinator`	False	No	The hostname or IP address of the node where you want to restore data in case of multi-node cluster. **Note:** Applicable only for multi-node cluster.
`--start-database`	False	No	Specify if you want to start the database at the end of the restore operation.
`--stop-database`	True	No	Suppose the database with the same name is already running on the cluster where you are restoring the database. Specify if you want to stop the database.
`--service-user`	Backup instance user	No	After the data is restored, you can start the database with the specified user. If the user is not specified, the same user with which the database was backed up is used to start the database.

Recover SAP Sybase IQ Databases

To recover SAP Sybase IQ databases:

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Click **Recover** at the top right of the page and then select **Universal Data Adapter**.
3. Search for the Protection Group that contains the snapshots to recover from by entering characters of the Protection Group name, or by specifying the wildcard character *.
4. From the list of search results, select the Protection Group that contains the snapshots to recover.

5. In the **Object** field, enter the name of the database or table that you had backed up using the selected Protection Group.
6. Click **Next: Recover Options**.
7. In the **Recover As** section, based on your requirements, select any one of the following options:

Options	Description
Replace Original	To restore to the same SAP Sybase IQ database.
New Object	To restore to a different SAP Sybase IQ cluster. Select the **Target** SAP Sybase IQ cluster to which the data needs to be restored. Also, enable **Overwrite existing object with the same name** and type **Yes**, if you want to overwrite the existing object with the same name.

8. In the **Recovery Options** section, based on your requirements, select any one of the following options:

Options	Description
Mounts	Enter the number of VIPs you want to use while reading data from the Cohesity storage.
Concurrency	Not applicable for SAP Sybase IQ database recovery.
Custom Options	Specify the Recovery Parameters based on your requirements. For examples, see Sample Recovery Use Cases.
Rename	Provide the new name for the object, if you want to restore the object with a new name.
Task Name	Change the default name of the recovery task.

9. Click **Start Recovery**.

Sample Recovery Use Cases

Use Case	Sample Recovery Parameters
Restore a database to the location: `/mnt/database1`	`--catalog-store-path=/mnt/database1`

Use Case	Sample Recovery Parameters
Restore a database with: • Catalog store at `/data/restore/catalog` • IQ_SYSTEM_MAIN at `/data/restore/main` • IQ_SYSTEM_TEMP at `/data/restore/temp`	`--catalog-store-path=/data/restore/catalog --main-store-path=/data/restore/main --temp-store-path=/data/restore/temp`

Cancel a Recovery Run

When you cancel a recovery run, the SAP Sybase IQ connector cancels the job by terminating the recovery processes.

To cancel a recovery run:

1. In the Cohesity Dashboard, select **Data Protection** > **Recoveries**.
2. Click the action icon (⋮) next to the recovery run and click **Cancel Run**.
3. In the **Cancel Recovery** dialog box, select any one of the following:
    - **Continue Recovery** if you want to continue to recovery run
    - **Cancel Recovery** if you want to cancel the recovery run.

SAP MaxDB on Linux

Cohesity natively integrates with SAP MaxDB to provide backup and recovery for clustered SAP MaxDB deployments. Using Cohesity Connector Agent, you can backup and restore the SAP MaxDB database.

Cohesity provides a Cohesity BACKINT plug-in for the backup and restore of enterprise SAP MaxDB deployments. The Cohesity BACKINT plug-in leverages the backup and restore capabilities provided by SAP MaxDB.

The Cohesity BACKINT plug-in enables you to back up and restore both TenantDB and SystemDB. It provides:

- Backup:
    - Full backup
    - Incremental backup
    - Scheduled Log backup
- Restore:
    - Restore the database to the point in time.
    - Restore the database to a specific data backup.

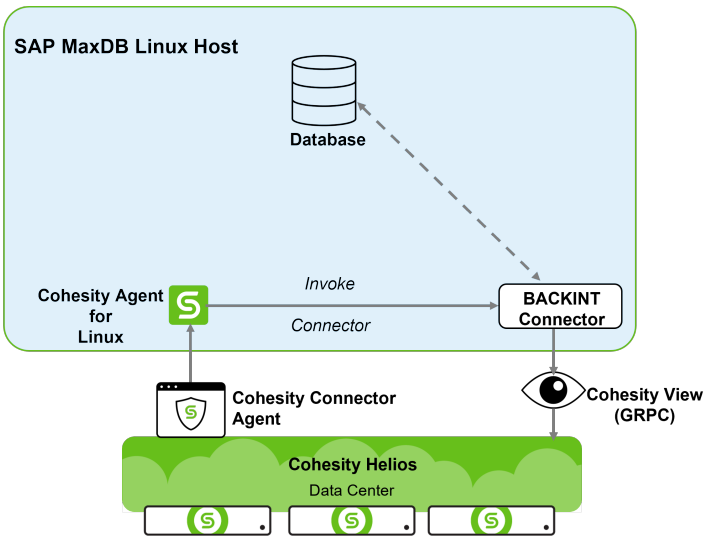
- Alternate restore of SAP MaxDB database:
  - Alternate restore to a new database or active database on the same SAP MaxDB system.
  - Alternate restore to a new or active database on a different SAP MaxDB system.

Core Components

The following are the core components for protecting SAP MaxDB databases:

- SAP MaxDB Linux machine
- Cohesity BACKINT plug-in
- Cohesity Connector Agent

As illustrated, you can integrate the Cohesity Cluster with your SAP MaxDB deployments using the Cohesity BACKINT plug-in and Cohesity Connector Agent.



Plan and Prepare for SAP MaxDB on Linux Protection

Before you register your SAP MaxDB deployment as a source with Cohesity Platform and protect SAP MaxDB databases, ensure the following prerequisites:

- Ensure that the fully qualified domain name (FQDN) of the Cohesity cluster is resolvable from the SAP MaxDB Linux machine.
- Synchronize the SAP MaxDB Linux machine time with a Network Time Protocol (NTP) server. For detailed instructions, see How to Sync Linux Server Time with an NTP Server

- Ensure that the NTP time is in sync between the client and the Cohesity cluster. Perform the following on the client:
  - Verify if NTP is enabled and synchronized in the client using the following command:

    ```
    timedatectl
    ```

  - If the NTP time is not synchronized, use the following command to synchronize the NTP time

    ```
    timedatectl set-ntp true
    ```

- A database user with database admin user privileges.
- Download and install the Cohesity Linux Agent on the SAP MaxDB Linux machine.
- Download and install the SAP MaxDB Connector agent.
- Create a XUSER key.
- Create a backup template.

Supported Versions

For more information on supported SAP MaxDB versions, see Supported Software versions.

SAP MaxDB Connector Requirements

To install and run the Cohesity SAP MaxDB Connector agent, ensure that the SAP MaxDB host meets the following specifications:

Components	Specification
SAP MaxDB Version	For details, see Supported Software.
Operating System	
Platform	x86_64
Disk Space	• Minimum 256 MB. Required for installing the SAP MaxDB Connector agent. • 1 GB. Required for the log directory.
Memory	8GB of free memory to run the SAP MaxDB Connector agent.

Port Requirements

Outgoing Traffic

Source	Destination	Port	Protocol	Type of Traffic
Cohesity cluster	SAP MaxDB Node	50051	TCP/IP	Control path for all workflows

Bidirectional Traffic

Source	Destination	Port	Protocol	Type of Traffic
SAP MaxDB Local Host	SAP MaxDB Local Host	59999	TCP/IP	Required only if local-to-local communication (used for self-monitoring and debugging purposes) is blocked by the firewall.

Incoming Traffic

Source	Destination	Port	Protocol	Type of Traffic
SAP MaxDB Node	Cohesity cluster	11113	TCP/IP	Backup and Recovery
SAP MaxDB Node	Cohesity cluster	11117	TCP/IP	Backup and Recovery with secure gRPC

Considerations

Review and understand the following before you protect your SAP MaxDB database:

- SAP MaxDB with liveCache technology is not supported.
- NFS datapath is not supported.
- Only PIPE backups are supported. File backups are not supported, and hence only scheduled log backups are supported, and automatic log backups are not supported.
- In a protection run, you cannot back up multiple objects.
- Only the single-node MAXDB database system is supported.
- Canceling restore operations is not supported.
- For alternate restore, the target SAP MaxDB database must be created before starting the restore operation.
- For alternate restore to a different SAP MaxDB host, the path specified in IndepDataPath must be the same.
- Cohesity replication is supported.

- After a successful database restore, Cohesity recommends to trigger a full backup to ensure that incremental and log backups do not fail. For more information, see Data backup missing (backup history lost).
- If the database system administration (SUPERDBA) password is different in both the source and the target SAP MaxDB hosts, then when you perform an alternate restore of a specific data backup to the target SAP MaxDB host, the recovery run completes with the following errors:

  ```
  -24907,ERR_DBAWRONG: Wrong database system administrator
  -24988,ERR_SQL: SQL error
  -4008,Unknown user name/password combination
  ```

  To avoid the issue in the future, you must change the database system administrator password on the target SAP MaxDB host before the system copy to be consistent with the source SAP MaxDB host's password. Once the system copy completes, you can change the password.
- Ensure that the SAP MaxDB database versions in both the source and target systems are compatible.
- Cohesity supports backup and restore of SAP MaxDB databases running on dual-stack (IPv4 and IPv6) mode or single-stack (only IPv6) mode.
- It is **mandatory** to connect to the Cohesity cluster securely using secure gRPC when writing or reading data.

Download and install the Cohesity Linux Agent

The Cohesity Linux Agent is available as script-based and RPM-based installers, based on your requirements download the installer and install it accordingly on the SAP MaxDB host. For detailed instructions, see Download and Install the Linux Agent.

Download and Install the SAP MaxDB Connector Installer

Cohesity Platform provides a SAP MaxDB Connector agent for the backup and restore of enterprise SAP MaxDB deployments. The SAP MaxDB Connector agent leverages the backup and restore capabilities provided by SAP MaxDB.

Prerequisites

- Before you install the SAP MaxDB Connector agent, make sure that you:
- Install java runtime environment (JRE) version 1.8 or above on the SAP MaxDB Linux machine.
- Download and install the Cohesity Linux Agent on the SAP MaxDB Linux machine. For more information, see Download and install the Cohesity Linux Agent.
- Download and copy the SAP MaxDB Connector agent (cohesity-maxdb-java-backint-<version>.noarch.rpm) to the SAP MaxDB Linux machine. For more information, see Download the SAP MaxDB Connector agent.

- Use a user with sudo privileges or root user to install or uninstall the SAP MaxDB Connector agent.
- Use "bash" shell to install the SAP MaxDB Connector and to run backups and restore workflows of SAP MaXDB databases.
- Configure the following environment variables on the SAP MaxDB Linux machine:

Environment Variable	Description	Mandatory?	Command
`SERVICE_USER`	The Operation System (OS) user account that has access to the `dbmcli` binaries and can connect to the database.	Yes	`export SERVICE_USER=<VALUE>`
`CLUSTER_IPS`	A comma-separated list of virtual IP addresses of the servers in the Cohesity cluster.	No	`export CLUSTER_IPS="<VIP1>,<VIP2>,<VIP3>"`
`VIEW_NAME`	The name of the Cohesity view that you have created for SAP MaxDB. For more information, see Plan and Prepare for SAP MaxDB on Linux Protection.	No	`export VIEW_NAME=<cohesity-view-name>`
`XUSER_KEY`	The database key to connect to the SAP MaxDB database. You can create the database key using the following command: `xuser -U <KEY_NAME> -u <username>,<password> -d <MaxDB_Name>` For more information, see Creating or Changing XUSER entries.	Yes	`export XUSER_KEY=<KEY_NAME>`
WORKFLOW	Type of workflow that you want to use for SAP MaxDB data protection. For example, UDA or RA. The default value is **UDA**.	No	

Download the SAP MaxDB Connector

Cohesity Platform provides a SAP MaxDB Connector agent for SAP MaxDB to back up and restore SAP MaxDB databases. The SAP MaxDB Connector agent for SAP MaxDB is available as a datasource agent on the Cohesity Download portal. Log on to the Cohesity Download portal, download the respective datasource agent for the Cohesity SAP MaxDB connector, and copy the datasource agent to the SAP MaxDB host.

Install the SAP MaxDB Connector

On the SAP MaxDB database host where you have copied the SAP MaxDB Connector agent (`cohesity-maxdb-java-backint-<version>.noarch.rpm`), perform the following to install the SAP MaxDB Connector agent.

To install the SAP MaxDB Connector agent:

1. Log on to the SAP MaxDB Linux machine using the user with `sudo` privileges.
2. Navigate to the directory where you have copied the RPM-based installer.
3. Install the SAP MaxDB Connector agent using the following command:

```
sudo -E rpm -ivh cohesity-maxdb-java-backint-<version>.noarch.rpm
```

The following is a sample output of the successful installation:

```
$sudo -E rpm -ivh cohesity-maxdb-java-backint-<version>.noarch.rpm
Preparing...                          ##################################

t/cohesity/agent/uda_scripts
Successful Installation of UDA MaxDB Java Agent
```

After the SAP MaxDB Connector agent is installed, the plug-ins are available at: `<backint_install_directory>/cohesity_backint_plug-in/uda_scripts`

For example:

```
/usr/sap/TEC/home/cohesity/cohesity_backint_plug-in/uda_scripts
```

Upgrade the SAP MaxDB Connector

To upgrade the SAP MaxDB Connector agent, run the following command with the appropriate parameters on SAP MaxDB host CLI:

```
sudo -E rpm -Uvh cohesity-maxdb-java-backint-<version>.noarch.rpm
```

Uninstall the SAP MaxDB Connector

To uninstall the SAP MaxDB Connector agent, run the following command with appropriate parameters on SAP MaxDB host CLI:

```
sudo -E rpm -evh cohesity-maxdb-java-backint-<version>.noarch.rpm
```

The following is a sample output of the successful uninstallation:

```
$sudo -E rpm -evh cohesity-maxdb-java-backint-<version>.noarch.rpm

Register and Manage the SAP MaxDB on Linux Source

To protect your SAP MaxDB databases, you need to register your SAP MaxDB deployment as a source on Cohesity. After registering your SAP MaxDB deployment as a source, you can:

- Update the username and password of the database user.
- Refresh the source details.
- Unregister the SAP MaxDB source from Cohesity.

Register SAP MaxDB as a Source

Before you register SAP MaxDB as a source, ensure that you:

- Review the requirements and limitations.
- Perform the prerequisite tasks.

For more information, see Plan and Prepare for SAP MaxDB on Linux Protection.

To register SAP MaxDB as a source:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Register** on the top-right of the page and then select **Universal Data Adapter**.
3. In the **Register Universal Data Adapter** page, perform the following:
   a. From the **Source Type** drop-down menu, select **SAP MaxDB**.
   b. From the **Host OS Type** drop-down menu, select **Linux**.
   c. In the **Hostname/IP Addresses** field, enter the hostname or IP address of the node(s) you have identified to run the Cohesity SAP MaxDB connector. For more information, see Plan and Prepare for SAP MaxDB on Linux Protection.

      > **Note:** Cohesity supports the backup and restore of SAP MaxDB databases running on dual-stack (IPv4 and IPv6) mode or single-stack (only IPv6) mode.

   d. In the **Datasource Agent Installation Path** field, enter the directory path on the SAP MaxDB node, where you have installed the Cohesity SAP MaxDB connector. For more information, see Install the SAP MaxDB Connector.
   e. Ignore the In the **APP Authentication** section. It is not applicable for SAP MaxDB source registration.
   f. Enable **Custom Options**, perform the following:
      i. Ignore the **Mounts View** option. It is not applicable for SAP MaxDB source registration.

ii. Ignore the **Source Registration Options** field.

g. Click **Register**.

Update the SAP MaxDB Source Configuration

After registering your SAP MaxDB as a source on Cohesity, you can:

- Update the username and password of the database user.
- Modify the **Source Registration Options** based on your requirements.
- Update the **Datasource Agent Installation Path** only if you have uninstalled and reinstalled the Cohesity SAP MaxDB connector in a different directory on the SAP MaxDB node.

To update the SAP MaxDB source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the SAP MaxDB source and select **Edit**.
3. On the **Update Universal Data Adapter** page, update the required configurations.
4. Click **Update**.

Refresh the SAP MaxDB Source Configuration

You can refresh the SAP MaxDB Source and re-verify the source with the available source registration parameters.

To refresh the SAP MaxDB Source Configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the SAP MaxDB Source and select **Refresh**.

Unregister the SAP MaxDB Source

If you plan to stop taking the backup of your SAP MaxDB databases, you can unregister the SAP MaxDB source from the Cohesity.

To unregister the SAP MaxDB source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the SAP MaxDB source and select **Unregister**.

Backup SAP MaxDB on Linux Database

Cohesity provides a simple workflow to back up your SAP MaxDB databases. After registering the SAP MaxDB as a source on Cohesity, you can start configuring your backups.

Backup Process

Cohesity provides a SAP MaxDB connector for backup and restore of enterprise SAP MaxDB deployments. The SAP MaxDB connector leverages the backup capabilities provided by SAP MaxDB.

After registering the SAP MaxDB source on Cohesity, you can create a Protection Group and specify the objects such as databases and tables that you want to backup. In the Protection Group, you need to define the parameters that enable you to provide additional parameters required by the backup statements provided by SAP MaxDB.

> **Note:** Cohesity recommends that you configure periodic full backups.

Backup Parameters

In the Protection Group, you can define the following parameters for your SAP MaxDB backup configuration:

Backup Parameters	Mandatory?	Description
`--xuser-key=<key>`	Optional	By default, SAP MaxDB uses the XUSER key provided during the SAP MaxDB connector installation. You can override the XUSER key using the parameter based on your requirements. For example: `--xuser-key=XUSER_KEY`
`--backup-template`	Mandatory	Specify the backup template that you have created for the backup. Ensure that you create specific backup templates for COMPLETE DATA, INCREMENTAL DATA, AND LOG DATA. For detailed instructions to create a backup template, see backup_template_create on SAP documentation. For example: `--backup-template=BACKData`
`--use-secure-grpc=<true/false>`	Optional	Set the parameter to true, if you want to use secure gRPC communication during backup. For example: `--use-secure-grpc=true` **Note:** It is **mandatory** to connect to the Cohesity cluster securely using secure gRPC when writing or reading data.

Backup Parameters	Mandatory?	Description
`--sap-certificate-path=<cert_file_path>`	Optional	Specify the path of the self-signed certificate if you want to use it for secure gRPC communication during backups. For example: `--sap-certificate-path=/tmp/certs/sap_cert1837348343.cfg`

Protect SAP MaxDB on Linux Deployments

SAP MaxDB deployments are protected using a Protection Group and a Protection Policy. A Protection Group enables you to:

- Specify the objects such as databases and tables that you want to backup.
- Based on your requirement, define the parameters for the backup statements provided by SAP MaxDB. For more information, see Backup Parameters.

The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select which standard or custom policy to use when creating a Protection Group. For more information, see About Policies and Protection Groups.

To protect SAP MaxDB deployments:

1. Do one of the following:
   - Select **Data Protection > Protection**. Click **Protect** on the top-right of the page and then select **Universal Data Adapter**.
   - Select **Data Protection > Sources**. Click the actions menu (⋮) next to the SAP MaxDB source and then select **Protect**.
2. From the **Source** drop-down list, select the registered SAP MaxDB source or click **Register Source** to register a SAP MaxDB source. For more information, see Register SAP MaxDB as a Source.
3. In the **Objects** section, add the object that you plan to protect. The object should be a database name. To back up a database, enter the name of the database. For example, `H00`. Then, click **Save Selection**.
4. In the **Protection Group** section, do one of the following:
   - Select **New Group** to create a new Protection Group. In the **Protection Name** field, enter a name from the Protection Group.
   - Select **Existing Group** to use the settings of an existing Protection Group. From the **Group** list, select an existing Protection Group and click **Protect**.

5. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy.
6. In the **Settings** section, do the following:
    1. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains.
    2. In the **Start Time** field, define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard.

       Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
    3. In the **Backup Script Arguments** section, enter the Backup Parameters in the **Full Backup**, **Incremental Backup**, and **Log Backup** fields based on your requirements.

       For example:

Use Cases	Sample Parameters
Create a full backup of the SAP MaxDB data.	In the **Full Backup** field, specify the following parameter: `--backup-template=BACKData` Where, `BACKData` is the backup template you have created for complete data backup.
Create a full backup of the SAP MaxDB data by overriding the xuser key.	In the **Full Backup** field, specify the following parameter: `--xuser-key=XUER_KEY --backup-template=BACKData` Where `USER_KEY` is the new xuser key and `BACKData` is the backup template you have created for complete data backup.
Create an incremental backup of the SAP MaxDB data.	In the **Incremental Backup** field, specify the following parameter: `--backup-template=BACKPages` Where, `BACKPages` is the backup template you have created for incremental data backup.

Use Cases	Sample Parameters
Create an incremental backup of the SAP MaxDB data by overriding the xuser key.	In the Incremental Backup field, specify the following parameter: `--xuser-key=XUSER_KEY --backup-template=BACKPages` Where `XUSER_KEY` is the new `xuser` key and `BACKPages` is the backup template you have created for complete data backup.
Create a backup of the SAP MaxDB log data.	In the **Log Backup** field, specify the following parameter: `--backup-template=BACKLog` Where, `BACKLog` is the backup template you have created for log data backup.

- Ignore the **Mounts** field. It is not applicable for SAP MaxDB data protection.

7. After you have completed the **Settings**, if you need to change any additional settings on the **New Universal Data Adapter Protection Group** page, scroll down and click Edit on the right. For more information, see Additional Settings.
8. Click **Protect**.

Additional Settings

Additional Settings	Description
Pause Future Run	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
End Time	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.

Additional Settings	Description
QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup Target HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup Target SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Concurrency	Not applicable for SAP MaxDB data protection.
Alerts	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs

Additional Settings	Description
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).
Description	**Optional**. Enter a brief description about the Protection Group.

Manage the SAP MaxDB on Linux Backup Configuration

A backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for SAP MaxDB.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ in the **Objects** section.
5. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
6. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for SAP MaxDB.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a recovery run:

1. Navigate to **Data Protection > Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity.

To delete the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for SAP MaxDB.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Delete Protection Group Only
    - Delete Protection Group and Snapshots

Recover SAP MaxDB on Linux Database

You can restore the SAP MaxDB object(s) such as databases in SAP MaxDB. You can restore to the same SAP MaxDB cluster or a different SAP MaxDB cluster.

The SAP MaxDB connector leverages the restore statements provided by SAP MaxDB. You can create a Recovery configuration and specify the objects such as databases backed up using the Protection Group.

In the Recovery configuration, you need to specify the object you plan to restore and define the parameters required by the restore statements provided by SAP MaxDB.

Recovery Parameters

In the Recovery configuration, you can define the following parameters for your SAP MaxDB recovery:

Recovery Parameters	Mandatory?	Description
`--xuser-key=<key>`	Mandatory	SAP MaxDB uses the xuser key provided during the SAP MaxDB connector installation. You can override the xuser key using the parameter based on your requirements. For example: `--xuser-key=XUSER_KEY`
`--data-backup-template`	Mandatory	The template used to restore the data from the backup.
`--pages-backup-template`	Mandatory	The template used to restore the data from the incremental backup.
`--log-backup-template`	Mandatory for PITR use cases	The template used to restore the log data for the backup.

Recovery Parameters	Mandatory?	Description
`--source-sid=<SOURCE_SID>`	Mandatory for alternate restore to SAP MaxDB host with Different SID usecases	The source SAP MaxDB host SID.
`--use-secure-grpc=<true/false>`	Optional	Set the parameter to true, if you want to use secure gRPC communication during restore. For example: `--use-secure-grpc=true`
`--sap-certificate-path=<cert_file_path>`	Optional	Specify the path of the self-signed certificate if you want to use it for secure gRPC communication during restore. For example: `--sap-certificate-path=/tmp/certs/sap_cert1837348343.cfg`

Prerequisites

Ensure that the Protection Group associated with the object that you plan to restore is paused or in not running state.

Recover SAP MaxDB on Linux Databases

To recover SAP MaxDB databases:

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Click **Recover** at the top right of the page and then select **Universal Data Adapter**.
3. Search for the Protection Group that contains the snapshots to recover from by entering characters of the Protection Group name, or by specifying the wildcard character *.
4. From the list of search results, select the Protection Group that contains the snapshots to recover.
5. In the **Object** field, enter the name of the database or table that you had backed up using the selected Protection Group. By default, the latest snapshot is selected for recovery. You can also select a point-in-time snapshot or specific data backup that you want to recover. Click the pencil icon and perform the following:
   - For point-in-time snapshots, in the **Edit recovery point for <Protection_Group_Name>** dialog, click the **Timeline** tab, choose the **Date** and select the **point-in-time** from the **timeline** slider and click **Select Recovery Point**.
   - For specific data backup snapshots, in the **Edit recovery point for <Protection_Group_Name>** dialog, click the **list** tab and select the specific **Snapshot Time** that you want and click **Select Recovery Point**.
6. Click **Next: Recover Options**.

7. In the **Recover As** section, based on your requirements, select any one of the following options:

Options	Description
Replace Original	To restore to the same SAP MaxDB database.
New Object	To restore to a different SAP MaxDB database. Select the **Target** SAP MaxDB host to which the data needs to be restored. Also, enable **Overwrite existing object with the same name** and type **Yes**, if you want to overwrite the existing object with the same name. > **Note:** Ensure that you register the target SAP MaxDB host as source in Cohesity. For more information, see Register SAP MaxDB as a Source.

8. In the **Recovery Options** section, based on your requirements, select any one of the following options:

Options	Description
Mounts	Select the number of VIPs you want to use while writing data to the Cohesity storage.
Concurrency	Not applicable for SAP MaxDB data protection.
Custom Options	Specify the Recovery Parameters based on your requirements. For examples, see Sample Recovery Use Cases.
Rename	Provide the new name for the object, if you want to restore the object with a new name.
Task Name	Change the default name of the recovery task.

9. Click **Start Recovery**.

Sample Recovery Use Cases

Use Case	Sample Instructions
Restore specific data backup from the snapshot to the same SAP MaxDB database overriding the xuser key.	In the **Recover As** section, select **Replace Original**. Under the Recovery Options section, specify `--xuser-key=XUSER_KEY --data-backup-template=BACKData --pages-backup-template=BACKPages` in the **Custom Options** field. Where, • `XUSER_KEY` is the new xuser key. • `BACKData` is the backup template you have created for complete data backup. • `BACKPages` is the backup template you have created for the incremental data backup.
Point In Time Restore (PITR) to a new database.	Perform the following: 1. In the **Recover As** section, select **New Object** and choose the target source name in the **Target** drop down. 2. Under the **Recovery Options** section, specify `--xuser-key=XUSER_KEY --data-backup-template=BACKData --pages-backup-template=BACKPages --log-backup-template=BACKPages` in the **Custom Options** field and specify the name for the new database in the **Rename** field. > **Note:** Ensure that the new database exists on the target SAP MaxDB host. Where, • `XUSER_KEY` is the `xuser` key on the target SAP MaxDB host. • `BACKData` is the back template you have created for complete data backup. • `BACKPages` is the back template you have created for incremental data backup. • `BACKLog` is the back template you have created for log data backup.

Use Case	Sample Instructions
Restore to a new database on a different SAP MaxDB host.	Perform the following: 1. In the **Recover As** section, select **New Object** and choose the target source name in the **Target** dropdown. 2. Under the **Recovery Options** section, specify `--xuser-key=XUSER_KEY --data-backup-template=BACKData --pages-backup-template=BACKPages` in the **Custom Options** field and specify the name for the new database in the **Rename** field. > **Note:** Ensure that the new database exists on the target SAP MaxDB host. Where: • `XUSER_KEY` is the `xuser` key on the target SAP MaxDB host. • `BACKData` is the back template you have created for complete data backup. • `BACKPages` is the back template you have created for incremental data backup.

Alternate Restore to SAP MaxDB Host with Different SIDs

You can perform an alternate restore to SAP MaxDB hosts with different SIDs.

Prerequisites

Ensure that you configure the source and target SAP MaxDB host's Cohesity BACKINT parameter files (`/opt/cohesity/maxdb_java_plugin/profile/init<SID>.utl`) with the same Cohesity cluster and Cohesity View details.

To perform an alternate restore to SAP MaxDB host with different SIDs:

1. Using the Command-Line Interface (CLI) or SAP MaxDB Studio, take backups on the source SAP MaxDB host.
2. Copy the recover catalog files from the source SAP MaxDB host to a temporary directory (/tmp/logs) on the target SAP MaxDB host.

   You can locate the recover catalog files using the param_directget command.

   For example:

   ```
   >dbmcli – u <username>,<password> –d <DBname> param_directget
   RunDirectoryPath
   ```

3. On the target SAP MaxDB host, update the temporary directory path in the `ORIGINAL_RUNDIRECTORY` parameter in the `/opt/cohesity/maxdb_java_plugin/profile/bsi.env` file.

   For example:

```
bash-4.2$ cat /opt/cohesity/maxdb_java_plugin/profile/bsi.env
BACKINT /opt/cohesity/maxdb_java_plugin/bin/backint.sh
INPUT /opt/cohesity/maxdb_java_plugin/workflow/input
OUTPUT /opt/cohesity/maxdb_java_plugin/workflow/output
ERROROUTPUT /opt/cohesity/maxdb_java_plugin/workflow/error
PARAMETERFILE /opt/cohesity/maxdb_java_plugin/profile/initSID.utl
TIMEOUT_SUCCESS 600
TIMEOUT_FAILURE 300
CHECK_AVAILABILITY YES
ORIGINAL_RUNDIRECTORY /tmp/logs
```

4. Restore to the target SAP MaxDB host using the restore commands.

   Sample for full database backup:

```
>db_activate recover BACKData DATA Externalbackupid "MAXDB 1630306452_
v48g /tmp/maxdb/pipe_data"
OK
Returncode 0
…
…
```

   Sample for incremental backup:

```
>recover_start BACKPages PAGES EBID "MAXDB 1630306540_bzx6
/tmp/maxdb/pipe_pages" [18/979]
OK
Returncode 0
…
…
```

   Sample for log backups:

```
>recover_start  BACKLog LOG EBID "MAXDB 1632394917_0af3 /tmp/maxdb_log_
pipe" UNTIL 20210923 163300
OK
Returncode              -8020
…

>recover_replace  BACKLog  ExternalBackupID "MAXDB 1632395036_yxg0
/tmp/maxdb_log_pipe"
```

```
OK
Returncode                -8020
```

> **Note:** Execute the following command, if the database is not online:
>
> ```
> >recover_ignore
> OK
> Returncode 0
> ```

5. Verify if the restored database is online using the following command:

```
>db_online
```

SAP MaxDB on Windows

Cohesity DataPlatform natively integrates with SAP MaxDB to provide backup and recovery for clustered SAP MaxDB deployments. Using Cohesity Connector Agent, you can backup and restore the SAP MaxDB database. The Cohesity Connector Agent provides a simple workflow to back up and restore your SAP MaxDB deployment.

Cohesity DataPlatform provides an SAP MaxDB Connector for backup and restore of enterprise SAP MaxDB deployments. The SAP MaxDB Connector leverages the backup and restore capabilities provided by SAP MaxDB.

The SAP MaxDB Connector enables you to back up the various databases. It provides:

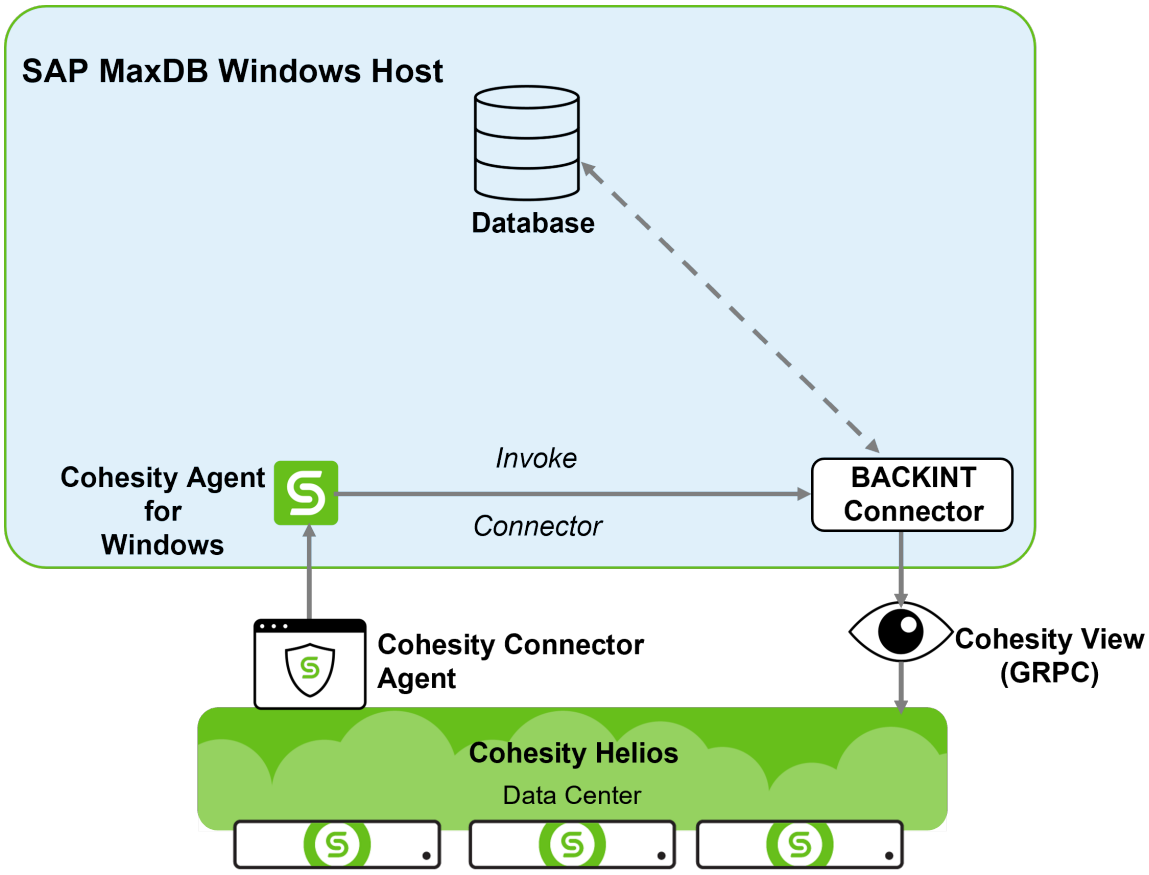
- **Backup**:
  - Full backup
  - Incremental backup
  - Scheduled Log backup
- **Restore**:
  - Restore the database to a specific data backup
  - Restore the database to the point in time
  - Alternate restore of SAP MaxDB database
    - Alternate restore to a new database or active database on the same SAP MaxDB system.
    - Alternate restore to a new or active database on a different SAP MaxDB system.

Core Components

The following are the core components for protecting SAP MaxDB databases:

- SAP MaxDB Windows machine
- SAP MaxDB Connector
- Cohesity Connector Agent

As illustrated, you can integrate the Cohesity DataPlatform with your SAP MaxDB deployments using the SAP MaxDB Connector and Cohesity Connector Agent.



Plan and Prepare for SAP MaxDB on Windows Protection

Before you register your SAP MaxDB deployment as a source with Cohesity and protect SAP MaxDB databases, ensure the following prerequisites:

- Ensure that the fully qualified domain name (FQDN) of the Cohesity cluster is resolvable from the SAP MaxDB Windows machine.
- Synchronize the SAP MaxDB Windows machine time with a Network Time Protocol (NTP) server.
- A database user with database admin user privileges.
- Download and install the Cohesity Windows Agent on the SAP MaxDB Windows machine.

- Download and install the SAP MaxDB Connector.
- Review and understand the limitations.

Supported Versions

For more information on supported SAP MaxDB versions, see Supported Software versions.

SAP MaxDB Connector Requirements

To install and run the Cohesity SAP MaxDB Connector, ensure that the SAP MaxDB host meets the following specifications:

Components	Specification
SAP MaxDB Version	For details, see Supported Software.
Operating System	
Powershell Version	5.1.14393.0
Platform	x86_64
Disk Space	• Minimum 256 MB. Required for installing the SAP MaxDB Connector. • 1 GB. Required for the log directory.
Memory	8GB of free memory to run the SAP MaxDB Connector agent.

Port Requirements

You must open certain ports in the firewall to allow the Cohesity cluster to transmit and receive data. Ensure that you open the following port in the firewall to allow data transfer between SAP MaxDB system and the Cohesity cluster:

Port	Source	Target	Direction	Network Protocol
11113	SAP MaxDB	Cohesity cluster	Bidirectional	TCP/IP

Considerations

Review and understand the following before you protect your SAP MaxDB database:

- SAP MaxDB with liveCache technology is not supported.
- Spaces in the installation path are not supported.

- Only PIPE backups are supported. File backups are not supported, and hence only scheduled log backups are supported, and automatic log backups are not supported.
- Only backup and restore to the same Operating System is supported.
- Only the single-node SAP MaxDB database system is supported.
- Cohesity replication is supported.
- For alternate restore, the target SAP MaxDB database must be created before starting the restore operation.
- If the database system administration (SUPERDBA) password is different in both the source and the target SAP MaxDB hosts, then when you perform an alternate restore of a specific data backup to the target SAP MaxDB host, the recovery run completes with the following errors:

  ```
  -24907,ERR_DBAWRONG: Wrong database system administrator
  -24988,ERR_SQL: SQL error
  -4008,Unknown user name/password combination
  ```

  To avoid the issue in the future, you must change the database system administrator password on the target SAP MaxDB host before the system copy to be consistent with the source SAP MaxDB host's password. Once the system copy is completed, you can change the password.
- Ensure that the SAP MaxDB database versions in both the source and target systems are compatible.
- It is **mandatory** to connect to the Cohesity cluster securely using secure gRPC when writing or reading data.

Download and install the Cohesity Windows Agent

The Cohesity Windows Agent is available as script-based and RPM-based installers, based on your requirements download the installer and install it accordingly on the SAP MaxDB host. For detailed instructions, see Install and Manage the Agent on Windows Servers.

Download and Install the SAP MaxDB Connector Installer

Cohesity DataPlatform provides an SAP MaxDB Connector for backup and restore of enterprise SAP MaxDB deployments. The SAP MaxDB Connector leverages the backup and restore capabilities provided by SAP MaxDB.

> **Note:** Ensure that you install the Cohesity Windows Agent using the ***<SID>adm*** user account.

Prerequisites

Before you install the SAP MaxDB Connector, make sure that you:

- Install java runtime environment (JRE) version 1.8 or above on the SAP MaxDB Windows machine.
- Download and install the Cohesity Windows Agent on the SAP MaxDB Windows machine. For more information, see Install and Manage the Agent on Windows Servers.
- Download and copy the SAP MaxDB Connector (`Cohesity_SAP_MaxDB_connector_<version>_Win_x64_Installer.exe`) to the SAP MaxDB Windows machine. For more information, see Download the SAP MaxDB Connector.
- Use an **<sid>adm** user to install or uninstall the SAP MaxDB Connector.

Download the SAP MaxDB Connector

Cohesity provides a SAP MaxDB Connector to backup and restore SAP MaxDB databases. The SAP MaxDB Connector is available as a datasource agent on the Cohesity Download portal. Log on to the Cohesity Download portal, download the respective datasource agent for SAP MaxDB Connector, and copy the datasource agent to the SAP MaxDB host.

Install the SAP MaxDB Connector

On the SAP MaxDB database host where you have copied the SAP MaxDB Connector (`Cohesity_SAP_MaxDB_connector_<version>_Win_x64_Installer.exe`), perform the following to install the SAP MaxDB Connector.

To install the SAP MaxDB Connector:

1. Log on to the SAP MaxDB Windows machine using the **<sid>adm** user. Ensure that you are logged as the same user with which you installed the Cohesity Windows agent.
2. Navigate to the directory where you have copied the installer.
3. Double-click on the Cohesity SAP MaxDB Connector installer and follow the instructions.

Silently Install the SAP MaxDB Connector

After you have downloaded the SAP MaxDB Connector, you can perform a silent installation of the Cohesity SAP MaxDB Connector.

To perform the silent installation:

1. Log on to the SAP MaxDB node where you have copied the Cohesity SAP MaxDB Connector installer executable, `Cohesity_SAP_MaxDB_connector_<version>_Installer.exe`. Ensure that you are logged as the same user with which you installed the Cohesity Windows agent.
2. Using the command-line interface, navigate to the directory where you have copied the Cohesity SAP MaxDB Connector installer executable, `Cohesity_SAP_MaxDB_connector_<version>_Installer.exe`.
3. Use the following command for the silent installation:

```
<InstallerExeFile> [/log="<absolute-path-to-log-file>"]
[/dir="<absolute-path-to-install-location>"] [/silent, /verysilent]
[/suppressmsgboxes] [/norestart]
```

Where:

- `/log="<absolute-path-to-log-file>"` - Records the events during installation and helps to debug the errors, if any, during the installation process.
- `/silent` - Suppresses the installation wizard and background window. Instead, it only displays the installation progress window.
- `/verysilent` - Suppresses the installation progress window.
- `/suppressmsgboxes` - Suppresses any message boxes if `/verysilent` is specified.
- `/norestart` - Prevents the setup from restarting the system following a successful installation, or after a Preparing to Install failure that requests a restart.
- `/dir="<absolute-path-to-install-location>"` - Specify the directory path where the SAP MaxDB Connector for Windows should be installed.

> **Note:** The installer creates the necessary folders if they do not exist. If this parameter is not specified, the SAP MaxDB Connector is installed in the default directory path: "`%SystemDrive%\Program Files\Cohesity\SAP MaxDB`".

Sample:

```
Cohesity_SAP_MaxDB_connector_<version>_Installer.exe
/log="C:\tmp\install_logs.txt" /verysilent /suppressmsgboxes /norestart
```

Upgrade the SAP MaxDB Connector

On the SAP MaxDB database host where you have copied the SAP MaxDB Connector (`Cohesity_SAP_MaxDB_connector_<version>_Win_x64_Installer.exe`), perform the following to upgrade the SAP MaxDB Connector.

Before you upgrade the SAP MaxDB Connector, ensure that you pause the existing protection runs.

To upgrade the SAP MaxDB Connector:

1. Log on to the SAP MaxDB Windows machine using the **<sid>adm** user. Ensure that you are logged as the same user with which you installed the Cohesity Windows agent.
2. Navigate to the directory where you have copied the installer.

3. Double-click on the Cohesity SAP MaxDB Connector installer, and when prompted, select **Upgrade** and follow the instructions.

Silently Upgrade the SAP MaxDB Connector

Before you upgrade the SAP MaxDB Connector, ensure that you pause the existing protection runs.

To silently upgrade the SAP MaxDB Connector, use the following command:

```
<InstallerExeFile> [/log="<absolute-path-to-log-file>"] [/dir="<absolute-path-to-install-location>"] [/silent, /verysilent] [/suppressmsgboxes] [/norestart]
```

1. Where:
   - `/log="<absolute-path-to-log-file>"` - Records the events during the upgrade and helps to debug the errors, if any, during the upgrade process.
   - `/silent` - Suppresses the upgrade wizard and background window. Instead, it only displays the upgrade progress window.
   - `/verysilent` - Suppresses the upgrade progress window.
   - `/suppressmsgboxes` - Suppresses any message boxes if `/verysilent` is specified.
   - `/norestart` - Prevents the setup from restarting the system following a successful upgrade or after a Preparing to upgrade failure that requests a restart.
   - `/dir="<absolute-path-to-install-location>"` - Specify the directory path where the SAP MaxDB Connector is installed.

   Sample:

   ```
   Cohesity_SAP_MaxDB_connector_<version>_Installer.exe /log="C:\tmp\upgrade_logs.txt" /verysilent /suppressmsgboxes /norestart
   ```

Uninstall the SAP MaxDB Connector

To uninstall the Cohesity SAP MaxDB Connector:

1. Log on to the SAP on MaxDB host.
2. Select the **Start** menu and look for the SAP MaxDB Connector in the list shown.
3. Press and hold (or right-click) on the SAP MaxDB Connector, then select **Uninstall**.

Silently Uninstall the SAP MaxDB Connector

To perform silent uninstallation:

1. Log on to the SAP MaxDB host.
2. Using the command-line interface, navigate to the directory where you have installed the Cohesity SAP MaxDB Connector, For example, `C:\Program Files\Cohesity\SAP MaxDB\Installer\`.

   > **Note:** The details of uninstaller executable are available in the registry value `"HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Uninstall\{CCEC1E9A-895C-4038-8CC9-31BBD31B9CA7}_is1\UninstallString"`. The default value is `"C:\Program Files\Cohesity\SAP MaxDB\Installer\unins000.exe"`, assuming `C:` is the default operating system installation volume and `"C:\Program Files\Cohesity\SAP MaxDB"` is the default SAP MaxDB Connector installation path.

3. Use the following command for the silent uninstallation:

   ```
   <UninstallerExeFile>  [/log="<absolute-path-to-log-file>"] [/silent, /verysilent] [/suppressmsgboxes] [/norestart] [/preservesettings]
   ```

   Where:

   - `/log="<absolute-path-to-log-file>"` - Records the events during the uninstallation process and helps to debug the errors, if any, during the uninstallation process.
   - `/silent` - Suppresses the uninstallation wizard and background window. Instead, it only displays the uninstallation progress window.
   - `/verysilent` - Suppresses the uninstallation progress window.
   - `/suppressmsgboxes` - Suppresses any message boxes if `/verysilent` is specified.
   - `/norestart` - Prevents the setup from restarting the system following a successful uninstallation.
   - `[/preservesettings]` - Preserve the registry settings when uninstalling the SAP MaxDB Connector.

     > **Note:** Uninstalling the SAP MaxDB Connector clears registration settings from the registry. You can preserve the registration settings in the registry by using the `/preservesettings` flag when uninstalling from the command line. Preserving registry settings are not supported when uninstalling from the GUI.

Sample:

```
unins000.exe /log="C:\tmp\uninstall_logs.txt" /verysilent
/suppressmsgboxes /norestart
```

Register and Manage the SAP MaxDB on Windows Source

To protect your SAP MaxDB databases, you need to register your SAP MaxDB deployment as a source on Cohesity. After registering your SAP MaxDB deployment as a source, you can:

- Update the username and password of the database user.
- Refresh the source details.
- Unregister the SAP MaxDB source from Cohesity.

Register SAP MaxDB as a Source

Before you register SAP MaxDB as a source, ensure that you:

- Review the requirements and limitations.
- Perform the prerequisite tasks.

For more information, see Plan and Prepare for SAP MaxDB on Windows Protection.

To register SAP MaxDB as a source:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Register** on the top-right of the page and then select **Universal Data Adapter**.
3. In the **Register Universal Data Adapter** page, perform the following:
    a. From the **Source Type** drop-down menu, select **SAP MaxDB**.
    b. From the **Host OS Type** drop-down menu, select **Windows**.
    c. In the **Hostname/IP Addresses** field, enter the hostname or IP address of the node(s) you have identified to run the SAP MaxDB connector. For more information, see Plan and Prepare for SAP MaxDB on Windows Protection.
    d. In the **Datasource Agent Installation Path** field, enter the directory path on the SAP MaxDB node, where you have installed the SAP MaxDB connector. For more information, see Install the SAP MaxDB Connector.
    e. Ignore the **APP Authentication** section. It is not applicable for SAP MaxDB source registration.
    f. Enable **Custom Options**, perform the following:
        i. Ignore the **Mounts View** option. It is not applicable for SAP MaxDB source registration.

ii. Ignore the **Source Registration Options** field.

g. Click **Register**.

Update the SAP MaxDB Source Configuration

After registering your SAP MaxDB as a source on Cohesity, you can:

- Update the username and password of the database user.
- Modify the **Source Registration Options** based on your requirements.
- Update the **Datasource Agent Installation Path** only if you have uninstalled and reinstalled the SAP MaxDB connector in a different directory on the SAP MaxDB node.

To update the SAP MaxDB source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the SAP MaxDB source and select **Edit**.
3. On the **Update Universal Data Adapter** page, update the required configurations.
4. Click **Update**.

Refresh the SAP MaxDB Source Configuration

You can refresh the SAP MaxDB source and re-verify the source with the available source registration parameters.

To refresh the SAP MaxDB Source Configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the SAP MaxDB source and select **Refresh**.

Unregister the SAP MaxDB Source

If you plan to stop taking the backup of your SAP MaxDB databases, you can unregister the SAP MaxDB source from Cohesity.

To unregister the SAP MaxDB source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the SAP MaxDB source and select **Unregister**.

Backup SAP MaxDB on Windows Database

Cohesity provides a simple workflow to back up your SAP MaxDB databases. After registering the SAP MaxDB as a source on Cohesity, you can start configuring your backups.

Backup Process

Cohesity provides an SAP MaxDB Connector for the backup and restore of enterprise SAP MaxDB deployments. The SAP MaxDB Connector leverages the backup capabilities provided

by SAP MaxDB.

After registering the SAP MaxDB source on Cohesity, you can create a Protection Group and specify the objects such as databases and tables that you want to backup. In the Protection Group, you need to define the parameters that enable you to provide additional parameters required by the backup statements provided by SAP MaxDB.

> **Note:** Cohesity recommends that you configure periodic full backups.

Backup Parameters

In the Protection Group, you can define the following parameters for your SAP MaxDB backup configuration:

Backup Parameters	Mandatory?	Description
`--xuser-key=<key>`	Optional	By default, SAP MaxDB uses the xuser key provided during the SAP MaxDB connector installation. You can override the xuser key using the parameter based on your requirements. For example: `--xuser-key=XUSER_KEY`
`--backup-template`	Mandatory	Specify the backup template that you have created for the backup. Ensure that you create specific backup templates for COMPLETE DATA, INCREMENTAL DATA, AND LOG DATA. For detailed instructions to create a backup template, see backup_template_create on SAP documentation. By default, SAP MaxDB uses the 'BACKData' template for full backup, 'BACKPages' template name for incremental backup, 'BACKLog' template name for log backups. For example: `--backup-template=BACKData`
`--use-secure-grpc=<true/false>`	Optional	Set the parameter to true, if you want to use secure gRPC communication during backup. For example: `--use-secure-grpc=true` > **Note:** It is **mandatory** to connect to the Cohesity cluster securely using secure gRPC when writing or reading data.
`--sap-certificate-path=<cert_file_path>`	Optional	Specify the path of the self-signed certificate if you want to use it for secure gRPC communication during backups. For example: `--sap-certificate-path=/tmp/certs/sap_cert1837348343.cfg`

Protect SAP MaxDB on Windows Deployments

SAP MaxDB deployments are protected using a Protection Group and a Protection Policy. A Protection Group enables you to:

- Specify the objects such as databases and tables that you want to backup.
- Based on your requirement, define the parameters for the backup statements provided by SAP MaxDB. For more information, see Backup Parameters.

The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select which standard or custom policy to use when creating a Protection Group. For more information, see About Policies and Protection Groups.

To protect SAP MaxDB deployments:

1. Do one of the following:
   - Select **Data Protection > Protection**. Click **Protect** on the top-right of the page and then select **Universal Data Adapter**.
   - Select **Data Protection > Sources**. Click the actions menu (⋮) next to the SAP MaxDB source and then select **Protect**.
2. From the **Source** drop-down list, select the registered SAP MaxDB source or click **Register Source** to register a SAP MaxDB source. For more information, see Register SAP MaxDB as a Source.
3. In the **Objects** section, add the object that you plan to protect. The object should be a database name. To back up a database, enter the name of the database. For example, `H00`. Then, click **Save Selection**.
4. In the **Protection Group** section, do one of the following:
   - Select **New Group** to create a new Protection Group. In the **Protection Name** field, enter a name from the Protection Group.
   - Select **Existing Group** to use the settings of an existing Protection Group. From the **Group** list, select an existing Protection Group and click **Protect**.
5. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy.
6. In the Settings section, do the following:
   1. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains.
   2. In the **Start Time** field, define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and

minutes, or use the up and down arrows on your keyboard.

Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.

3. In the **Custom Options** section, enter the Backup Parameters in the **Full Backup**, **Incremental Backup**, and **Log Backup** fields based on your requirements.

   For example:

Use Cases	Sample Parameters
Create a full backup of the SAP MaxDB data.	In the **Full Backup** field, specify the following parameter: `--backup-template=BACKData` Where, `BACKData` is the back template you have created for complete data backup.
Create a full backup of the SAP MaxDB data by overriding the xuser key.	In the **Full Backup** field, specify the following parameter: `--xuser-key=XUER_KEY --backup-template=BACKData` Where `USER_KEY` is the new xuser key and `BACKData` is the back template you have created for complete data backup.
Create an incremental backup of the SAP MaxDB data.	In the **Incremental Backup** field, specify the following parameter: `--backup-template=BACKPages` Where, `BACKPages` is the back template you have created for incremental data backup.
Create an incremental backup of the SAP MaxDB data by overriding the xuser key.	In the Incremental Backup field, specify the following parameter: `--xuser-key=XUSER_KEY --backup-template=BACKPages` Where `XUSER_KEY` is the new `xuser` key and `BACKPages` is the back template you have created for complete data backup.

Use Cases	Sample Parameters
Create a backup of the SAP MaxDB log data.	In the **Log Backup** field, specify the following parameter: `--backup-template=BACKLog` Where, `BACKLog` is the back template you have created for log data backup.

- Ignore the **Mounts** field. It is not applicable for SAP MaxDB data protection.

7. After you have completed the **Settings**, if you need to change any additional settings on the **New Universal Data Adapter Protection Group** page, scroll down and click Edit on the right. For more information, see Additional Settings.
8. Click **Protect**.

Additional Settings

Additional Settings	Description
Pause Future Run	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
End Time	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup Target HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup Target SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Concurrency	The maximum number of streams that are created to exchange data with the cluster. By default, maximum scaling is set to empty.

Additional Settings	Description
Alerts	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).
Description	**Optional**. Enter a brief description about the Protection Group.

Manage the SAP MaxDB on Windows Backup Configuration

A backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for SAP MaxDB.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ on the **Objects** section.
5. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
6. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for SAP MaxDB.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a recovery run:

1. Navigate to **Data Protection > Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for SAP MaxDB.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
   - Delete Protection Group Only
   - Delete Protection Group and Snapshots

Purge SAP MaxDB on Windows Backups

Cohesity cluster provides an in-built purge functionality that you can use to automatically remove the expired data and log backups from the Cohesity cluster.

The purge operation works based on the retention period that you have configured on the Protection policy associated with the data backup. For information on how to set the retention period for a data backup, see About Policies and Protection Groups.

> **Note:** The retention period you have configured for log backups is not honored because only the last successful full backup is considered based on the retention period. Any backups older than the full backup are deleted.

For example, In the protection policy, if you have configured to take backup every day, the retention period is 14 days. Assuming that the current date is November 26th, in that case, the last successful full backup on or before November 12th is retained, and any backups older than the full backup are deleted.

Recover SAP MaxDB on Windows Database

You can restore the SAP MaxDB object(s) such as databases in SAP MaxDB. You can restore to the same SAP MaxDB cluster or a different SAP MaxDB cluster.

The SAP MaxDB Connector leverages the restore statements provided by SAP MaxDB. You can create a Recovery configuration and specify the objects such as databases backed up using the Protection Group.

In the Recovery configuration, you need to specify the object you plan to restore and define the parameters required by the restore statements provided by SAP MaxDB.

Recovery Parameters

In the Recovery configuration, you can define the following parameters for your SAP MaxDB recovery:

Recovery Parameters	Mandatory?	Description
`--xuser-key=<key>`	Mandatory	SAP MaxDB uses the xuser key provided during the SAP MaxDB connector installation. You can override the xuser key using the parameter based on your requirements. For example: `--xuser-key=XUSER_KEY`
`--data-backup-template`	Mandatory	The template used to restore the data from the backup.
`--pages-backup-template`	Mandatory	The template used to restore the data from the incremental backup.
`--log-backup-template`	Mandatory for PITR use cases	The template used to restore the log data for the backup.

Recovery Parameters	Mandatory?	Description
`--use-secure-grpc=<true/false>`	Optional	Set the parameter to true, if you want to use secure gRPC communication during restore. For example: `--use-secure-grpc=true`
`--sap-certificate-path=<cert_file_path>`	Optional	Specify the path of the self-signed certificate if you want to use it for secure gRPC communication during restore. For example: `--sap-certificate-path=/tmp/certs/sap_cert1837348343.cfg`

Prerequisites

Ensure that the Protection Group associated with the object that you plan to restore is paused or in not running state.

Recover SAP MaxDB on Windows Databases

To restore SAP MaxDB databases:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** at the top right of the page and then select **Universal Data Adapter**.
3. Search for the Protection Group that contains the snapshots to recover from by entering characters of the Protection Group name, or by specifying the wildcard character *.
4. From the list of search results, select the Protection Group that contains the snapshots to recover.
5. In the **Object** field, enter the name of the database or table that you had backed up using the selected Protection Group. By default, the latest snapshot is selected for recovery. You can also select a point-in-time snapshot or specific data backup that you want to recover. Click the pencil icon and perform the following:
    - For point-in-time snapshots, in the **Edit recovery point for <Protection_Group_Name>** dialog, click the **Timeline** tab, choose the **Date** and select the **point-in-time** from the **timeline** slider and click **Select Recovery Point**.
    - For specific data backup snapshots, in the **Edit recovery point for <Protection_Group_Name>** dialog, click the **list** tab and select the specific **Snapshot Time** that you want and click **Select Recovery Point**.
6. Click **Next: Recover Options**.
7. In the **Recover As** section, based on your requirements, select any one of the following options:

Options	Description
Replace Original	To restore to the same SAP MaxDB database.
New Object	To restore to a different SAP MaxDB database. Select the **Target** SAP MaxDB host to which the data needs to be restored. Also, enable **Overwrite existing object with the same name** and type **Yes**, if you want to overwrite the existing object with the same name. > **Note:** Ensure that you register the target SAP MaxDB host as source in Cohesity. For more information, see Register SAP MaxDB as a Source.

8. In the **Recovery Options** section, based on your requirements, select any one of the following options:

Options	Description
Mounts	Select the number of VIPs you want to use while writing data to the Cohesity storage.
Concurrency	The maximum number of streams that are created to exchange data with the cluster. By default, maximum scaling is set to empty.
Recovery Script Arguments	Specify the Recovery Parameters based on your requirements. For examples, see Sample Recovery Use Cases.
Rename	Provide the new name for the object, if you want to restore the object with a new name.
Task Name	Change the default name of the recovery task.

9. Click **Start Recovery**.

Sample Recovery Use Cases

Use Case	Sample Recovery Parameters
Restore specific data backup from the snapshot to the same SAP MaxDB database overriding the xuser key.	In the **Recover As** section, select **Replace Original**. Under the **Recovery Options** section, specify `--xuser-key=XUSER_KEY --data-backup-template=BACKData --pages-backup-template=BACKPages` in the **Recovery Script Arguments** field. Where, • `XUSER_KEY` is the new xuser key. • `BACKData` is the backup template you have created for complete data backup. • `BACKPages` is the backup template you have created for the incremental data backup.
Point in Time Restore (PITR) same SAP MaxDB database.	In the **Recover As** section, select **Replace Original**. Under the **Recovery Options** section, specify `--xuser-key=XUSER_KEY --data-backup-template=BACKData --pages-backup-template=BACKPages --log-backup-template=BACKLog` in the **Recovery Script Arguments** field. Where: • `XUSER_KEY` is the new xuser key. • `BACKData` is the backup template you have created for complete data backup. • `BACKPages` is the backup template you have created for the incremental data backup. • `BACKLog` is the back template you have created for log data backup.

Use Case	Sample Recovery Parameters
Restore specific data backup to a new database on a different SAP MaxDB host.	Perform the following: 1. In the **Recover As** section, select **New Object** and choose the target source name in the **Target** dropdown. 2. Under the **Recovery Options** section, specify `--xuser-key=XUSER_KEY --data-backup-template=BACKData --pages-backup-template=BACKPages` in the **Recovery Script Arguments** field and specify the name for the new database in the **Rename** field. > **Note:** Ensure that the new database exists on the target SAP MaxDB host. Where, • `XUSER_KEY` is the `xuser` key on the target SAP MaxDB host. • `BACKData` is the back template you have created for complete data backup. • `BACKPages` is the back template you have created for incremental data backup. • `BACKLog` is the back template you have created for log data backup.

Use Case	Sample Recovery Parameters
Point In Time Restore (PITR) to a new database.	Perform the following: 1. In the **Recover As** section, select **New Object** and choose the target source name in the **Target** dropdown. 2. Under the **Recovery Options** section, specify `--xuser-key=XUSER_KEY --data-backup-template=BACKData --pages-backup-template=BACKPages --log-backup-template=BACKPages` in the **Recovery Script Arguments** field and specify the name for the new database in the **Rename** field. > **Note:** Ensure that the new database exists on the target SAP MaxDB host. Where, • `XUSER_KEY` is the `xuser` key on the target SAP MaxDB host. • `BACKData` is the back template you have created for complete data backup. • `BACKPages` is the back template you have created for incremental data backup. • `BACKLog` is the back template you have created for log data backup.

SAP Sybase ASE on Linux

Cohesity Platform natively integrates with SAP Sybase ASE to provide backup and recovery for SAP Sybase ASE deployments. Using Cohesity Connector Agent, you can backup and restore the SAP Sybase ASE databases.

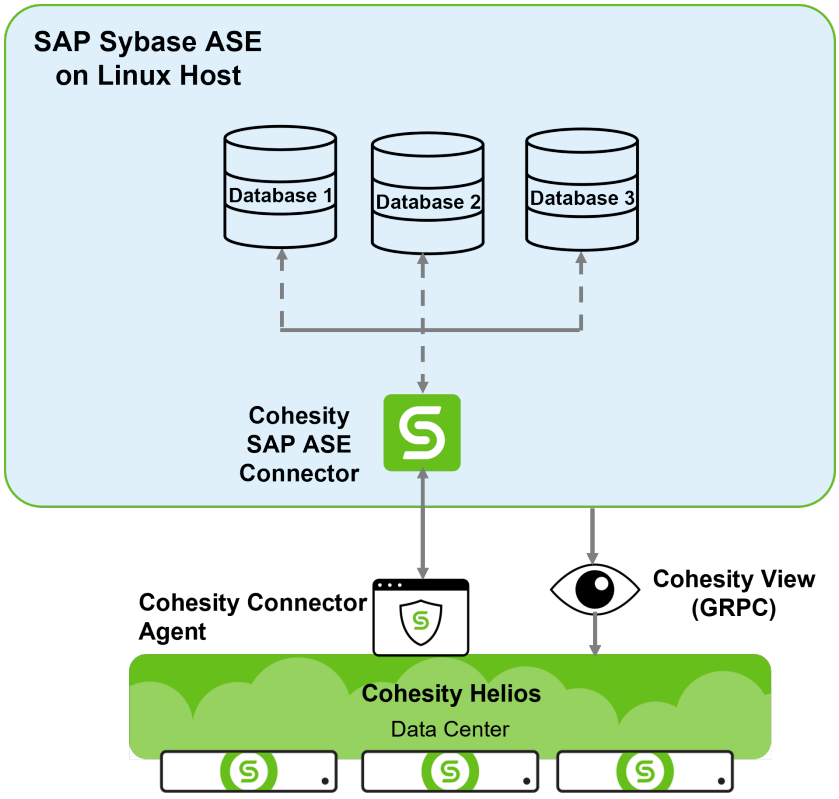
Cohesity Platform provides a SAP Sybase ASE connector that enables you to perform a full backup, differential backup, log backup, restore and point in time restore at the database level. The SAP Sybase ASE connector leverages the third-party dynamic link library (DLL) based capabilities provided by SAP Sybase ASE for backup and restore functionality.

Core Components

The following are the core components for protecting SAP Sybase ASE databases:

- SAP Sybase ASE Linux Machine
- Cohesity SAP Sybase ASE connector
- Cohesity Connector Agent

As illustrated, you can integrate the Cohesity Platform with your SAP Sybase ASE deployments using the SAP Sybase ASE connector and Cohesity Connector Agent.



Plan and Prepare for SAP Sybase ASE on Linux Protection

Before you register your SAP Sybase ASE deployment as a source with Cohesity Platform, ensure the following prerequisites:

- The user account for the SAP Sybase ASE instance must have either database administrator or operator privileges. If administrator privileges cannot be granted, the following permissions are required along with operator privileges:
  - Create Database
  - Own Any Database
  - Manage Disk
- Download and install the Cohesity Linux Agent RPM on the SAP Sybase ASE host.
- Download and install the Cohesity SAP Sybase ASE Connector RPM on the SAP Sybase ASE host

Supported Versions

For more information on supported SAP Sybase ASE versions, see SAP Sybase ASE versions.

Port Requirements

Outgoing Traffic

Source	Destination	Port	Protocol	Type of Traffic
Cohesity cluster	SAP Sybase ASE Node	50051	TCP/IP	Control path for all workflows

Bidirectional Traffic

Source	Destination	Port	Protocol	Type of Traffic
SAP Sybase ASE Local Host	SAP Sybase ASE Local Host	59999	TCP/IP	Required only if local-to-local communication (used for self-monitoring and debugging purposes) is blocked by the firewall.

Incoming Traffic

Source	Destination	Port	Protocol	Type of Traffic
SAP Sybase ASE Node	Cohesity cluster	11113	TCP/IP	Backup and Recovery
SAP Sybase ASE Node	Cohesity cluster	11117	TCP/IP	Backup and Recovery with secure gRPC

Considerations

Review and understand the following requirements before you protect your single node SAP Sybase ASE deployment.

- Backup or restore for SAP Sybase ASE HA cluster deployments are not supported.
- Ensure that the database is not in use (active connections) during recovery.
- Once Cohesity protects the Sybase ASE database, it is not recommended to use the SAP backup and/or restore tools outside of Cohesity, including native dump or load tools provided by SAP Sybase ASE.
- The same database should not be part of multiple Protection Groups.
- If the hole is introduced in the backup timeline, then point-in-time recovery (PITR) is possible only after the subsequent successful full or incremental backup is completed.
- Cohesity supports backup and restore of SAP Sybase ASE databases running on dual-stack (IPv4 and IPv6) mode or single-stack (only IPv6) mode.

Prerequisites

Ensure that:

- You use root user or non-root user to install the Cohesity Linux agent and SAP ASE Connector. If you choose to use a non-root user, you must add the `sudo` privileges for the non-root user using the syntax given below:

  ```
  <user_name> ALL=(ALL) NOPASSWD:SETENV: /path/to/command1,
  /path/to/command2, /path/to/command3
  ```

  The following is the `sudo` commands for SAP ASE Connector:

  ```
  cohesityagent ALL=
  NOPASSWD:SETENV:/usr/bin/mkdir,/usr/bin/chmod,/usr/bin/chown,/usr/bin/
  cmp,/opt/cohesity/sapase/.temp.*/run_ase_
  connector.java,/opt/sap/shared/SAPJRE-8_1_097_
  64BIT/bin/java,/usr/bin/cp,/usr/bin/find,/usr/bin/kill,/usr/bin/kinit,
  /usr/bin/mv,/usr/bin/rm,/usr/bin/tee,/usr/bin/test
  ```

  Where, **/opt/cohesity/sapase** is the SAP ASE connector installation directory and **/opt/sap/shared/SAPJRE-8_1_097_64BIT** is the JRE-8 environment directory within the SAP ASE database installation directory.

  > **Note:**
  > - If the **cohesityagent** user entry is already present in **/etc/sudoers**, append the list of commands to the existing entry.
  > - The actual paths for each command might vary depending on the platform and distribution. For more information, see Download and Install the Linux Agent.

- You enable incremental backups on the SAP Sybase ASE host using the following database command:

  ```
  sp_dboption '<DBNAME>','allow incremental dumps', 'true'
  ```

  > **Note:** After you have enabled incremental backups, ensure that you first initiate a full backup through the Cohesity Dashboard.

- If you want to authenticate to the Cohesity cluster using key-based authentication, ensure that you install the SAP Sybase ASE Connector using the same user running the ASE server and Cohesity Agent.
- Ensure that the SAP ASE environment file path (`SAPASE_ENV_PATH`) has following environment variables:

Environment Variable	Description
SYBASE	The path of the Sybase installation directory.
SYBASE_ASE	The subdirectory of the Adaptive Server component.
SAP_JRE8_64	The location of the Java Runtime Environment.
SAP_JCONNECT	The Sybase JDBC driver.

- To securely connect to the Cohesity cluster while reading or writing data, you can use secure gRPC.

  > **Note:**
  > - It is **mandatory** to connect to the Cohesity cluster securely using secure gRPC when writing or reading data.
  > - Using non-secure gRPC for data transfer between Cohesity and database hosts will result in unsecured communication.
  > - Enabling secure gRPC will increase data transfer time between Cohesity and database hosts compared to non-secure communication.

  To use secure gRPC, perform the following:

  1. Generate the certificate config file on the Cohesity node using the following command:

     ```
     ~/<release-version>/crux/bin/client_tls_cert_generator_exec -cert_name <clustername> -output_file /home/cohesity/<clustername>.cfg
     ```

  2. Copy `/home/cohesity/<clustername>.cfg` from the Cohesity node to all SAP ASE nodes at the same location. For example, `/opt/certs/<clustername>.cfg`.

     > **Note:** Ensure that the `root` or `non-root` user used to install the Cohesity Linux agent and SAP ASE Connector has read access to the generated certificate config file.

  3. While registering the SAP Sybase ASE source, provide the path of the certificate config file in the **Cohesity SSL Settings** field.

4. Increase the SAP Sybase ASE backup server memory to 1GB. For more information, see Utility Commands Reference in SAP Documentation.

Download and install the Cohesity Linux Agent

The Cohesity Linux Agent is available as an RPM installer. Download this installer and install it accordingly on the SAP Sybase ASE hosts to be protected. For detailed instructions, see Download and Install the Linux Agent.

> **Note:** Ensure that you install the Cohesity Linux Agent using the RPM-based installer.

Download and Install the SAP Sybase ASE Connector Installer

Cohesity Platform provides a SAP Sybase ASE Connector for backup and restore of enterprise SAP Sybase ASE deployments.

Download the SAP Sybase ASE Connector

Cohesity Platform provides a SAP Sybase ASE Connector to backup and restore SAP Sybase ASE databases. The SAP Sybase ASE Connector is available as a datasource agent on the Cohesity Download portal. Log on to the Cohesity Download portal, download the respective datasource agent for SAP Sybase ASE Connector, and copy the datasource agent to the SAP Sybase ASE host.

Install the SAP Sybase ASE Connector

On the SAP Sybase ASE database host where you have copied the SAP Sybase ASE Connector, perform the following to install the SAP Sybase ASE Connector.

To install the SAP Sybase ASE connector:

1. Log on to the SAP Sybase ASE Linux machine using the user with sudo privileges.
2. Navigate to the directory where you have copied the RPM-based installer.
3. Install the Cohesity SAP Sybase ASE connector using the following command:

   ```
   sudo sh -c 'export SAPASE_ENV_PATH=; rpm -ivh <rpm_file_name>'
   ```

   The `ENV-PATH` path can be found in the following file:

   ```
   $SYBASE/SYBASE.sh
   ```

   The **SYBASE.sh** file should have at least the following mandatory environment variables:

   - `SYBASE=<The SYBASE ASE Installation Path>`
   - `SYBASE_ASE=<The SYBASE ASE Version>`

- `SAP_JRE8_64=<The JRE directory path>`
- `SAP_JCONNECT=<The directory path for the JDBC driver>`

If you do not want to use the default values for the above parameters, then create a new file with these environment variables and point them to custom locations, and provide this file path using the following command:

```
export SAPASE_ENV_PATH=<ENV-PATH>
```

Uninstall the SAP Sybase ASE Connector

Before you uninstall the Cohesity SAP Sybase ASE connector, ensure that you set the following environment file:

```
export SAPASE_ENV_PATH=<ENV-PATH>
```

The `ENV-PATH` path can be found in the following file:

```
$SYBASE/SYBASE.sh
```

The **SYBASE.sh** file should have at least the following mandatory environment variables:

- `SYBASE=<The SYBASE ASE Installation Path>`
- `SYBASE_ASE=<The SYBASE ASE Version>`
- `JRE_PATH=<The JRE directory path>`
- `SAP_JCONNECT=<The directory path for the JDBC driver>`

If you do not want to use the default values for the above parameters, then create a new file with these environment variables and point them to custom locations, and provide this file path using the following command:

```
export SAPASE_ENV_PATH=<ENV-PATH>
```

To uninstall the Cohesity SAP Sybase ASE connector, run the following command with appropriate parameters on SAP Sybase ASE host CLI:

Using `yum`:

```
sudo yum remove <package>
```

Using `rpm`:

```
sudo rpm -e cohesity-sapase-connector-<version>.x86_64.rpm
```

Upgrade the SAP Sybase ASE Connector

To upgrade the Cohesity SAP Sybase ASE connector, run the following command on SAP Sybase ASE host:

```
sudo sh -c 'export SAPASE_ENV_PATH=<ENV-PATH>; rpm -U cohesity-sapase-connector-<version>.rpm'
```

The `ENV-PATH` path can be found in the following file:

```
$SYBASE/SYBASE.sh
```

The **SYBASE.sh** file should have at least the following mandatory environment variables:

- `SYBASE=<The SYBASE ASE Installation Path>`
- `SYBASE_ASE=<The SYBASE ASE Version>`
- `JRE_PATH=<The JRE directory path>`
- `SAP_JCONNECT=<The directory path for the JDBC driver>`

If you do not want to use the default values for the above parameters, then create a new file with these environment variables and point them to custom locations, and provide this file path using the following command:

```
export SAPASE_ENV_PATH=<ENV-PATH>
```

Register and Manage the SAP Sybase ASE on Linux Source

To protect your SAP Sybase ASE databases, you need to register your SAP Sybase ASE deployment as a source on the Cohesity Platform. After registering your SAP Sybase ASE deployment as a source, you can:

- Update the SAP Sybase ASE source configuration.
- Refresh the source details.
- Unregister the SAP Sybase ASE source from the Cohesity Platform.

Register SAP Sybase ASE as a Source

Before you register SAP Sybase ASE as a source, ensure that you:

- Review the considerations.
- Perform the prerequisite tasks.

For more information, see Plan and Prepare for SAP Sybase ASE on Linux Protection.

To register SAP Sybase ASE as a source:

1. In the Cohesity Dashboard, select **Data Protection** > **Sources**.
2. Click **Register** on the top-right of the page and then select **Universal Data Adapter**.
3. In the **Register Universal Data Adapter** page, perform the following:
    a. From the **Source Type** drop-down menu, select **SAP Sybase ASE**.
    b. From the **Host OS Type** drop-down menu, select **Linux**.
    c. In the **Hostname/IP Addresses** field, enter the hostname or IP address of the node(s) you have identified to run the SAP Sybase ASE Connector. For more

information, see Plan and Prepare for SAP Sybase ASE on Linux Protection.

> **Note:** Cohesity supports backup and restore of SAP Sybase ASE databases running on dual-stack (IPv4 and IPv6) mode or single-stack (only IPv6) mode.

d. In the **Datasource Agent Installation Path** field, enter the directory path on the SAP Sybase ASE node, where you have installed the SAP Sybase ASE Connector. For more information, see Install the SAP Sybase ASE Connector.

e. In the **Authentication Settings**, configure any one of the following authentication methods based on your requirements:

Authentication Method	Fields	Description
Password	Select if you want to use password-based authentication.	
	Username	The SAP ASE backup or restore user name.
	Password	The SAP ASE backup or restore user password.
Kerberos	Select if you want to use Kerberos-based authentication.	
	Kerberos Principal	The Kerberos principal that is required to connect to the database.
	Keytab File Path	The absolute path of the keytab file for the given Kerberos principal. **Note:** The path must be accessible by the Cohesity Agent user.
	Kerberos Credential Cache Path	The absolute path of the Kerberos ticket cache.

Authentication Method	Fields	Description
SecureStoreKey	Select if you want to use key-based authentication.	

	SecureStoreKey	The secure store key for key-based authentication.
		
		Note: For key-based authentication, ensure that Cohesity Agent and ASE server is running with the same user, aseuserstore.
		The following is the command to create the key:
		`aseuserstore set <KEY> <HOST>:<PORT> <USERNAME> <PASSWORD>`
		
		Sample key:
		`> aseuserstore list`
		`KEY: SYSKEY`
		`CON_ENV : COH6XTXXT2:5000`
		`USERNAME : sa`
		`PASSWORD : ***`

f. Optional. Enable **SAP ASE Client SSL Setting** and provide the absolute SSL certificate path on the SSL-enables SAP ASE cluster to enable a secure connection between the SAP ASE client and the SAP ASE Server.

> **Note:** Ensure that the Cohesity Agent user has access to the SSL Certificate path.

g. Enable **Cohesity SSL Settings** to enable a secure connection to the Cohesity cluster while reading or writing data. Enter the path to the SSL certificate used for secure data transfer between the Cohesity cluster and the SAP ASE cluster.

Note:

- It is **mandatory** to connect to the Cohesity cluster securely using secure gRPC when writing or reading data.
- Ensure that you generate and copy the certificate file from the Cohesity node to all the SAP ASE nodes. For more information, see Prerequisites.
- Using non-secure gRPC for data transfer between Cohesity and database hosts will result in unsecured communication.
- Enabling secure gRPC will increase data transfer time between Cohesity and database hosts compared to non-secure communication.

h. Under **Source Settings**, enter the details of the SAP Sybase ASE source:

Field	Mandatory?	Description
Datasource Name	Yes	A unique name to identify your SAP Sybase ASE host.

SAP ASE Server Name	Yes	The SAP Sybase ASE server name. The server name can be found with the following SQL command. Connect to the database and execute the following commands:
		`>SELECT @@SERVERNAME`
		`>go`

SAP ASE Server Port	No	If you are not using the default port, specify the port on which the SAP Sybase ASE server is listening. The default port is 4091.
SAP ASE Server Hostname/IP	No	The hostname or IP address where the SAP ASE server is listening.

4. Click **Register**.

Update the SAP Sybase ASE Source Configuration

After registering your SAP Sybase ASE as a source on the Cohesity Platform, you can update the SAP Sybase ASE source configuration.

> **Important:** You cannot modify the source name.

To update the SAP Sybase ASE source configuration:

1. In the Cohesity Dashboard, select **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the SAP Sybase ASE source and select **Edit**.
3. On the **Update Universal Data Adapter** page, update the required configurations.
4. Click **Update**.

Refresh the SAP Sybase ASE Source Configuration

You can refresh the SAP Sybase ASE Source and re-verify the source with the available source registration parameters.

To refresh the SAP Sybase ASE Source Configuration:

1. In the Cohesity Dashboard, select **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the SAP Sybase ASE Source and select **Refresh**.

Unregister the SAP Sybase ASE Source

If you plan to stop protecting your SAP Sybase ASE databases, you can unregister the SAP Sybase ASE source from the Cohesity Platform.

To unregister the SAP Sybase ASE source:

1. In the Cohesity Dashboard, select **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the SAP Sybase ASE source and select **Unregister**.

Backup SAP Sybase ASE on Linux Database

Cohesity Platform provides a simple workflow to back up your SAP Sybase ASE databases. After registering the SAP Sybase ASE as a source on the Cohesity Platform, you can start configuring your backups.

Backup Process

Cohesity Platform provides a SAP Sybase ASE connector for backup and restore of SAP Sybase ASE deployments. The SAP Sybase ASE connector leverages the native backup capabilities provided by SAP Sybase ASE. Cohesity SAP Sybase ASE connector uses JDBC interface to connect the SAP Sybase ASE Server.

After registering the SAP Sybase ASE source on the Cohesity Platform, you can create a Protection Group and specify the objects such as databases you want to backup.

Protect SAP Sybase ASE on Linux Deployments

In Cohesity Platform, SAP Sybase ASE deployments are protected using a Protection Group and a Protection Policy. A Protection Group enables you to specify the objects such as databases that you want to backup.

The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select the standard or custom policy to use when creating a Protection Group. For more information, see About Policies and Protection Groups.

To protect SAP Sybase ASE deployments:

1. In the Cohesity Dashboard, do one of the following:
   - Select **Data Protection > Protection**. Click **Protect** on the top-right of the page and then select **Universal Data Adapter**.
   - Select **Data Protection > Sources**. Click the actions menu (⋮) next to the SAP Sybase ASE source and then select **Protect**.
2. From the **Source** drop-down list, select the registered SAP Sybase ASE source or click **Register Source** to register a SAP Sybase ASE source. For more information, see Register SAP Sybase ASE as a Source.
3. In the **Objects** section, add the object that you plan to protect. The object should be a database name. To back up a database, enter the name of the database. For example, `H00`. Then, click **Save Selection**.
4. In the **Protection Group** section, do one of the following:
   - Select **New Group** to create a new Protection Group. In the **Protection Name** field, enter a name from the Protection Group.
   - Select **Existing Group** to use the settings of an existing Protection Group. From the **Group** list, select an existing Protection Group and click **Protect**.
5. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy.
6. In the **Backup Settings** section, enable the following configuration based on your requirements:

Options	Mandatory?	Description
Convert Incremental Backup To Full Backup On failure	No	Enable if you want to convert the incremental backup run to full backup in case of an error.

Options	Mandatory?	Description
Enable Incremental dumps for databases	No	Enable incremental/differential backups on the SAP Sybase ASE host. **Note:** After you have enabled incremental backups, ensure that you first initiate a full backup through Cohesity Dashboard.

7. Optional. Enable **Advanced Options** to configure advanced settings:

Field	Mandatory?	Default	Description
Parallel Objects	No	6	The number of databases for parallel data movement.
IO Thread Count	No	0	The number of threads that can be used for processing parallel I/O operations. The default value is calculated by the SAP ASE connector.
RPC Timeout In Seconds	No	120	The RPC request timeout between the SAP ASE source and the Cohesity cluster.
Hang Timeout in Seconds	No	1200	Define the duration in seconds, after which if there is no data movement, the protection run is marked as hung and killed by the SAP ASE Connector.
Max IO Write Size To Cohesity	No	4194304 bytes	The maximum size of the data packet that can be sent to the Cohesity cluster.
Environment Variables	No		The custom environment variables used by SAP ASE connector. **Expected value**: `KEY=VALUE` **Valid Environment Variable**: `ASE_BLOCK_SIZE`

8. In the **Settings** section, do the following:
    1. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains.

2. In the **Start Time** field, define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard.

   Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.

3. In the **Mounts** field, enter the number of VIPs you want to use while writing data to the Cohesity storage.

   > **Note:** Cohesity recommends that the number of mounts is equal to the number of nodes or Hybrid Extenders.

9. After you have completed the **Settings**, if you need to change any additional settings on the **New Universal Data Adapter Protection Group** page, scroll down and click Edit on the right. For more information, see Additional Settings.
10. Click **Protect**.

Additional Settings

Additional Settings	Description
Pause Future Run	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
End Time	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup Target HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup Target SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.

Additional Settings	Description
Concurrency	Maximum number of backup streams that will be created to exchange data with the Cohesity cluster. By default, maximum scaling is 16. Available concurrency is distributed across multiple databases to be backed up or restored.
Alerts	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.
Priority	Select a priority for the Protection Group execution. Cohesity Platform supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).
Description	**Optional**. Enter a brief description about the Protection Group.

Manage the SAP Sybase ASE on Linux Backup Configuration

In the Cohesity Platform, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for SAP Sybase ASE.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ in the **Objects** section.
5. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
6. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for SAP Sybase ASE.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a recovery run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for SAP Sybase ASE.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Delete Protection Group Only
    - Delete Protection Group and Snapshots

Recover SAP Sybase ASE on Linux Database

You can restore to the same SAP Sybase ASE deployment or to a different SAP Sybase ASE deployment. The Cohesity SAP Sybase ASE connector leverages the restore tool provided by SAP Sybase ASE. You can create a Recovery configuration and specify the object such as a database to recover.

> **Note:** Ensure that the database is not in use (active connections) during recovery.

Recover SAP Sybase ASE on Linux Databases

To restore SAP Sybase ASE databases:

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Click **Recover** at the top right of the page and then select **Universal Data Adapter**.
3. Search for the Protection Group that contains the snapshots to recover from by entering characters of the Protection Group name, or by specifying the wildcard character *.
4. From the list of search results, select the Protection Group that contains the snapshots to recover.
5. In the **Object** field, enter the name of the database or table that you had backed up using the selected Protection Group. By default, the latest snapshot is selected for recovery. You can also select a point-in-time snapshot or specific data backup that you want to recover.
6. Click **Next: Recover Options**.
7. In the **Recover As** section, based on your requirements, select any one of the following options:

Options	Description
Replace Original	To restore to the same SAP Sybase ASE database on the same SAP Sybase ASE host.
New Object	To restore to a different SAP Sybase ASE host or to the same SAP Sybase host as different objects. Select the **Target** SAP Sybase ASE host to which the data needs to be restored. Also, enable **Overwrite existing object with the same name** and type **Yes**, if you want to overwrite the existing object with the same name.

8. In the **Restore Settings** section, enable **Create Database** if you want the restore job to create a database schema on the target cluster. For the database creation during restoration, the details provided in the following table are honored:

	Database already exists	Overwrite	Create Database	Action
1	False	-	-	Create
2	True	Yes	Enabled	Drop and create
3	True	Yes	Disabled	Load
4	True	no	-	Error

> **Note:** For option (1) and (2), schema from source database will be replayed as it is; Hence "disk init" will use the same location as source database to create a physical device

9. Optional. Enable **Advanced Options** to configure advanced settings:

Field	Mandatory?	Default	Description
Parallel Objects	No	6	The number of databases for parallel data movement.
IO Thread Count	No	0	The number of threads that can be used for processing parallel I/O operations. The default value is calculated by the SAP ASE connector.
RPC Timeout In Seconds	No	120	The RPC request timeout between the SAP ASE source and the Cohesity cluster.
Hang Timeout in Seconds	No	1200	Define the duration in seconds, after which if there is no data movement, the protection run is marked as hung and killed by the SAP ASE Connector.
Max IO Write Size To Cohesity	No	4194304 bytes	The maximum size of the data packet that can be sent to the Cohesity cluster.

Field	Mandatory?	Default	Description
Environment Variables	No		The custom environment variables used by SAP ASE connector. **Expected value**: `KEY=VALUE` **Valid Environment Variable**: `ASE_BLOCK_SIZE`

10. In the **Recovery Options** section, based on your requirements, select any one of the following options:

Options	Description
Mounts	Enter the number of VIPs you want to use while reading data from the Cohesity storage.
Concurrency	The maximum number of restore streams that is created to exchange data with the cluster.
Rename	Provide the new name for the object, if you want to restore the object with a new name.
Task Name	Change the default name of the recovery task.

11. Click **Recover**.

Restore SAP Sybase ASE System Databases

The Cohesity SAP Sybase ASE connector enables you to restore system databases such as `sybsystemdb` and `master` database.

Restore Sybsystemdb Database

Before you restore the `sybsystemdb` database, ensure that you perform the following on the SAP ASE host:

1. Execute the following SQL command:

```
sp_configure "enable xact coordination",0
```

2. Stop and start the SAP ASE service.

To restore the `sybsystemdb` database, follow the steps in the SAP Sybase ASE Databases restore procedure, and ensure that you disable the **Create Database** option in the **Restore Settings** section.

Restore Master Database

Before you restore the master database, ensure that you perform the following on the SAP ASE host:

1. Start Adaptive Server in single-user mode, for detailed instructions, see How to Start Adaptive Server in Single-User Mode in SAP documentation.
2. Restart the SAP ASE server.

To restore the master database, follow the steps in the SAP Sybase ASE Databases restore procedure, and ensure that you disable the **Create Database** option in the **Restore Settings** section.

SAP Sybase ASE on Microsoft Windows

Cohesity Platform natively integrates with SAP Sybase ASE to provide backup and recovery for SAP Sybase ASE deployments on Microsoft Windows. Using Cohesity Connector Agent, you can backup and restore the SAP Sybase ASE databases.

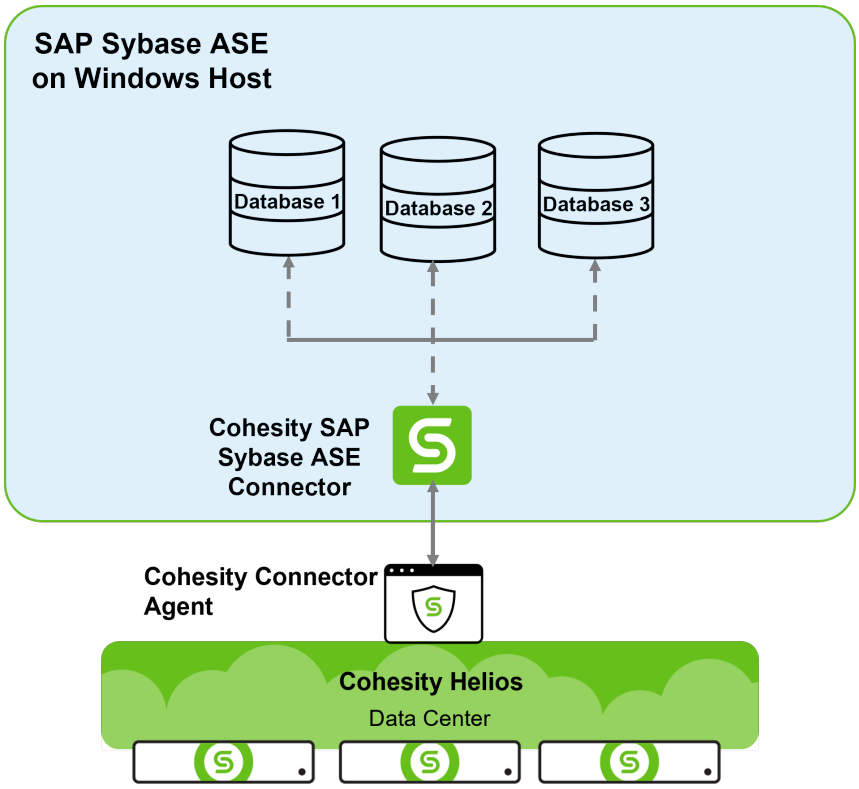
Cohesity Platform provides a SAP Sybase ASE connector that enables you to perform a full backup, differential backup, log backup, restore and point in time restore at the database level.

Core Components

The following are the core components for protecting SAP Sybase ASE databases:

- Cohesity SAP Sybase ASE connector
- Cohesity Connector Agent

As illustrated, you can integrate the Cohesity Platform with your SAP Sybase ASE deployments using the Cohesity SAP Sybase ASE connector and Cohesity Connector Agent.



Plan and Prepare for SAP Sybase ASE on Windows Protection

Before you register your SAP Sybase ASE deployment as a source with Cohesity Platform, ensure the following prerequisites:

- The user account of the SAP Sybase ASE instance must have database admin privileges or operator privileges.
- Download and install the Cohesity Windows Agent on the SAP Sybase ASE host.
- Download and install the Cohesity SAP Sybase ASE Connector on the SAP Sybase ASE host using the same user that was used for installing Cohesity Windows Agent.
- Review and understand the limitations.

Supported Versions

For more information on supported SAP Sybase ASE versions, see SAP Sybase ASE versions.

Port Requirements

You must open certain ports in the firewall to allow the Cohesity cluster to transmit and receive data. Ensure that you open the following port in the firewall to allow data transfer between the SAP Sybase ASE host and the Cohesity cluster:

Port	Source	Target	Direction	Network Protocol
50051	SAP Sybase ASE	Cohesity cluster	Bidirectional	TCP/IP
11113	SAP Sybase ASE	Cohesity cluster	Unidirectional	TCP/IP

Considerations

Review and understand the following requirements before you protect your single-node SAP Sybase ASE deployment.

- Backup or restore for SAP Sybase ASE HA cluster deployments are not supported.
- Ensure that the database is not in use (active connections) during recovery.
- Once Cohesity protects the Sybase ASE database, it is not recommended to use the SAP backup and/or restore tools outside of Cohesity, including native dump or load tools provided by SAP Sybase ASE.
- The same database should not be part of multiple Protection Groups.
- Kerberos authentication is currently not supported.
- Backup or restore not supported if the SAP Sybase ASE server is listening on IPV6.
- If the hole is introduced in the backup timeline, then point-in-time recovery (PITR) is possible only after the subsequent successful full or incremental backup is completed.
- Cohesity supports backup and restore of SAP Sybase ASE databases running on dual-stack (IPv4 and IPv6) mode, single-stack (only IPv6) mode, and single-stack (only IPv4) mode.

Prerequisites

- The user account used to install the Cohesity Windows Agent and Cohesity ASE connector must have administrator privileges
- Local System Account must not be used for installing and running Cohesity Windows agent and connector.
- Enable incremental backups on the SAP Sybase ASE host using the following database command:

```
use <dbname> master ..sp_dboption <dbname>, "allow incremental dumps", false
```

> **Note:** After enabling incremental backups, you have to first initiate a full backup through the Cohesity Dashboard.

- Only IPv4 is supported and hence ensure that the SAP Sybase ASE server listens on IPv4 address.
- In a multitenant environment that has a hybrid extender-based configuration, if the data source does not use a secure gRPC client, then ensure that you execute the following commands on each hybrid extender before registering the SAP Sybase ASE source on the Cohesity cluster:

```
$bifrost.sh stop
$bifrost.sh start --magneto_grpc_timeout_msecs=300000 --tcp_proxy_
connector_ports=445:445,2049:2049,80:80,443:443,11117:11117,11113:11113
$sudo firewall-cmd --add-port=11113/tcp --zone=public --permanent &&
sudo firewall-cmd --reload
```

- Set the following variables in the system environment variables:

Environment Variable	Description
SYBASE	The path of the Sybase installation directory.
SYBASE_ASE	The subdirectory of the Adaptive Server component.
SAP_JRE8_64	The location of the Java Runtime Environment.
SAP_JCONNECT	The Sybase JDBC driver.

- To securely connect to the Cohesity cluster while reading or writing data, you can use secure gRPC.

  Note:
  - It is **mandatory** to connect to the Cohesity cluster securely using secure gRPC when writing or reading data.
  - Using non-secure gRPC for data transfer between Cohesity and database hosts will result in unsecured communication.
  - Enabling secure gRPC will increase data transfer time between Cohesity and database hosts compared to non-secure communication.

  To use secure gRPC, perform the following:

  1. Generate the certificate config file on the Cohesity node using the following command:

```
~/<release-version>/crux/bin/client_tls_cert_generator_exec -cert_
name <clustername> -output_file /home/cohesity/<clustername>.cfg
```

2. Copy `/home/cohesity/<clustername>.cfg` from the Cohesity node to all SAP ASE nodes at the same location. For example, `/opt/certs/<clustername>.cfg`.

   > **Note:** Ensure that the administrator account user used to install the Cohesity Windows agent and SAP ASE Connector has read access to the generated certificate config file.

3. While registering the SAP Sybase ASE source, provide the path of the certificate config file in the **Cohesity SSL Settings** field.

- Increase the SAP Sybase ASE backup server memory to 1GB. For more information, see Utility Commands Reference in SAP Documentation.

Download and Install the Cohesity Windows Agent

The Cohesity Windows Agent is available as an executable installer. Download this installer and install it accordingly on the SAP Sybase ASE hosts to be protected. For detailed instructions, see Download and Install the Windows Agent.

> **Note:** Make sure that you do not select any add-ons.

Download and Install the SAP Sybase ASE Connector Installer

Cohesity Platform provides a SAP Sybase ASE Connector for backup and restore of enterprise SAP Sybase ASE deployments.

Download the SAP Sybase ASE Connector

Cohesity Platform provides a SAP Sybase ASE Connector to backup and restore SAP Sybase ASE databases. The SAP Sybase ASE Connector is available as a datasource agent on the Cohesity Download portal. Log on to the Cohesity Download portal, download the respective datasource agent for SAP Sybase ASE Connector, and copy the datasource agent to the SAP Sybase ASE host.

Install the Cohesity SAP Sybase ASE Connector

Before you install the Cohesity SAP Sybase ASE connector, ensure that you are logged as the same user with which you installed the Cohesity Windows agent.

To install the Cohesity SAP Sybase ASE connector:

1. Log on to the SAP Sybase ASE node where you have copied the Cohesity SAP Sybase ASE connector installer executable, `Cohesity_SAP_ASE_connector_<version>_Win_`

`x64_Installer.exe`.

2. Double-click the installer and follow the instructions to Install the Cohesity SAP Sybase ASE connector.

Upgrade the SAP Sybase ASE Connector

To upgrade the SAP Sybase ASE Connector:

1. Log on to the SAP Sybase ASE node where you have copied the Cohesity SAP Sybase ASE connector installer executable, `Cohesity_SAP_ASE_connector_<version>_Win_x64_Installer.exe`. Ensure that you are logged in as the same user with which you installed the Cohesity Windows agent.
2. Double-click on the Cohesity SAP Sybase ASE Connector installer, and when prompted, select **Upgrade** and follow the instructions.

Uninstall the SAP Sybase ASE Connector

To uninstall the Cohesity SAP Sybase ASE connector:

1. Log on to the SAP Sybase ASE host.
2. Select the **Start** menu and look for the SAP Sybase ASE Connector in the list shown.
3. Press and hold (or right-click) on the SAP Sybase ASE Connector, then select **Uninstall**.

Register and Manage the SAP Sybase ASE on Windows Source

To protect your SAP Sybase ASE databases, you need to register your SAP Sybase ASE deployment as a source on the Cohesity Platform. After registering your SAP Sybase ASE deployment as a source, you can:

- Update the SAP Sybase ASE source configuration.
- Refresh the source details.
- Unregister the SAP Sybase ASE source from the Cohesity Platform.

Register SAP Sybase ASE as a Source

Before you register SAP Sybase ASE as a source, ensure that you:

- Review the considerations.
- Perform the prerequisite tasks.

For more information, see Plan and Prepare for SAP Sybase ASE on Windows Protection.

To register SAP Sybase ASE as a source:

1. In the Cohesity Dashboard, select **Data Protection** > **Sources**.
2. Click **Register** on the top-right of the page and then select **Universal Data Adapter**.
3. In the **Register Universal Data Adapter** page, perform the following:
   a. From the **Source Type** drop-down menu, select **SAP ASE**.
   b. From the **Host OS Type** drop-down menu, select **Windows**.
   c. In the **Hostname/IP Addresses** field, enter the hostname or IP address of the node(s) you have identified to run the SAP Sybase ASE connector. For more information, see Plan and Prepare for SAP Sybase ASE on Windows Protection.

      > **Note:** Cohesity supports backup and restore of SAP Sybase ASE databases running on dual-stack (IPv4 and IPv6) mode, single-stack (only IPv6) mode, and single-stack (only IPv4) mode.

   d. In the **Datasource Agent Installation Path** field, enter the directory path on the SAP Sybase ASE node, where you have installed the SAP Sybase ASE connector. For more information, see Install the Cohesity SAP Sybase ASE Connector.
   e. In the **Authentication Settings**, configure any one of the following authentication methods based on your requirements:

Authentication Method	Fields	Description	
Password	Select if you want to use password-based authentication.		
	Username	The SAP ASE backup or restore user name.	
	Password	The SAP ASE backup or restore user password.	

Authentication Method	Fields	Description	
SecureStoreKey	Select if you want to use key-based authentication.		

	SecureStoreKey	The secure store key for key-based authentication.
		Note: Ensure that the key is generated using the same user with which Cohesity agent service is running. For more details, refer to SAP jConnect for JDBC Programmers Reference.
		The following is the sample command to create a key:
		`aseuserstore set <KEY> <HOST>:<PORT> <USERNAME> <PASSWORD>`
		Sample key:
		`> aseuserstore list`
		`KEY: SYSKEY`
		`CON_ENV : COH6XTXXT2:5000`
		`USERNAME : sa`
		`PASSWORD : ***`	

f. Optional. Enable **SAP ASE Client SSL Setting** and provide the absolute SSL certificate path on the SSL-enables SAP ASE cluster to enable a secure connection between the SAP ASE client and the SAP ASE Server.

> **Note:** Ensure that the Cohesity Agent user has access to the SSL Certificate path.

g. Enable **Cohesity SSL Settings** to enable a secure connection to the Cohesity cluster while reading or writing data. Enter the path to the SSL certificate used for secure data transfer between the Cohesity cluster and the SAP ASE cluster.

Note:

- It is **mandatory** to connect to the Cohesity cluster securely using secure gRPC when writing or reading data.
- Ensure that you generate and copy the certificate file from the Cohesity node to all the SAP ASE nodes. For more information, see Prerequisites.
- Using non-secure gRPC for data transfer between Cohesity and database hosts will result in unsecured communication.
- Enabling secure gRPC will increase data transfer time between Cohesity and database hosts compared to non-secure communication.

h. Under **Source Settings**, enter the details of the SAP Sybase ASE source:

Field	Mandatory?	Description
Datasource Name	Yes	A unique name to identify your SAP Sybase ASE host.

SAP ASE Server Name	Yes	The SAP Sybase ASE server name. The server name can be found with the following SQL command. Connect to the database and execute the following commands:
		`>SELECT @@SERVERNAME`
		`>go`

SAP ASE Server Hostname/IP	No	The hostname or IP address where the SAP ASE server is listening.
SAP ASE Server Port	No	If you are not using the default port, specify the port on which the SAP Sybase ASE server is listening. The default port is 4091.

i. Click **Register**.

Update the SAP Sybase ASE Source Configuration

After registering your SAP Sybase ASE as a source on the Cohesity Platform, you can update the SAP Sybase ASE source configuration.

> **Important:** You cannot modify the source name.

To update the SAP Sybase ASE source configuration:

1. In the Cohesity Dashboard, select **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the SAP Sybase ASE source and select **Edit**.
3. On the **Update Universal Data Adapter** page, update the required configurations.
4. Click **Update**.

Refresh the SAP Sybase ASE Source Configuration

You can refresh the SAP Sybase ASE Source and re-verify the source with the available source registration parameters.

To refresh the SAP Sybase ASE Source Configuration:

1. In the Cohesity Dashboard, select **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the SAP Sybase ASE Source and select **Refresh**.

Unregister the SAP Sybase ASE Source

If you plan to stop taking the backup of your SAP Sybase ASE databases, you can unregister the SAP Sybase ASE source from the Cohesity Platform.

To unregister the SAP Sybase ASE source:

1. In the Cohesity Dashboard, select **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the SAP Sybase ASE source and select **Unregister**.

Backup SAP Sybase ASE on Windows Database

Cohesity Platform provides a simple workflow to back up your SAP Sybase ASE databases. After registering the SAP Sybase ASE as a source on the Cohesity Platform, you can start configuring your backups.

Backup Process

Cohesity Platform provides a SAP Sybase ASE connector for backup and restore of SAP Sybase ASE deployments. The SAP Sybase ASE connector leverages the native backup capabilities provided by SAP Sybase ASE. Cohesity SAP Sybase ASE connector uses the JDBC interface to connect the SAP Sybase ASE Server. Ensure that the JDBC driver is installed for the SAP Sybase ASE database.

After registering the SAP Sybase ASE source on the Cohesity Platform, you can create a Protection Group and specify the objects such as databases you want to backup.

Protect SAP Sybase ASE on Windows Deployments

In Cohesity Platform, SAP Sybase ASE deployments are protected using a Protection Group and a Protection Policy. A Protection Group enables you to specify the objects such as databases that you want to backup.

The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select which standard or custom policy to use when creating a Protection Group. For more information, see About Policies and Protection Groups.

To protect SAP Sybase ASE deployments:

1. In the Cohesity Dashboard, do one of the following:
   - Select **Data Protection > Protection**. Click **Protect** on the top-right of the page and then select **Universal Data Adapter**.
   - Select **Data Protection > Sources**. Click the actions menu (⋮) next to the SAP Sybase ASE source and then select **Protect**.
2. From the **Source** drop-down list, select the registered SAP Sybase ASE source or click **Register Source** to register a SAP Sybase ASE source. For more information, see Register SAP Sybase ASE as a Source.
3. In the **Objects** section, add the object that you plan to protect. The object should be a database name. To back up a database, enter the name of the database. For example, `H00`. Click the plus icon (+) to enter multiple objects that you plan to back up. Then, click **Save Selection**.
4. In the **Protection Group** section, do one of the following:
   - Select a **New Group** to create a new Protection Group. In the **Protection Name** field, enter a name from the Protection Group.
   - Select **Existing Group** to use the settings of an existing Protection Group. From the **Group** list, select an existing Protection Group and click **Protect**.
5. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy.
6. In the **Backup Settings** section, enable the following configuration based on your

requirements:

Options	Mandatory?	Description
Convert Incremental Backup To Full Backup On failure	No	Enable if you want to convert the incremental backup run to full backup in case of an error.
Enable Incremental dumps for databases	No	Enable incremental/differential backups on the SAP Sybase ASE host. **Note:** After you have enabled incremental b ackups, ensure that you first initiate a full ba ckup through Cohesity Dashboard.

7. Optional. Enable **Advanced Options** to configure advanced settings:

Field	Mandatory?	Default	Description
Parallel Objects	No	6	The number of databases for parallel data movement.
IO Thread Count	No	0	The number of threads that can be used for processing parallel I/O operations. The default value is calculated by the SAP ASE connector.
RPC Timeout In Seconds	No	120	The RPC request timeout between the SAP ASE source and the Cohesity cluster.
Hang Timeout in Seconds	No	1200	Define the duration in seconds, after which if there is no data movement, the protection run is marked as hung and killed by the SAP ASE Connector.
Max IO Write Size To Cohesity	No	4194304 bytes	The maximum size of the data packet that can be sent to the Cohesity cluster.
Environment Variables	No		The custom environment variables used by SAP ASE connector. **Expected value**: `KEY=VALUE` **Valid Environment Variable**: `ASE_BLOCK_SIZE`

8. In the **Settings** section, do the following:
    1. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains.
    2. In the **Start Time** field, define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard.

       Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
    3. In the **Mounts** field, enter the number of VIPs you want to use while writing data to the Cohesity storage.

       > **Note:** Cohesity recommends that the number of mounts is equal to the number of nodes or Hybrid Extenders.
9. After you have completed the **Settings**, if you need to change any additional settings on the **New Universal Data Adapter Protection Group** page, scroll down and click **Edit** on the right. For more information, see Additional Settings.
10. Click **Protect**.

Additional Settings

Additional Settings	Description
Pause Future Run	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.
End Time	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.

Additional Settings	Description
QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup Target HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup Target SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Concurrency	Maximum number of backup streams that will be created to exchange data with the Cohesity cluster. By default, maximum scaling is 16. Available concurrency is distributed across multiple databases to be backed up or restored.
Alerts	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.
Priority	Select a priority for the Protection Group execution. Cohesity Platform supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs

Additional Settings	Description
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).
Description	**Optional**. Enter a brief description about the Protection Group.

Manage the SAP Sybase ASE on Windows Backup Configuration

In the Cohesity Platform, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for SAP Sybase ASE.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ in the **Objects** section.
5. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
6. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to

execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for SAP Sybase ASE.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a recovery run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for SAP Sybase ASE.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Delete Protection Group Only
    - Delete Protection Group and Snapshots

Recover SAP Sybase ASE on Windows Database

You can restore to the same SAP Sybase ASE deployment or to a different SAP Sybase ASE deployment. The Cohesity SAP Sybase ASE connector leverages the restore tool provided by SAP Sybase ASE. You can create a Recovery configuration and specify the object such as a database to recover.

Recover Sybase ASE on Windows Databases

To restore SAP Sybase ASE databases:

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Click **Recover** at the top right of the page and then select **Universal Data Adapter**.
3. Search for the Protection Group that contains the snapshots to recover from by entering characters of the Protection Group name, or by specifying the wildcard character ***.
4. From the list of search results, select the Protection Group that contains the snapshots to recover.
5. In the **Object** field, enter the name of the database or table that you had backed up using the selected Protection Group. By default, the latest snapshot is selected for recovery. You can also select a point-in-time snapshot or specific data backup that you want to recover.
6. Click **Next: Recover Options**.
7. In the **Recover As** section, based on your requirements, select any one of the following options:

Options	Description
Replace Original	To restore to the same SAP Sybase ASE database on the same SAP Sybase ASE host.

Options	Description
New Object	To restore to a different SAP Sybase ASE host or to the same SAP Sybase host as different objects. Select the **Target** SAP Sybase ASE host to which the data needs to be restored

8. In the **Restore Settings** section, enable **Create Database** if you want the restore job to create a database schema on the target cluster. For the database creation during restoration, the details provided in the following table are honored:

	Database already exists	Overwrite	Create Database	Action
1	False	-	-	Create
2	True	Yes	Enabled	Drop and create
3	True	Yes	Disabled	Load
4	True	no	-	Error

> **Note:** For options (1) and (2), schema from the source database will be replayed as it is; Hence "disk init" will use the same location as the source database to create a physical device

9. Optional. Enable **Advanced Options** to configure advanced settings:

Field	Mandatory?	Default	Description
Parallel Objects	No	6	The number of databases for parallel data movement.
IO Thread Count	No	0	The number of threads that can be used for processing parallel I/O operations. The default value is calculated by the SAP ASE connector.
RPC Timeout In Seconds	No	120	The RPC request timeout between the SAP ASE source and the Cohesity cluster.

Field	Mandatory?	Default	Description
Hang Timeout in Seconds	No	1200	Define the duration in seconds, after which if there is no data movement, the protection run is marked as hung and killed by the SAP ASE Connector.
Max IO Write Size To Cohesity	No	4194304 bytes	The maximum size of the data packet that can be sent to the Cohesity cluster.
Environment Variables	No		The custom environment variables used by SAP ASE connector. **Expected value**: `KEY=VALUE` **Valid Environment Variable**: `ASE_BLOCK_SIZE`

10. In the **Recovery Options** section, based on your requirements, select any one of the following options:

Options	Description
Mounts	Enter the number of VIPs you want to use while reading data from the Cohesity storage.
Concurrency	The maximum number of restore streams that is created to exchange data with the cluster.
Rename	Provide the new name for the object, if you want to restore the object with a new name.
Task Name	Change the default name of the recovery task.

11. Click **Recover**.

Restore SAP Sybase ASE System Databases

The Cohesity SAP Sybase ASE connector enables you to restore system databases such as `sybsystemdb` and `master` database.

Restore Sybsystemdb Database

Before you restore the `sybsystemdb` database, ensure that you perform the following on the SAP ASE host:

1. Execute the following SQL command:

```
sp_configure "enable xact coordination",0
```

2. Stop and start the SAP ASE service.

To restore the `sybsystemdb` database, follow the steps in the SAP Sybase ASE Databases restore procedure, and ensure that you disable the **Create Database** option in the **Restore Settings** section.

Restore Master Database

Before you restore the master database, ensure that you perform the following on the SAP ASE host:

1. Start the Adaptive Server in single-user mode, for detailed instructions, see How to Start Adaptive Server in Single-User Mode in SAP documentation.
2. Restart the SAP ASE server.

To restore the master database, follow the steps in the SAP Sybase ASE Databases restore procedure, and ensure that you disable the **Create Database** option in the **Restore Settings** section.

Cancel a Recovery Run

When you cancel a recovery run, the SAP Sybase ASE connector cancels the job by terminating the recovery processes.

To cancel a recovery run:

1. In the Cohesity Dashboard, select **Data Protection** > **Recoveries**.
2. Click the action icon (...) next to the recovery run and click **Cancel Run**.
3. In the **Cancel Recovery** dialog box, select any one of the following:
    - **Continue Recovery** if you want to continue the recovery task.
    - **Cancel Recovery** if you want to cancel the recovery task.

Troubleshooting Sybase ASE on Windows Protection

The following table lists the logs that you can use to troubleshoot failures during the data protection workflows:

Component	Path to the log file
Cohesity SAP Sybase ASE Connector logs	`C:\ProgramData\Cohesity\uda`
Cohesity Windows Agent service logs	`C:\ProgramData\Cohesity`

> **Note:** The `C:\ProgramData` folder is a hidden folder in Windows.

Known Issues and Workaround

The following table lists the known issues and workarounds:

Known Issue	Workaround
After the Cohesity Windows Agent is restarted, in certain cases a few stale DBs may continue to run during a recovery job run.	Manually drop the database, recreate and retry the restore.
PITR restore fails with the following error: `error "[13]:Cannot find data backup run for PITR 1623883236"`	If the point in time selected for restore is before the first full backup, then you may see this error. Please select a point later than the end of the first full backup.
In case of SAP Sybase ASE version mismatch , database fails to come online after a successful restore.	Try to online the database manually, `online database <dbname>`

SAP on Oracle for Linux

Cohesity natively integrates with SAP on Oracle to provide backup and recovery for SAP on Oracle deployments. Cohesity provides an Oracle Connector that enables you to do the following:

- Backs up data files, control files, and online redo log files of the database.
- Backs up offline redo log files.
- Restores data files, control files, and online and offline redo log files.
- Recovers database files and restores profiles and log files.
- Manages the database instance, space, and segments (that is, tables and indexes).
- Performs database administration tasks such as statistics update, check database system, adapt next extents, clean up logs and DBA tables.
- Functions as a help tool to monitor the database during a backup.
- Functions as an internal help tool started by BRBACKUP, BRARCHIVE, and BRRESTORE.

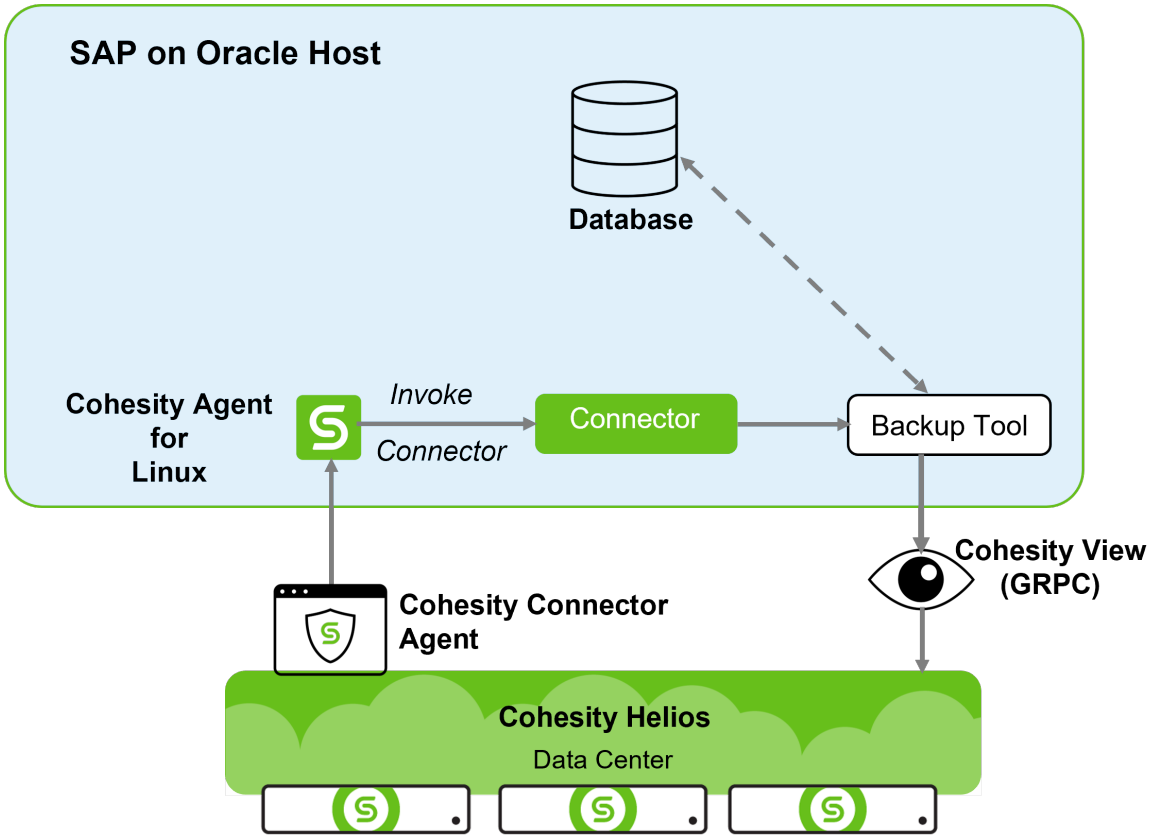
Core Components

The following are the core components for protecting SAP on Oracle databases:

- Oracle Database
- SAP on Oracle Connector

- Cohesity Connector Agent
- Cohesity View

As illustrated, you can integrate the Cohesity with your SAP on Oracle deployments using the SAP on Oracle Connector and Cohesity Connector Agent.



Plan and Prepare for SAP on Oracle for Linux Protection

Before you register your SAP on Oracle deployment as a source with Cohesity and protect SAP on Oracle databases, ensure you meet the prerequisites in the install section and understand the limitations.

Supported Versions

For more information on supported SAP on Oracle versions, see Supported Software versions.

Port Requirements

Outgoing Traffic

Source	Destination	Port	Protocol	Type of Traffic
Cohesity cluster	SAP on Oracle Node	50051	TCP/IP	Control path for all workflows

Bidirectional Traffic

Source	Destination	Port	Protocol	Type of Traffic
SAP on Oracle Local Host	SAP on Oracle Local Host	59999	TCP/IP	Required only if local-to-local communication (used for self-monitoring and debugging purposes) is blocked by the firewall.

Incoming Traffic

Source	Destination	Port	Protocol	Type of Traffic
SAP on Oracle Node	Cohesity cluster	11113	TCP/IP	Backup and Recovery
SAP on Oracle Node	Cohesity cluster	11117	TCP/IP	Backup and Recovery with secure gRPC

Considerations

Review and understand the following before you protect your Oracle database:

- SAP on Oracle installations performed using the oracle user are not supported because they require a BRTools configuration as specified in SAP Note 1598594. However, Cohesity only supports the BRTools configuration outlined in SAP Note 113747.
- Automatic database creation is not supported. You need to create a database before running either backup or restore.
- Alternate restore to a new database on a different SAP on Oracle system with a different SID option is not supported.
- SAP on Oracle Connector agent does not support auto-discovery and entity hierarchy; hence you cannot browse or search and select objects for backup.
- Offline backup of the database is not supported.
- Indexing is not supported.
- You cannot protect multiple hosts using a single Protection Group.

- You cannot backup multiple databases in a single Protection Group.
- You cannot restore multiple objects, search, and recover an object.
- The RPM-based installer is not currently supported.
- SAP Oracle ASM deployment is not supported.
- Ensure that the SAP on Oracle DB instance uses an SPFILE to start up as recommended by SAP. For more information, see https://me.sap.com/notes/1598594.
- It is **mandatory** to connect to the Cohesity cluster securely using secure gRPC when writing or reading data.

Download and install the Cohesity Linux Agent

The Cohesity Linux Agent is available as script-based and RPM-based installers, based on your requirements download the installer and install it accordingly on the SAP on Oracle database. For detailed instructions, see Download and Install the Linux Agent.

> **Note:** Ensure you meet the following prerequisites below before you install the Cohesity Linux agent.

Download and Install the SAP on Oracle Connector

Cohesity provides a SAP on Oracle Connector to backup and restore SAP on Oracle databases. The SAP on Oracle Connector is available as a datasource agent on the Cohesity Download portal. Log on to the Cohesity Download portal, download the respective datasource agent for SAP on Oracle Connector, and copy the datasource agent to the SAP on Oracle host.

Install the SAP on Oracle Connector

On the SAP on Oracle host where you have copied the SAP on Oracle Connector (`scp cohesity_secure_connector_service_6.6.0b_ent_sap_oracle_java_installer`), perform the following to install the SAP on Oracle Connector:

Before You Install

- Before you install the SAP on Oracle Connector, ensure the following prerequisites:

  Ensure the variables $SAPDATA_HOME and $ORACLE_HOME are set for the user performing the installation.

  > **Note:** Cohesity recommends using the "root" user account to install the SAP on Oracle Connector.

  Example:

```
$ export ORACLE_HOME=</oracle/SID/121>
$ export SAPDATA_HOME=</oracle/SID>
```

- During the SAP on Oracle Connector installation, you need permission to write to /usr/sap/<SID>/ directory as it is the default installation location. If you do not have write access, please specify the custom installation directory using "-I" or "--install-dir" while running the installer.

  Example:

  ```
  ./cohesity_secure_connector_service_sap_oracle_java_installer -- --
  install -s SID -w uda -S ora<sid> -I /home/ora<sid>/uda_install/
  ```

- The BRTOOLS are pre-installed on the SAP on Oracle System. The Cohesity SAP on Oracle connector integrates with BRTOOLS for backup and restore. SAP recommends BRTOOLS version 7.40 Patch 46 or greater. For more information, see https://launchpad.support.sap.com/#/notes/3060252.
- Ensure that the BRTOOLS' ownership and permissions follow the SAP note: https://me.sap.com/notes/113747.

  For example:

  ```
  -rwsrwxr-- 1 orasid sapsys 10022600 Aug 23 2012 brarchive
  -rwsrwxr-- 1 orasid sapsys 10251536 Aug 23 2012 brbackup
  -rwsrwxr-- 1 orasid sapsys 12179560 Aug 23 2012 brconnect
  -rwxr-xr-x 1 sidadm sapsys 10708840 Aug 23 2012 brrecover
  -rwxr-xr-x 1 sidadm sapsys 4140576 Aug 23 2012 brrestore
  -rwxr-xr-x 1 sidadm sapsys 12778384 Aug 23 2012 brspace
  -rwxr-xr-x 1 sidadm sapsys 4711664 Aug 23 2012 brtools
  ```

- Use "bash" shell to install the SAP on Oracle Connector and to run backups and restore workflows of SAP on Oracle databases.
- Ensure that the NTP time is in sync between the client and the Cohesity cluster. Perform the following on the client:
  - Verify if NTP is enabled and synchronized in the client using the following command:

    ```
    timedatectl
    ```

  - If the NTP time is not synchronized, use the following command to synchronize the NTP time

    ```
    timedatectl set-ntp true
    ```

To install the SAP on Oracle Connector:

1. Log on to the SAP on Oracle host as a root user where you have copied the SAP on Oracle script-based installer, `cohesity_secure_connector_service_6.6.0b_ent_`

sap_oracle_java_installer.

> **Note:** During the SAP on Oracle connector installation, by default, the script installer extracts the files to the /tmp directory. If you plan to extract the files to a different directory, you can define the directory path in the TMPDIR environment variable as follows: export TMPDIR=<directory_path>.

2. Run the following command to install the SAP on Oracle Connector (cohesity_secure_connector_service_6.6.0b_ent_sap_oracle_java_installer):

```
./cohesity_secure_connector_service_6.6.0b_ent_sap_oracle_java_
installer -- --install -I <install_directory> -s <SID> -w uda
```

Where:

1. **-i <install_directory>** - The directory on the SAP on Oracle host on which you want to install the SAP on Oracle Connector.

   By default, the SAP on Oracle Connector is installed in the /usr/sap/<SID>/cohesity directory.

   You can use -i <install_directory> if you want to change the default installation location from /usr/sap/SID/cohesity/.

2. **-w <workflow>** - The type of workflow you intend to install the SAP on Oracle Connector. For UDA workflow, specify **uda**.

3. **-s <SID>** - SAP System Identification (SID) is a unique three-character code that is available for every R/3 installation (SAP system) that consists of a database server and several application servers.

   If you have different permissions (for the owner user and group) in the above-mentioned files, it is necessary to run backup and restore operations with the sudo user. Cohesity recommends adding the following in the sudoers file:

   1. Add the following in the sudoers file:

      ```
      ora<sid> ALL=(ALL) NOPASSWD:SETENV: /bin/chown, /bin/java,
      /bin/chmod
      ```

   2. Edit following line in ${INSTALL_DIR}/backint.sh to:

      ```
      JAVA="sudo -E java"
      ```

Refer to SAP recommendations for the default owner and permissions of init<DBSID>.ora, init<DBSID>.sap, $SAPDATA_HOME: https://launchpad.support.sap.com/#/notes/113747.

You can also run the following command to know more details about the options used in the above command.

```
$ ./cohesity_secure_connector_service_6.6.0b_ent_sap_oracle_java_
installer -- --help
```

3. After installation, if the user does not have access to `$SAPEXE (/usr/sap/<SID>/SYS/exe/run)`, create a soft link to backint.sh in `$SAPEXE` directory using the following command.

   Example:

   ```
   ln -sf '/home/ora<sid>/uda_install/backint.sh' '${SAPEXE}/backint'
   chown -h "ora<sid>":"sapsys" "${SAPEXE_DIR}/backint"
   ```

4. Optional. Create a softlink to uda_scripts manually, if the installer (`cohesity_secure_connector_service_6.6.0b_ent_sap_oracle_java_installer`) fails to create the soft link using the following command:

   ```
   chmod -R 755 /opt/cohesity ln -sf /home/ora<sid>/uda_install/uda_
   scripts /opt/cohesity/agent/uda_scripts
   ```

The following is a sample output of the successful installation:

```

```

After the SAP on Oracle Connector is installed, the agent is available at:

```
/usr/sap/<SID>/cohesity
```

Uninstall the SAP on Oracle Connector

To uninstall the SAP on Oracle Connector:

1. Log on to the SAP on Oracle host where you have installed the SAP on Oracle Connector.
2. Run the following command to uninstall the SAP on Oracle Connector:

   ```
   ./cohesity_secure_connector_service_6.6.0b_ent_sap_oracle_java_
   installer
   -- -u -I <install_directory> -s <sid> -w uda
   ```

The following is a sample output of the successful uninstallation:

```

Upgrade the SAP on Oracle Connector

To upgrade the SAP on Oracle Connector, run the following command on the SAP on Oracle hosts:

```
./cohesity_secure_connector_service_6.6.0b_ent_sap_oracle_java_installer
-- -n -I <install_directory> -s <sid> -w uda
```

After you have upgraded the SAP on Oracle Secure Connector, log on to the SAP on Oracle host as root user and create a soft link to uda_scripts using the following command:

```
chmod -R 755 /opt/cohesity ln -sf
/home/ora<sid>/uda_install/uda_scripts
/opt/cohesity/agent/uda_scripts
```

Register and Manage the SAP on Oracle for Linux Source

To protect your SAP on Oracle databases, you need to register your SAP on Oracle deployment as a source on Cohesity. After registering your SAP on Oracle deployment as a source, you can:

- Update the username and password of the database user.
- Refresh the source details.
- Unregister the SAP on Oracle source from Cohesity.

Register SAP on Oracle as a Source

Before you register SAP on Oracle as a source, ensure that you:

- Review the requirements and limitations.
- Perform the prerequisite tasks.

For more information, see Plan and Prepare for SAP on Oracle for Linux Protection.

To register SAP on Oracle as a source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the **Register** on the top-right of the page and then select **Universal Data Adapter**.
3. In the **Register Universal Data Adapter** page, perform the following:
    1. From the **Source Type** drop-down menu, select **SAP Oracle**.
    2. From the **Host OS Type** drop-down menu, select **Linux**.
    3. In the **Hostname / IP Addresses** field, enter the hostname or IP address of the SAP on the Oracle host you have identified to run the secure connector service for SAP Oracle. For more information, see Plan and Prepare for SAP on Oracle for Linux Protection.
    4. In the **Datasource Agent Installation Path**, enter the directory path on the SAP on Oracle host, where you have installed the secure connector service for SAP Oracle. For more information, see Download and Install the SAP on Oracle Connector.
    5. In the **APP Authentication** section, provide the SAP on Oracle database's Username and Password.

        > **Note:** The Password field is optional.

    6. Enable **Custom Options**, and perform the following:
        1. Ignore the **Mounts View** option. It is not applicable for SAP on Oracle source registration.
        2. Ignore the **Source Registration Options**. It is not applicable to SAP on Oracle registration.
    7. Click **Register**.

Update the SAP on Oracle Source Configuration

After registering your SAP on Oracle as a source on Cohesity, you can:

- Update the username and password of the database user.
- Update the Script Directory Path only if you have uninstalled and reinstalled the secure connector service for SAP Oracle in a different directory on the SAP on Oracle host.

To update the SAP on Oracle source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the SAP on Oracle source and select **Edit**.
3. On the **Update Universal Data** Adapter page, update the required configurations.
4. Click **Update**.

Refresh the SAP on Oracle Source Configuration

You can refresh the SAP on Oracle Source and re-verify the source with the available source registration parameters.

To refresh the SAP on Oracle Source Configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the SAP on Oracle Source and select **Refresh**.

Unregister the SAP on Oracle Source

If you plan to stop taking the backup of your SAP on Oracle databases, you can unregister the SAP on Oracle source from the Cohesity Cluster.

To unregister the SAP on Oracle source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the SAP on Oracle source and select **Unregister**.

Backup SAP on Oracle for Linux Database

Cohesity provides a simple workflow to back up your SAP on Oracle databases. After registering the SAP on Oracle as a source on Cohesity, you can start configuring your backups.

Backup Process

Cohesity provides a SAP on Oracle Connector for backup and restore of enterprise SAP on Oracle deployments. The SAP on Oracle Connector leverages the backup capabilities provided by SAP.

After registering the SAP on Oracle source on Cohesity, you can create a Protection Group and specify the objects such as databases and tables that you want to backup. In the Protection Group, you need to define the parameters that enable you to provide additional parameters required by the backup statements provided by SAP on Oracle.

> **Note:** Cohesity recommends that you configure periodic full backups.

Backup Parameters

In the Protection Group, you can define the following parameters for your SAP on Oracle backup configuration:

Backup Parameters	Mandatory?	Description
`--use-secure-grpc=<true/false>`	Optional	Set the parameter to true, if you want to use secure gRPC communication during backup. For example: `--use-secure-grpc=true` > **Note:** It is **mandatory** to connect to the Cohesity cluster securely using secure gRPC when writing or reading data.
`--sap-certificate-path=<cert_file_path>`	Optional	Specify the path of the self-signed certificate if you want to use it for secure gRPC communication during backups. For example: `--sap-certificate-path=/tmp/certs/sap_cert1837348343.cfg`
`--sbt-certificate-file=<cert_file_path>`	Optional	Specify the path of the self-signed certificate if you want to use it for secure gRPC communication during backups. For example: `--sbt-certificate-file=/tmp/cert.cfg`

Protect SAP on Oracle for Linux Deployments

SAP on Oracle deployments is protected using a Protection Group and a Protection Policy. A Protection Group enables you to specify the objects such as databases and tables that you want to back up.

The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select which standard or custom policy to use when creating a Protection Group. For more information, see About Policies and Protection Groups.

To protect SAP on Oracle deployments:

1. Do one of the following:
    1. Select **Data Protection** > **Protection**. Click Protect on the top-right of the page and then select **Universal Data Adapter**.
    2. Select **Data Protection** > **Source**. Click the actions menu (⋮) next to the SAP on Oracle source and then select **Protect**.
2. From the **Source** drop-down list, select the registered SAP on Oracle source or click **Register Source** to register an SAP on Oracle source. For more information, see Register SAP on Oracle as a Source.
3. In the **Objects** section, add the object that you plan to protect. The object can be a database or a table. To back up a database, enter the name of the database.
4. In the **Protection Group** section, do one of the following:
    1. Select a **New Group** to create a new Protection Group. In the **Protection Name** field, enter a name from the Protection Group.
    2. Select **Existing Group** to use the settings of an existing Protection Group. From the Group list, select an existing Protection Group and click Protect.
5. In the **Settings** section, do the following:
    1. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains.
    2. In the **Start Time** field, define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard.

       Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
    3. In the **Custom Options** section, you need not add any backup parameters. If you want to use secure gRPC communication during backup, enter the respective Backup Parameters.

       For advanced log backup use cases, you can provide the BRARCHIVE command options in the **Log Backup** field. By default, the BRARCHIVE command option for -o parameter is `-cds | -copy_delete_save`.

       ```
       -o <brarchive_command_option>
       ```
    4. In the **Mounts** field. Select the number of mounts for the SAP on the Oracle host.

       > **Note:** Cohesity recommends that the number of mounts is equal to the number of nodes or Hybrid Extenders.

5. After you have completed the **Settings** configuration, if you need to change any additional settings on the **New Universal Data Adapter Protection Group** page, scroll down and click **Edit** on the right. For more information, see Additional Settings below.
6. Click **Protect**.

Additional Settings

Additional Settings	Description
Pause Future Run	Enable Pause Future Run only if you do not want to schedule future runs of the Protection Group.
End Time	Optional. Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts before this date runs until completion even if it completes after this date.
QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup Target HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup Target SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Concurrency	The maximum number of restore streams that are created to exchange data with the cluster. By default, maximum scaling is set to 16. **Note:** Cohesity recommends that concurrency should be set to the number of nodes on the Cohesity cluster.

Additional Settings	Description
Alerts	Optional. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection groups exceeds the ability to process protection groups, this will be the priority of implementation of the protection groups: • High-priority protection groups • Medium-priority protection groups • Low-priority protection groups.
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).
Description	Optional. Enter a brief description of the Protection Group.

Manage the SAP on Oracle for Linux Backup Configuration

In the Cohesity Platform, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups associated with the Protection Policy. You

can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group in the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the Protection page, select the Protection Group that you had created for SAP on Oracle.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the Protection page, select the Protection Group that you had created for SAP on Oracle.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the Protection page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a protection run:

1. Navigate to **Data Protection** > **Protection**.
2. Click the action menu (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups, local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group, the reclaimed storage space details will not be displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the Protection page, select the Protection Group that you had created for SAP on Oracle.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    1. Delete Protection Group Only
    2. Delete Protection Group and Snapshots

Recover SAP on Oracle for Linux Database

You can restore the SAP on Oracle host or object(s) such as databases in SAP on Oracle deployment. You can restore to the same SAP on the Oracle host or a different host. The SAP on Oracle Connector leverages the restore capabilities provided by SAP.

You can create a Recovery configuration and specify the objects such as databases backed up using the Protection Group.

Prerequisites

Ensure that:

- The Oracle Database state should be `nomount` state when performing alternate or cross restores.
- The Protection Group associated with the object that you plan to restore is paused or in not running state.
- If you perform an alternate restore, ensure the SAP on Oracle versions on the source and the target host are the same.

Recovery Parameters

In the Recovery configuration, you can define the following script parameters for your SAP on Oracle recovery:

Recovery Parameters	Mandatory?	Description
`--use-secure-grpc=<true/false>`	Optional	Set the parameter to true, if you want to use secure gRPC communication during restore. For example: `--use-secure-grpc=true`
`--sap-certificate-path=<cert_file_path>`	Optional	Specify the path of the self-signed certificate if you want to use it for secure gRPC communication during restore. For example: `--sap-certificate-path=/tmp/certs/sap_cert1837348343.cfg`
`--sbt-certificate-file=<cert_file_path>`	Optional	Specify the path of the self-signed certificate if you want to use it for secure gRPC communication during restore. For example: `--sbt-certificate-file=/tmp/cert.cfg`

Recover SAP on Oracle for Linux Databases

To restore SAP on Oracle deployments:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **Universal Data Adapter**.
3. Search for the Protection Group that contains the snapshots to recover from by entering characters of the Protection Group name, or by specifying the wildcard character *.
4. From the list of search results, select the Protection Group that contains the snapshots to recover.
5. In the **Object** field, enter the name of the database or table that you had backed up using the selected Protection Group. By default, the latest snapshot is selected for

recovery.

6. Accept the latest Recovery Point or click the change icon and select a different recovery point.
    1. **Snapshots**: Select a different recovery point. You can change the time zone before or after selecting a new restore time.
    2. **Point in Time**: Use the slide control to adjust the date and time and click Save.
7. Click **Next: Recover Options**.
8. In the **Recover As** section, select one of the following.
    - **Replace Original**: To restore to the same SAP on Oracle host.
    - **New Object**: To restore to a different SAP on Oracle host, do the following:
        - Select the **Target** SAP on the Oracle host to which the data needs to be restored.
        - Enable **Overwrite existing object with the same name** toggle option to overwrite the existing data.
9. In the **Recovery Options** section, based on your requirements, select any one of the following options:
    - **Mounts**: Select the number of mounts for the SAP on the Oracle host.
    - **Concurrency**: The maximum number of restore streams that are created to exchange data with the cluster. By default, maximum scaling is set to 1.

      > **Note:** Cohesity recommends that concurrency should be set to the number of nodes on the Cohesity cluster.

    - **Custom Options**: Specify the parameters based on your requirements. See Sample Recovery Use Cases for examples.

      > **Note:** if you want to use it for secure gRPC communication during restore, ensure that you use the appropriate recovery parameter.

    - **Rename**: Provide the new name for the database, if you want to restore the database with a new name.
    - **Task Name**: Change the default name of the recovery task.
10. Click **Recover**.

Sample Recovery Use Cases

Use Case	Instructions with Sample Parameters
Overwrite Point In Time Restore (PITR) to the same SAP on Oracle database.	In the **Recover As** section, select **Replace Original**. Under the **Recovery Options** section, does not specify any parameters in the **Custom Options** field.
Restore specific data backup from the snapshot to the same SAP on Oracle database.	In the **Recover As** section, select **Replace Original**. Under the **Recovery Options** section, does not specify any parameters in the **Custom Options** field.
Point In Time Restore (PITR) to a different SAP on Oracle host with the same database name.	Perform the following: 1. In the **Recover As** section, select **New Object** and choose the target source name in the **Target** dropdown. 2. Under the **Recovery Options** section, do not specify any parameters in the **Custom Options** field. 3. Specify the existing database name in the **Rename** field.
Restore specific data backup from the snapshot to the different SAP on Oracle host with the same database name.	Perform the following: 1. In the **Recover As** section, select **New Object** and choose the target source name in the **Target** dropdown. 2. Under the **Recovery** Options section, do not specify any parameters in the **Custom Options** field. 3. Specify the existing database name in the **Rename** field.

Use Case	Instructions with Sample Parameters

Point In Time Restore (PITR) to a different SAP on Oracle host with different database name.	Perform the following:
	1. In the **Recover As** section, select **New Object** and choose the target source name in the **Target** dropdown.
	2. Under the **Recovery Options** section, do not specify any parameters in the **Custom Options** field.
	Note:
	If the source database does not have the `SAPDATA_HOME` with the format `/oracle/SID`, then provide the source database `SAPDATA_HOME` path using the following parameter in the **Custom Options** field.
	`-h | --source-sapdata-home`
	For example: If the source database `SAPDATA_HOME` path is `/usr/sap/oracle/SID` then you pass the following arugment in the **Custom Options** field:
	`-h /usr/sap/oracle/SID`
	3. Specify the existing database name in the **Rename** field.

Use Case	Instructions with Sample Parameters

Restore specific data backup from the snapshot to the different SAP on Oracle host with different database name.	Perform the following:
	1. In the **Recover As** section, select **New Object** and choose the target source name in the **Target** dropdown.
	2. Under the **Recovery** Options section, do not specify any parameters in the **Custom Options** field.
	Note:
	If the source database does not have the `SAPDATA_HOME` with the format `/oracle/SID`, then provide the source database `SAPDATA_HOME` path using the following parameter in the **Custom Options** field.
	`-h | --source-sapdata-home`
	For example: If the source database `SAPDATA_HOME` path is `/usr/sap/oracle/SID` then you pass the following arugment in the **Custom Options** field:
	`-h /usr/sap/oracle/SID`
	3. Specify the existing database name in the **Rename** field.

Use Case	Instructions with Sample Parameters
Restore the SAP on Oracle instance to its original host, but assign it a new SID. Ensure that the original database is not overwritten during this process.	For example, consider an instance named `XR1` on `dbhost1` that has been successfully backed up. If you want to restore it as a new instance on the same host, follow these steps before starting the restore process: 1. Ensure the new instance already exists on the original host or create it manually. 2. Since Cohesity protects SAP on Oracle at the instance level, install the SAP on Oracle connector for the new instance (SID). For details, see Install the SAP on Oracle Connector. 3. Register the new SAP on Oracle instance as a source. For more information, see Register SAP on Oracle as a Source. To restore the backup to the new SID on the original host: 1. Recover the `XR1` instance to a new object. • In the **Recover As** section, select **New Object** and choose the newly registered source from the **Target** dropdown. • Enable the **Overwrite existing object with the same name** option. 2. In the **Recovery Options** section, leave the **Custom Options** field empty. 3. Specify the new SID name in the **Rename** field.

Cancel a Recovery Run

When you cancel a recovery run, the SAP on Oracle Connector leverages the Cancel-Job capabilities provided by SAP on Oracle.

To cancel a recovery run:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click the action menu (⋮) next to the recovery run and click **Cancel Run**.
3. In the **Cancel Recovery** dialog box, select any one of the following:
    1. Click **Continue Recovery** if you want to continue a recovery run.
    2. Click **Cancel Recovery** if you want to cancel the recovery run.

SAP on Oracle for Microsoft Windows

Cohesity natively integrates with SAP on Oracle to provide backup and recovery for SAP on Oracle deployments running on the Microsoft Windows platform. Using Cohesity Connector Agent, you can backup and restore the SAP on Oracle databases. The Cohesity Connector Agent provides a simple workflow to back up and restore your SAP on Oracle deployment.

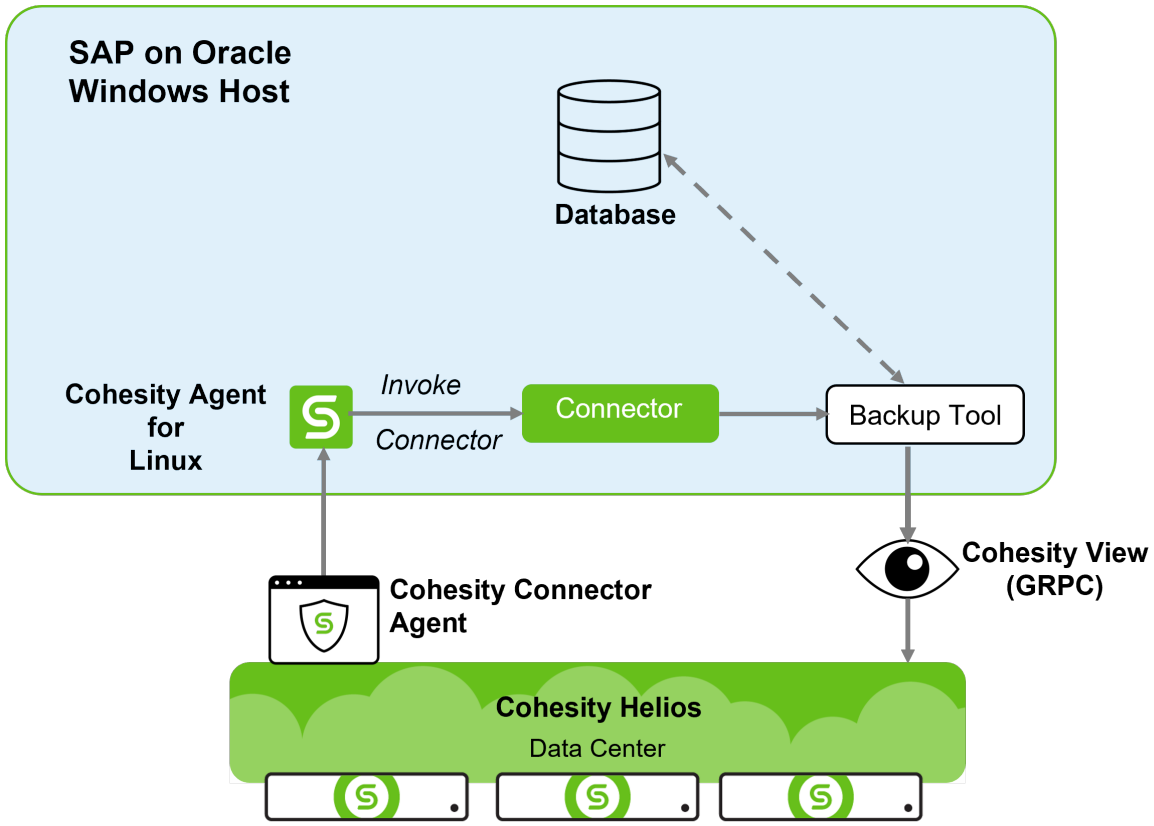
Cohesity provides an SAP on Oracle connector that enables you to perform a full backup, incremental (differential) backup, log backup, restore and point in time restore at the database level.

Core Components

The following are the core components for protecting SAP on Oracle databases:

- Oracle Database
- Cohesity SAP on Oracle Connector
- Cohesity Connector Agent
- Cohesity View

As illustrated, you can integrate Cohesity with your SAP on Oracle deployments using the SAP on Oracle connector and Cohesity Connector Agent.



Plan and Prepare for SAP on Oracle for Windows Protection

Before you register your SAP on Oracle deployment as a source with Cohesity, ensure the following prerequisites:

- The user account of the SAP on Oracle instance must have database admin privileges.
- Download and install the Cohesity Windows Agent on the SAP on Oracle host.
- Download and install the Cohesity SAP on the Oracle Connector on the SAP on Oracle host using the same user account that you used to install the Cohesity Windows Agent.

Supported Versions

For more information on supported SAP on Oracle versions, see Supported Software versions.

Considerations

Review and understand the following before you protect your Oracle database:

- Automatic database creation is not supported. You need to create a database before running either backup or restore.
- In a protection run, you cannot back up multiple objects.
- In a recovery run, you cannot restore multiple objects.
- Cross-platform (Windows to Linux or vice versa) backup and restore are not supported.
- SAP on Oracle Connector agent does not support auto-discovery and entity hierarchy; hence you cannot browse or search and select objects for backup.
- Indexing is not supported.
- Offline backup of the database is not supported.
- You cannot protect multiple hosts using a single Protection Group.
- You cannot backup multiple databases in a single Protection Group.
- You cannot restore multiple objects, search and recover an object.
- You cannot cancel a running restore operation.
- SAP Oracle ASM deployment is not supported.
- Ensure that the SAP on Oracle DB instance uses an SPFILE to start up as recommended by SAP. For more information, see https://me.sap.com/notes/1598594.
- It is **mandatory** to connect to the Cohesity cluster securely using secure gRPC when writing or reading data.

Allowlist the SAP on Oracle Windows Host IP address

To provide effective authorization and prevent rogue access to the Cohesity cluster, the SAP on Oracle Windows host IP address must be whitelisted in the Cohesity view configuration.

To allowlist the SAP on Oracle Windows host IP address:

1. Navigate to **File Services** > **Views**.
2. Click the **Global Settings** tab.
3. Under **Global Subnet Allowlist**, click the **+Add** button.
4. In the **Add Allowlist** dialog box, perform the following:
    1. In the **Server** field, enter the SAP on the Oracle host IP address.
    2. Select **Read/Write** for **SMB Permissions**.
    3. Select **None** for **NFS Squash**.
    4. In the **Description** field, enter a brief description.
    5. Click **Add**.

Download and Install the Cohesity Windows Agent

The Cohesity Windows Agent is available as an executable installer. Download this installer and install it accordingly on the SAP on Oracle host to be protected. For detailed instructions, see Download and Install the Windows Agent.

> **Note:** Ensure that you:
> - Install the Cohesity Windows Agent using the `<SID>adm` user account.
> - Select **Oracle SBT Library** as an add-on component in the Cohesity Windows Agent installer.

Download and Install the SAP on Oracle Connector

Cohesity provides a SAP on Oracle Connector to backup and restore SAP on Oracle databases. The SAP on Oracle Connector is available as a datasource agent on the Cohesity Download portal. Log on to the Cohesity Download portal, download the respective datasource agent for SAP on Oracle Connector, and copy the datasource agent to the SAP on Oracle host.

Install the Cohesity SAP on Oracle Connector

On the SAP on Oracle host where you have copied the SAP on Oracle Connector (`Cohesity_SAP_Oracle_connector_<version>_Installer.exe`), perform the following to install the SAP on Oracle Connector.

Prerequisites

Before you install the SAP on Oracle Connector, ensure that:

- The environment variables SAPDATA_HOME and ORACLE_HOME are set for the user performing the installation.
- You have Installed java runtime environment (JRE) version 1.8 (64-bit) or above on the SAP on Oracle host.
- The Cohesity cluster and the SAP on Oracle source are on the same NTP server.
- The BRTOOLS are pre-installed on the SAP on Oracle System. The Cohesity SAP on Oracle Connector integrates with BRTOOLS for backup and restore. SAP recommends BRTOOLS version 7.40 Patch 46 or greater. For more information, see more information, refer https://launchpad.support.sap.com/#/notes/3060252.
- Ensure that the NTP time is in sync between the client and the Cohesity cluster.

To install the SAP on Oracle Connector:

1. Log on to the SAP on the Oracle node where you have copied the Cohesity SAP on Oracle Connector installer executable, `Cohesity_SAP_Oracle_connector_<version>_Installer.exe`. Ensure that you are logged in as the same user with which you installed the Cohesity Windows agent.
2. Double-click on the Cohesity SAP on the Oracle Connector installer and follow the instructions.

Silently Install the SAP on Oracle Connector

After you have downloaded the SAP on Oracle Connector, you can perform a silent installation of the Cohesity SAP on Oracle Connector.

To perform the silent installation:

1. Log on to the SAP on the Oracle node where you have copied the Cohesity SAP on Oracle Connector installer executable, `Cohesity_SAP_Oracle_connector_<version>_Installer.exe`. Ensure that you are logged in as the same user with which you installed the Cohesity Windows agent.
2. Using the command-line interface, navigate to the directory where you have copied the Cohesity SAP on Oracle Connector installer executable, `Cohesity_SAP_Oracle_connector_<version>_Installer.exe`.
3. Use the following command for the silent installation:

   ```
   <InstallerExeFile> [/log="<absolute-path-to-log-file>"]
   [/dir="<absolute-path-to-install-location>"] [/silent, /verysilent]
   [/suppressmsgboxes] [/norestart]
   ```

   Where:

   - `/log="<absolute-path-to-log-file>"` - Records the events during installation and helps to debug the errors, if any, during the installation process.

- `/silent` - Suppresses the installation wizard and background window. Instead, it only displays the installation progress window.
- `/verysilent` - Suppresses the installation progress window.
- `/suppressmsgboxes` - Suppresses any message boxes if `/verysilent` is specified.
- `/norestart` - Prevents the setup from restarting the system following a successful installation, or after a Preparing to Install failure that requests a restart.
- `/dir="<absolute-path-to-install-location>"` - Specify the directory path where the SAP Oracle Connector for Windows should be installed.

  > **Note:** The installer creates the necessary folders if they do not exist. If this parameter is not specified, the SAP Oracle Connector is installed in the default directory path: `"%SystemDrive%\Program Files\Cohesity\SAP Oracle"`.

Sample:

```
Cohesity_SAP_Oracle_connector_<version>_Installer.exe
/log="C:\tmp\install_logs.txt" /verysilent /suppressmsgboxes /norestart
```

Upgrade the SAP on Oracle Connector

Before you upgrade the SAP on Oracle Connector, ensure that you pause the existing protection runs.

To upgrade the SAP on Oracle Connector:

1. Log on to the SAP on the Oracle node where you have copied the Cohesity SAP on Oracle Connector installer executable, `Cohesity_SAP_Oracle_connector_<version>_Installer.exe`. Ensure that you are logged in as the same user with which you installed the Cohesity Windows agent.
2. Double-click on the Cohesity SAP on the Oracle Connector installer, and when prompted, select **Upgrade** and follow the instructions.

Silently Upgrade the SAP on Oracle Connector

Before you upgrade the SAP on Oracle Connector, ensure that you pause the existing protection runs.

To silently upgrade the SAP on Oracle Connector, use the following command:

```
<InstallerExeFile> [/log="<absolute-path-to-log-file>"] [/dir="<absolute-
path-to-install-location>"] [/silent, /verysilent] [/suppressmsgboxes]
[/norestart]
```

1. Where:
   - `/log="<absolute-path-to-log-file>"` - Records the events during the upgrade and helps to debug the errors, if any, during the upgrade process.
   - `/silent` - Suppresses the upgrade wizard and background window. Instead, it only displays the upgrade progress window.
   - `/verysilent` - Suppresses the upgrade progress window.
   - `/suppressmsgboxes` - Suppresses any message boxes if `/verysilent` is specified.
   - `/norestart` - Prevents the setup from restarting the system following a successful upgrade or after a Preparing to upgrade failure that requests a restart.
   - `/dir="<absolute-path-to-install-location>"` - Specify the directory path where the SAP Oracle Connector is installed.

   Sample:

   ```
   Cohesity_SAP_Oracle_connector_<version>_Installer.exe
   /log="C:\tmp\upgrade_logs.txt" /verysilent /suppressmsgboxes /norestart
   ```

Uninstall the SAP on Oracle Connector

To uninstall the Cohesity SAP on Oracle Connector:

1. Log on to the SAP on the Oracle host.
2. Select the **Start** menu and look for the **SAP on Oracle Connector** in the list shown.
3. Press and hold (or right-click) on the SAP on Oracle Connector, then select **Uninstall**.

Silently Uninstall the SAP on Oracle Connector

To perform silent uninstallation:

1. Log on to the SAP on the Oracle host.
2. Using the command-line interface, navigate to the directory where you have installed the Cohesity SAP on Oracle Connector, For example, `C:\Program Files\Cohesity\SAP Oracle\Installer\`.

> **Note:** The details of the uninstaller executable are available in the registry value "HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Uninstall\{CCEC1E9A-895C-4038-8CC9-31BBD31B9CA7}_is1\UninstallString". The default value is "C:\Program Files\Cohesity\SAP Oracle\Installer\unins000.exe", assuming C: is the default operating system installation volume and "C:\Program Files\Cohesity\SAP Oracle" is the default SAP Oracle Connector installation path.

3. Use the following command for the silent uninstallation:

```
<UninstallerExeFile>  [/log="<absolute-path-to-log-file>"] [/silent, /verysilent] [/suppressmsgboxes] [/norestart] [/preservesettings]
```

Where:

- /log="<absolute-path-to-log-file>" - Records the events during the uninstallation process and helps to debug the errors, if any, during the uninstallation process.
- /silent - Suppresses the uninstallation wizard and background window. Instead, it only displays the uninstallation progress window.
- /verysilent - Suppresses the uninstallation progress window.
- /suppressmsgboxes - Suppresses any message boxes if /verysilent is specified.
- /norestart - Prevents the setup from restarting the system following a successful uninstallation.
- [/preservesettings] - Preserve the registry settings when uninstalling the SAP Oracle Connector.

> **Note:** Uninstalling the SAP Oracle Connector clears registration settings from the registry. You can preserve the registration settings in the registry by using the /preservesettings flag when uninstalling from the command line. Preserving registry settings are not supported when uninstalling from the GUI.

Sample:

```
unins000.exe /log="C:\tmp\uninstall_logs.txt" /verysilent /suppressmsgboxes /norestart
```

Register and Manage the SAP on Oracle for Windows Source

To protect your SAP on Oracle databases, you need to register your SAP on Oracle deployment as a source on Cohesity. After registering your SAP on Oracle deployment as a source, you can:

- Update the username and password of the database user, if you connect to the database using password-based authentication.
- Refresh the source details.
- Unregister the SAP on Oracle source from Cohesity.

Register SAP on Oracle as a Source

Before you register SAP on Oracle as a source, ensure that you:

- Review the requirements and limitations.
- Perform the prerequisite tasks.

For more information, see Plan and Prepare for SAP on Oracle for Windows Protection.

To register SAP on Oracle as a source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the **Register** on the top-right of the page and then select **Universal Data Adapter**.
3. In the **Register Universal Data Adapter** page, perform the following:
    1. From the **Source Type** drop-down menu, select **SAP Oracle**.
    2. From the **Host OS Type** drop-down menu, select **Windows**.
    3. In the **Hostname / IP Addresses** field, enter the hostname or IP address of the SAP on the Oracle host you have identified to run the SAP on Oracle Connector. For more information, see Plan and Prepare for SAP on Oracle for Windows Protection.
    4. In the **Datasource Agent Installation Path**, enter the directory path on the SAP on Oracle host, where you have installed the SAP on Oracle Connector. For more information, see Install the Cohesity SAP on Oracle Connector.
    5. In the **APP Authentication** section, provide the SAP on the Oracle database's **Username** and **Password**.

        > **Note:** The **Password** field is optional.

    6. Enable **Custom Options**, and perform the following:
        1. Ignore the **Mounts View** option. It is not applicable for SAP on Oracle source registration.

2. In the **Source Registration Options** field, enter the following optional source registration parameters in a space-separated format based on your requirement:

   ```
   --source-name=<unique_name_of_your_choice>
   ```

   If you do not define the source name using the parameter, the default hostname is used as the source name.

7. Click **Register**.

Update the SAP on Oracle Source Configuration

After registering your SAP on Oracle as a source on Cohesity, you can:

- Update the username and password of the database user.
- Update the **Datasource Agent Installation Path** only if you have uninstalled and reinstalled the SAP on Oracle Connector in a different directory on the SAP on Oracle host.

To update the SAP on Oracle source configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the SAP on Oracle source and select **Edit**.
3. On the **Update Universal Data** Adapter page, update the required configurations.
4. Click **Update**.

Refresh the SAP on Oracle Source Configuration

You can refresh the SAP on Oracle Source and re-verify the source with the available source registration parameters.

To refresh the SAP on Oracle Source Configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the SAP on Oracle Source and select **Refresh**.

Unregister the SAP on Oracle Source

If you plan to stop taking the backup of your SAP on Oracle databases, you can unregister the SAP on Oracle source from Cohesity.

To unregister the SAP on Oracle source:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the SAP on Oracle source and select **Unregister**.

Backup SAP on Oracle for Windows Database

Cohesity provides a simple workflow to back up your SAP on Oracle databases. After registering the SAP on Oracle as a source on Cohesity, you can start configuring your backups.

Backup Process

Cohesity provides a SAP on Oracle Connector for backup and restore of enterprise SAP on Oracle deployments. The SAP on Oracle Connector leverages the backup capabilities provided by SAP.

After registering the SAP on Oracle source on Cohesity, you can create a Protection Group and specify the objects such as databases and tables that you want to backup. In the Protection Group, you need to define the script parameters that enable you to provide additional parameters required by the backup statements provided by SAP on Oracle.

> **Note:** Cohesity recommends that you configure periodic full backups.

Backup Parameters

In the Protection Group, you can define the following parameters for your SAP on Oracle backup configuration:

Backup Parameters	Mandatory?	Description
`--use-secure-grpc=<true/false>`	Optional	Set the parameter to true, if you want to use secure gRPC communication during backup. For example: `--use-secure-grpc=true` > **Note:** It is **mandatory** to connect to the Cohesity cluster securely using secure gRPC when writing or reading data.
`--sap-certificate-path=<cert_file_path>`	Optional	Specify the path of the self-signed certificate if you want to use it for secure gRPC communication during backups. For example: `--sap-certificate-path=/tmp/certs/sap_cert1837348343.cfg`
`--sbt-certificate-file=<cert_file_path>`	Optional	Specify the path of the self-signed certificate if you want to use it for secure gRPC communication during backups. For example: `--sbt-certificate-file=/tmp/cert.cfg`

Troubleshooting Backup Error

Issue: Log backup fails with the following error:

```
BR0013W No offline redolog files found for processing
```

Problem: The issue occurs when the Oracle database is opened after recovery with `ALTER DATABASE OPEN RESETLOGS`, and the "`log sequence number`" is reset to `1`. However, since the BRARCHIVE log arch<SID>.log in the directory `$ORACLE_HOME/saparch` still contains entries for successful archive log backups with higher numbers. BRARCHIVE does not recognize the new logs as the logs to be saved.

Workaround: To mitigate this issue, refer to the following SAP recommendation:

- https://me.sap.com/notes/490976 (refer to step 4. Database was reset with RESET LOGS)
- https://me.sap.com/notes/10170

Protect SAP on Oracle SAP on Oracle for Windows Deployments

SAP on Oracle deployments is protected using a Protection Group and a Protection Policy. A Protection Group enables you to specify the objects such as databases and tables that you want to backup.

The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select which standard or custom policy to use when creating a Protection Group. For more information, see About Policies and Protection Groups.

To protect SAP on Oracle deployments:

1. Do one of the following:
    1. Select **Data Protection** > **Protection**. Click Protect on the top-right of the page and then select **Universal Data Adapter**.
    2. Select **Data Protection** > **Source**. Click the actions menu (⋮) next to the SAP on Oracle source and then select **Protect**.
2. From the **Source** drop-down list, select the registered SAP on Oracle source or click **Register Source** to register an SAP on Oracle source. For more information, see Register SAP on Oracle as a Source.
3. In the **Objects** section, enter the name of the database that you plan to protect.
4. In the **Protection Group** section, do one of the following:
    1. Select a **New Group** to create a new Protection Group. In the **Protection Name** field, enter a name from the Protection Group.

2. Select **Existing Group** to use the settings of an existing Protection Group. From the Group list, select an existing Protection Group and click Protect.

5. In the **Settings** section, do the following:
    1. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains.
    2. In the **Start Time** field, define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard.

       Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
    3. In the **Custom Options** section, you need not add any backup parameters. By default, the BRARCHIVE command option for `-o` parameter is `-cds | -copy_delete_save`. That is, in the case of log backups, it does not delete offline redo log files from the hosts that have been saved once in the Cohesity cluster. You can override the default BRARCHIVE command option by providing the BRARCHIVE command options in the **Log Backup** field as follows:

       ```
       -o=<brarchive_command_option>
       ```

       > **Note:** If you want to use secure gRPC communication during backup, enter the respective backup parameter.

    4. In the **Mounts/VIPs** field. Select the number of mounts or VIPs for the SAP on Oracle host.

       > **Note:** Cohesity recommends that the number of mounts is equal to the number of nodes or Hybrid Extenders.

    5. After you have completed the **Settings** configuration, if you need to change any additional settings on the **New Universal Data Adapter Protection Group** page, scroll down and click **Edit** on the right. For more information, see Additional Settings below.
6. Click **Protect**.

Additional Settings

Additional Settings	Description
Pause Future Run	Enable Pause Future Run only if you do not want to schedule future runs of the Protection Group.
End Time	Optional. Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts before this date runs until completion even if it completes after this date.
QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup Target HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup Target SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Concurrency	Define the concurrency or number of channels to use for exchanging data with the cluster. For SAP on Oracle data protection on Windows, the concurrency depends on the SAP on Oracle license. • For Standard editions, only a single channel is supported. • For Enterprise editions, more than one channel is supported.
Alerts	Optional. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.

Additional Settings	Description
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection groups exceeds the ability to process protection groups, this will be the priority of implementation of the protection groups: • High-priority protection groups • Medium-priority protection groups • Low-priority protection groups.
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).
Description	Optional. Enter a brief description of the Protection Group.

Manage the SAP on Oracle for Windows Backup Configuration

A backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group in the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the Protection page, select the Protection Group that you had created for SAP on Oracle.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the Protection page, select the Protection Group that you had created for SAP on Oracle.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection** > **Protection**.
2. On the Protection page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a protection run:

1. Navigate to **Data Protection** > **Protection**.
2. Click the action menu (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups, local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group, the reclaimed storage space details will not be displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. Navigate to **Data Protection** > **Protection**.
2. On the Protection page, select the Protection Group that you had created for SAP on Oracle.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    1. **Delete Protection Group Only**
    2. **Delete Protection Group and Snapshots**

Recover SAP on Oracle for Windows Database

You can restore the SAP on Oracle host or object(s) such as databases in SAP on Oracle deployment. You can restore to the same SAP on the Oracle host or a different host. The SAP Oracle Connector leverages the restore capabilities provided by SAP.

You can create a Recovery configuration and specify the objects such as databases backed up using the Protection Group.

Prerequisites

Ensure that:

- The Protection Group associated with the object that you plan to restore is paused or in not running state.
- If you perform an alternate restore, ensure the SAP on Oracle versions on the source and the target host are the same.

Recovery Parameters

In the Recovery configuration, you can define the following script parameters for your SAP on Oracle recovery:

Recovery Parameters	Mandatory?	Description
`--use-secure-grpc=<true/false>`	Optional	Set the parameter to true, if you want to use secure gRPC communication during restore. For example: `--use-secure-grpc=true`
`--sap-certificate-path=<cert_file_path>`	Optional	Specify the path of the self-signed certificate if you want to use it for secure gRPC communication during restore. For example: `--sap-certificate-path=/tmp/certs/sap_cert1837348343.cfg`
`--sbt-certificate-file=<cert_file_path>`	Optional	Specify the path of the self-signed certificate if you want to use it for secure gRPC communication during restore. For example: `--sbt-certificate-file=/tmp/cert.cfg`

Recover SAP on Oracle for Windows Database

To restore SAP on Oracle deployments:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **Universal Data Adapter**.
3. Search for the Protection Group that contains the snapshots to recover from by entering characters of the Protection Group name, or by specifying the wildcard character *.
4. From the list of search results, select the Protection Group that contains the snapshots to recover.
5. In the **Object** field, enter the name of the database or table that you had backed up using the selected Protection Group. By default, the latest snapshot is selected for recovery.
6. Accept the latest Recovery Point or click the change icon and select a different recovery point.
    1. **Snapshots**: Select a different recovery point. You can change the time zone before or after selecting a new restore time.
    2. **Point in Time**: Use the slide control to adjust the date and time and click Save.
7. Click **Next: Recover Options**.
8. In the **Recover As** section, select one of the following:

Options	Description
Replace Original	To restore to the same SAP on Oracle host.
New Object	To restore to a different SAP on Oracle host. Select the **Target** SAP on the Oracle host to which the data needs to be restored. Enable **Overwrite existing object with the same name** toggle option to overwrite the existing data.

9. In the **Recovery Options** section, based on your requirements, select any one of the following options:

Options	Description
Mounts	Select the number of mounts for the SAP on the Oracle host.
Concurrency	Define the concurrency or number of channels to use for exchanging data with the cluster. For SAP on Oracle data protection on Windows, the concurrency depends on the SAP on Oracle license. • For Standard editions, only a single channel is supported. • For Enterprise editions, more than one channel is supported.
Custom Options	Specify the recovery parameters based on your requirements. For examples, see Sample Recovery Use Cases. **Note:** if you want to use it for secure gRPC communication during restore, ensure that you use the appropriate recovery parameter.
Rename	Provide the new name for the object, if you want to restore the object with a new name.
Task Name	Change the default name of the recovery task.

10. Click **Recover**.

Sample Recovery Use Cases

Use Case	Instructions
Overwrite Point In Time Restore (PITR) to the same SAP on Oracle database.	In the **Recover As** section, select **Replace Original**. Under the **Recovery Options** section, does not specify any parameters in the **Custom Options** field.
Restore specific data backup from the snapshot to the same SAP on Oracle database.	In the **Recover As** section, select **Replace Original**. Under the **Recovery Options** section, does not specify any parameters in the **Custom Options** field.
Point In Time Restore (PITR) to a different SAP on Oracle host with the same database name.	Perform the following: 1. In the **Recover As** section, select **New Object** and choose the target source name in the **Target** dropdown. 2. Under the **Recovery Options** section, do not specify any parameters in the **Custom Options** field. 3. Specify the existing database name in the **Rename** field.
Restore specific data backup from the snapshot to the different SAP on Oracle host with the same database name.	Perform the following: 1. In the **Recover As** section, select **New Object** and choose the target source name in the **Target** dropdown. 2. Under the **Recovery** Options section, do not specify any parameters in the **Custom Options** field. 3. Specify the existing database name in the **Rename** field.

Use Case	Instructions

Point In Time Restore (PITR) to a different SAP on Oracle host with different database name.	Perform the following:
	1. In the **Recover As** section, select **New Object** and choose the target source name in the **Target** dropdown.
	2. Under the **Recovery Options** section, do not specify any parameters in the **Custom Options** field.
	> **Note:**
	If the source database does not have the `SAPDATA_HOME` with the format `/oracle/SID`, then provide the source database `SAPDATA_HOME` path using the following parameter in the **Custom Options** field.
	`-h | --source-sapdata-home`
	For example: If the source database `SAPDATA_HOME` path is `/usr/sap/oracle/SID` then you pass the following arugment in the **Custom Options** field:
	`-h /usr/sap/oracle/SID`
	3. Specify the existing database name in the **Rename** field.

Use Case	Instructions

Restore specific data backup from the snapshot to the different SAP on Oracle host with different database name.	Perform the following:
	1. In the **Recover As** section, select **New Object** and choose the target source name in the **Target** dropdown.
	2. Under the **Recovery** Options section, do not specify any parameters in the **Custom Options** field.
	> **Note:**
	If the source database does not have the `SAPDATA_HOME` with the format `/oracle/SID`, then provide the source database `SAPDATA_HOME` path using the following parameter in the **Custom Options** field.
	`-h | --source-sapdata-home`
	For example: If the source database `SAPDATA_HOME` path is `/usr/sap/oracle/SID` then you pass the following arugment in the **Custom Options** field:
	`-h /usr/sap/oracle/SID`
	3. Specify the existing database name in the **Rename** field.

Cancel a Recovery Run

When you cancel a recovery run, the SAP on Oracle Connector leverages the Cancel-Job capabilities provided by SAP on Oracle.

To cancel a recovery run:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click the action menu (⋮) next to the recovery run and click **Cancel Run**.
3. In the **Cancel Recovery** dialog box, select any one of the following:
    1. Click **Continue Recovery** if you want to continue a recovery run.
    2. Click **Cancel Recovery** if you want to cancel the recovery run.

PostgreSQL

Cohesity Platform natively integrates with PostgreSQL to provide backup and recovery for PostgreSQL deployments. Using Cohesity Connector Agent, you can backup and restore the PostgreSQL databases.

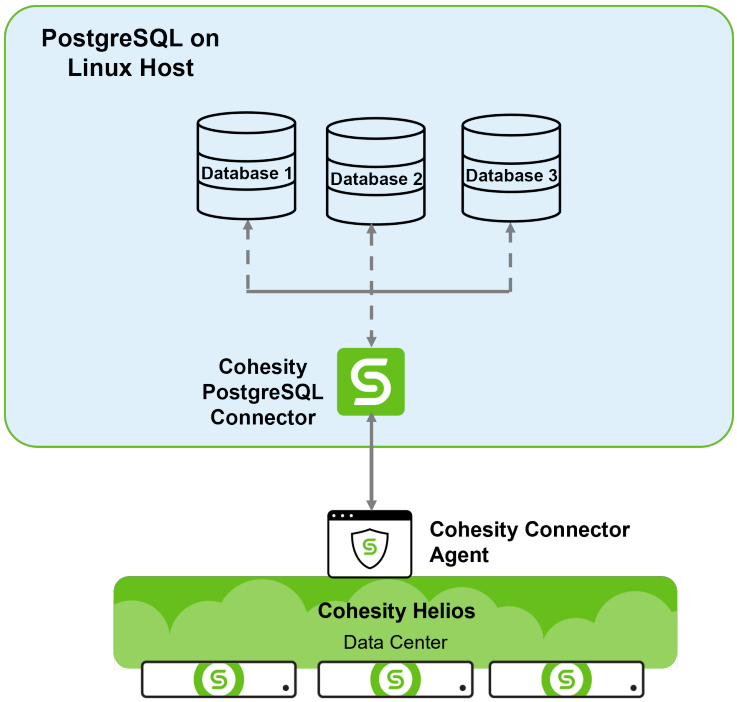
Cohesity Platform provides a PostgreSQL connector that enables you to perform a full backup, differential backup, log backup, restore and point in time restore at the cluster level.

Core Components

The following are the core components for protecting PostgreSQL databases:

- PostgreSQL Installation
- Cohesity PostgreSQL connector
- Cohesity Connector Agent

As illustrated, you can integrate the Cohesity Platform with your PostgreSQL deployments using the Cohesity PostgreSQL connector and Connector Agent.



Plan and Prepare for PostgreSQL Protection

Before registering your PostgreSQL deployment as a source with Cohesity Platform, ensure the following prerequisites:

- The user account of the PostgreSQL instance must have database admin privileges.
- Download and install the Cohesity Linux Agent RPM on the PostgreSQL host.
- Download and install the Cohesity PostgreSQL Connector RPM on the PostgreSQL host

- Cohesity provides a script to migrate existing PostgreSQL source to the new workflow. After running the script, the instances appear under **Data Protection** > **Sources** > **PostgreSQL**. For more information, see Migration script for New User Experience.
- Review and understand the limitations.

Supported Versions

For more information on supported PostgreSQL versions, see PostgreSQL versions.

Port Requirements

Outgoing Traffic

Source	Destination	Port	Protocol	Type of Traffic
Cohesity cluster	PostgreSQL Node	50051	TCP/IP	Control path for all workflows

Bidirectional Traffic

Source	Destination	Port	Protocol	Type of Traffic
PostgreSQL Local Host	PostgreSQL Local Host	59999	TCP/IP	Required only if local-to-local communication (used for self-monitoring and debugging purposes) is blocked by the firewall.

Incoming Traffic

Source	Destination	Port	Protocol	Type of Traffic
PostgreSQL Node	Cohesity cluster	11113	TCP/IP	Backup and Recovery
PostgreSQL Node	Cohesity cluster	11117	TCP/IP	Backup and Recovery with secure gRPC

Prerequisites

Ensure that:

- You use a root user or non-root user to install the Cohesity Linux agent and Cohesity PostgreSQL Connector. If you choose to use a non-root user, you must add the `sudo` privileges for the non-root user using the syntax given below:

  ```
  <user_name> ALL=(ALL) NOPASSWD:SETENV: /path/to/command1,
  /path/to/command2, /path/to/command3
  ```

  The following is the `sudo` commands for PostgreSQL Connector:

```
cohesityagent ALL=NOPASSWD:SETENV: /bin/chmod, /bin/chown, /bin/mkdir,
/bin/rm, /bin/psql, /usr/bin/ps, /usr/sbin/runuser, /bin/java,
/usr/bin/netstat, /bin/test
```

> **Note:**
> - If the **cohesityagent** user entry is already present in **/etc/sudoers**, append the list of commands to the existing entry.
> - The actual paths for each command might vary in each system. For more information, see Download and Install the Linux Agent.

- Java version 1.8 or higher is installed on all PostgreSQL nodes and available in the path for the Cohesity agent, the root user, and the postgres user.
- Java binary is available in the `$PATH` environment variable.
- The default `postgres` database is present on the PostgreSQL instance.
- To securely connect to the Cohesity cluster while reading or writing data, you can use secure gRPC.

> **Note:**
> - It is **mandatory** to connect to the Cohesity cluster securely using secure gRPC when writing or reading data.
> - Using non-secure gRPC for data transfer between Cohesity and database hosts will result in unsecured communication.
> - Enabling secure gRPC will increase data transfer time between Cohesity and database hosts compared to non-secure communication.

To use secure gRPC, perform the following:

1. Generate the certificate config file on the Cohesity node using the following command:

   ```
   ~/<release-version>/crux/bin/client_tls_cert_generator_exec -cert_
   name <clustername> -output_file /home/cohesity/<clustername>.cfg
   ```

2. Copy `/home/cohesity/<clustername>.cfg` from the Cohesity node to all PostgreSQL nodes at the same location. For example, `/opt/certs/<clustername>.cfg`.

> **Note:** Ensure that the `root` or `non-root` user used to install the Cohesity Linux agent and PostgreSQL Connector has read access to the generated certificate config file.

3. While registering the PostgreSQL source, provide the path of the certificate config file in the **Cohesity SSL Settings** field.

- If you are restoring to the same or different cluster, ensure that the port you want to use for the restored instance is not in use.

Considerations

Review and understand the following limitations and known issues before you protect your PostgreSQL deployment:

- Only physical backup is supported.
- Backup or restore is performed at the cluster level. Object-level backup or restore is not supported.
- In the case of the HA cluster, the backup is executed from the active node only.
- In case of a failover in the HA cluster, the next backup run will be a full backup.
- Restore across different PostgreSQL versions is not supported.
- For optimum performance in log backups, it is recommended to set the WAL size to 1GB.
- If the hole is introduced in the backup timeline, then point-in-time recovery (PITR) is possible only after the subsequent successful full or incremental backup is completed.
- Cohesity supports backup and restore of PostgreSQL databases running on dual-stack (IPv4 and IPv6) mode or single-stack (only IPv6) mode.
- If you have not set **archive_mode=on**, the PostgreSQL database is restarted to set **archive_mode=on**.
- Cohesity supports granular-level database permissions which allows the non-superuser to register the PostgreSQL source and perform the backups. See Configure Privileges for Non-Admin Users.

Download and Install the Cohesity Linux Agent

The Cohesity Linux Agent is available as RPM-based installers, based on your requirements download the installer and install it accordingly on the PostgreSQL hosts to be protected. For detailed instructions, see Download and Install the Linux Agent.

Download and install the PostgreSQL Connector

Cohesity Platform provides a PostgreSQL Connector for backup and restore of enterprise PostgreSQL deployments.

Download the PostgreSQL Connector

Cohesity Platform provides a PostgreSQL Connector to backup and restore PostgreSQL deployments. The PostgreSQL Connector is available as a datasource agent on the Cohesity Download portal. Log on to the Cohesity Download portal, download the respective datasource agent for PostgreSQL Connector, and copy the datasource agent to the PostgreSQL database host.

Install the PostgreSQL Connector

On the PostgreSQL database host where you have copied the PostgreSQL Connector, perform the following to install the PostgreSQL Connector.

To install the Cohesity PostgreSQL connector:

1. Log on to the PostgreSQL Linux machine using the user with sudo privileges.
2. Navigate to the directory where you have copied the RPM-based installer.
3. Install the Cohesity PostgreSQL connector using the following command:

   Using `yum`:

   ```
   # sudo yum -y install cohesity-postgres-connector-<version>.rpm
   ```

   Using `rpm -ivh`:

   ```
   # sudo rpm -ivh cohesity-postgres-connector-<version>.rpm
   ```

Uninstall the PostgreSQL Connector

To uninstall the Cohesity PostgreSQL connector, run the following command on PostgreSQL host:

Using `yum`:

```
# sudo yum -y remove cohesity-postgres-connector-<version>
```

Using `rpm`:

```
# sudo rpm -e cohesity-postgres-connector-<version>.rpm
```

Upgrade the PostgreSQL Connector

To upgrade the Cohesity PostgreSQL connector, run the following command on PostgreSQL host:

```
sudo rpm -U cohesity-postgres-connector-<version>.rpm
```

Migration script for New User Experience

Cohesity provides a new improved user experience that streamlines the process of registration, protection, and recovery of PostgreSQL database. To migrate the existing PostgreSQL database to the new workflow, Cohesity provides a migration script. However,

the source and protection jobs for the existing PostgreSQL will continue to function as they are.

After the migration script is runned successfully, Cohesity displays the PostgreSQL instances listed separately under the **DataProtection** > **Sources** > **PostgreSQL** section.

Ensure that:

- Cohesity cluster is accessible by running anyone of the following commands:

```
ping <cluster_ip>
ssh admin@<cluster_ip>
```

- Migration script file should have execute permission on the PostgreSQL server.
- Cohesity admin or equivalent user should perform the task.

To migrate the PostgreSQL database to new workflow:

1. Log on to the PostgreSQL Linux machine.
2. Navigate to `/opt/cohesity/postgreSQL/scripts`.
3. Run the following script files using `chmod +x` command:
   a. `migrate_scource.sh` - to migrate the source configurations.
   b. `migrate_protection.sh` - to migrate the protection jobs.
   For example: `chmod +x migrate_source.sh`
   To view the help options, run the command as `chmod +x migrate_source.sh --help`

> **Note:**
> - Original backup jobs are paused and not deleted.
> - No roll back script provided. If the migration script fails, check the logs to resolve the issue and re-run the migration script.
>
>   The log file for **Source** is located: `registration_$(date +%Y%m%d_%H%M%S).log`
>
>   The log file for **Protection Groups** is located: `create_protection_groups_$(date +%Y%m%d_%H%M%S).log`
> - Verify the new source in the UI: Navigate to **Data Protection** > **Sources**.

Configure Privileges for Non-Admin Users

Previously, the PostgreSQL connectors required admin or superuser privileges for backups due to PostgreSQL's design for physical backups using CHECKPOINT. See, CHECKPOINT in PostgreSQL for more details.

Cohesity now supports granular-level database permission. From PostgreSQL version 15 onwards, non-admin users can perform backup operation by applying the required configurations and grants. This can be configured manually and script based.

Ensure that:

- The instance must be running PostgreSQL version 15 or later.
- The PostgreSQL instance is up-and-running on the specified port.
- The user executing the script must have PostgreSQL superuser credentials.

To configure the privileges using script:

1. Navigate to Datasource Agent Installation path.
2. Run the *configure-pg-backup.sh* script file with the following parameters on the PostgreSQL host machine where the database is installed:

   ```
   <installation_dir>/configure-pg-backup.sh --host <host> --port <port> --db <database> \
   --superuser <user> --superuser-pass <password> \
   --db-user <backup_user> [--restart true|false] [--pgctl /path/to/pg_ctl]
   ```

   For example:

   ```
   ../configure-pg-backup.sh --host 10.14.20.60 --port 6004  \
   --superuser 'postgres' --superuser-pass xxxxxx \
   --db-user user1 --restart true --pgctl /usr/pgsql-15/bin/pg_ctl
   ```

   Refer to the table below for script parameters
3. You need to restart PostgreSQL database to reflect the changes. Run the following command:

   ```
   pg_ctl restart -D <datadirectory>
   ```

Script parameters	Parameter descriptions	Default values
--host	Database host	127.0.0.1
--port	Database port	5432
--db	Database to connect	postgre
--superuser	PostgreSQL superuser (required)	N/A

Script parameters	Parameter descriptions	Default values
--superuser-pass	Superuser password (required)	N/A
--db-user	Database user to whom privileges to be granted (required)	N/A
--restart	Restart PostgreSQL after applying settings (true or false)	false
--pgctl	Explicit path to pg_ctl binary (if not in PATH)	N/A
-h, --help	Display help and exit	N/A

To configure the privileges manually:

1. Log on to the PostgreSQL database as a super user and execute the following command to grant the required roles to the backup users:

   ```
   GRANT pg_read_all_settings, pg_checkpoint TO <dbuser>;
   ```

2. Grant the execute permissions on the SQL functions using the following command:

   ```
   GRANT EXECUTE ON FUNCTION pg_switch_wal() TO <dbuser>;
   GRANT EXECUTE ON FUNCTION pg_backup_start(text, boolean) TO <dbuser>;
   GRANT EXECUTE ON FUNCTION pg_backup_stop(boolean) TO <dbuser>;
   ```

3. Edit and update the archive parameter in postgresql.cong file with the following parameters:

   ```
   archive_mode = on
   wal_level = replica
   archive_command = '<installation_dir>/stream-log.sh %p %f
   <installation_dir>/archive_config_<system_id>'
   ```

4. Restart PostgreSQL database using the following command. The restart is required to reflect the changes to archive_mode and wal_level:

   ```
   pg_ctl restart -D <data_directory>
   ```

Sample output:

```
==> Checking server version...
[18-11-2025 11:11:40 IST configure-pg-backup.sh:154] Info: server_version_
num=150015
[18-11-2025 11:11:40 IST configure-pg-backup.sh:192] Info: Generated

```

Register and Manage the PostgreSQL Source

To protect your PostgreSQL databases, you need to register your PostgreSQL deployment as a source on theCohesity Platform. After registering your PostgreSQL deployment as a source, you can:

- Update the PostgreSQL source configuration.
- Refresh the source details.
- Unregister the PostgreSQL source from the Cohesity Platform.

Register PostgreSQL as a Source

Before you register PostgreSQL as a source, ensure that you:

- Review the considerations.
- Perform the prerequisite tasks.

For more information, see Plan and Prepare for PostgreSQL Protection.

To register PostgreSQL as a source:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Register** at the top-right of the page. Click **Databases** > **PostgreSQL**.
3. In the **Source Details** section of the **Register PostgreSQL** dialog, perform the following:
    a. Specify a unique **Source Name** to identify the PostgreSQL deployment.
    b. Specify the Host details such as IP Addresses and Port number.
    c. In the **Datasource Agent Installation Path**, enter the directory path on the PostgreSQL Linux machine, where you have installed the PostgreSQL connector scripts.

For example: `/opt/cohesity/ postgres/scripts/`.

For more information, see Install the PostgreSQL Connector.

d. In the **Authentication Method** section, configure anyone of the following based on your requirements and then click **Proceed**.

Authentication Method	Fields	Description
User Credentials	Select if you want to use password-based authentication. **Note:** For more information on the required setting for client authentication, see Client Authentication in PostgreSQL documentation.	
	Username	The PostgreSQL database username. **Note:** Ensure that the PostgreSQL database user has superuser privileges or equivalent. Refer to Plan and Prepare for PostgreSQL Protection section to grant super privileges.
	Password	The PostgreSQL database user's password. **Note:** If the database is configured to use authentication methods that do not require passwords such as ident, trust, cert, or similar–the **Password** field can be blank.

Authentication Method	Fields	Description
Kerberos	Select if you want to use Kerberos-based authentication.	
	Kerberos Principal	The Kerberos principal that is required to connect to the database.
	Keytab File Path	The absolute path of the keytab file for the given Kerberos principal. **Note:** The path must be accessible by the Cohesity Agent user.
Certification	Select if you want to use certification-based authentication	
	Username	The PostgreSQL database user with superuser or other user with the equivalent privileges.
	SSL Certificate Directory	Specify the absolute path of the directory where the SSL certificates such as client.crt, client.key, or root.crt are located. **Note:** The client certificate should be in X.509 format (V1 or V3).

4. In the **Optional Configuration** of the **Register PostgreSQL** dialog, specify the following parameters:
   a. In the **Host Configurations**, specify the Hostname or IP address of PostgreSQL in **PostgreSQL Hostname/IP** field.

      Note: This is required in case of private network. If not specified, the system uses localhost by default. Ensure that the PostgreSQL server is reachable on the IP address or hostname provided for the Source, then specify the IP address or hostname on which the PostgreSQL server is listening.

   b. Specify the absolute directory location where PostgreSQL executable files (binaries) are installed on your PostgreSQL host machine in PostgreSQL

binaries path.

For example: `/usr/pgsql-15/bin/`

c. In **Advanced Settings**, specify the **Environment Variables**.

Environment variables override defaults and allow fine-tuning of backup performance, storage usage, and cleanup. They influence paths, compression, snapshot size, and cleanup actions.

d. Enable **Check Database Connectivity** if you want to verify the PostgreSQL connection as a part of source verification.

Default: Disabled

e. Enable **Archive Mode** to restart the PostgreSQL during the first backup. Archive mode is a PostgreSQL setting that enables archiving Write-Ahead Logs (WAL) files. This will restart your database as part of the first full backup and may lead to downtime, so plan accordingly before enabling this option.

Default: Disable

5. Click **Register**.

Update the PostgreSQL Source Configuration

After registering your PostgreSQL as a source on Cohesity, you can update the PostgreSQL source configuration.

> **Important:** You cannot modify the source name.

To update the PostgreSQL source configuration:

1. In the Cohesity Dashboard, select **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the PostgreSQL source and select **Edit**.
3. On the **Update Universal Data Adapter** page, update the required configurations.
4. Click **Update**.

Unregister the PostgreSQL Source

If you plan to stop protecting your PostgreSQL databases, you can unregister the PostgreSQL source from the Cohesity Platform.

To unregister the PostgreSQL source:

1. In the Cohesity Dashboard, select **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the PostgreSQL source and select **Unregister**.

Backup PostgreSQL Database

Cohesity Platform provides a simple workflow to back up your PostgreSQL deployment. After registering the PostgreSQL as a source on Cohesity DataPlatform, you can start configuring your backups.

Backup Process

Cohesity Platform provides a PostgreSQL connector for backup and restore of PostgreSQL deployments. Cohesity PostgreSQL connector uses the JDBC interface to connect the PostgreSQL Server. After registering the PostgreSQL source on the Cohesity Platform, you can create a Protection Group with the required parameters and start protecting PostgreSQL deployment.

Protect PostgreSQL Deployments

In Cohesity Platform, PostgreSQL deployments are protected using a Protection Group and a Protection Policy. The Protection Group uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. You can select a standard or custom policy to use when creating a Protection Group. For more information, see Manage Protection Policy.

> **Important:** If you have upgraded your PostgreSQL server version after registering the source, it's important to update the directory path to the PostgreSQL binaries that you set using the `--pg-bin` parameter during registration. Make sure to update the path to the new PostgreSQL binaries path, such as "`/usr/pgsql-14/bin`" if `pgsql-14` is the upgraded version.
> Also, you need to create a new Protection Group to protect the upgraded PostgreSQL instance.

To protect PostgreSQL deployments:

1. In the Cohesity Dashboard, do one of the following:
   - Select **Data Protection > Protection**. Click **Protect** on the top-right of the page and then select **Databases** > **PostgreSQL**.
   - Select **Data Protection > Sources**. Click the actions menu (⋮) next to the PostgreSQL source and then select **Protect**.
2. From the **Source** drop-down list, select the registered PostgreSQL source or click **Register Source** to register a PostgreSQL source. For more information, see Register PostgreSQL as a Source.

3. Click **Add Objects** and **Add Objects** dialog is displayed. Select the required instance. Cohesity displays all the database in the selected instance. Select the instance and click **Continue**.

   > **Note:** Cohesity supports instance level and NOT database level protection.

4. Click **Protection Group**, to specify a unique name.
5. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, see Manage Protection Policy.
6. Click **More Options** and perform the following:
   1. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains.
   2. In the **Start Time** field, define when the protection run should start. This option is only available if the selected policy is set to Backup Daily. Enter the hour and minutes, or use the up and down arrows on your keyboard.

      Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
   3. In the **SLA**, configure the settings which defines the expected level of service for backup and recovery operations.

      By default, 2 hours for Full Backup and 1 Hour for incremental backup is defined.
7. After you have completed the **Settings**, if you need to change any additional settings on the **New Database Protection Group** page, scroll down and click **Edit** on the right. For more information, see Additional Settings.
8. Click **Protect**.

Additional Settings

Additional Settings	Description
Convert to Full Backup on Node Failure	Enable this option if you want to convert the incremental backup to full backup in case of an error.
Pause Future Run	Enable **Pause Future Run** only if you do not want to schedule future runs of the Protection Group.

Additional Settings	Description
End Time	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup Target HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup Target SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Concurrency	Maximum number of backup streams that will be created to exchange data with the cluster. By default, maximum scaling is set to 16.
Alerts	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.

Additional Settings	Description
Priority	Select a priority for the Protection Group execution. Cohesity Platform supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs
Description	**Optional**. Enter a brief description about the Protection Group.

Manage the PostgreSQL Backup Configuration

In the Cohesity Platform, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Object(s) to the Protection Group

You can add new databases or tables to the existing Protection Group for backup. The newly added object is backed up from the next protection run, and it will be a full backup for the newly added object.

To add object(s) to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for PostgreSQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ in the **Objects** section.
5. In the **Objects** section, Click the plus icon (**+**) to enter multiple objects that you plan to back up. click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for PostgreSQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for PostgreSQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired, then a full backup is triggered.

To resume a paused protection run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Cancel Protection Run

To cancel a recovery run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. Click the action icon (⋮) next to the protection run and click **Cancel Run**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for PostgreSQL.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
   - **Delete Snapshots**: If you enable **Delete Snapshots** and then click **Delete Group**, protection group along with the snapshot will be deleted.
   - **Delete Group**
5. Click **Delete Group**.

Recover PostgreSQL Database

You can restore the protected PostgreSQL data to the same PostgreSQL deployment or to a different PostgreSQL deployment.

Instant Restore

Instant restore allows you to start a PostgreSQL instance instantly after the restore. Instant restore mounts the Cohesity View as a PostgreSQL data directory and immediately starts a PostgreSQL instance pointing to the same data directory.

The pulse logs show the instance restore's status and whether the PostgreSQL instance is ready to use. The following is a sample of the pulse log:

```
Instant restore is done, it's ready for use. Please cancel the restore job
when done using the instantly restored data
```

Note:

- For external tablespaces, soflinks are created from the mounted Cohesity View (pointing to the tablespace data) to the expected tablespace location on the local filesystem.
- The instant restore run is shown in the **Running** state, until you explicitly cancel it from the Cohesity UI.
- To shut down the PostgreSQL instance that started using instant restore, you must cancel the instant restore run from Cohesity UI. Once you cancel the instant restore run, the PostgreSQL instance is stopped, and the Cohesity View is unmounted from the cluster.
- Instant restore does not support point-in-time recovery (PITR).

Recover using Instant Restore to Original Location

Instant restore to original location allows you to instantly restore the PostgreSQL instance to the existing location by selecting the protection group, choosing the new source, and configuring recovery options.

To restore PostgreSQL:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** at the top right of the page and then select **Databases** > **PostgreSQL**.
3. Search for the Protection Group that contains the snapshots to recover from by entering characters of the Protection Group name, or by specifying the wildcard character ***.
4. From the list of search results, select the Protection Group that contains the snapshots to recover.
5. Click **Next: Recover Options**.
6. In the **Recover To** section, to restore to the **Original Location** and type **YES** to perform instant restore to the same PostgreSQL node.
7. Configure the following parameters for **Recovery Options**:
    - Enable **Start PostgreSQL Server After Restore**, to start the PostgreSQL server after the data restore is complete. By default, **Start PostgreSQL Server After Restore** is disabled.

> **Note:** Ensure that the port you have specified during the PostgreSQL source registration is not in use.

- Disable **Permissions for Restored Files** option to specify the permissions to the restored files or directories. The permission options is displayed. Select the required permissions.

  By default, the **Permissions for Restored Files** option is enabled which applies the original permissions to the restored files or directories as it was in the source.
- In the **PostgreSQL Server CLI** option, enter the options required to start the PostgreSQL instance. For more information on the options, see pg_ctl command reference in the PostgreSQL documentation.

  > **Note:** Ensure that you do not pass the **-D <datadir>** option.
- For the **Mount/VIPs**, **Concurrency**, and **Task Name** fields, refer to the table below.

Options	Description
Mounts/VIPs	Enter the number of VIPs you want to use while reading data from the Cohesity storage.
Concurrency	Number of parallel streams to use for reading data from Cohesity storage.
Task Name	Change the default name of the recovery task.

8. Click **Recover**.

Recover using Instant Restore to a New Location

Instant restore to new location allows you to instantly restore the PostgreSQL instance to a new location by selecting the protection group, choosing a new source, and configuring recovery options.

To restore PostgreSQL:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** at the top right of the page and then select **Databases** > **PostgreSQL**.

3. Search for the Protection Group that contains the snapshots to recover from by entering characters of the Protection Group name, or by specifying the wildcard character *.
4. From the list of search results, select the Protection Group that contains the snapshots to recover.
5. Click **Next: Recover Options**.
6. In the **Recover To** section, click **New Location** option and select the appropriate **Source** from the drop-down menu.
7. Configure the following parameters for **Recovery Options**:
   - Enable **Start PostgreSQL Server After Restore**, to start the PostgreSQl server after the data restore is completed. By default, **Start PostgreSQL Server After Restore** is disabled.

     > **Note:** Ensure that the port you have specified during the PostgreSQL source registration is not in use.

   - In the **PostgreSQL Service User**, specify the user having access to PostgreSQL with super-user privileges. The default user is "`postgres`".

     > **Note:** Cohesity now supports granting admin privileges to other non-admin users. For more information, see Plan and Prepare for PostgreSQL Protection section.

   - Disable **Permissions for Restored Files** option to specify the permissions you want to set for the files or directories after the restoration. Select the appropriate privileges.

     By default, **Permissions for Restored Files** option is enabled to apply original permissions to the restored files or directories as it was in the source.
   - In the **PostgreSQL Server CLI** options field, enter the options required to start the PostgreSQL instance. For more information on the options, see pg_ctl command reference in the PostgreSQL documentation.

     > **Note:** Ensure that you do not pass the **-D <datadir>** option.

   - For the **Mount/VIPs**, **Concurrency**, and **Task Name** fields, refer to the table below.

Options	Description
Mounts/VIPs	Enter the number of VIPs you want to use while reading data from the Cohesity storage.
Concurrency	Number of parallel streams to use for reading data from Cohesity storage.
Task Name	Change the default name of the recovery task.

8. Click **Recover**.

Regular Restore

Regular restore allows you to restore PostgreSQL instance using latest backups and applying write-ahead-logging (WAL) files during recovery. This recovery method allows you to specify mapping of the PostgreSQL tablespaces to an alternate directory.

> **Note:**
> - For versions prior to 7.1.2_u4, redirected restore is not supported for external tablespaces. All tablespaces are restored to the same location as the source. Ensure that the same location as the source is available on the cluster where you are restoring the PostgreSQL data. If the same locations are unavailable on the target cluster, you can create softlinks pointing to the actual storage location.
>
>   For example:
>
>   ```
>   ln -s <actual-storage-location> <tablespace-location-same-as-source>
>   ```

Recover using Regular Restore to the Original Location

Perform a regular restore of the PostgreSQL instance to its original location by selecting the protection group, confirming restoration, and configuring recovery options.

To restore PostgreSQL:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** at the top right of the page and then select **Databases** > **PostgreSQL**.
3. Search for the Protection Group that contains the snapshots to recover from by entering characters of the Protection Group name, or by specifying the wildcard character *.

4. From the list of search results, select the Protection Group that contains the snapshots to recover.
5. Click **Next: Recover Options**.
6. In the **Recover To** section, click **Original Location** and type **YES** to perform instant restoration to same PostgreSQL node.
7. Configure the following parameters for **Recovery Options**:
   - Enable **Start PostgreSQL Server After Restore**, to start the PostgreSQL server after the restore is complete. By default, **Start PostgreSQL Server After Restore** is disabled.

     > **Note:** Ensure that the port you have specified during the PostgreSQL source registration is not in use.

   - Disable **Permissions for Restored Files** option to specify the permissions to the restored files or directories. The permission options is displayed. Select the required permissions.

     By default, the **Permissions for Restored Files** option is enabled which applies the original permissions to the restored files or directories as it was in the source.
   - In the **PostgreSQL Server CLI** options field, enter the options required to start the PostgreSQL instance. For more information on the options, see pg_ctl command reference in the PostgreSQL documentation.

     > **Note:** Ensure that you do not pass the **-D <datadir>** option.

   - For the **Mount/VIPs**, **Concurrency**, and **Task Name** fields, refer to the table below.

Options	Description
Mounts/VIPs	Enter the number of VIPs you want to use while reading data from the Cohesity storage.
Concurrency	Number of parallel streams to use for reading data from Cohesity storage.
Task Name	Change the default name of the recovery task.

8. Click **Recover**.

Recover using Regular Restore to a New Location

Perform a regular restore of PostgreSQL to a new location by selecting the protection group, specifying new data/log paths, configuring overwrite and recovery options.

> **Note:**
> Using this recovery method you can:
>
> - Map the directory to an alternate directory by specifying the parameters in the **Tablespace Directories** field.
> - Recover PostgreSQL using the latest backup snapshots and WAL file using **Roll Forward Database** option.

To restore PostgreSQL:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** at the top right of the page and then select **Databases** > **PostgreSQL**.
3. Search for the Protection Group that contains the snapshots to recover from by entering characters of the Protection Group name, or by specifying the wildcard character *.
4. From the list of search results, select the Protection Group that contains the snapshots to recover.
5. Click **Next: Recover Options**.
6. In the **Recover To** section, recovering to a New Location, configure the following fields:
    a. select the appropriate **Source** from the drop-down menu.
    b. Specify the new path on the target cluster where you want to restore the new path in the **New Data Path** field.
    c. Specify the absolute path of the directory for PostgreSQL server logs in **New Log Path** (optional) field.
    d. Enable **Overwrite existing database(s)** option and type **YES**, if you want to overwrite the existing instance with the same name.
7. In the **Recover Options**, configure the following fields:
    a. Enable **Start PostgreSQL Server After Restore**, if you want to start the PostgreSQL server after the data restore is complete. By default, **Start PostgreSQL Server After Restore** is disabled.

> **Note:**
> Select this option:
>
> - Ensure that the port you have specified during the PostgreSQL source registration is not in use.
> - This option must be selected when using **Roll Forward Database** option.

b. In the **PostgreSQL Service User**, specify the user having access to PostgreSQL with super-user privileges. The default user is "`postgres`".

> **Note:** Cohesity supports granting admin privileges to other non-admin users. For more information, see Configure Privileges for Non-Admin Users.

c. Disable **Permissions for Restored Files** to specify the permissions you want to set for the files or directories after the restore. Select the appropriate privileges.

   By default, **Permissions for Restored Files** field is enabled to apply original permissions to the restored files or directories as it was in the source.

d. Enable **Roll Forward Database** to recover the instance using the most recent snapshot backup along with write-ahead-logging (WAL) files that are backed up to Cohesity. Select one of the options from the following:

> **Note:** By default, **No Rollforward** option is selected.

   i. **Automatic Rollforward**: Cohesity automatically applies latest snapshot along with the WAL files during recovery. Specifying the path of the WAL files is optional.

   ii. **Manual Rollforward**: Cohesity only copies the WAL files; you must apply them manually to achieve point-in-time recovery. Specify the path where the WAL files need to be copied with read-write permissions.

   For more information, see Roll Forward Recovery Mode section.

e. In the **Tablespace Directory** field, Cohesity auto-populates the directories. You need to specify the path for each tablespace along with their names.

   For example: /tmp/ts1. The /tmp/ts1 is the absolute alternate path of the directory where you want tablespace to be restored.

> **Note:**
> - If path is not specified, PostgreSQL tablespace directory path from backup instance will be used.
> - If the directories are not auto-populated, refer to the Directories are not auto-populated for Tablespace during recovery in the troubleshooting section.

f. In the **PostgreSQL Server CLI** options field, enter the options required to start the PostgreSQL instance. For more information on the options, see pg_ctl command reference in the PostgreSQL documentation.

> **Note:** Ensure that you do not pass the **-D <datadir>** option.

g. For the **Mount/VIPs**, **Concurrency**, and **Task Name** fields, refer to the table below.

Options	Description
Mounts/VIPs	Enter the number of VIPs you want to use while reading data from the Cohesity storage.
Concurrency	Number of parallel streams to use for reading data from Cohesity storage.
Task Name	Change the default name of the recovery task.

8. Click **Recover**.

Roll Forward Database

The **Roll Forward Database** feature allows to recover PostgreSQL instance using the most recent snapshot backup along with write-ahead-logging (WAL) files that are backed up to Cohesity but not part of a log backup. This feature is supported only when recovering to the latest snapshot backup and applying all WAL files that are available after it.

To enable this option during recovery, select **Regular Restore** to a **New Location** option.

> **Note:** Default is **No RollForward** where recovery is performed without applying the WAL files.

Cohesity supports two roll forward recovery modes:

1. **Automatic RollForward**: Cohesity automatically applies these logs during recovery. Select this method for quick recovery.
2. **Manual RollForward**: Cohesity only copies WAL files to the specified path. Specify the path where the WAL files need to be copied with read-write permissions.

Refer the following table to understand the differences between **Automatic RollForward** and **Manual RollForward** options.

UI Field	Automatic RollForward	Manual RollForward	UI Location
Start PostgreSQL Server After Restore	This option must be **enabled**. Enabling this option will re-start the database, automatically. If not enabled, manual restart is required.	This option must be disabled. If enabled, restoration fails. After the recovery, the database is left in stopped state. You need to start the database manually. For more information to start the database, refer PostgreSQL: Documentation: 15: 19.3. Starting the Database Server.	**Recovery Options**
WAL Files Path	**Optional**: Cohesity applies all the WAL files.	**Required**: Specify the path where WAL files, with read-write permission, will be copied. Cohesity only copies WAL files; you must apply them manually to achieve point-in-time recovery. However, you need to apply them manually after snapshot restore. If not specified, recovery is performed without applying the backed-up WAL files. For more information, see PostgreSQL document.	

> **Note:** In case of **Automatic RollForward**, Cohesity does not support timestamp-based selection of the WAL files; therefore, all the available WAL files are applied during recovery. Using Instant restore mode of recovery is not supported.

Cancel a Recovery Run

When you cancel a recovery run, the PostgreSQL connector cancels the job by terminating the recovery processes.

To cancel a recovery run:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click the action menu (⋮) next to the recovery run and click **Cancel Run**.
3. In the **Cancel Recovery** dialog, select any one of the following:
    1. Click **Continue Recovery** if you want to continue a recovery run.
    2. Click **Cancel Recovery** if you want to cancel the recovery run.

Troubleshooting PostgreSQL Protection

The following table lists the logs that you can use to troubleshoot failures during the data protection workflows:

Component	Path to the log file
Cohesity PostgreSQL Connector logs	`/var/log/cohesity/uda/`
Cohesity Linux Agent service logs	`/var/log/cohesity/`

Directories are not Auto-populated for Tablespace during Recovery

When recoverying a PostgreSQL instance using the new workflow, the directories for tablespaces may not auto-populate. In such cases, manually specify the mapping between directories and tablespaces using the following format:

1. In the **Tablespace Directory** field, specify the tablespace along with the path in the following format:

    ```
    <TablespaceName>:/<AbsolutePath>
    ```

    For multiple tablespace entries, specify comma separated values.

    For example, `Ts1:/tmp/ts1,Ts2:/mytmp/ts2`
2. Click ☑.

In the above example,

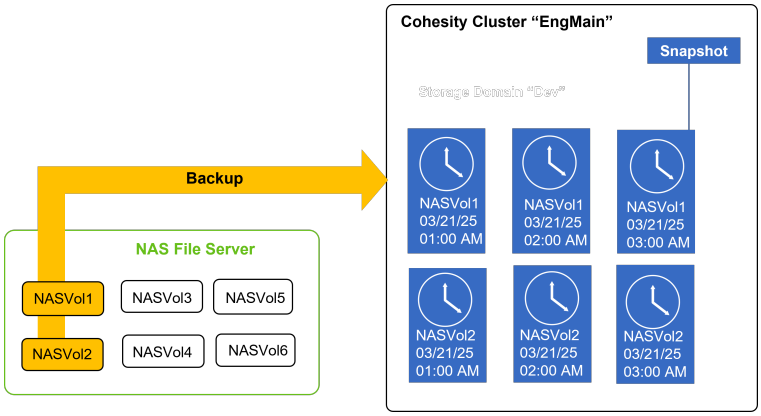
- `Ts1` and `Ts2` are tablespaces.
- `/tmp/ts1` is the absolute path of the directory where you want to restore `Ts1`.
- `/mytmp/ts2` is the absolute path of the directory where you want to restore `Ts2`.

Chapter 13: NAS

Cohesity supports backing up multiple NAS volumes in a single Protection Group. Protection Groups can run repetitively on a schedule.

To learn more about the relationship between Protection Groups and Policies, see Manage Protection Policy. To learn more about managing Protection Groups, see Manage Protection Groups.

For example, you could create a Protection Group with a schedule that backs up specific NAS volumes every hour as illustrated in the following figure.



During a Protection Group Run, Cohesity Snapshots of the NAS volumes are saved on the Cohesity cluster with a date and time stamp.

For instructions on how to use the Cohesity Dashboard to back up NAS volumes, see Protect NAS.

Plan and Prepare for NAS Protection

Review and understand the following before you perform the backup and recovery of NAS:

Elastifile

Considerations

- Recovering an NFS 4.1 volume to NFSv3 is not supported.
- For application containers, you must add Cohesity client IPs for all the nodes with read/write access onto the container's root share.
- CohesityCloud Edition must have access to the Elastifile load balancer VIP.
- For Elastifile, the Incremental forever backup uses Cohesity built-in Change File Tracking (CFT) to locate the changed file/folder.
- If multiple shares support both SMB and NFS in one Protection Group, you can select all of them to back up using only SMB or NFS.
- Cohesity supports the backup of the symbolic link reparse point, **IO_REPARSE_TAG_SYMLINK** in an SMB share.
- Cohesity recommends a first full and incremental forever backup approach to back up your NAS sources.
- When browsing files or folders for recovery, Cohesity does not display files or folders with an absolute path length exceeding approximately 3,500 characters. To recover these files or folders, select the parent directory.

Generic NAS

Considerations

- Generic NAS mount-based backup can be used to back up any NAS device.
- For Generic NAS, Cohesity scans through the live file system during backup. And, the open or locked files may be excluded during backup.
- Custom Pre/Post scripts can be used to take snapshot-based backups.
- Cohesity supports the backup of the symbolic link reparse point, **IO_REPARSE_TAG_SYMLINK** in an SMB share.
- Cohesity recommends a first full and incremental forever backup approach to back up your NAS sources.
- When browsing files or folders for recovery, Cohesity does not display files or folders with an absolute path length exceeding approximately 3,500 characters. To recover these files or folders, select the parent directory.
- Encryption authentication with NFS v4.1 is not supported.

> **Note:**
> - NFS export permissions may be required on the source to allow the Cohesity IPs to be added to the Nutanix export rules for Generic NAS share.
> - Generic NAS protection supports the backup of regular files, directories, symlinks (only in NFS), and hardlinks.
> - Kerberos authentication with NFS v4.1 is supported.

IBM Spectrum Scale (GPFS)

Considerations

- Cohesity only supports fileset-based NFS backups that use simple user-based authentication.
- Unlinked filesets are not displayed in the cluster source tree.
- Junction Path can be used to create a fileset in a fileset, but Cohesity excludes these during backups as they can have cyclic dependencies.
- Cohesity supports only the backup and restore of POSIX attributes for GPFS. The backup of ACLs is not supported for GPFS.
- For IBM Spectrum Scale, Incremental forever backup uses Cohesity built-in Change File Tracking (CFT) to locate the changed file or folder.
- Cohesity supports NFS-based backup and restore of GPFS cluster.
- Cohesity supports the backup of the symbolic link reparse point, **IO_REPARSE_TAG_SYMLINK** in an SMB share.
- Cohesity recommends a first full and incremental forever backup approach to back up your NAS sources.
- When browsing files or folders for recovery, Cohesity does not display files or folders with an absolute path length exceeding approximately 3,500 characters. To recover these files or folders, select the parent directory.

Prerequisites

- The NFS protocol must be enabled on the GPFS cluster.
- GUI services must be installed on at least one of the GPFS nodes as REST APIs are enabled only if the GUI services are enabled that are used for registration and other orchestrations.
- Cohesity uses the IP addresses of Cluster Export Services(CES) to connect the GPFS cluster using the NFS protocol. Therefore, at least one IP address of Cluster Export Services(CES) must be reachable from the Cohesity cluster nodes. The CES IP addresses that are not reachable must be added to the **Deny IPs** field while registering the GPFS cluster with the Cohesity cluster. Else, the backup of the GPFS cluster will fail.
- If AD is not configured make sure the file level authentication is set up properly.

Isilon

For information about the prerequisites and considerations for Isilon, see Dell EMC Isilon.

NetApp

For information about the prerequisites and considerations for NetApp ONTAP, see NetApp ONTAP.

Nutanix Files

For information about the prerequisites and considerations for Nutanix Files, see Nutanix Files.

Pure FlashBlade

Considerations

- Incremental forever backup uses Cohesity built-in Change File Tracking (CFT) to locate the changed file or folder.
- If multiple shares support both SMB and NFS in one protection group, you can select all of them to back up using only SMB or NFS.
- Cohesity supports the backup of the symbolic link reparse point, **IO_REPARSE_TAG_SYMLINK** in an SMB share.
- Cohesity recommends a first full and incremental forever backup approach to back up your NAS sources.
- When browsing files or folders for recovery, Cohesity does not display files or folders with an absolute path length exceeding approximately 3,500 characters. To recover these files or folders, select the parent directory.

Prerequisites

- For Cohesity to protect Pure FlashBlade File Systems:
  - Each File System must have NFS and/or SMB enabled.
  - Each File System must have the Special Directory "Snapshot" enabled.
- To register the Pure Storage Flash Blade with the Cohesity cluster, ensure that you have the default *pureuser* FlashBlade administrator account. If not, create the *pureuser* with full admin permissions.
- For Pure Storage FlashBlade, the recovery of SMB data may fail if the files and folders being recovered have restrictive permissions. Cohesity recommends you either create folders or directories manually in the target location before initiating the recovery or use an SMB user with read/write permissions when registering the Pure Storage FlashBlade source.

Register or Edit NAS

Registering a NAS makes its content eligible to be protected or backed up on the Cohesity cluster.

1. Navigate to **Data Protection > Sources**.
2. Click **Register > NAS**.
3. Select the **NAS Source**.
4. Enter the information for the NAS.

   Isilon (Cluster)

For information on registering and protecting Isilon, see Dell EMC Isilon.

NetApp

For information on registering and protecting NetApp, see NetApp ONTAP.

GPFS

Cohesity supports NFS-based backup and restore of the GPFS cluster.

Prerequisites:

Before you register the GPFS cluster with the Cohesity cluster, ensure that:

- NFS protocol is enabled on the GPFS cluster.
- GUI services are installed on at least one of the GPFS nodes.
- Cohesity uses the IP addresses of Cluster Export Services(CES) to connect the GPFS cluster using NFS protocol. Therefore, at least one IP address of Cluster Export Services(CES) must be reachable from the Cohesity cluster nodes. The CES IP addresses that are not reachable must be added to the **Deny IPs** field while registering the GPFS cluster with the Cohesity cluster. Else, the backup of the GPFS cluster will fail.

Field Name	Description
Host or IP Address	Enter the host or IP address of one of the GPFS nodes with UI access.
Username	Enter the user name used to access the GPFS cluster. A user with GUI role should register the GPFS on Cohesity. Cohesity uses this GUI user to access the REST APIs. If you are providing a domain user account, then you must specify the user name in the following format: `fully_qualified_domain_name\username`. For example, `xydc.local\user1`.
Password	Enter the password for the specified user.

Field Name	Description
Filter IPs	Enable this option to filter the IP addresses of the GPFS cluster. By filtering IP addresses, you can allow or deny the communication of Cohesity cluster to specific IP addresses or subnets of the GPFS cluster. To filter the IP addresses of the GPFS cluster, select one of the following options: • **Allow IPs**: Select this option and specify the IP addresses of the GPFS cluster source through which the communication to Cohesity cluster must happen. You can provide the IP addresses in a comma-separated list or in a CIDR format. • **Deny IPs**: Select this option and specify the IP addresses of the GPFS cluster source through which the communication to Cohesity cluster must not happen. You can provide the IP addresses in a comma-separated list or in a CIDR format.

If Active Directory is not configured make sure the file-level authentication is set up properly for the backups and recovery tasks to go through.

Generic NAS

Field Name	Description
Mode	NFSv3, NFSv4.1, or SMB
Mount Path	The path for mounting the NAS. Use the following format: • Hostname or IP:/Volume for NFS mode • \\Hostname or IP\Share path for SMB mode. **Note:** Do not edit an existing mount path. To change the mount path perform the following: Register the new mount path Source. Edit any Protection Groupto remove the old mount path and add the new mount path. Unregister the old mount path Source.

Field Name	Description
Skip Mount Point validation during registration	The option to skip the mount point validation during registration. The following will be skipped: • for NFS mount point, mounting the volumes that have been tested whether the mount point actually exists and is reachable from the Cohesity cluster. • for SMB mount point, establishing connection with the sources and consequently querying some basic information of the share (like size).
Description	An optional description for the mount point.
Username	SMB mount credentials that allow the reading and backing up of files. If you are providing a domain user account, then you must specify the user name in the following format: `fully_qualified_domain_name\username`. For example, `xydc.local\user1`.
Password	SMB mount credentials that allow the reading and backing up of files.

SMB DFS Referral

The Cohesity SMB client now follows the Distributed File System (DFS) referral. The Distributed File System has a collection of shares on different machines that serve a file system namespace. If one machine does not have a particular file requested by the client, it is referred to check the other machine.

Users can now backup the entire DFS namespace by simply registering the share with the hostname directly as a Generic NAS SMB mount point.

> **Note:**
> Before the 6.8 version, registering each share as a Generic NAS source and backing it up in a Protection Group was suggested by Cohesity support as a workaround in some cases. After the upgrade, the Cohesity cluster may end up backing up the same data multiple times causing data bloat and an increase in the run time.
>
> If you are using this method, then you should contact Cohesity Support to transition to the SMB DFS Referral method.

Pure Storage FlashBlade

Field Name	Description
Hostname or IP Address	The hostname or IP address of the FlashBlade to register.
API Token	API Token The API token of the Admin user for logging in to the FlashBlade. You can use the FlashBlade CLI to find the API token of the administrator: `pureadmin list --api-token --expose`
SMB Volumes Access	Enable this option to back up SMB volumes. Provide Active Directory user credentials that allow read and write access on the FlashBlade. SMB support is currently a beta feature.
Filter IPs	To filter the IP addresses of the FlashBlade, select one of the following options: • **Allow IPs**: Select this option and specify the IP addresses of the FlashBlade source through which the communication to Cohesity cluster must happen. You can provide the IP addresses in a comma-separated list or in a CIDR format. • **Deny IPs**: Select this option and specify the IP addresses of the FlashBlade source through which the communication to Cohesity cluster must not happen. You can provide the IP addresses in a comma-separated list or in a CIDR format. **Note:** The "Filter IPs" feature can be found under “Additional Settings” on the “Protection Group” page and under “Recovery Options” on the “Restore” page. You must enable the feature flag **nasFilterIpsEnabled** for the Filter IPs feature to appear.

Elastifile

You can perform NFS-based backup and restore of Elastifile data containers present on Elastifile Cloud File System.

Prerequisites:

Before you register the cloud edition of Elastifile with Cohesity cluster, ensure that:

- Elastifile Cloud File System is of version 3.1.0.31 and above.
- Elastifile Cloud File System is deployed using load balancer configuration.
- The load balancer VIP is accessible from the Cohesity cluster as it is used for data ingestion during backups and restores.
- The Elastifile user is an admin or has Provisioner role.

Field Name	Description
Host or IP Address	Enter the host or IP address of the Elastifile Management interface to register.
Username	Enter the username used to access Elastifile Cloud File System. The user must be an admin or a user with provisioner role. If you are providing a domain user account, then you must specify the user name in the following format: `fully_qualified_domain_name\username`. For example, `xydc.local\user1`.
Password	Enter the password for the specified user.
Filter IPs	Enable this option to filter the IP addresses of the Elastifile Cloud File System. By filtering IP addresses, you can allow or deny the communication of Cohesity cluster to specific IP addresses or subnets of the Elastifile Cloud File System. To filter the IP addresses of the Elastifile Cloud File System, select one of the following options: • **Allow IPs**: Select this option and specify the IP addresses of the Elastifile Cloud File System source through which the communication to Cohesity cluster must happen. You can provide the IP addresses in a comma-separated list or in a CIDR format. • **Deny IPs**: Select this option and specify the IP addresses of the Elastifile Cloud File System through which the communication to Cohesity cluster must not happen. You can provide the IP addresses in a comma-separated list or in a CIDR format.

You must open the following ports in the firewall to allow the Cohesity cluster to send and receive data and register Elastifile on Cohesity cluster to perform data backup operations.

Port Number	Network Protocol	Operationss
443	TCP	For EMS/API operations
111 2049 644 4040 4045	TCP	For NFS Operations

Port Number	Network Protocol	Operationss
111 2049 644 4040 4045	UDP	For NFS Operations

5. Click **Register**.

   When registration finishes, a new entry appears on the Sources page.

Automatic Denylisting in NAS Sources

When connecting to a NAS source's IP address, network issues such as timeouts can result in backup failures. Cohesity now supports implementation of automatic denylisting of problematic IP addresses associated with a NAS source. This feature aims to prevent NAS protection jobs from failing due to specific IPs or interfaces becoming unreachable or having limited bandwidth, ensuring smoother backup operations.

Protect NAS

NAS Protection Group captures snapshots and these snapshots are required for the following tasks:

- Recover volumes
- Replicate snapshots
- Archive snapshots
- Files and folders recovery (CloudArchive Direct)

> **Note:**
> - Cohesity recommends a first full and incremental forever backup approach to back up your NAS sources.
> - NAS backup and restore do not support Junction points and ADS (Alternate Data Stream).

Before you begin

When you create a Protection Group, you can select an existing source, policy, or storage domain. You can also create them while creating the Protection Group. However, you might find it easier to create them prior to creating the Protection Group, as described in the following topics.

- Register or Edit NAS
- Create or Edit a Standard Policy
- Create or Edit Storage Domains

Create a Protection Group for NAS Volumes

1. Navigate to **Data Protection > Protection** and do one of the following:
   - To create a Protection Group—Click **Protect** on the top-right of the page and then select the type of Protection Group.
   - To edit a Protection Group—Click the action icon (⋮) next to the Protection Group and select **Edit**.
2. If creating a new Protection Group, select **Protect > NAS**.
3. In the **New Protection** pop-up, do one of the following:
   - Protect the NAS volumes database by specifying a subset of options such as objects, protection group and policy by clicking the edit icon corresponding to the following options:
     i. **Add Objects**: Select the registered NAS source or click **Register Source** to register a NAS source. From the **Objects** list, select the volumes you want to back up.
     ii. **Protection Group**: Specify a name for the Protection Group.
     iii. **Policy**: Select an existing policy or click **Create Policy** to create a new protection policy.
     iv. **Storage Domain**: Select the appropriate storage domain.

     > **Note:** This option is visible on the **New Protection** pop-up only if there is more than one storage domain.

     v. Click **Protect**.
   - To protect NAS volumes by specifying all the options, click **More Options**.
4. Click **Add Objects** and from the **Registered Source** drop-down list, select the NAS source that contains the volumes you want to back up. You can also register a new source with the Cohesity cluster so you can protect it.

5. From the **Objects** list, select the volumes to back up. You can select volumes that are of NFS exports, SMB shares or the volumes that are exposed to both NFS and SMB protocols (mixed volumes). By default, all volumes in the source are excluded as indicated by the unselected check box. Select the volumes you want to include in the Protection Group. A selected check box ( ) indicates the volume is selected to be backed up.

   If appropriate for your organization, enable Auto Protect.

   Click to turn on Auto Protect. Turn on this option to protect new volumes that are added to a selected parent SVM. When a parent SVM is selected and this option is enabled, all volumes that are added to the SVM in the future are automatically added to this Protection Group and become protected on the next run. For example, you create a Protection Group that backs up a SVM. The Protection Group runs for two weeks and then a new volume is added to the SVM. The next time the Protection Group runs, if the object hierarchy has been refreshed on the Cohesity cluster, the new volume is also backed up even though the new volume has not been explicitly selected to be included in the Protection Group. The object hierarchy is automatically refreshed every four hours. To manually refresh the object hierarchy, select **Data Protection > Sources**, find the source in the list and click . To exclude an object from Auto Protect, click .

   - Indicates an Auto Protected object.
   - Excluded objects are not protected. The icon indicates that an ancestor of the object is Auto Protected but this object is explicitly excluded.

   You can optionally filter the volumes displayed.

   - In the Search field, enter part of volume or SVM name.
   - In the **Show All** drop-down, select one of the following options:
     - **Selected objects**—Displays the volumes that are currently selected for protection.
     - **Unprotected**—Displays the volumes that are not protected by any Protection Groups in the Cohesity cluster—not protected by Cohesity.
     - **Protected** —Displays the volumes that are protected by all the Protection Groups in the Cohesity cluster.
   - You can also filter with the following options:
     - **NFS** -Displays NFS volumes only.

       For Generic NAS and NetApp ONTAP sources, **NFSv3** and **NFSv4.1** filters are supported from Cohesity 6.6.0d version onwards. To enable this

feature, contact Cohesity Support.

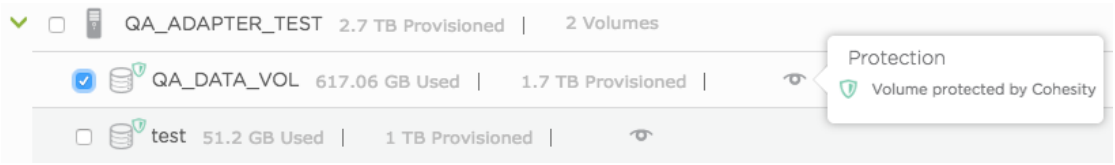
- **SMB** - Displays SMB volumes only.

- Selecting the check box adjacent to **Volumes** selects all filtered volumes.

The graphical representations are described below.

- If you are creating a new Protection Group and the shield appears next to the volume, this volume is protected by another Protection Group.

- If you are editing an existing Protection Group and the shield appears next to the volume and the volume is selected ( ), it will be protected by the current Protection Group. (It may also be protected by another Protection Group.)



- Click the icon to see details about the object.

6. Select the backup preference mode of the volume you want to backup.
7. Click **Continue** to save and go back to the New Protection page.
8. **Protection Group**: Enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes and periods. This field is required.
9. **Policy:** Select an existing protection policy or create a new one by selecting **New Policy**.
10. **Storage Domain:** Select an existing storage domain or create a new one by selecting **New Storage Domain**.
11. If you want to change or configure any of the additional settings, then select **More Options** and perform the below steps or else, Click **Protect**.
12. Optionally, from the **Protection Group** field, you can select an existing Protection Group settings for this Protection Group by enabling **Existing Group**, and then by selecting an existing Protection Group from the **Group** drop-down list.
13. **Start Time:** Indicates when the Protection Group should run. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up

and down arrows on your keyboard. Verify the AM or PM setting.

The default time zone is the browser's time zone. You can change the time zone by selecting a different time zone.

14. **End Date:** Optional. Toggle on and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
15. **QoS Policy:** Select an appropriate quality of service (QoS) policy.

    > **Note:** Cohesity recommends specifying **Backup HDD**, which is the default.

    - **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group.
    - **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups.
    - **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy.
    - **TestAndDev High:** The Cohesity cluster writes the data to an SSD drive for this Protection Group. The I/Os with this QoS policy are given higher priority compared to other QoS policies. Use this policy for workloads that require lower I/O latency.
16. **Pre & Post Scripts:** Toggle **Enable** to run scripts on a Unix server before and/or after a Protection Group runs. If configured, scripts are run every time an object (or entity) is backed by a protection run. For example if there are five mount/shares that are backed up as part of the NAS Protection Group and the Pre Script is configured, then five instances of the Pre Script is executed in parallel. You can distinguish between the scripts that are run on the different objects (entities) using the `COHESITY_BACKUP_ENTITY` environment variable. The Cohesity cluster populates this environment variable with the name of the backed object (or entity).

    > **Note:** The specified Unix server does not need to be attached to the NAS target, it just needs to be a Linux VM or machine that can either invoke APIs on or ssh in to a NAS target.

    Configure the settings for running the Pre and Post scripts.

Hostname or IP Address (Unix only): Specify either the hostname or the IP address of the remote Unix server where the script will run. (Only Unix is currently supported.)

Cluster SSH Public Key: Click **Copy Key to Clipboard** to copy the entire string including the `ssh-rsa` string preceding the key, the public key and the `username@cluster_name` string after the key. Open the `authorized_keys` file (typically located in the `~/.ssh` directory) and paste the entire string to the end of the file.

Username: Specify the username on the remote Unix machine that will execute the script. The username must match the username specified in the `authorized_keys` file.

You can configure a Pre-Script, a Post-Script or both scripts.

Pre-Script

- **Script Full Path:** Specify the full path and name of the script to run. A script matching the specified name must be available in the specified directory. The script can be in any format, such as a shell script or executable. The script must be configured with the permissions to allow execution (`+x`).

  > **Important:** Cohesity does not validate the content of the script and is not responsible for the content of the script or any actions done by the script. You must verify the script actions before a script or executable is run.

- **Script Params**: Optional field for passing one or more parameters to the script. All specified parameter values are passed as a single string to the script.
- **Timeout**: Optional field for specifying how long a script is allowed to execute before the Cohesity cluster stops the execution of the script. By default, the timeout is 15 minutes. If no value is specified, there is no timeout and the script is not stopped. This can cause a protection run to hang if the script never completes. The timeout is applied from the moment the script starts. For example, if the timeout is set to 15 minutes but the script takes 20 minutes to complete, it will be stopped after 15 minutes. Therefore, users should set the timeout based on the expected runtime of the script to avoid premature termination.
- **Continue Backup if script fails**: This toggle applies only to Pre-Scripts and is enabled by default. When this toggle is enabled, the Protection Group backs up the objects even if the Pre-Script fails. If this toggle is disabled and the Pre-Script fails, the backup is canceled but the Post-Script still runs.

Post-Script

- **Script Full Path:** Specify the full path and name of the script to run. A script matching the specified name must be available in the specified directory. The script can be in any format, such as a shell script or executable. The script must be configured with the permissions to allow execution (`+x`).

  > **Important:** Cohesity does not validate the content of the script and is not responsible for the content of the script or any actions done by the script. You must verify the script actions before a script or executable is run.

- **Script Params**: Optional field for passing one or more parameters to the script. All specified parameter values are passed as a single string to the script.
- **Timeout**: Optional field for specifying how long a script is allowed to execute before the Cohesity cluster stops the execution of the script. By default, the timeout is 15 minutes. If no value is specified, there is no timeout and the script is not stopped. This can cause a protection run to hang if the script never completes. The timeout is applied from the moment the script starts. For example, if the timeout is set to 15 minutes but the script takes 20 minutes to complete, it will be stopped after 15 minutes. Therefore, users should set the timeout based on the expected runtime of the script to avoid premature termination.

More about failures, cancellations and logging:

- If the backup is successful but the Pre-Script or Post-Script fails, a warning is issued with the script error. A script failure occurs for any of the following conditions:
  - script is not found in the expected location
  - script cannot be executed
  - script returns a failure return code of non-zero

  A script is successful when the return code is 0.
- If a Post-Script is configured, the script always executes even if the backup fails.
- If a protection run is canceled, all subsequent phases are canceled.
  - For example, if a protection run is canceled while the Pre-Script is running, the Pre-Script is canceled, then the backup task is canceled and then the Post-Script is canceled.
  - For example, if a protection run is canceled while the backup task is running, the backup task is canceled and then the Post-Script is canceled.

- The logging information reported by the script is available from the Protection Group details page. To open the page, log in to the Cohesity Dashboard, select **Data Protection > Protection**, and under **Last Run** click on a date. In the Run Details page, click the green > icon next to the protected object (entity) to view the job details.

Available Environment Variables

The Cohesity cluster populates the following environment variables with values before the Pre-Script or the Post-Script is run. You can use these environment variables in your script.

Variable Name	Available from Script	Description
`COHESITY_JOB_ID`	Pre-Script and Post-Script	Specifies the Cohesity id assigned to the Protection Group.
`COHESITY_JOB_NAME`	Pre-Script and Post-Script	Specifies the name of the Protection Group as displayed in the Cohesity Dashboard.
`COHESITY_BACKUP_TYPE`	Pre-Script and Post-Script	`kRegular` indicates an incremental (CBT) backup. Incremental backups utilizing CBT (if supported) are captured of the target protection objects. The first run of a kRegular schedule captures all the blocks. `kFull` indicates a full (no CBT) backup. A complete backup (all blocks) of the target protection objects are always captured and Change Block Tracking (CBT) is not utilized. `kLog` indicates a database log backup. Capture the database transaction logs to allow rolling back to a specific point in time. `kSystem` indicates a system backup. System backups are used to do bare metal recovery of the system to a specific point in time. (*Applies only to IBM*) `kStorageArraySnapshot` indicates storage array snapshot backup. This backup method creates point-in-time snapshots of data on a storage array, allowing for data protection and recovery without impacting the primary storage's performance.
`COHESITY_BACKUP_ENTITY`	Pre-Script and Post-Script	Specifies the name of the object (or entity) being backed up that triggered the script execution.

Variable Name	Available from Script	Description
COHESITY_BACKUP_HOST_ENTITY	Pre-Script and Post-Script	Specifies the name of the host that contains the object (or entity) being backed up that triggered the script execution.
COHESITY_CLUSTER_IP_ADDRESSES	Pre-Script and Post-Script	Specifies a comma separated list of IP Addresses of the nodes that make up the Cohesity cluster.
COHESITY_JOB_STATUS	Post-Script	SUCCEEDED indicates the protection run ran successfully. ERRORED indicates the protection run reported an error.

17. **Skip Files on Errors:** Toggled on by default. The Protection Group continues to run even if it encounters errors on files, such as permissions errors. If files are skipped, the protection run details page indicates a warning status and provides additional information. If toggled off, the Protection Group stops when it encounters an error.
18. **Encryption**: Toggle on this option to enable in-flight encryption of data traffic between the Cohesity cluster and external NAS source while backing up NFS AND SMB Volumes. This option is disabled by default.

    > **Note:** Encrypting in-flight data will have a minor impact on the performance. To use the encryption functionality for NFS volumes, you must join the Cohesity cluster to the active directory as the Kerberos server or add the Kerberos provider in the Cohesity cluster Access Management section.

19. **File DataLock**: Toggle on this option to preserve the access time of the files and folders of the selected volumes. The access time provides the lock period of the files and folders that are applied when these files and folders are recovered to the Cohesity View. For more information on File DataLock, see NAS File DataLock.

    Select one of the following **DataLock** modes:

    - **Compliance**: In this mode, files and folders cannot be deleted or modified during the retention period. After the lock expires, no user can modify the files folder. However, a root user can delete the files and folders. Only a user with Data Security role can edit the File DataLock settings in the Compliance mode.

- **Enterprise**: In this mode, files and folders cannot be modified by any user before or after the lock retention period expiration. However, a root user can delete the files and folders before or after the lock retention period. An admin user or a user with a Data Security role can edit the File DataLock settings in the Enterprise mode. This mode is useful for giving storage administrators additional control over the file.

You can further configure the File DataLock settings to:

- Set the lock period for the new files and folders created on the recovered Cohesity View

  Provide the following information to set the lock period for the new files and folders that will be created on the recovered Cohesity View. These settings are not applicable to the existing NAS source files and folders recovered on the Cohesity View.

  - **Default Lock Period**: Provide the time period during which the files should remain locked. When the time period ends, files can be deleted but not changed. By default, the files are locked forever.
  - **Autolock Files**: By enabling this option, the files are automatically locked if they are not modified in the time period you specify. By default, this option is disabled.
  - **Manually Lock Using**: Select when the files are to be locked:
    - **Read-Only**: Select this option to lock files when the file permission is set to read only, for example; by setting the Windows file properties attribute or using the Linux chmod command. By default, the files are locked when the file permission is set to read only.
    - **FutureATime**: Select this option to lock files when the last access time (atime) is set, for example, by using Windows PowerShell commands or the Linux touch command.

      Optionally you can set a Minimum Retention and/or a Maximum Retention period to ensure that a file's last access time cannot be set outside this period. A request to do so results in a permission denied error if the manual locking mode is FutureATime. Otherwise, the request will be silently rejected and the file will be locked for the minimum retention duration.
- Override the locking period of the existing files and folders recovered on the Cohesity View:

  The following option can be applied to all the existing files and folders that will be recovered on the Cohesity View.

- **Override (Lock all files until a specific date)**: Enable this option and select a date to override the locking period of the existing files and folders.

  When you recover the files to the Cohesity View, Cohesity applies the farthest lock period between the override lock period you specify and the source file's lock period.

  For example;

  - The lock period of the source file is 09/09/2023 and the override lock period you specified is 09/08/2022. When you recover the file to the Cohesity View, then the lock period of the source file is applied to the recovered file, which is 09/09/2023.
  - The lock period of the source file is 09/09/2022 and the override lock period you specified is 09/08/2024. When you recover the file to the Cohesity View, then the override lock period you specified is applied to the recovered file, which is 09/08/2024.

  In **Compliance** mode, a user with Data Security privileges can extend the override date into the future, but no user can shorten the date.

  In **Enterprise** mode, a user with admin or Data Security privileges can extend or shorten the override date.

> **Note:**
> - You cannot enable or disable File DataLock once the Protection Group is created.
> - If you have disabled File DataLock while creating a Protection Group, then when you edit this Protection Group, the File DataLock option will not be displayed.
> - You can delete Protection Groups and Snapshots having File DataLock enabled.
>
>   File DataLock also preserves the ATimes of the hardlinks and symlinks.

20. **Filter IPs**: Enable this option to filter the IP addresses of the NAS source. By filtering IP addresses, you can restrict the communication of the Cohesity cluster to specific IP addresses or subnets of the NAS source.

    To filter the IP addresses of the NAS source, select one of the following options:

    - **Allow IPs**: Select this option and specify the IP addresses of the NAS source through which the communication to the Cohesity cluster must happen. You can

provide the IP addresses in a comma-separated list or in a CIDR format.

- **Deny IPs**: Select this option and specify the IP addresses of the NAS source through which the communication to the Cohesity cluster must not happen. You can provide the IP addresses in a comma-separated list or in a CIDR format.

> **Note:**
> - This option does not apply to the NAS Generic Mount Point Protection Group creation.
> - If you have specified the IP filtering at the source-level also, then the IP filtering specified at the Protection Group-level will take precedence over the IP filtering specified at the source-level.

21. **Exclusions and Inclusions:** Everything is included by default. Toggle on **Exclusions and Inclusions** if you want to exclude or include locations. By creating exclusion and inclusion rules, you can limit the Protection Group to a specific set of files and directories and therefore minimize the disk space used to store the data.

> **Note:**
> To add an exclusion or inclusion, you must prefix a forward slash ('/') or suffix an asterisk ('*') to the path or to a particular file within the protected object. For example, '**/test**' or '***.txt**'.

Add Inclusion: Click to include a particular path or a particular file within the protected object.

For example, consider four directories - **test**, **test1**, **test2**, and **test3** under the protected object with path `/ifs/TestShare1/Folder1`. The table below lists the input types for an inclusion list of folders and their respective outcome:

Input	Outcome
/	Everything inside the protection path is backed up, if exclusions are not defined.

Input	Outcome
/test	When the inclusion path is not suffixed by '/', Protection Group will include all folders starting from the protection path. In this example, /test will behave as /test* and Protection Group will include '**test**', '**test1**', '**test2**', and '**test3**' from protection path for backup.
/test/	When inclusion path is suffixed by '/' , it will only include specific folder. In this example, /test/ behaves as /test/* and Protection Group will only include '**test**' from protection path for backup.

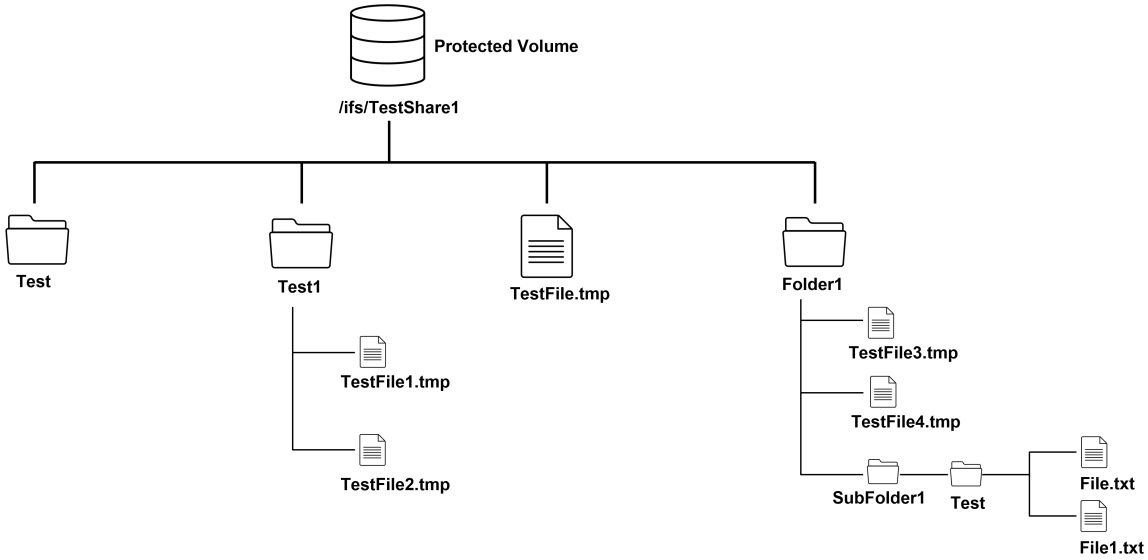
> **Note:**
> Do not provide the folder name along with the backup path while including files and folders for a Protection Group. The backup path is considered by default. For example, `/ifs/TestShare1/Folder1/test` does not include any folder.
>
> If exclusions are defined, they will take precedence over inclusions.

Add Exclusion: Click to exclude a particular path or a particular file within the protected object. You can also specify regular expressions for excluding files in the format `regex:<regex pattern>`

For example, consider there are three directories-**Test**, **Test1**, and **Folder1** and a file, **TestFile.tmp** under the protected object with path **/ifs/TestShare1**.

- **Test1** folder has **TestFile1.tmp**, **TestFile2.tmp** files.
- **Folder1** folder has **TestFile3.tmp**, **TestFile4.tmp files**, and **SubFolder1** which further has a **Test** folder with **File.txt**, **File1.txt** files in it.

The following figure illustrates the directory structure under the protected object with path **/ifs/TestShare1**.



The table below lists the input types for an exclusion list of folders and their respective outcome:

Input	Description	Outcome
/Test	When the exclusion path is not suffixed by a '/', the Protection Group will exclude all files and folders with **Test** as the prefix . For exclusions, **/Test** behaves as **/Test***. **Note:** Exclusion will not be effective on the sub-directory level.	Excludes **Test** and **Test1** folders, and **TestFile1.tmp** file from the protection path. **TestFile3.tmp** and **TestFile4.tmp** files in the **Folder1** folder will not be excluded.
/Test/	When the exclusion path is suffixed by '/' , the Protection Group excludes only the files and folders with the name **Test**. For exclusions, **/Test/** behaves as **/Test/***. **Note:** Exclusion will not be effective on the sub-directory level.	Excludes the **Test** folder of the parent directory. The **Test** sub-folder in **/Folder1/SubFolder1** will not be excluded.

Input	Description	Outcome
*/Test	Excludes all the files and directories with the name '**Test**'. **Note:** Exclusion will be effective on all levels of sub-directories.	Excludes the **Test** folder of the parent directory and the **Test** sub-folder in **/Folder1/SubFolder1**.
*.tmp	Excludes all the files that with '**.tmp**'. **Note:** Exclusion will be effective on all levels of sub-directories.	Excludes **TestFile.tmp**, **TestFile1.tmp**, **TestFile2.tmp**, **TestFile3.tmp**, **TestFile4.tmp** files.
regex:.*\.tmp	Excludes the files and folders with '**.tmp**'. **Note:** Exclusion will be effective on all levels of sub-directories.	Excludes **TestFile.tmp**, **TestFile1.tmp**, **TestFile2.tmp**, **TestFile3.tmp**, **TestFile4.tmp** files.
regex:/Folder1/.*/Test/.*\.txt$	Excludes all files with **.txt** extension from all the **Test** folders directory in **/Folder1/**.	Excludes **File.txt** and **File1.txt** files in the **/Folder1/SubFolder/Test** folder.

> **Note:** Do not provide the folder name along with the backup path while excluding files and folders for a Protection Group. The backup path is considered by default. For example, `/ifs/TestShare1/Folder1/test` does not exclude any folder.

Cohesity automatically excludes the following NetApp system files:

- .vtoc_internal and .bplusvtoc_internal files
- .copy-offload directory and .tokens file

22. **Indexing**: Toggle on this option to index the data of the Protection Group. Indexing improves files and folders search.

    Cohesity performs incremental indexing where only the data that has changed since the previous snapshot is scanned and indexed.

    You can add custom indexing rules.

By default, a rule to include the root directory (`/`) is defined and therefore by default the entire file system is indexed. When a directory is indexed, all of the child sub-directories are also indexed. (Indexing is recursive.)

By creating exclusion and inclusion rules, you can limit indexing to a specific set of files and directories and therefore minimizing the disk space used to store the index. For example, you could add two additional rules to the first default rule:

- include `/`
- exclude `/var`
- include `/var/log`

In this example, all files in the `/` root directory are indexed except the files found in the `/var` directory. However, the files in the `/var/log` are indexed because there is an explicit include rule.

23. **Quiet Time:** This option is available only if the selected policy has at least one quiet time period. Toggle the **Stop in-progress runs when quiet time starts** option to pause or abort the runs during quiet time. If this option is toggled off, after a protection run starts, execution continues even when the quiet time period specified for this Protection Group starts. However, a new protection run will not start during a quiet time period.
    - **Pause Runs** - Select this option to pause the currently executing protection runs and resume the runs when quiet time ends.
    - **Abort Runs** - Select this option to abort the currently executing protection runs when the quiet time period specified for the Protection Group starts.

    > **Note:** If the quiet time window for multiple protection runs is scheduled at the same time, then when the protection run is resumed, prioritization of the protection run does not work

24. **Alerts:** Optional. Select one or more of the following settings if you want alerts to be created for the following triggers:
    - **Success:** Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created.
    - **Failure:** Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created.
    - **SLA Violation:** Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created.

    For more information, see Alerts.

25. **Priority:** Select a priority for the Protection Group execution. Cohesity supports concurrent backups, but if the number of Protection Groups exceeds the ability to process them, those with **High** priority are given the highest priority to execute, **Medium** the second-highest priority, and **Low** the lowest priority.
26. **Email Recipients**: You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the Protection Group.

    > **Note:**
    > The connection to the SMTP Server must be enabled to send email notification. You can enable the SMTP Server connection in the configuration settings page (Cohesity UI > **Settings** > **Summary** > **Configure** > **Enable SMTP Server**).

27. **SLA:** The service-level agreement (SLA) defines the expected time to complete either a full backup or incremental backup. The backup completion time depends on the Windows volume size on AD, objects changed between incremental backups, network speed, and other Protection Groups running on the Cohesity cluster.
    - **Incremental:** Enter the number of minutes you expect an incremental protection run to complete. An incremental backup captures only the differences (changed blocks) since the last protection run.
    - **Full:** Enter the number of minutes you expect a full backup protection run to complete. A full backup captures the entire object (all blocks).
28. **Description:** Optional. Click the plus sign and enter a description for the Protection Group.
29. Click **Protect**.

    The Protection page is displayed and includes the new Protection Group.

Manage the NAS Backup Configuration

In Cohesity, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirement.

> **Note:** You cannot update the registered NAS server and the assigned Storage Domain in the Protection Group settings.

Add NAS to the Protection Group

You can add new NAS volumes to the existing Protection Group for backup. The newly added NAS volumes are backed up from the next protection run and it will be a full backup.

Perform the following steps to add NAS volumes to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you created for NAS.
3. Click the Actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** field, click the edit icon.
5. Select the NAS volume you want to add to the Protection Group.
6. Click **Save Selection** > **Save**.

The newly added NAS volumes are backed in the next scheduled protection run.

Remove NAS from the Protection Group

From the Edit Protection page, you can remove NAS volumes from the Protection Group that you do not want to back up in the next protection run.

Perform the following steps to remove NAS volumes from the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you created for NAS.
3. Click the Actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** field, click the edit icon.
5. Unselect the NAS volume you want to remove from the Protection Group.
6. Click **Save Selection** > **Save**.

Enable or Disable Auto Protect

The Auto Protect option enables you to automatically protect the new NAS volumes that are added to the selected parent NAS server. However, you cannot enable auto-protect at the server-level containing both Read-Write volumes and Data-Protect volumes.

Perform the following steps to enable auto protect:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you created for NAS.
3. Click the Actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** field, click the edit icon.

5. Click the shield icon to enable Auto Protect.
6. Click **Save Selection** > **Save**.

When this option is enabled on the parent NAS server, all the NAS volumes that are added to the parent NAS server in the future are automatically added to the Protection Group and are protected from the next protection run.

For example, you create a Protection Group that backs up a NAS. The Protection Group runs for two weeks and then a new volume is added to the NAS. The next time the Protection Group runs, if the object hierarchy has been refreshed on the Cohesity cluster, the new volume is also backed up even though the new volume has not been explicitly selected to be included in the Protection Group. The object hierarchy is automatically refreshed every four hours. To manually refresh the object hierarchy, select **Data Protection > Sources**, find the source in the list, and click . To exclude an object from Auto Protect, click .

- Indicates an Auto Protected object.
- Excluded objects that are not protected. The icon indicates that an ancestor of the object is Auto Protected but this object is explicitly excluded.

Edit Existing Protection Policy

You can edit the existing Protection Policy that is attached to the Protection Group based on your requirement.

Perform the following steps to edit the policy settings:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you created for NAS.
3. Click the Actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Policy** field, click the **Edit Policy** icon .

   The **Edit Policy** page appears
5. Edit the settings and then click **Save**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

You can attach a new Protection Policy to the Protection Group. The new policy is applied to the Protection Group in the next scheduled protection run.

Perform the following steps to attach a new protection policy to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you created for NAS.
3. Click the Actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, from the **Policy** drop-down, select a new Protection Policy for the Protection Group.
5. Click **Save**.

Start an On-demand Protection Run

You can instantly start a protection run of the Protection Group that you have created to back up NAS volumes. It provides you options to back up all the objects, only selected objects, or failed objects in the Protection Group. If the policy associated with the Protection Group:

- Supports multiple backup types, you can select an incremental or full backup.
- Is configured with replication targets, you can select those targets.
- Is configured with archival targets, you can select those targets.

Perform the following steps to start an on-demand protection run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you created for NAS.
3. Click the actions menu (⋮) next to the Protection Group and select **Run Now**.
4. In the pop-up window, perform the following:
    1. From the **Backup** drop-down list, select any one of the following:
        - **All objects in the Protection Group**.
        - **All objects that failed last run**.
        - **All objects that succeeded last run**.
        - **Selected objects in the protection run**.
    2. In the **Backup Type** drop-down list, select the backup type.
    3. Optional. In the **Replicate** section, select the replication target and the retention duration or click **Add** to add the replication target and the retention duration. Also, select **Replicate only fully successful runs** to replicate the data only from the completed protection runs.
    4. Optional. In the **Archive** section, click **Add** to add the external target to which you want to archive the data and the retention duration. Also, select **Archive only fully successful runs** checkbox to archive the data only from the completed protection runs.
5. Click **Backup Now**.

Pause Protection Runs Instantly

You can instantly pause a protection run of the Protection Group that you have created to back up the NAS sources.

Perform the following steps to pause a currently executing protection run of a Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, click the NAS Protection Group that has been created.
3. Click the Actions menu (⋮) next to the protection run and click **Pause Run**.

   The **Pause Run?** window appears, allowing you to add a note for reference.
4. Click **Confirm**.

   You can see who paused the run and view the note associated with the paused run.

Pause Future Protection Runs

You can pause future protection runs for the Protection Group. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

Perform the following steps to pause the future protection runs:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you created for NAS.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.
   The **Pause Future Runs** window appears, allowing you to add a note for reference.
4. Click **Confirm**.

   You can see who paused the Protection Group and view the note associated with the paused Protection Group.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired then a full backup is triggered

Perform the following steps to resume paused protection runs:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you paused.
3. Click the Actions menu (⋮) next to the Protection Group and select **Resume**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Delete only the Protection Group. Any local snapshots and or archived snapshots stored on the external targets that were captured by this Protection Group are not deleted.
- **Delete Protection Group and Snapshots**: Delete the Protection Group and all snapshots, any local snapshots captured by this Protection Group and stored on this cluster are deleted. In addition, any archived snapshots stored on external targets that were captured by this Protection Group are also deleted.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

Perform the following steps to delete the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you created for NAS.
3. Click the Actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Delete Protection Group Only
    - Delete Protection Group and Snapshots

If the current Protection Group is replicating snapshots to a remote cluster or archiving snapshots to an external target, you should cancel these replication or archive tasks before deleting the Protection Group. For instructions, see Cancel Replication and Archive Copy Tasks of a Protection Run.

If the Protection Group is replicating to a remote cluster, the failover job created on the remote cluster is not deleted. In addition, the snapshots that were replicated (copied) to the remote cluster by this job are not deleted. You can log in to the remote cluster to delete the snapshots and the failover job.

Download Error Report for a NAS Protection Group

You can now download the list of all the errors encountered during the protection run for a NAS backup. Once the protection run is complete, you can download the details of the files that are skipped or have encountered errors in a CSV format.

Follow the steps below to download the errors report for a Protection Group.

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. In the **Protection** page, select a protection group that has the warning icon (ICON) in the **Status** column.
3. In the backup run details page, click the **Warning** icon .
4. In the **Warning** page, click **View More** in the **Message** column to view a list of errors for the Protection Group run and then click **Download Error Logs**.

This will download all the error logs in a CSV file format.

Re-sync Protection Groups

Re-sync refers to manually triggering an archive task and archiving the snapshot again, for example, if an archive has failed earlier. The re-sync operation can be performed only if the local copy has not expired.

Follow the steps below to perform the re-sync operation.

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. In the **Protection** page, select the required Protection Group.
3. In the backup run details page, click the action icon (⋮) for the run and click **Edit Run**.
4. In the **Edit Run** page, click **Re-sync** under the **Archival** section.

   > **Note:** This option is displayed if the protection run includes an associated archive run.

5. Click **Update Retention**, provide the retention duration, and click **Save**. Re-sync will be performed and all the objects will be re-archived.

NAS File DataLock

Many organizations now rely on WORM (Write Once Read Many) data storage such as Nutanix Files, NetApp Snaplock, and Isilon Smartlock volumes to retain their files and folders in unmodified form for compliance and regulatory purposes and to protect the files from accidental deletion or modification.

When you backup these WORM-capable volumes to the Cohesity cluster, it is essential to have the ability to easily lock the files and folders of the volumes while protecting themselves from accidental or malicious attempts to delete or modify these files. The backup should also provide a strong guarantee for data non-mutability and non-erasability for a certain period of time.

This capability is achieved using Cohesity's File DataLock feature.

FileDataLock is a Cohesity feature that preserves the WORM attributes of any files and folders created in the Cohesity View. You can apply the File DataLock feature for NAS backup (NFS exports and SMB shares) while creating a NAS Protection Group.

With File DataLock enabled in a NAS Protection Group, Cohesity preserves the future AccessTime (ATime) of the files and folders. The AccessTime provides the lock period for files and folders. You can also override this lock period in the File DataLock settings of the NAS Protection Group. This lock period is applied to these files and folders when they are recovered to the Cohesity View. This prevents the users or administrator from modifying or deleting these locked files until the locking period expires.

You can also set lock periods for the new files and folders created on recovered Cohesity View in the File DataLock settings of the NAS Protection Group.

When you recover File DataLock enabled storage volumes to the Cohesity View, the View details page will display a lock icon for the files and folders having File DataLock.

File DataLock is supported for all types of NAS sources including NetApp 7-mode and is agnostic of the NAS protocol.

For information on how to enable File DataLock, see Protect NAS.

File DataLock Modes

You can use the File DataLock feature in one of the two modes:

- **Compliance mode**: The WORM files are protected at the disk level. This mode implements strict regulatory requirements for data retention and complies with SEC Rule 17a-4. In this mode, files and folders cannot be deleted or modified during the retention period. After the lock expires, no user can modify the files and folders. However, a root user can delete the files and folders. Only a user with a Data Security role can edit the File DataLock settings in the Compliance mode.
- **Enterprise mode**: The WORM files are protected at the file level. This mode does not implement strict regulatory requirements for data retention. In this mode, files and folders cannot be modified by any user before or after the lock retention period expiration. However, a root user can delete the files and folders during or after the lock retention period. An admin user or a user with the Data Security role can edit the File DataLock settings in the Enterprise mode

> **Note:** An admin user or a user with the Data Security role can edit the File DataLock settings and switch from the Enterprise mode to Compliance mode. But switching from Compliance mode to Enterprise mode is not supported.

Things to remember for File DataLock

- You cannot enable or disable File DataLock once the View is created.
- If you have disabled File DataLock while creating a Protection Group, then when you edit this Protection Group, the File DataLock option will not be displayed.
- You can delete Protection Groups and snapshots having File DataLock enabled.

  File DataLock also preserves the ATimes of the hardlinks and symlinks.
- **Recovery**
  - Recovering a File DataLock enabled backed-up volume as a Cohesity View will preserve ATimes and the locking period for the file.
  - Recovering a File DataLock enabled volume to the original location with 'Overwrite existing files/folder' as the recovery option will encounter an error if the files and folders are read-only. However, the ATime and other attributes of other files and folders of the source volumes are preserved.
  - Recovering a File DataLock enabled volume to an alternate NAS recovery will preserve ATimes and other attributes of files and folders of the source volumes.
  - Cloning a recovered View having File DataLock enabled will not inherit the File DataLock properties.
- **Replication**

  When you replicate to a remote Cohesity cluster, the File DataLock settings are also replicated.
- **Archival**

  File DataLock settings are preserved when you recover volume from an archived snapshot whose Protection Group has File Datalock enabled, to a Cohesity View.
- **Cloud Archive Direct**

  File DataLock settings are preserved when you recover from a Cloud ArchiveDirect snapshot whose Protection Group has File Datalock enabled, to a Cohesity View.

NetApp ONTAP

NetApp ONTAP is a hardware and software-based data storage and retrieval system. It responds to network requests from clients and fulfills them by writing data to or retrieving data from its disk array.

You can backup and recovery NetApp ONTAP volumes using the following two backup approaches:

- **Cohesity File-Runner based backup approach**: Cohesity uses the Cohesity's built-in CFT method to protect data. In this method, Cohesity uses its internal File-Runner to discover the delta between two snapshot copies.
- **NetApp SnapDiff-based backup approach**: Cohesity leverages NetApp's SnapMirror cloud functionality to move the data to the Cohesity cluster and NetApp's SnapDiff functionality to get the changed file list.

> **Note:**
> - In this document, NetApp SnapDiff means Cohesity's implementation of SnapDiff using NetApp SnapDiff v3 APIs.

Supplemental terms regarding the Cohesity implementation of the SnapDiff API. Please review before use.

NetApp ONTAP File-Runner Based Backup

In the Cohesity File-Runner based backup approach for NetApp ONTAP, Cohesity uses the Cohesity's built-in CFT method to protect data. In this method, Cohesity uses its internal File-Runner to discover the delta between two snapshot copies.

Plan and Prepare for File-Runner Based NetApp ONTAP Backup

This topic provides information on the supported NetApp ONTAP versions and volumes, minimum permissions, and the prerequisites to register and protect NetApp ONTAP with Cohesity cluster. For more information, see Register NetApp ONTAP.

Before you register your NetApp ONTAP with Cohesity cluster and protect the volumes and data, ensure the following prerequisites:

- The Storage Virtual Machines (SVMs) that you plan to protect have:
  - an active logical interface attached to the SVM.
  - the NFS and CIFS services configured on the SVM.
- The Cohesity cluster requires access to the snapshot directory on ONTAP. This access is enabled by default. However, it is recommended to verify that it is enabled in your environment.
  1. To check the access status of the snapshot directory, run the following command:

     ```
     volume show -vserver -volume -fields snapdir-access
     ```

     Example output, where volume name is vol1:

```
clus1::> volume show -vserver vs0 -volume vol1 -fields snapdir-
access
```

vserver	volume	snapdir-access
vs0	vol1	true

2. If the snapshot directory access is False, enable it using the following command:

   ```
   volume modify -vserver <SVM_name> -volume <vol_name> -snapdir-
   access true
   ```

   Example output, where volume name is vol1:

   ```
   clus1::> volume modify -vserver vs0 -volume vol1 -snapdir-access
   true
   ```

   Volume modify successful on volume vol1 of Vserver vs0.

For more information about performing these changes through the ONTAP System Manager console, see the NetApp documentation.

- The **Allow Superuser Access** check box is selected in export policy to register SVM with the Cohesity cluster.
- Read or write or full control permissions are added under Share Access Control for the registered SMB user,
  for the volume share being backed up using the SMB protocol.
- The required firewall ports are open to enable communication between Cohesity cluster and NetApp ONTAP.
- If volume export policies are not in use, but export policies are applied at the Qtree level, Cohesity IP addresses must be manually added to the Qtree-level export policies to ensure proper access.
- Review and understand the considerations and best practices.

Support Matrix

Before you register your NetApp ONTAP with Cohesity cluster, ensure that Cohesity cluster supports the NetApp ONTAP versions and volumes you want to protect. For more information, see Supported Software

Supported NetApp ONTAP Volumes

The following table lists the supported NetApp ONTAP versions and volume types for backup:

Volume Type	Volume Sub-Type
Flex Volume*	Normal Flex Volume
	SnapLock Enterprise Volume
	SnapLock Compliance Volume
	Encrypted Volume Storage
Data Protection Volume	SnapMirror Destination Volume
	SnapVault Destination Volume

- Flex Volume support also includes FlexGroup Volume support.
- Cohesity does not support the backup of the following NetApp ONTAP volumes:
  - Flex Volume sub-type of Flex Volume

Supported NFS and SMB versions

The following table lists the supported NFS and SMB versions for backup:

Protocol	Version	Notes
NFS	NFSv3, NFSv4.1	• If NFSv4 volume backup is triggered, the Cohesity cluster performs the backup in NFSv3 mode. • NFS v4.1 Kerberos authentication is supported.
SMB	SMB v2.x, v3	

Supported Security Style of Qtree with Root Volume's Security Style

You can back up Qtrees even if their security style does not match the root-volume security style.

Volume Type	Volume Sub-Type	Qtree	
		Supported	Not Supported*
NTFS	Indicates that the file security style of the qtree is UNIX based.	NTFS	UNIX, MIXED
UNIX	Indicates that the file security style of the qtree is Windows based.	NTFS, UNIX	MIXED
MIXED	Indicates that either the UNIX or the NTFS file security style could be the effective security style for each file or folder within the qtree.	NTFS, UNIX	MIXED

*Cohesity skips the backup of Qtree security styles that are not supported.

Minimum Permissions

Ensure you have the required minimum permissions to register NetApp ONTAP as a source with the Cohesity cluster, and to perform backup and recovery.

Minimum Permissions for Registering NetApp ONTAP

The user account used for registering NetApp ONTAP SVM or NetApp ONTAP Cluster must have the required permissions to communicate with the Cohesity cluster.

The following login methods are used for File-Runner-based NetApp ONTAP Backup:

- ONTAPI
- HTTP

Before registering a NetApp ONTAP Cluster as the source type, ensure you have the following command permissions:

Access-level	Command	Description
All	vserver export-policy	Adds the Cohesity cluster subnet to the export-policy so that Cohesity can mount volumes.
	volume snapshot	Allows fetching, creating, and deleting snapshots for volumes.

Access-level	Command	Description
ReadOnly	vserver cifs	Fetches information about CIFS/SMB shares for volumes .
	cluster identity	Fetches information about the cluster.
	network interface	Fetches information about network interfaces that Cohesity connects to for mounting volumes.
	volume	Fetches information about volumes.
	vserver	Fetches information about SVM.

When registering a NetApp ONTAP SVM as the source type, ensure you have the following command permissions:

Access-level	Command	Description
All	vserver export-policy	Adds the Cohesity subnet to the export-policy so that Cohesity cluster can mount volumes.
	volume snapshot	Allows fetching, creating, and deleting snapshots for volumes.
ReadOnly	vserver cifs	Fetches information about CIFS/SMB shares for volumes.
	network interface	Fetches information about network interfaces to which Cohesity cluster connects for mounting volumes.
	volume	Fetches information about volumes.
	vserver	Fetches information about SVM.

Minimum Permissions for SMB/CIFS Shares Backup and Recovery

To backup NetApp ONTAP SMB/CIFS shares to the Cohesity cluster, the user must have local or domain user credentials that allow at least read access to the SMB share.

To recover the SMB/CIFS shares from the Cohesity cluster, the local or domain user must have full access control on the target where data is being restored.

You can assign the following privileges to the user:

- **SeBackupPrivilege** to the SMB user to be able to back up the SMB data without modifying the ACL on the SMB shares.
- **SeRestorePrivilege** to restore files and directories, override any ACLs, and set a valid user or group SID as the file owner.
- **SeChangeNotifyPrivilege** to bypass traverse checking. Users with this privilege are not required to have traverse (x) permissions to traverse folders, symlinks, or junctions.

Minimum Permissions for NFS Export Backup and Recovery

To backup NFS export, the user must have the read and superuser access permissions on the NFS volume that needs to be backed up and on the parent root volume. Before starting the backup, Cohesity verifies if the user has these permissions, if not, the Cohesity cluster adds a new rule index for the Cohesity node subnet in the export policy attached to the backup volume. You must add the permissions manually for the Cohesity node subnet for the parent root volume.

To restore NFS export, the user needs the read/write and superuser access permissions on the NFS volume that needs to be restored. Before starting the restore, you must add a new rule index for the Cohesity node subnet in the export policy attached to the source volume and parent root volume to give permissions to the Cohesity node subnet/IPs.

Credentials for NetApp ONTAP Backup with Multiple SVMs

To register NetApp ONTAP with multiple storage virtual machine (SVM), create a custom role with the required permissions and a local user at the SVM level. Assign the custom role to the local user. Use the respective local user account to register multiple SVMs.

Ports Used for Communication

For information on port numbers required, see Manage Firewall Ports.

Best Practices

Cohesity protects NetApp ONTAP volumes by communicating with a NetApp ONTAP cluster or Storage Virtual Machine (SVM).

As a security best practice, you must enable SSL before registering the cluster or SVM as a source on the Cohesity cluster.

To enable SSL, run the following ONTAP CLI commands on your NetApp ONTAP cluster:

1. To verify the settings, run the following command:

   ```
   netapp_cluster::> security ssl show -vserver <cluster/vservername>
   ```

2. To enable SSL, run the following command:

   ```
   netapp_cluster::> security ssl modify -vserver <cluster/vservername> -
   server-enabled true
   ```

3. After enabling SSL, run the following command to verify the settings:

```
netapp_cluster::> security ssl show -vserver <cluster/vservername>.
```

Considerations

Review and understand the following considerations before you protect your NetApp ONTAP data:

- Instant Volume Mount for NetApp ONTAP stub file is not supported.
- You cannot restore the NetApp Data-Protect volume to the original location or to an alternate Data-Protect volume because the Data-Protect volume is a read-only volume.
- To backup NetApp DP volumes with SMB share, the volume needs to be in the junction path on the NetApp.
- Cohesity skips the backup of the following security style Qtrees:
  - Mixed-mode security style Qtrees
  - UNIX security style Qtree when root volume security style is NTFS.
- **Volume recovery**: The restored volume (target volume) should have the same security style as that of the volume being protected.

  When volumes with Qtrees are recovered and the Qtrees have a different export policy than the parent volume, update the export policy on the recovered Qtrees to match the original Qtrees.
- If volume export policies are not in use, but export policies are applied at the Qtree level, Cohesity IP addresses must be manually added to the Qtree-level export policies to ensure proper access.
- **Recovering files/folders with Qtrees**: The security style of the location (target) to which the files or folders are restored should have the same security style as the restored files and folders.
- Cohesity supports the backup of the symbolic link reparse point, **IO_REPARSE_TAG_SYMLINK** in an SMB share.
- Cohesity recommends a first full and incremental forever backup approach to back up your NAS sources.
- When browsing files or folders for recovery, Cohesity does not display files or folders with an absolute path length exceeding approximately 3,500 characters. To recover these files or folders, select the parent directory.

The following are the considerations for NetApp NFSv4.1 volumes:

- Encryption is not supported.
- Kerberos is not supported.

- If the NFS backup preference selected in the Cohesity UI is NFSv4.1, and if the NetApp Vserver has NFSv4.1 disabled, all the volumes belonging to this Vserver will use the NFSv3 protocol for backup.
- Recovering an NFS 4.1 volume to NFSv3 is not supported.
- Recovering an NFS 4.1 volume to the Cohesity View is not supported.

Register and Manage NetApp ONTAP Source

To protect your NetApp ONTAP data, you need to register your NetApp ONTAP as a source on the Cohesity cluster. After registration, you can manage the source on the Cohesity cluster in the following ways:

- Update the NetApp ONTAP source configuration
- Refresh the source details
- Unregister the NetApp ONTAP source from the Cohesity cluster.

Register NetApp ONTAP as a Source

Before you register NetApp ONTAP as a source on the Cohesity cluster, ensure that you:

1. Review the requirements, considerations, and best practices.
2. Perform the prerequisite tasks.

For more information, see Plan and Prepare for File-Runner Based NetApp ONTAP Backup.

> **Note:** Before you register NetApp ONTAP as a source on the Cohesity cluster, ensure that you have reviewed and completed the instructions provided in the Plan and Prepare for File-Runner Based NetApp ONTAP Backup

To register NetApp ONTAP as a source:

> **Note:** To register the NetApp ONTAP cluster for NetApp SnapDiff-based backup, you must obtain the SnapMirror Cloud license from NetApp.

1. In the Cohesity Dashboard, select **Data Protection > Sources**.
2. Click **Register** on the top-right of the page and then select **NAS**.

   The Register NAS page appears.
3. From the NAS Source drop-down list, select **NetApp**.
4. Enter the following information, and then click **Register**.

Field Name	Description
NetApp Source Type	The NetApp ONTAP cluster or Vserver/SVM to register. **Note:** Cohesity does not support SnapDiff-based backup if the NetApp source is registered as NetApp ONTAP SVM.
Host or IP Address	The Host or IP address of the NetApp ONTAP cluster or SVM to register. For NetApp SnapDiff-based backup, use the Host or IP address of the NetApp ONTAP cluster to register.
Username	Username used to access the NetApp ONTAP cluster or SVM. Specify a user that has adequate privileges to perform actions on the Source. If you are providing a domain user account, then you must specify the user name in the following format: `fully_qualified_domain_name\username`. For example, `xydc.local\user1`. For more information, see Minimum Permissions. **Note:** The username used to register the NetApp ONTAP cluster and SVM is case sensitive.
Password	Enter the password for the specified user.
Back Up SMB Volumes	Whether NetApp ONTAP will back up SMB volumes. If yes, provide the local or Active Directory user credentials that allow at least read access on the NetApp ONTAP cluster or SVM. **Note:** The user must have full control on the restore target during restore.
Filter IPs	Enable this option to filter the IP addresses of the NetApp ONTAP cluster. By filtering IP addresses, you can allow or deny the communication of the Cohesity cluster to specific IP addresses or subnets of the NetApp ONTAP cluster. To filter the IP addresses of the NetApp ONTAP cluster, select one of the following options: • **Allow IPs**: Select this option and specify the IP addresses of the NetApp ONTAP source through which the communication to the Cohesity cluster must happen. You can provide the IP addresses in a comma-separated list or in a CIDR format. • **Deny IPs**: Select this option and specify the IP addresses of the NetApp ONTAP source through which the communication to the Cohesity cluster must not happen. You can provide the IP addresses in a comma-separated list or in a CIDR format.

Field Name	Description
Storage Array Snapshots	Enable this option to manage the snapshots of VMware VMs stored in NetApp NFS volumes from the Cohesity cluster. • **Cap number of snapshot per volume**: Enter the maximum number of snapshots that can be stored on each NetApp storage volume. • **Cap storage consumed by snapshot per volume**: Enter the percentage of the NetApp volume's storage you want the snapshots to consume. **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

When registration finishes, a new entry appears on the Sources page. You can now create a Protection Group to backup NetApp ONTAP volumes. For more information, see Backup NetApp ONTAP Using File-Runner .

Update the NetApp ONTAP Source Configuration

You can update the NetApp ONTAP details that you had provided during the registration process with the latest NetApp ONTAP configuration.

To edit the NetApp ONTAP source configuration:

1. In the Cohesity Dashboard, select **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the NetApp ONTAP source and select **Edit**.
3. In the Edit NAS page, update the respective configurations.
4. In the **Password** field, enter the password of the NetApp ONTAP user account, and then click **Update**.

Refresh the NetApp ONTAP Source

You can refresh the NetApp ONTAP configuration and fetch the latest changes on the NetApp ONTAP.

To refresh the NetApp ONTAP source configuration:

1. In the Cohesity Dashboard, select **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the NetApp ONTAP source and select **Refresh**.

Unregister NetApp ONTAP

If you plan to stop taking backups of the NetApp ONTAP volumes, you can unregister the NetApp ONTAP source from the Cohesity cluster. Before you unregister, you must delete all the Protection Groups associated with the NetApp ONTAP server. For more information, see Delete the Protection Group.

To unregister the NetApp ONTAP server on the Cohesity cluster:

1. In the Cohesity Dashboard, select **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the NetApp ONTAP source and select **Unregister**.
3. Click **Unregister**.

Backup NetApp ONTAP Using File-Runner

After registering your NetApp ONTAP server as a source on the Cohesity cluster, you can create a Protection Group to backup NetApp ONTAP. You can backup one or more NetApp ONTAP NFS or SMB shares in a Protection Group while preserving ACLs on SMB.

Select NetApp ONTAP Volumes for Backup

Cohesity supports the backup of both NetApp ONTAP read-write (RW) and data protection (DP) volumes. NetApp ONTAP DP volumes are read-only volumes which are used as destination volumes for NetApp ONTAP's replication applications such as SnapMirror and SnapVault. These applications replicate data from NetApp ONTAP primary source volumes to NetApp secondary destination DP volumes. The volume can be of NFS export only, SMB share only, or of both NFS and SMB (mixed) type. Based on the volume and protocol you select for backup, you must provide additional information when creating a Protection Group. For more information, see Protect NetApp ONTAP Using File-Runner Based Backup.

> **Note:** The file-runner is supported on the NetApp Storage Virtual Machine (SVM) and Storage Virtual Machine for Disaster Recovery (SVM-DR).

The following table lists the additional information required to perform backup based on the volume type and protocol you choose while creating a Protection Group:

Volume type	Protocol	Required additional information
Data protection	NFS	Snapshot Prefix for DP Volumes
	SMB	• Snapshot Prefix for DP Volumes • User Access Credentials to Back Up SMB Shares
	SMB, NFS	• Backup Preferences For Mixed Mode Volumes • User Access Credentials to Back Up SMB Shares • Snapshot Prefix for DP Volumes
	NFS v3 & NFSv4.1	• Backup Preferences for NFS Volumes • Snapshot Prefix for DP Volumes
	SMB, NFSv3 & NFSv4.1	• Backup Preferences For Mixed Mode Volumes • User Access Credentials to Back Up SMB Shares • Snapshot Prefix for DP Volumes • Backup Preferences for NFS Volumes
Read-write	NFS	None
	SMB	User Access Credentials to Back Up SMB Shares
	SMB, NFS	• Backup Preferences For Mixed Mode Volumes • User Access Credentials to Back Up SMB Shares
	NFS v3 & NFSv4.1	Backup Preferences for NFS Volumes
	SMB, NFSv3 & NFSv4.1	• Backup Preferences For Mixed Mode Volumes • User Access Credentials to Back Up SMB Shares • Backup Preferences for NFS Volumes

Considerations

- You cannot select both RW and DP volumes in the same Protection Group. For example, in a Protection Group, if you select a RW volume, then you cannot select another volume with the DP mode.
- If you are selecting the objects to be backed up at a NetApp ONTAP cluster-level or server-level having both RW volumes and DP volumes, then RW volumes will take precedence over data protection volumes. That is, only RW volumes of the NetApp ONTAP server will be selected for the backup.

- You cannot enable auto-protect at the server-level containing both RW volumes and data protection volumes.
- The snapshot prefix setting is applicable to both DP and RW volumes. However, Cohesity will only implement these settings on DP volumes.
- To backup NetApp DP volumes with NFS/SMB share, the volume needs to be in the junction path on the NetApp.

Snapshot Prefix for DP Volumes

Cohesity cannot create snapshots of the NetApp data protection volume because it is a read-only volume. Therefore, for backing up NetApp data protection volume, Cohesity DataPlatform leverages the existing snapshots present in the DP volume that are replicated from the NetApp ONTAP source volume to the DP volume. When creating a Protection Group, you can select one of the following options and provide the required information to leverage the existing snapshots present in the DP volume:

- **None**: By selecting this option, Cohesity will take the full backup from the oldest snapshot available on the DP volume and incremental backup from the latest snapshots available on the DP volume.
- **Snapshot Prefix**: By selecting this option, Cohesity will take the full and incremental backup from the snapshots that have the prefix name you specify.
  - **Incremental snapshot label**

    The prefix of the snapshot name present in the DP volume from which the Cohesity cluster can take incremental backup. If there are multiple snapshots that match the specified name, then theCohesity cluster will take the backup from the latest snapshot. The create time of this latest snapshot should be later than the create time of the snapshot that was last used in the most recent backup.

    If the snapshot label specified in the Protection Group is not present in the DP volume, then the following error message appears when you run the Protection Group:

    ```
    No snapshot with label: <label_name> found in the volume: <DP_
    volume_name> on vserver <NAS_server_name>. Cohesity discovers
    snapshots for DataProtect volumes and use existing snapshots for
    taking backups. Please verify the labels for the snapshot
    provided.
    ```

  - **Full snapshot label**: The prefix of the snapshot name present in the DP volume from which theCohesity cluster can take the first full backup. If there are multiple snapshots that match the specified name, then the Cohesity cluster will take the backup from the latest snapshot. For example, if you specify the prefix name of snapshot label as weekly and in the DP volume there are three snapshots with labels, weekly1, weekly2, and weekly3 (latest snapshot), then

the Cohesity cluster will take the first full backup from the latest snapshot, which is weekly3.

Considerations

- When creating the SnapMirror policy to replicate the source volume to the DP volume, ensure to provide the snapshot retention period depending on the size of the volume you backup.
- Since Cohesity does not create and manage the snapshots present in the DP volume, you must ensure that the snapshot label of the DP volume you specified does not get deleted within the backup duration you configured in the protection policy.
- When assigning or creating backup policies to a Protection Group for DP volumes, it is recommended to create the schedule of backup policy in-sync or less aggressive than the SnapMirror or SnapVault schedule. This ensures the presence of the snapshot in the DP volume, prior to the incremental backup triggered by Cohesity backup policy schedule.
- When creating snapshots for DP volume backup, ensure not to use the same prefixes that are automatically generated by NetApp SnapMirror.

User Access Credentials to Back Up SMB Shares

To back up SMB shares of any volume type, you must provide the local or Active Directory user credentials that allow at least read access to the NetApp ONTAP SMB share. You can provide these credentials while registering the NetApp ONTAP server with the Cohesity cluster or later when creating the Protection Group. For more information, see, Register and Manage NetApp ONTAP Source.

Backup Preferences For Mixed Mode Volumes

If the volume you plan to backup is exposed to both NFS export and SMB share, then you must choose how you want the Cohesity cluster to backup that volume while creating the Protection Group. Cohesity will backup the ACLs according to the selected backup preference.

If you select NFS as the preference mode, then the SMB access control lists (ACLs) would be lost and only the NFS POSIX ACLs will be backed up.

If you select SMB as the preference mode, then the NFS POSIX ACLs would be lost and only the SMB ACLs will be backed up.

Backup Preferences for NFS Volumes

If you select NFS as the preference mode and the selected volume has:

- NFSv3 enabled, then the SMB ACLs will be lost and only the NFS POSIX ACLs will be backed up.
- NFSv3 and NFSv4.1 enabled, then you can choose to use NFSv4.1 to back up the volume. If you choose NFSv4.1, then the SMB ACLs will be lost, and the NFSv4.1 ACLs

will be backed up. However, if you do not toggle the "Use NFSv4.1 protocol for NFS volumes" option on the Cohesity Dashboard, then only the NFS POSIX ACLs will be backed up.

- NFSv4.1 enabled (NFSv3 disabled), the backup will be performed using NFSv4.1 automatically and the **Use NFSv4.1 protocol for NFS volumes** toggle option will not be available on the Cohesity Dashboard.

> **Note:** NetApp NFSv4.1 volumes are supported from the Cohesity 6.6.0d version onwards. To enable this feature, contact Cohesity Support.

Extended Attributes using SMB2 Protocol on NetApp ONTAP 9.15.1

Cohesity's NAS Data Protection supports the restore of extended attributes of entities using the SMB2 protocol on NetApp. You can now preserve and restore the file content along with any associated extended attributes, which are metadata that provide additional information about the .

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

Protect NetApp ONTAP Using File-Runner Based Backup

In Cohesity, NetApp ONTAP volumes are protected using a Protection Group and a Protection Policy. A Protection Group uses the schedules and settings defined in the policy to determine when and how backups are captured, archived, or replicated.

A Protection Policy is a reusable set of settings that define how and when objects are protected and replicated. You can select which standard or custom policy to use when creating a Protection Group. For more information, see Manage Protection Policy.

This topic provides information on how to protect NetApp ONTAP volumes using a Protection Group and a Protection Policy:

- Protect Data Protection Volumes with Only SMB Share or NFS Export
- Protect Data Protection Volumes with Both NFS and SMB Share (Mixed Mode)
- Protect Read-Write volumes with Only SMB Share or NFS Export
- Protect Read-Write Volumes with Both NFS and SMB Share (Mixed Mode)
- Protect Snapshots of VMware VMs stored in NetApp NFS volumes

> **Note:** Cohesity recommends a first full and incremental forever backup approach to back up your NAS sources.

Protect Data Protection Volumes with Only SMB Share or NFS Export

You can protect NetApp ONTAP DP volumes with only SMB share or NFS export by creating a Protection Group.

To protect DP volumes with only SMB share or NFS export:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then select **NAS**.
3. Click **Add Objects** and from the **Registered Source** drop-down list, select the NAS source that contains the volumes you want to back up.

   You can also register a new source with the Cohesity cluster so you can protect it. For more information, see Register and Manage NetApp ONTAP Source.
4. From the **Objects** list, select DP volumes of NFS exports or SMB shares.
5. Click **Continue**.
6. For NetApp volumes enabled for NFSv3 and NFSv4.1 protocol, the Backup Preferences for NFS Volumes field will be enabled. Toggle the **Use NFSv4.1 protocol for NFS volumes** to back up the volume via NFSv4.1 protocol.

   > **Note:** This feature is supported from the Cohesity 6.6.0d version onwards. To enable this feature, contact Cohesity Support.

   To back up SMB shares, provide the user access credentials if you have not provided when registering the NetApp ONTAP source.

   > **Note:** To backup NetApp DP volumes with SMB share, the volume needs to be in the junction path on the NetApp.
7. In the **Protection Group** field, enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.
8. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, see Create or Use an Existing Protection Policy.
9. Select the appropriate Storage Domain. For more information, see Manage Storage Domains.
10. If you want to change or configure any of the additional settings, then select **More Options** and perform the below steps or else, click **Protect**.
11. Optionally, from the **Protection Group** field, you can select an existing Protection Group. By selecting an existing Protection Group, the settings configured in the existing Protection Group will be applied to this Protection Group. To select an existing

Protection Group, perform the following steps or else, go to step 13:

a. From the **Protection Group** field, enable **Existing Group**.

b. Select an existing Protection Group from the **Group** drop-down list.

c. Click **Protect**.

12. In the **Start Time** field, the default time zone is the browser's time zone. You can change the time zone of the job by selecting a different time zone.
13. If you need to change any of the additional settings on the Protection Group page, click the down arrow icon next to **Additional Settings** and click **Edit** on the right. For more information, see Additional Settings.
14. Click **Protect**.

    Your new Protection Group is now active and running.

Protect Data Protection Volumes with Both SMB Share and NFS Export (Mixed Mode)

You can protect NetApp ONTAP DP volumes that are exposed to both NFS and SMB protocols. If the volume is exposed to both NFS export and SMB share, then you must choose how you want Cohesity to back up the NetApp ONTAP volume. Cohesity will backup the ACLs according to the backup preference mode you select.

If you select NFS as the preference mode and the selected volume has:

- NFSv3 enabled, then the SMB ACLs will be lost and only the NFS POSIX ACLs will be backed up.
- NFSv3 and NFSv4.1 enabled, then you can choose to use NFSv4.1 to back up the volume. If you choose NFSv4.1, then the SMB ACLs will be lost, and the NFSv4.1 ACLs will be backed up. However, if you do not toggle the **Use NFSv4.1 protocol for NFS volumes** option on the Cohesity Dashboard, then only the NFS POSIX ACLs will be backed up.

If you select SMB as the preference mode, then the NFS POSIX ACLs will be lost and only the SMB ACLs will be backed up.

> **Note:** NetApp NFSv4.1 volumes are supported from the Cohesity 6.6.0d version onwards. To enable this feature, contact Cohesity Support.

To protect DP volumes exposed to both NFS and SMB protocols:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then select **NAS**.
3. Click **Add Objects** and from the **Registered Source** drop-down list, select the NAS source that contains the volumes you want to back up.

You can also register a new source with the Cohesity cluster so you can protect it. For more information, see Register and Manage NetApp ONTAP Source.

4. From the Object list, select DP volumes that are exposed to both NFS and SMB protocols.
5. Click **Continue**.
6. Select the backup preference mode for the mixed-mode volume you want to backup.
7. For NetApp volumes exposed to the NFSv4.1 protocol, the Backup Preferences for the NFS Volumes field will be enabled. Toggle the **Use NFSv4.1 protocol for NFS volumes** option to use the NFSv4.1 protocol.

   > **Note:** This feature is supported from the Cohesity 6.6.0d version onwards. To enable this feature, contact Cohesity Support.

8. To back up SMB shares, provide the user access credentials if you have not provided when registering the NetApp ONTAP source.

   > **Note:** To backup NetApp DP volumes with SMB share, the volume needs to be in the junction path on the NetApp.

9. In the **Protection Group** field, enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.
10. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, see Create or Use an Existing Protection Policy.
11. Select the appropriate Storage Domain. For more information, see Manage Storage Domains.
12. If you want to change or configure any of the additional settings, then select **More Options** and perform the below steps or else, click **Protect**.
13. Optionally, from the **Protection Group** field, you can select an existing Protection Group. By selecting an existing Protection Group, the settings configured in the existing Protection Group will be applied to this Protection Group. To select an existing Protection Group, perform the following steps or else, go to step 13:
    a. From the **Protection Group** field, enable **Existing Group**.
    b. Select an existing Protection Group from the **Group** drop-down list.
    c. Click **Protect**.
14. In the **Start Time** field, the default time zone is the browser's time zone. You can change the time zone of the job by selecting a different time zone.

15. If you need to change any of the additional settings on the Protection Group page, click the down arrow icon next to **Additional Settings** and click **Edit** on the right. For more information, see Additional Settings.
16. Click **Protect**.

    Your new Protection Group is now active and running.

Protect Read-Write volumes with Only SMB Share or NFS Export

You can protect NetApp ONTAP RW volumes with only SMB share or NFS export by creating a Protection Group.

To protect RW volumes with only SMB share or NFS export:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then select **NAS**.
3. Click **Add Objects** and from the **Registered Source** drop-down list, select the NAS source that contains the volumes you want to back up.

   You can also register a new source with the Cohesity cluster so you can protect it. For more information, see Register and Manage NetApp ONTAP Source.
4. From the Object list, select RW volumes of NFS exports or SMB shares.
5. Click **Continue**.
6. For NetApp volumes enabled for NFSv3 and NFSv4.1 protocol, the Backup Preferences for NFS Volumes field will be enabled. Toggle the Use NFSv4.1 protocol for NFS volumes to back up the volume via NFSv4.1 protocol.

   > **Note:** This feature is supported from the Cohesity 6.6.0d version onwards.
   > To enable this feature, contact Cohesity Support.
7. To back up SMB shares, provide the user access credentials if you have not provided when registering the NetApp ONTAP source.
8. In the **Protection Group** field, enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.
9. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, see Create or Use an Existing Protection Policy.
10. Select the appropriate Storage Domain. For more information, see Manage Storage Domains.
11. If you want to change or configure any of the additional settings, then select **More Options** and perform the below steps or else, click **Protect**.

12. Optionally, from the **Protection Group** field, you can select an existing Protection Group. By selecting an existing Protection Group, the settings configured in the existing Protection Group will be applied to this Protection Group. To select an existing Protection Group, perform the following steps or else, go to step 13:
    a. From the **Protection Group** field, enable **Existing Group**.
    b. Select an existing Protection Group from the **Group** drop-down list.
    c. Click **Protect**.
13. In the **Start Time** field, the default time zone is the browser's time zone. You can change the time zone of the job by selecting a different time zone.
14. If you need to change any of the additional settings on the Protection Group page, click the down arrow icon next to **Additional Settings** and click **Edit** on the right. For more information, see Additional Settings.
15. Click **Protect**.

    Your new Protection Group is now active and running.

Protect RW Volumes with Both SMB Share and NFS Export (Mixed mode)

You can protect NetApp ONTAP RW volumes that are exposed to both NFS and SMB protocols. If the volume is exposed to both NFS export and SMB share, then you must choose how you want Cohesity to back up the NetApp ONTAP volume. Cohesity will backup the ACLs according to the backup preference mode you select.

If you select NFS as the preference mode and the selected volume has:

- NFSv3 enabled, then the SMB ACLs will be lost and only the NFS POSIX ACLs will be backed up.
- NFSv3 and NFSv4.1 enabled, then you can choose to use NFSv4.1 to back up the volume. If you choose NFSv4.1, then the SMB ACLs will be lost, and the NFSv4.1 ACLs will be backed up. However, if you do not toggle the **Use NFSv4.1 protocol for NFS volumes** option on the Cohesity Dashboard, then only the NFS POSIX ACLs will be backed up.

If you select SMB as the preference mode, then the NFS POSIX ACLs will be lost and only the SMB ACLs will be backed up.

> **Note:** NetApp NFSv4.1 volumes are supported from the Cohesity 6.6.0d version onwards. To enable this feature, contact Cohesity Support.

To protect RW volumes exposed to both NFS and SMB protocols:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then select **NAS**.

3. Click **Add Objects** and from the **Registered Source** drop-down list, select the NAS source that contains the volumes you want to back up.

   You can also register a new source with the Cohesity cluster so you can protect it. For more information, see Register and Manage NetApp ONTAP Source.
4. From the Object list, select RW volumes that are exposed to both NFS and SMB protocols.
5. Click **Continue**.
6. Select the backup preference mode for the mixed-mode volume you want to backup.
7. For NetApp volumes exposed to the NFSv4.1 protocol, the Backup Preferences for the NFS Volumes field will be enabled. Toggle the Use NFSv4.1 protocol for NFS volumes option to use the NFSv4.1 protocol.

   > **Note:** This feature is supported from the Cohesity 6.6.0d version onwards.
   > To enable this feature, contact Cohesity Support.
8. To back up SMB shares, provide the user access credentials if you have not provided when registering the NetApp ONTAP source.
9. In the **Protection Group** field, enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.
10. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, see Create or Use an Existing Protection Policy.
11. Select the appropriate Storage Domain. For more information, see Manage Storage Domains.
12. If you want to change or configure any of the additional settings , then select **More Options** and perform the below steps or else, click **Protect**.
13. Optionally, from the **Protection Group** field, you can select an existing Protection Group. By selecting an existing Protection Group, the settings configured in the existing Protection Group will be applied to this Protection Group. To select an existing Protection Group, perform the following steps or else, go to step 13:
    a. From the **Protection Group** field, enable **Existing Group**.
    b. Select an existing Protection Group from the **Group** drop-down list.
    c. Click **Protect**.
14. In the **Start Time** field, the default time zone is the browser's time zone. You can change the time zone of the job by selecting a different time zone.
15. If you need to change any of the additional settings on the Protection Group page, click the down arrow icon next to **Additional Settings** and click **Edit** on the right. For more information, see Additional Settings.

16. Click **Protect**.

    Your new Protection Group is now active and running.

Protect Snapshots of VMware VMs stored in NetApp NFS volumes

The prerequisites for protecting snapshots of VMware VMs stored in NetApp NFS volumes are:

- Register your NetApp ONTAP as a source on Cohesity and enable the Storage Array Snapshots option during registration. For details, see Register and Manage NetApp ONTAP Source.
- Set how often the Storage Array Snapshots have to be taken and how long they have to be retained in the Protection Policy. For details, see Policy Settings for NetApp ONTAP

Perform these steps to protect snapshots of VMware VMs stored in NetApp NFS volumes by creating a Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. Click **Protect** on the top-right of the page and then select **Virtual Machines**.
3. Click **Add Objects** and from the **Registered Source** drop-down list, select the registered source (the vCenter).
4. From the **Objects** list, select the VMware VMs that are backed up by the registered NAS source.

   You can also register a new source with the Cohesity cluster so you can protect it. For more information, see Register and Manage NetApp ONTAP Source.
5. Click **Continue**.
6. In the **Protection Group** field, enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.

   Optionally, select **Existing Group** to use the settings of an existing Protection Group. From the **Group** list, select an existing **Protection Group**.
7. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. The policy you select or create must have the **Storage Array Snapshot** option enabled. For more information, see Policy Settings for NetApp ONTAP.
8. Selection one of the following options:
   - **Protect**: Select this option if you want to complete the Protection Group creation without changing or configuring any of the additional settings. Your new Protection Group is now active and running.
   - **More Options**: If you want to change or configure any of the additional settings, then select **More Options**. For more information, see Add or Edit a

Protection Group for Virtual Servers. After configuring the settings, click **Protect**.

> **Note:** To delete the VMs from a Storage Array Snapshot backup job, select all the VMs in that backup job. The **Delete** or **Delete All Snapshots** buttons are not enabled until all the VMs are selected.

Recover Snapshots of VMware VMs stored in NetApp NFS volumes

To recover Snapshots of VMware VMs stored in NetApp NFS volumes to the original or new location:

1. In the Cohesity Dashboard, select **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then do one of the following:
    1. If you want to recover VMs, select **Virtual Machines** > **VMs**. The Virtual Machines page appears. Continue to Step 3.
    2. If you want to recover virtual disks, select **Virtual Machines** > **VMDK**. Follow the procedure described in Recover Virtual Disks to recover the virtual disk to an original or new location.
3. Search for a protected object (VM) or Protection Group that contains the snapshots to recover from by entering characters of the VM name, Protection Group name, or by specifying the wildcard character *. A list of VMs displays.

    You can optionally filter the search results by Source, Protection Group, Storage Domain, or Date.
4. From the list of search results, select one or more VMs or Protection Groups that contain the snapshots to recover. **Ensure that all the VMs you select are from Storage Array Snapshots backups.**
5. From the selected lists, mouse over the snapshot, and then click the edit icon.

    The Edit recovery point for <VM_name> page appears.

    > **Note:** By default, the option to select the snapshot is displayed in **Timeline** mode. You can also choose to view the option in **List** mode by clicking the List tab in the top-right corner of the page.

    1. To select a snapshot from the Timeline mode:
        i. From the **Choose a date** drop-down, select a date.

        The snapshots available on the selected date are displayed in blue dots on the timeline bar.

ii. Select the snapshot to be recovered by clicking the corresponding blue dot.

For CDP, select the point-in-time restore. You can specify the exact point-in-time recovery by sliding the timeline bar.

iii. By default, the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.

iv. Click **Select Recovery Point** and then go to step 6.

2. To select a snapshot from the **List** mode:

i. Select the List tab from the top-right corner of the Edit recovery point for <VM_name> page.

By default, the page displays the snapshots available in the last one month.

ii. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.

iii. Select the snapshots to be recovered.

iv. By default, the snapshot is recovered from the local Cohesity cluster. You can also select snapshots archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.

a. Click **Select Recovery Point** and then go to step 6.

6. Click **Next: Recover Options**.
7. From the **Recover To** options, select **Original Location** to recover the VM to the original location or select **New Location** to recover the volume to an alternate location as a new storage volume.
8. Select **Select Instant Recovery** as the **Recovery Type**.

The VMs will be instantly available after recovery in the target location. The data will be moved to the target storage later.

> **Note:** You should have the VirtualMachine.Config.Rename permission on your user account to use this recovery option.

9. Optional. Edit the default settings under **Recovery options**.
10. Click **Start Recovery**.

The recovery task is initiated. You can monitor the recovery task from the **Recoveries** page.

Additional Settings

Additional Settings	Description
Pause Future Runs	Toggle on this option to stop protection runs of the Protection Group from executing. Once you enable this option, no protection runs will be scheduled for this Protection Group.
End Date	Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts prior to this date runs until completion even if it completes after this date.
QoS Policy	Select an appropriate quality of service (QoS) policy. **Note:** Cohesity recommends specifying **Backup HDD**, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.

Additional Settings	Description

Snapshot Prefix for DP Volumes	(*Applies only for DP volumes*) Select one of the following options to backup the snapshots from the DP volume to the Cohesity cluster.
	• **None**: Enable this option if you want the Cohesity cluster to take the full backup from the oldest snapshot available on the DP volume and incremental backup from the latest snapshots available on the DP volume. This option is enabled by default.
	> **Note:** If you have selected None as the Snapshot Backup Preferences option in a Protection Group, then you can edit the Protection Group and change the Snapshot Backup Preferences option to Snapshot Prefix or SnapDiff Backup.
	• **Snapshot Prefix**: Enable this option if you want the Cohesity cluster to take the full and incremental backup from the snapshots that match the prefix name you specify:
	  • In the **Incremental Snapshot Prefix** field, specify the prefix of the snapshot name present in the DP volume from which Cohesity cluster can take incremental backup.
	  • In the **Full Snapshot Prefix** field, specify the prefix of snapshot name present in the DP volume from which Cohesity cluster can take the first full backup.

Pre & Post Scripts	Toggle **Enable** to run scripts on a Unix server before and/or after a Protection Group runs. If configured, scripts are run every time an object (or entity) is backed by a protection run. For example, if there are five mount/shares that are backed up as part of the NAS Protection Group and the Pre Script is configured, then five instances of the Pre Script is executed in parallel. You can distinguish between the scripts that are run on the different objects (entities) using the `COHESITY_BACKUP_ENTITY` environment variable. The Cohesity cluster populates this environment variable with the name of the backed object (or entity).
Skip Files on Errors	Toggled on by default. The Protection Group continues to run even if it encounters errors on files, such as permissions errors. If files are skipped, the protection run details page indicates a warning status and provides additional information. If toggled off, the Protection Group stops when it encounters an error.

Additional Settings	Description
Encryption	**Note:** If you want to encrypt NFS data traffic between the NetApp source and Cohesity cluster while backing up NFS volumes, you must modify the supported encryption types value on the compute object to 24 (0x18). This change is required as NetApp does not support ARCFOUR Encryption. Setting the value to 24 (0x18) configures the object to only use AES Encryption. This is needed only for NFS encryption. Toggle on this option to enable in-flight encryption of data that are backed up to the Cohesity cluster. To use the encryption functionality for NFS volumes, you must join the Cohesity cluster to the active directory as the Kerberos server or add the Kerberos provider in the Cohesity cluster Access Management section. This option is disabled by default. **Note:** Encrypting in-flight data will have a minor impact on the performance.

Additional Settings	Description
File DataLock	Toggle on this option to preserve the AccessTime of the files and folders of the selected volumes. The AccessTime provides the lock period of the files and folders that are applied when these files and folders are recovered to the Cohesity View. For more information on File DataLock, see NAS File DataLock. Select one of the following **DataLock** modes: • **Compliance**: In this mode, files or folders cannot be deleted or modified during the retention period. After the lock expires, no user can modify the files or folders. However, a root user can delete the files and folders. Only a user with Data Security role can edit the File DataLock settings in the Compliance mode. • **Enterprise**: In this mode, files or folders cannot be modified by any user before or after the lock retention period expiration. However, a root user can delete the files or folders before or after the lock retention period. An admin user or a user with a Data Security role can edit the File DataLock settings in the Enterprise mode. This mode is useful for giving storage administrators additional control over the file. You can further configure the File DataLock settings to: • Set the lock period for the new files and folders created on the recovered Cohesity View Provide the following information to set the lock period for the new files and folders that will be created on the recovered Cohesity View. These settings are not applicable for the existing NAS source files and folders recovered on the Cohesity View. • **Default Lock Period**: Provide the time period during which the files should remain locked. When the time period ends, files can be deleted but not changed. By default, the files are locked forever. • **Autolock Files**: By enabling this option, the files are automatically locked if they are not modified in the time period you specify. By default, this option is disabled. • **Manually Lock Using**: Select when the files are to be locked: • **Read-Only**: Select this option to lock files when the file permission is set to read only, for example; by setting the Windows file properties attribute or using the Linux `chmod` command. By default, the files are locked when the file permission is set to read only. • **FutureATime**: Select this option to lock files when the last access time (atime) is set, for example, by using Windows `PowerShell` commands or the Linux touch command.

Additional Settings	Description
	Optionally you can set a **Minimum Retention** and/or a **Maximum Retention** period to ensure that a file's last access time cannot be set outside this period. A request to do so results in a permission denied error if manual locking mode is FutureATime. Otherwise, the request will be silently rejected and the file will be locked for the minimum retention duration. • Override the locking period of the existing files and folders recovered on the Cohesity View: The following option can be applied to all the existing files and folders that will be recovered on the Cohesity View. • **Override (Lock all files until a specific date)**: Enable this option and select a date to override the locking period of the existing files and folders. When you recover the files to the Cohesity View, Cohesity applies the farthest lock period between the override lock period you specify and the source file's lock period. For example; • The lock period of the source file is 09/09/2023 and the override lock period you specified is 09/08/2022. When you recover the file to the Cohesity View, then the lock period of the source file is applied to the recovered file, which is 09/09/2023. • The lock period of the source file is 09/09/2022 and the override lock period you specified is 09/08/2024. When you recover the file to the Cohesity View, then the override lock period you specified is applied to the recovered file, which is 09/08/2024. In **Compliance** mode, a user with Data Security privileges can extend the override date into the future, but no user can shorten the date. In **Enterprise** mode, a user with admin or Data Security privileges can extend or shorten the override date.

Additional Settings	Description
	Note: • You cannot enable or disable File DataLock once the Protection Group is created. • If you have disabled File DataLock while creating a Protection Group, then when you edit this Protection Group, the File DataLock option will not be displayed. • You can delete Protection Groups and snapshots having File DataLock enabled. File DataLock also preserves the ATimes of the hardlinks and symlinks.
Exclusions and Inclusions	Toggle on this option if you want to exclude or include locations. By creating exclusion and inclusion rules, you can limit the Protection Group to a specific set of files and directories and therefore minimize the disk space used to store the data. All the files and folders are included for by default for protection. For more information, see Exclusions and Inclusions for NAS Protection Group. **Note:** Cohesity does not support inclusion or exclusion of paths in a NetApp Snapdif-based Protection Group.
Indexing	This option is toggled on by default to index the data of the Protection Group. Indexing improves files and folders search. Cohesity performs incremental indexing where only the data that has changed since the previous snapshot is scanned and indexed.

Additional Settings	Description
Quiet Times	This option is available only if the selected policy has at least one quiet time period. Toggle the **Stop in-progress runs when quiet time starts** option to pause or abort the runs during quiet time. If this option is toggled off, after a protection run starts, execution continues even when the quiet time period specified for this Protection Group starts. However, a new protection run will not start during a quiet time period. • **Pause Runs** - Select this option to pause the currently executing protection runs and resume the runs when quiet time ends. • **Abort Runs** - Select this option to abort the currently executing protection runs when the quiet time period specified for the Protection Group starts. > **Note:** If the quiet time window for multiple protection runs is scheduled at the same time, then when the protection run is resumed, prioritization of the protection run does not work. 
Additional Settings	Description
Alerts	Select one or more of the following **Alerts On** settings if you want alerts to be created for the following triggers: • SLA Violation: Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts. • Failure: Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • Success: Create an informational alert when the Protection Group completes successfully. Emails are not sent when informational alerts are created. To send emails when alerts are triggered for the Protection Group, in the **Email Recipients** field, add the email addresses of the recipients.
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of jobs exceeds the ability to process jobs, this will be the priority of implementation of the jobs: a. High b. Medium c. Low
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks). • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. > **Note:** Users with similar SLAs can be grouped together and a custom policy and Protection Group can be created to achieve different SLAs.
Description	Enter a brief description about the Protection Group.

Create or Use an Existing Protection Policy

A Protection Policy is a reusable set of settings. It enables you to define how and when NetApp ONTAP data is protected, replicated, and archived. A standard policy provides various settings that you can configure for a Protection Group.

Create a Protection Policy with the settings listed in the Policy Settings for NetApp ONTAP. For detailed instructions on how to create a Protection Policy, see Create or Edit a Standard Policy.

Policy Settings for NetApp ONTAP

The following table lists the applicable policy settings for NetApp ONTAP:

Field	Description
Primary Copy	Select **Local** from the drop-down to keep the primary copy data on the Cohesity cluster. Select any external target for performing CloudArchive Direct wherein the primary copy of the data is stored on the external targets. For more information, see CloudArchive Direct.
DataLock	If applicable, add a DataLock for compliance and regulatory requirements, to ensure that your protected data, including local backups, archives, and replication, cannot be modified until the DataLock expiration. Once applied, a DataLocked Snapshot will be deleted only after its retention period expires. A DataLock prevents all users, including those who have the Data Security role in Cohesity, from modifying or deleting any Snapshots that were generated by theProtection Groups that use this Policy. Only users with the Data Security role can add, modify, or remove a DataLock from a Policy.
Scheduled Backup	Defines when backups are captured, how long they are retained and the type of backup to capture.
Extended Retention	Add this to retain a subset of snapshots (backups) for longer than defined by the protection schedule.
Retry Options	Use this option to customize the retry settings for capturing Snapshots. By default, Cohesity attempts to capture Snapshots three times before the Protection Group fails. The default time between retries is five minutes. You can customize the number of retries and how long to wait between each attempt.
Periodic full backup	Use this option to choose when to run a periodic full backup.

Field	Description
Quiet Times	Quiet Times defines time periods when new protection runs are not started. For example, you might want to configure hourly backups that run during weekdays but not on Saturday or Sunday. Quiet Times only prevents new protection runs from starting during the specified time period. The protection runs that started before the quiet time period will be dependent on the quiet time settings configured in the additional settings of the protection Group. For example, if a protection run starts at 12:45 AM on Saturday morning and there is a weekend quiet time period that starts at 1 AM on Saturday morning, the protection run will continue to run past 1 AM. No new protection runs are started during the quiet time period.
Replication	To replicate snapshots to another , click the replication icon from the floating menu. The copied snapshots are stored in the storage domain of the remote cluster.
Archival	To add an archive schedule, click the archival icon from the floating menu.
Storage Array Snapshot	Select **Snapshot Array Snapshot** from the floating menu to manage snapshots of VMs stored in NetApp NFS volumes. • **Every**: Specify how often the snapshots have to be taken. • **Retain for xx days**: Specify how long the snapshots are retained on the NetApp NFS volume. Consider the following when you are enabling this option: • **Storage Array Snapshot** can be enabled only on new or existing Protection Policies with Scheduled Backup configured. • If **Replication** or **Archive** is enabled for a Protection Policy along with **Storage Array Snapshot**, replication or archival will only work on the regular backups and not on the Storage Array Snapshots. • **Storage Array Snapshot** cannot be enabled with backup options such as **Continuous Data Protection**.

Use an Existing Protection Policy

You can use an existing Protection Policy protecting NetApp ONTAP. If you are selecting an existing protection policy, then the following options are ignored if they are already configured in the protection policy:

- **Log Backup (Databases)**
- **Continuous Data Protection**
- **Add BMR Backup (Physical Server)**
- **CloudSpin**

NAS File DataLock

Many organizations now rely on WORM (Write Once Read Many) data storage such as Nutanix Files, NetApp Snaplock, and Isilon Smartlock volumes to retain their files and folders in unmodified form for compliance and regulatory purposes and to protect the files from accidental deletion or modification.

When you backup these WORM-capable volumes to the Cohesity cluster, it is essential to have the ability to easily lock the files and folders of the volumes while protecting themselves from accidental or malicious attempts to delete or modify these files. The backup should also provide a strong guarantee for data non-mutability and non-erasability for a certain period of time.

This capability is achieved using Cohesity's File DataLock feature.

FileDataLock is a Cohesity feature that preserves the WORM attributes of any files and folders created in the Cohesity View. You can apply the File DataLock feature for NAS backup (NFS exports and SMB shares) while creating a NAS Protection Group.

With File DataLock enabled in a NAS Protection Group, Cohesity preserves the future AccessTime (ATime) of the files and folders. The AccessTime provides the lock period for files and folders. You can also override this lock period in the File DataLock settings of the NAS Protection Group. This lock period is applied to these files and folders when they are recovered to the Cohesity View. This prevents the users or administrator from modifying or deleting these locked files until the locking period expires.

You can also set lock periods for the new files and folders created on recovered Cohesity View in the File DataLock settings of the NAS Protection Group.

When you recover File DataLock enabled storage volumes to the Cohesity View, the View details page will display a lock icon for the files and folders having File DataLock.

File DataLock is supported for all types of NAS sources including NetApp 7-mode and is agnostic of the NAS protocol.

For information on how to enable File DataLock, see Protect NAS.

File DataLock Modes

You can use the File DataLock feature in one of the two modes:

- **Compliance mode**: The WORM files are protected at the disk level. This mode implements strict regulatory requirements for data retention and complies with SEC Rule 17a-4. In this mode, files and folders cannot be deleted or modified during the retention period. After the lock expires, no user can modify the files and folders. However, a root user can delete the files and folders. Only a user with a Data Security role can edit the File DataLock settings in the Compliance mode.
- **Enterprise mode**: The WORM files are protected at the file level. This mode does not implement strict regulatory requirements for data retention. In this mode, files and folders cannot be modified by any user before or after the lock retention period

expiration. However, a root user can delete the files and folders during or after the lock retention period. An admin user or a user with the Data Security role can edit the File DataLock settings in the Enterprise mode

> **Note:** An admin user or a user with the Data Security role can edit the File DataLock settings and switch from the Enterprise mode to Compliance mode. But switching from Compliance mode to Enterprise mode is not supported.

Things to remember for File DataLock

- You cannot enable or disable File DataLock once the View is created.
- If you have disabled File DataLock while creating a Protection Group, then when you edit this Protection Group, the File DataLock option will not be displayed.
- You can delete Protection Groups and snapshots having File DataLock enabled.

  File DataLock also preserves the ATimes of the hardlinks and symlinks.
- **Recovery**
  - Recovering a File DataLock enabled backed-up volume as a Cohesity View will preserve ATimes and the locking period for the file.
  - Recovering a File DataLock enabled volume to the original location with 'Overwrite existing files/folder' as the recovery option will encounter an error if the files and folders are read-only. However, the ATime and other attributes of other files and folders of the source volumes are preserved.
  - Recovering a File DataLock enabled volume to an alternate NAS recovery will preserve ATimes and other attributes of files and folders of the source volumes.
  - Cloning a recovered View having File DataLock enabled will not inherit the File DataLock properties.
- **Replication**

  When you replicate to a remote Cohesity cluster, the File DataLock settings are also replicated.
- **Archival**

  File DataLock settings are preserved when you recover volume from an archived snapshot whose Protection Group has File Datalock enabled, to a Cohesity View.
- **Cloud Archive Direct**

  File DataLock settings are preserved when you recover from a Cloud ArchiveDirect snapshot whose Protection Group has File Datalock enabled, to a Cohesity View.

Exclusions and Inclusions for NAS Protection Group

In a NAS Protection Group, all the files and folders are included by default for data protection. While creating a Protection Group, you can toggle on **Exclusions and Inclusions** from the **Advanced Settings** options if you want to exclude or include locations. By creating the exclusion and inclusion rules, you can limit the Protection Group to a specific set of files and directories. As a result, you can minimize the disk space used to store the data.

> **Note:**
> - To add an exclusion or inclusion rule, you must prefix a forward slash (‘/’) or suffix an asterisk (‘*’) to the path or to a particular file within the protected object. For example, ‘**/test**’ or ‘***.txt**’.
> - In exclusion or inclusion rules, file names and folder names are case-sensitive, which means ‘**test.txt**’ and ‘**Test.txt**’ are considered separate files. Use the correct capitalization of file or folder names to ensure that the rules recognize your file or folder.

Add Inclusion

From the Additional Settings options on the Protection Group page, toggle on **Exclusions and Inclusions**. Click **Add Inclusion** to include a particular path or a particular file within the protected object.

For example, consider four directories - **test**, **test1**, **test2**, and **test3** under the protected object with path `/ifs/TestShare1/Folder1`. The table below lists the input types for an inclusion list of folders and their respective outcome:

Input	Outcome
/	Everything inside the protection path is backed up if exclusions are not defined.
/test	When the inclusion path is not suffixed by '/', Protection Group will include all folders starting from the protection path. In this example, /test will behave as /test* and Protection Group will include '**test**', '**test1**', '**test2**', and '**test3**' from the protection path for backup.

Input	Outcome
/test/	When the inclusion path is suffixed by '/', it will only include the specific folder. In this example, /test/ behaves as /test/* and Protection Group will only include '**test**' from the protection path for backup.

- Do not provide the folder name along with the backup path while including files and folders for a Protection Group. The backup path is considered by default. For example, `/ifs/TestShare1/Folder1/test` does not include any folder.
- If exclusions are defined, they will take precedence over inclusions.

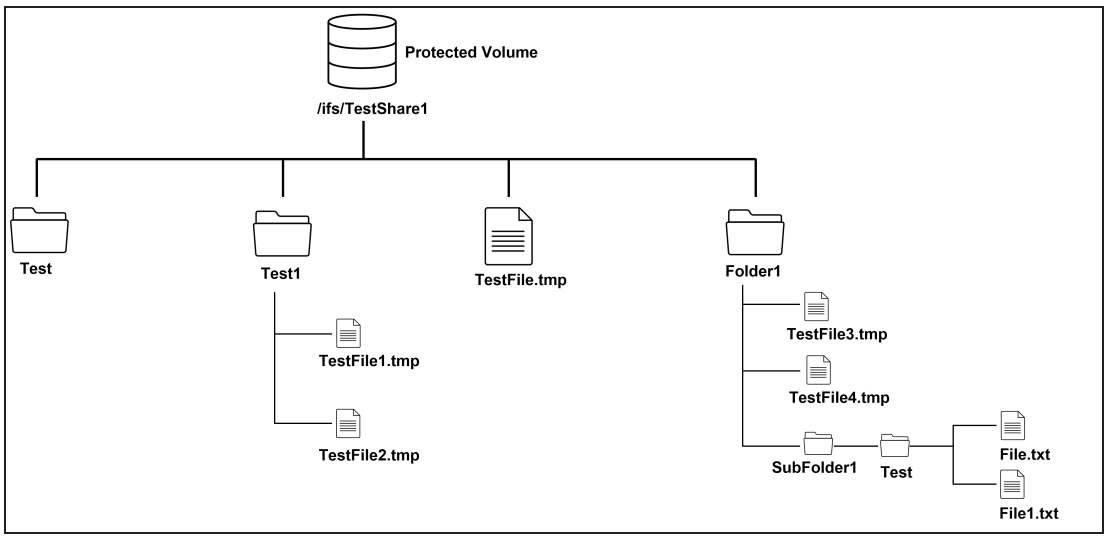
Add Exclusion

From the Additional Settings options on the Protection Group page, toggle on **Exclusions and Inclusions**. Click **Add Exclusion** to exclude a particular path or a particular file within the protected object. You can also specify regular expressions for excluding files in the format `regex:<regex pattern>`.

For example, consider there are three directories - **Test**, **Test1**, and **Folder1** and a file, **TestFile.tmp** under the protected object with path **/ifs/TestShare1**.

- The **Test1** folder has **TestFile1.tmp**, **TestFile2.tmp** files.
- The **Folder1** folder has **TestFile3.tmp**, **TestFile4.tmp files**, and **SubFolder1** which further has a **Test** folder with **File.txt**, **File1.txt** files in it.

The following figure illustrates the directory structure under the protected object with path **/ifs/TestShare1**.



The table below lists the input types for an exclusion list of folders and their respective outcome:

Input	Description	Outcome
/Test	When the exclusion path is not suffixed by '**/**', the Protection Group will exclude all files and folders with **Test** as the prefix. For exclusions, **/Test** behaves as **/Test***. **Note:** Exclusion will not be effective on the sub-directory level.	Excludes **Test** and **Test1** folders, and **TestFile1.tmp** file from the protection path. **TestFile3.tmp** and **TestFile4.tmp** files in the **Folder1** folder will not be excluded.
/Test/	When the exclusion path is suffixed by '**/**', the Protection Group excludes only the files and folders with the name **Test**. For exclusions, **/Test/** behaves as **/Test/***. **Note:** Exclusion will not be effective on the sub-directory level.	Excludes the **Test** folder of the parent directory. The **Test** sub-folder in **/Folder1/SubFolder1** will not be excluded.
*/Test	Excludes all the files and directories with the name '**Test**'. **Note:** Exclusion will be effective on all levels of sub-directories.	Excludes the **Test** folder of the parent directory and the **Test** sub-folder in **/Folder1/SubFolder1**.
*.tmp	Excludes all the files that with '**.tmp**'. **Note:** Exclusion will be effective on all levels of sub-directories.	Excludes **TestFile.tmp**, **TestFile1.tmp**, **TestFile2.tmp**, **TestFile3.tmp**, **TestFile4.tmp** files.
regex:.*\.tmp	Excludes the files and folders with '**.tmp**'. **Note:** Exclusion will be effective on all levels of sub-directories.	Excludes **TestFile.tmp**, **TestFile1.tmp**, **TestFile2.tmp**, **TestFile3.tmp**, **TestFile4.tmp** files.

Input	Description	Outcome
regex:/Folder1/.*/Test/.*\.txt$	Excludes all files with **.txt** extension from all the **Test** folders directory in **/Folder1/**.	Excludes **File.txt** and **File1.txt** files in the **/Folder1/SubFolder/Test** folder.

> **Note:** Do not provide the folder name along with the backup path while excluding files and folders for a Protection Group. The backup path is considered by default. For example, `/ifs/TestShare1/Folder1/test` does not exclude any folder.

Cohesity automatically excludes the following NetApp system files:

- .vtoc_internal and .bplusvtoc_internal files
- .copy-offload directory and .tokens file

Considerations

Cohesity does not support inclusion or exclusion of paths in:

- an IsilonProtection Group with Changelist enabled.
- a NetApp SnapDiff-basedProtection Group.

Adaptive Backup for NetApp

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

You can now apply a threshold on the CPU capacity utilization for the NetApp source. The Cohesity cluster will adaptively adjust the number of backup IO requests sent to the NetApp source such that the CPU capacity utilized does not exceed the set threshold.

For example, if the threshold value specified is 40% and the primary workload utilizes 30% of the CPU capacity, then the Cohesity cluster will send backup IO requests so as not to exceed 40% CPU on NetApp by consuming only 10% CPU for backup. If the primary load on the NetApp now increases to 35%, then Cohesity cluster will adapt to drop its IO request to consume only 5% of CPU capacity instead of 10% of the CPU capacity. To summarize, Cohesity backup is adaptive, source aware, and sensitive to the load condition on the NetApp primary device.

> **Note:** Since the Cohesity cluster adaptively increases or decreases the percentage of the CPU capacity utilized for the backup operations, setting up a low CPU utilization threshold value might affect the backup duration.

Manage the NetApp ONTAP Backup Configuration

In Cohesity, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirement.

> **Note:** You cannot update the registered NetApp ONTAP Server and the assigned Storage Domain in the Protection Group settings. You cannot enable or disable the NetApp SnapDiff option on an existing Protection Group.

Add NetApp ONTAP volumes to the Protection Group

You can add new NetApp ONTAP volumes to the existing Protection Group for backup. The newly added volumes are backed up from the next protection run and it will be a full backup.

To add NetApp ONTAP volumes to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for NetApp ONTAP.
   For NetApp Snapdiff backup, select the NetApp SnapDiff-enabled Protection Group that you had created for NetApp ONTAP.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** field, click the **Edit** icon.
5. Select the NetApp ONTAP volumes you want to add to the Protection Group.
6. Click **Save Selection** > **Save**.

The newly added NetApp ONTAP volumes will be backed in the next scheduled protection run.

Remove NetApp ONTAP volumes from the Protection Group

From the **Edit Protection** page, you can remove NetApp ONTAP volumes from the Protection Group that you do not want to back up in the next protection run.

To remove NetApp ONTAP volumes from the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for NetApp ONTAP.

For NetApp Snapdiff backup, select the NetApp SnapDiff-enabled Protection Group that you had created for NetApp ONTAP.

3. Click the action icon next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** field, click the **Edit** icon.
5. Unselect the NetApp ONTAP volumes that you want to remove from the Protection Group.
6. Click **Save Selection** > **Save**.

The removed NetApp ONTAP volumes will not be backed in the next scheduled protection run.

Enable Auto Protect

The Auto Protect option enables you to automatically protect the new NetApp ONTAP volumes that are added to the selected parent NetApp ONTAP server. However, you cannot enable auto-protect at the server-level containing both Read-Write volumes and Data-Protect volumes.

To enable auto protect:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for NetApp ONTAP.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** field, click **Edit Objects**.
5. Click the shield icon to enable Auto Protect.
6. Click **Save Selection** > **Save**.

When this option is enabled on the parent NetApp ONTAP server, all the NetApp ONTAP volumes that are added to the parent NetApp ONTAP server in the future are automatically added to the Protection Group and are protected from the next protection run.

For example, you create a Protection Group that backs up a NetApp ONTAP SVM. The Protection Group runs for two weeks and then a new volume is added to the NetApp ONTAP SVM. The next time the Protection Group runs, if the object hierarchy has been refreshed on the Cohesity cluster, the new volume is also backed up even though the new volume has not been explicitly selected to be included in the Protection Group. The object hierarchy is automatically refreshed every four hours. To manually refresh the object hierarchy, select **Data Protection > Sources**, find the source in the list, and click . To exclude an object from Auto Protect, click .

- Indicates an Auto Protected object.
- Excluded objects are not protected. The icon indicates that an ancestor of the object is Auto Protected but this object is explicitly excluded.

Edit Existing Protection Policy

You can edit the existing Protection Policy that is attached to the Protection Group based on your requirement. In the Protection Policy, you can edit the settings listed in the Create or Use an Existing Protection Policy.

> **Note:** You cannot enable or disable the NetApp SnapDiff option on an existing Protection Group.

To the policy settings:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for NetApp ONTAP.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Policy** field, click **Edit**.

   The Edit Policy page appears.
5. Edit the settings listed in the Create or Use an Existing Protection Policy and then click **Save**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

You can attach a new Protection Policy to your Protection Group. The new policy is applied to the Protection Group in the next scheduled protection run.

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for NetApp ONTAP.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, from the drop-down list in the **policy** field, select a new Protection Policy for the Protection Group.
5. Click **Save**.

Start an On-demand Protection Run

You can instantly start a protection run of the Protection Group that you have created to back up NetApp ONTAP volumes. It provides you options to back up all the objects or only selected objects in the Protection Group. If the policy associated with the Protection Group:

- Supports multiple backup types, you can select an incremental or full backup.
- Is configured with replication targets, you can select those targets.
- Is configured with archival targets, you can select those targets.

To start a protection run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for NetApp ONTAP.
3. Click the action icon next to the Protection Group and select **Run Now**.
4. In the pop-up window, perform the following:
    a. In the **Backup** drop-down list, select any one of the following:
        - **Backup all Objects in the Protection Group**
        - **Backup only selected Objects in the Protection Group**
    b. In the **Backup Type** drop-down list, select the backup type.
    c. In the Replicate section, select the replication target, the retention duration, and enable the **Replicate only fully successful runs** checkbox if you want to replicate the data only after a successful protection run.
    d. In the Archive section, select the archive target, the retention duration, and enable the **Archive only fully successful runs** checkbox if you want to archive the data only after a successful protection run
5. Click **Run Now**.

Pause Protection Runs Instantly

You can instantly pause a protection run of the Protection Group that you have created to back up the NetApp ONTAP sources.

Perform the following steps to pause a currently executing protection run of a Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, click the NetApp ONTAP Protection Group that has been created.
3. Click the action icon next to the protection run and click **Pause Run**.

Pause Future Protection Runs

You can stop the protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for NetApp ONTAP.
3. Click the action icon next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run.

To resume a paused protection run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the action icon next to the Protection Group and select **Resume**.

Delete the Protection Group

Cohesity provides the following ways to delete the Protection Group associated with NetApp ONTAP:

- **Delete Protection Group Only**: Delete only the Protection Group. Any local snapshots and or archived snapshots stored on the external targets that were captured by this Protection Group are not deleted
- **Delete Protection Group and Snapshots**: Delete the Protection Group and all Snapshots, any local Snapshots captured by this Protection Group and stored on this Cluster are deleted. In addition, any archived Snapshots stored on external targets that were captured by this Protection Group are also deleted.

For NetApp SnapDiff-based backup:

- You cannot delete the latest snapshot available on both local and remote clusters.
- You cannot delete the snapshot when indexing is in progress.

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

To delete the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for NetApp ONTAP.
3. Click the action icon next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Delete Protection Group Only
    - Delete Protection Group and Snapshots

If the current Protection Group is replicating snapshots to a remote cluster or archiving snapshots to an external target, you should cancel these replication or archive tasks before deleting the Protection Group. For instructions, see Cancel Replication and Archive Copy Tasks of a Protection Group Run.

If the Protection Group is replicating to a remote cluster, the inactive job created on the remote cluster is not deleted. In addition, the snapshots that were replicated (copied) to the

remote cluster by this job are not deleted. You can log in to the remote cluster to delete the snapshots and the inactive job.

NetApp ONTAP SnapDiff-based Backup

In the SnapDiff-based backup approach, Cohesity leverages NetApp's SnapMirror cloud functionality to move the data to the Cohesity cluster and NetApp's SnapDiff functionality to get the changed file list. This section provides information on how Cohesity performs the backup and recovery of NetApp ONTAP data protection (DP) and Read-Write (RW) volumes using the SnapDiff-based backup approach.

> **Note:** In this document, NetApp SnapDiff means Cohesity's implementation of SnapDiff using NetApp SnapDiff v3 APIs.

Supplemental terms regarding the Cohesity implementation of the SnapDiff API. Please review before use.

Plan and Prepare for NetApp ONTAP SnapDiff-based Backup

This topic provides information on the supported NetApp ONTAP versions and volumes, minimum permissions, and the prerequisites to register and protect NetApp ONTAP with Cohesity cluster using SnapDiff-based backup approach. For more information, see Register NetApp ONTAP.

Before you register your NetApp ONTAP with the Cohesity cluster and protect the DP volumes and read-write volumes using the NetApp SnapDiff-based backup approach, ensure the following prerequisites:

Prerequisites for NetApp

- Obtain the SnapMirror Cloud license or ONTAP One license for enabling NetApp SnapDiff-based backup.
- Ensure the Cohesity cluster has the FQDN setup configured and all VIPs resolved to the FQDN of the NetApp cluster.
- Enable NetApp Snapdiff V3 on your NetApp Vservers/SVMs by running the following commands:

```
::> set adv
```

```
::*> vserver snapdiff-rpc-server on -vserver <svm_name>
```

- NFS must be enabled on the data LIFs to run SnapDiff APIs for File Level Recovery and to allow RPC initialization.
- To ensure protection using the SnapDiff approach, all NetApp ONTAP volumes must have the 'snapdif-access' capability enabled.

Support Matrix

Before you register your NetApp ONTAP with the Cohesity cluster, ensure that the Cohesity cluster supports the NetApp ONTAP versions and volumes you want to protect. For more information, see Supported Software.

Supported NetApp ONTAP Volumes

The following table lists the supported NetApp ONTAP versions and volume types for NetApp SnapDiff-based backup:

Volume Type	Volume Sub-Type
Data Protection Volume (DP volume)	SnapMirror Destination Volume
	SnapVault Destination Volume
Read-Write Volume (RW volume)	

Volumes that are configured to use NetApp Volume Encryption are supported.

Cohesity does not support the backup of the following NetApp ONTAP volumes for NetApp Snapdiff backup:

- SnapLock Enterprise Volume
- SnapLock Compliance Volume
- Flex Group Volume

Supported NFS and SMB versions

For NetApp Snapdiff DP volume and read-write volume backup, Cohesity supports all the versions of NFS and SMB that NetApp supports.

Minimum Permissions

Ensure you have the required minimum permissions to register NetApp ONTAP as a source with the Cohesity cluster, and to perform backup and recovery.

Minimum Permissions for Registering NetApp ONTAP

The user account used for registering NetApp ONTAP SVM or NetApp ONTAP Cluster must have the required permissions to communicate with the Cohesity cluster

> **Note:** Cohesity does not support SnapDiff based backups when registering a NetApp SVM. SnapDiff based backups are only supported when registering the NetApp cluster.

Required Permissions for NetApp ONTAP Cluster

For NetApp SnapDiff-based backup, you must create two roles for the user account you use for registering the NetApp ONTAP Cluster with the Cohesity cluster:

- rest-role
- a role dealing with commands

For the role dealing with commands the user account must have the following permissions:

Access-level	Command*	Description	Protocol
All	volume snapshot	Allows fetching, creating, and deleting snapshots for volumes.	SMB / NFS
ReadOnly	cifs	Fetches information about CIFS/SMB shares for volumes.	SMB / NFS
	cluster identity	Fetches information about the cluster.	SMB / NFS
	network interface	Fetches information about network interfaces to which Cohesity cluster connects for mounting volumes.	SMB / NFS
	volume	Fetches information about volumes.	SMB / NFS
	vserver	Fetches information about SVM.	SMB / NFS
	version	Fetches information about ONTAP version	SMB/NFS
	system license	Fetches information about system licenses	SMB/NFS

*For the above command listed, the login method is ONTAPI.

For the rest-role, the user account must have the following API permissions:

Access-level	API	Description	Protocol
All	/api/cloud/targets	Allows fetching, creating and deleting object store configs.	SMB / NFS
	/api/cluster/licensing	Fetches access tokens for REST API calls.	SMB / NFS
	/api/snapmirror	Allows fetching, creating and deleting snapshots in a SnapMirror cloud.	SMB / NFS
	/api/snapmirror/policies	Manage SnapMirror policies of type 'async and 'sync'.	SMB / NFS
	/api/snapmirror/relationships	Creates and manages the SnapMirror relationships. SnapMirror transfer APIs are used to manage data transfers.	SMB / NFS
	/api/snapmirror/relationships/<relationship_ID>/transfer	Manage data transfers.	SMB / NFS
	/api/storage/volumes	Fetches information about volumes.	SMB / NFS
ReadOnly	/api/cluster/jobs	Fetches the status of long running jobs.	SMB / NFS

* For the above command listed, the login method is HTTP.

Credentials for NetApp ONTAP Backup with Multiple SVMs

To register NetApp ONTAP with multiple storage virtual machine (SVM), create a custom role with the required permissions and a local user at the SVM level. Assign the custom role to the local user. Use the respective local user account to register multiple SVMs.

Ports Used for Communication

For information on port numbers required, see Manage Firewall Ports.

Considerations

The following are the important considerations to be noted before you protect your NetApp ONTAP data using NetApp SnapDiff-based backup:

- To use NetApp SnapDiff-based backup, ensure your Cohesity cluster has the FQDN setup configured and all VIPs resolve to the cluster name.
- Cohesity does not support NetApp SnapDiff-based backup if the NetApp source is registered as NetApp ONTAP SVM.
- You cannot protect the same NetApp volume in two Protection Groups (Protection Groups created within a Cohesity cluster or different Cohesity clusters) with NetApp SnapDiff-based backup. However, you can protect the same NetApp volume in two Protection Groups if one Protection Group is with SnapDiff enabled and the other Protection Group is without SnapDiff enabled.
- The backup of a NetApp volume will fail if there is already a SnapMirror cloud relationship created between the NetApp volume and another Cohesity S3 View.
- SnapDiff-based backups are immutable. That is, you cannot delete the SnapDiff-based backed-up data.
- When assigning or creating backup policies to a Protection Group for NetApp volumes, it is recommended to create the schedule of backup policy in-sync or less aggressive than the SnapMirror or SnapVault schedule. This ensures the presence of the snapshot in the volume, prior to the incremental backup triggered by the Cohesity backup policy schedule.
- CloudArchive Direct is not supported.
- CloudArchive with Periodic full is not supported. However, CloudArchive with incremental forever format to an S3-compatible target, NAS, and Tape is supported.
- You cannot delete the latest snapshot available on both local and remote clusters.
- You cannot delete the snapshot when indexing is in progress.
- NetApp requires an S3 Access key for accessing a Cohesity S3 view. For generating Cohesity S3 access keys, you must use one of the following accounts to create an S3 View:
  - A local Cohesity user.
  - An Active Directory user that was explicitly added to the Cohesity cluster and assigned a role. This user does not rely on an AD group for access to the Cohesity cluster.

  S3 access keys will not be generated for a Helios user or for an AD user that has Cohesity cluster access through an Active Directory group only.
- Pausing an ongoing SnapDiff-based protection run and resuming the protection run at a later time is not supported.
- Failover and failback are not supported.
- If the latest snapshot in the NetApp ONTAP volume is already backed up and there is no new snapshot in the NetApp volume, then the backup will fail.

- You should not manually perform 'snapmirror update'. Ie, you should not update the Cohesity S3 View. The following error message will be displayed when you perform SnapDiff-based backup after updating Cohesity S3 View:

  ```
  Unable to establish a SnapDiff session.
  ```

- Cohesity recommends a first full and incremental forever backup approach to back up your NAS sources.

The following are the considerations for Storage Volume Recovery:

- The recovery target must be a DP volume.
- Recover to the **Original Location** recovery workflow is not supported.
- You must select a new DP volume, which is not in a SnapMirror relationship. When a volume that was backed up via SnapDiff is recovered to an alternate NetApp DP volume, then the target DP volume will become an RW volume. Therefore, you cannot use the same volume as the target volume for the next volume recovery task.
- Recovering data to the following is not supported as NetApp SnapDiff stores the data in a proprietary format:
- Recovering to a non-NetApp NAS.
- Recovering to a new Cohesity View.

The following are the considerations for File-level Recovery:

- The recovery target must be a Read-Write volume.
- To perform file recovery, indexing must be enabled on the Protection Group.
- You can select up to eight files for recovery at a time. If you select more than eight files for recovery, then the recovery task will fail.
- Downloading zip files is not supported.
- Recovery of hardlinks and symbolic links is not supported.
- Mtime is not preserved for SMB.
- File and folder recovery from an archive (incremental forever archival format) is not supported.
- When browsing files or folders for recovery, Cohesity does not display files or folders with an absolute path length exceeding approximately 3,500 characters. To recover these files or folders, select the parent directory.

Best Practices for SnapDiff-based Backup

1. NFS protocol must be enabled on the SVM from which volumes are backed up using SnapDiff.
2. The SnapDiff API will run over data LIFs (logical interface) since they cannot be run over management LIF. Therefore, NFS must be enabled on the data LIFs used by the

SVM to allow RPC initialization.

3. An inter-cluster LIF must be configured on the NetApp ONTAP cluster. NetApp ONTAP verifies connectivity prior to saving this configuration information.

Register and Manage NetApp ONTAP Source

To protect your NetApp ONTAP data, you need to register your NetApp ONTAP as a source on the Cohesity cluster. After registration, you can manage the source on the Cohesity cluster in the following ways:

- Update the NetApp ONTAP source configuration
- Refresh the source details
- Unregister the NetApp ONTAP source from the Cohesity cluster.

Register NetApp ONTAP as a Source

Before you register NetApp ONTAP as a source on the Cohesity cluster, ensure that you:

1. Review the requirements, considerations, and best practices.
2. Perform the prerequisite tasks.

For more information, see Plan and Prepare for File-Runner Based NetApp ONTAP Backup.

> **Note:** Before you register NetApp ONTAP as a source on the Cohesity cluster, ensure that you have reviewed and completed the instructions provided in the Plan and Prepare for File-Runner Based NetApp ONTAP Backup

To register NetApp ONTAP as a source:

> **Note:** To register the NetApp ONTAP cluster for NetApp SnapDiff-based backup, you must obtain the SnapMirror Cloud license from NetApp.

1. In the Cohesity Dashboard, select **Data Protection > Sources**.
2. Click **Register** on the top-right of the page and then select **NAS**.

   The Register NAS page appears.
3. From the NAS Source drop-down list, select **NetApp**.
4. Enter the following information, and then click **Register**.

Field Name	Description
NetApp Source Type	The NetApp ONTAP cluster or Vserver/SVM to register. **Note:** Cohesity does not support SnapDiff-based backup if the NetApp source is registered as NetApp ONTAP SVM.
Host or IP Address	The Host or IP address of the NetApp ONTAP cluster or SVM to register. For NetApp SnapDiff-based backup, use the Host or IP address of the NetApp ONTAP cluster to register.
Username	Username used to access the NetApp ONTAP cluster or SVM. Specify a user that has adequate privileges to perform actions on the Source. If you are providing a domain user account, then you must specify the user name in the following format: `fully_qualified_domain_name\username`. For example, `xydc.local\user1`. For more information, see Minimum Permissions. **Note:** The username used to register the NetApp ONTAP cluster and SVM is case sensitive.
Password	Enter the password for the specified user.
Back Up SMB Volumes	Whether NetApp ONTAP will back up SMB volumes. If yes, provide the local or Active Directory user credentials that allow at least read access on the NetApp ONTAP cluster or SVM. **Note:** The user must have full control on the restore target during restore.
Filter IPs	Enable this option to filter the IP addresses of the NetApp ONTAP cluster. By filtering IP addresses, you can allow or deny the communication of the Cohesity cluster to specific IP addresses or subnets of the NetApp ONTAP cluster. To filter the IP addresses of the NetApp ONTAP cluster, select one of the following options: • **Allow IPs**: Select this option and specify the IP addresses of the NetApp ONTAP source through which the communication to the Cohesity cluster must happen. You can provide the IP addresses in a comma-separated list or in a CIDR format. • **Deny IPs**: Select this option and specify the IP addresses of the NetApp ONTAP source through which the communication to the Cohesity cluster must not happen. You can provide the IP addresses in a comma-separated list or in a CIDR format.

Field Name	Description
Storage Array Snapshots	Enable this option to manage the snapshots of VMware VMs stored in NetApp NFS volumes from the Cohesity cluster. • **Cap number of snapshot per volume**: Enter the maximum number of snapshots that can be stored on each NetApp storage volume. • **Cap storage consumed by snapshot per volume**: Enter the percentage of the NetApp volume's storage you want the snapshots to consume. **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

When registration finishes, a new entry appears on the Sources page. You can now create a Protection Group to backup NetApp ONTAP volumes. For more information, see Backup NetApp ONTAP Using File-Runner .

Update the NetApp ONTAP Source Configuration

You can update the NetApp ONTAP details that you had provided during the registration process with the latest NetApp ONTAP configuration.

To edit the NetApp ONTAP source configuration:

1. In the Cohesity Dashboard, select **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the NetApp ONTAP source and select **Edit**.
3. In the Edit NAS page, update the respective configurations.
4. In the **Password** field, enter the password of the NetApp ONTAP user account, and then click **Update**.

Refresh the NetApp ONTAP Source

You can refresh the NetApp ONTAP configuration and fetch the latest changes on the NetApp ONTAP.

To refresh the NetApp ONTAP source configuration:

1. In the Cohesity Dashboard, select **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the NetApp ONTAP source and select **Refresh**.

Unregister NetApp ONTAP

If you plan to stop taking backups of the NetApp ONTAP volumes, you can unregister the NetApp ONTAP source from the Cohesity cluster. Before you unregister, you must delete all the Protection Groups associated with the NetApp ONTAP server. For more information, see Delete the Protection Group.

To unregister the NetApp ONTAP server on the Cohesity cluster:

1. In the Cohesity Dashboard, select **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the NetApp ONTAP source and select **Unregister**.
3. Click **Unregister**.

Backup NetApp ONTAP Using SnapDiff

After registering your NetApp ONTAP server as a source on the Cohesity cluster, you can create a Protection Group to back up your NetApp ONTAP DP and RW volumes. You can back up one or more NetApp ONTAP NFS or SMB shares in a Protection Group while preserving the ACLs and Extended attributes on SMB.

To perform SnapDiff-based backup, you must enable the **NetApp SnapDiff** option available while creating a Protection Group. For leveraging the existing snapshots present in a NetApp ONTAP volume using SnapDiff-based backup, you must create a Cohesity S3 View.

When a Protection Group with the **NetApp SnapDiff** option enabled is run, Cohesity will request NetApp to transfer the data. For the full backup, NetApp starts ingesting the list of files in the volume to Cohesity in parallel to the data transfer. For incremental backup, ingesting the list of files and data transfer occurs sequentially.

For ingesting the list of files, Cohesity creates a SnapDiff session and ingest files sequentially. For data transfer, Cohesity uses NetApp's SnapMirror cloud functionally which writes to the Cohesity S3 View.

Once the SnapDiff session is initialized, for NetApp ONTAP DP volume, a snapshot with the label, `snapmirror.<cluster_ID>.<Year-Month-Date-time>` is created on the NetApp ONTAP volume. Cohesity takes the full backup from this snapshot leveraging NetApp to write the data from this snapshot to the Cohesity S3 View. For taking a full backup of a DP volume, you must initialize the DP volume with the RW volume before creating a Protection Group.

When you create a Protection Group for the NetApp ONTAP volumes with the NetApp SnapDiff option enabled, you must select an existing or create a new Cohesity S3 View. When creating an S3 view, ensure to select :

- **Object Services** as the **Category** value
- **Object ID** as the **Object Key Pattern** value.
- **S3** as the **Read/Write Protocol** value

For information see, Create Views Using a Custom Template.

For information on:

- The prerequisites for registering and protecting NetApp, see Plan and Prepare for NetApp ONTAP SnapDiff-based Backup.

- Registering NetApp ONTAP with Cohesity cluster, see Register and Manage NetApp ONTAP Source.

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

Protect NetApp ONTAP Using SnapDiff-based Backup

In Cohesity, NetApp ONTAP volumes are protected using a Protection Group and a Protection Policy. A Protection Group uses the schedules and settings defined in the policy to determine when and how backups are captured, archived, or replicated.

A Protection Policy is a reusable set of settings that define how and when objects are protected and replicated. You can select which standard or custom policy to use when creating a Protection Group. For more information, see Manage Protection Policy.

> **Note:** Cohesity recommends a first full and incremental forever backup approach to back up your NAS sources.

To protect NetApp ONTAP volumes with SnapDiff-based backup approach:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. Click **Protect** on the top-right of the page and then select **NAS**.
3. Click **Add Objects** and from the **Registered Source** drop-down list, select the NetApp source that contains the volumes you want to back up. You can also register a NAS new source with the Cohesity cluster so you can protect it. To register a new NAS source, click Register Source from the drop-down. For more information, see Register and Manage NetApp ONTAP Source.
4. From the list of volumes, select the NetApp ONTAP volumes for which you want to perform the SnapDiff-based backup.
5. Click **Continue**.

   You can ignore the **Backup Preference for Mixed Mode Volumes** field, as it is not applicable for SnapDiff-based backup.
6. In the **Protection Group** field, enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.
7. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, see Create or Edit a Standard Policy.
8. Select **More Options** to enable NetApp SnapDiff and configure settings, and additional settings.

9. Enable the **NetApp SnapDiff** option and provide the following details to leverage SnapMirror to take the full and incremental backup of the NetApp volume.
    1. From the **Cohesity S3 View** field, select an existing or create a new Cohesity S3 View. The snapshot taken from the volume will be written to the Cohesity S3 View. When creating an S3 view, ensure to select:
        1. **Object Services** as the **Category** value.
        2. **Object ID** as the **Object Key Pattern** value.
        3. **S3** as the **Read/Write Protocol** value.

        For information see, Create Views Using a Custom Template.
10. Optionally, from the **Protection Group** field, you can select an existing Protection Group. By selecting an existing Protection Group, the additional settings configured in the existing Protection Group will be applied to this Protection Group. To select an existing Protection Group, perform the following steps or else, go to step 12:
    1. From the **Protection Group** field, enable **Existing Group**.
    2. Select an existing Protection Group from the **Group** drop-down list.
    3. Click **Protect**.
11. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains.
12. In the **Start Time** field, the default time zone is the browser's time zone. You can change the time zone of the job by selecting a different time zone.
13. If you need to change any of the advanced settings on the Protection Group page, click the down arrow icon next to **Advance Settings** and click **Edit** of the respective field. For more information, see Additional Settings.
14. Click **Protect**.

Your new Protection Group is now active and running

Additional Settings

Additional Settings	Description
Pause Future Runs	Toggle on this option to stop protection runs of the Protection Group from executing. Once you enable this option, no protection runs will be scheduled for this Protection Group.
End Date	Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts prior to this date runs until completion even if it completes after this date.

Additional Settings	Description
Indexing	This option is toggled on by default to index the data of the Protection Group. Indexing improves files and folders search. Cohesity performs incremental indexing where only the data that has changed since the previous snapshot is scanned and indexed.
Quiet Times	This option is available only if the selected policy has at least one quiet time period. Toggle the **Stop in-progress runs when quiet time starts** option to pause or abort the runs during quiet time. If this option is toggled off, after a protection run starts, execution continues even when the quiet time period specified for this Protection Group starts. However, a new protection run will not start during a quiet time period. • **Pause Runs** - Select this option to pause the currently executing protection runs and resume the runs when quiet time ends. • **Abort Runs** - Select this option to abort the currently executing protection runs when the quiet time period specified for the Protection Group starts. > **Note:** If the quiet time window for multiple protection runs is scheduled at the same time, then when the protection run is resumed, prioritization of the protection run does not work.
Alerts	Select one or more of the following **Alerts On** settings if you want alerts to be created for the following triggers: • SLA Violation: Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts. • Failure: Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • Success: Create an informational alert when the Protection Group completes successfully. Emails are not sent when informational alerts are created. To send emails when alerts are triggered for the Protection Group, in the **Email Recipients** field, add the email addresses of the recipients.

Additional Settings	Description
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of jobs exceeds the ability to process jobs, this will be the priority of implementation of the jobs: a. High b. Medium c. Low
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks). • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. **Note:** Users with similar SLAs can be grouped together and a custom policy and Protection Group can be created to achieve different SLAs.
Description	Enter a brief description about the Protection Group.

Create or Use an Existing Protection Policy

A Protection Policy is a reusable set of settings. It enables you to define how and when NetApp ONTAP data is protected, replicated, and archived. A standard policy provides various settings that you can configure for a Protection Group.

Create a Protection Policy with the settings listed in the Policy Settings for NetApp ONTAP. For detailed instructions on how to create a Protection Policy, see Create or Edit a Standard Policy.

Policy Settings for NetApp ONTAP

The following table lists the applicable policy settings for NetApp ONTAP:

Field	Description
Primary Copy	Select **Local** from the drop-down to keep the primary copy data on the Cohesity cluster.

Field	Description
DataLock	If applicable, add a DataLock for compliance and regulatory requirements, to ensure that your protected data, including local backups, archives, and replication, cannot be modified until the DataLock expiration. Once applied, a DataLocked Snapshot will be deleted only after its retention period expires. A DataLock prevents all users, including those who have the Data Security role in Cohesity, from modifying or deleting any Snapshots that were generated by theProtection Groups that use this Policy. Only users with the Data Security role can add, modify, or remove a DataLock from a Policy.
Backup	Defines when backups are captured, how long they are retained and the type of backup to capture.
Periodic full backup	Use this option to choose when to run a periodic full backup.
Quiet Times	Quiet Times defines time periods when new protection runs are not started. For example, you might want to configure hourly backups that run during weekdays but not on Saturdays or Sundays. Quiet Times only prevent new protection runs from starting during the specified time period. The protection runs that started before the quiet time period will be dependent on the quiet time settings configured in the additional settings of the protection Group. For example, if a protection run starts at 12:45 AM on Saturday morning and there is a weekend quiet time period that starts at 1 AM on Saturday morning, the protection run will continue to run past 1 AM. No new protection runs are started during the quiet time period.
Retry Options	Use this option to customize the retry settings for capturing Snapshots. By default, Cohesity attempts to capture Snapshots three times before the Protection Group fails. The default time between retries is five minutes. You can customize the number of retries and how long to wait between each attempt.
Primary Copy	Select the primary copy to be on the local cluster. For NetApp SnapDiff-enabled Protection Group, only the metadata is copied onto the Cohesity cluster. The data will be backed up to the Cohesity S3 View. **Retain for**: Specify how many days backups are retained on the Cohesity cluster before they are deleted.
Extended Retention	Add this to retain a subset of snapshots (backups) for longer than defined by the protection schedule.
Replication	To replicate snapshots to another , click the replication icon from the floating menu. The copied snapshots are stored in the storage domain of the remote cluster.
Archival	To add an archive schedule, click the archival icon from the floating menu.

Use an Existing Protection Policy

You can use an existing Protection Policy protecting NetApp ONTAP (also using NetApp Snapdiff backup). If you are selecting an existing protection policy, then the following options are ignored if they are already configured in the protection policy:

- **Log Backup (Databases)**
- **Continuous Data Protection**
- **Add BMR Backup (Physical Server)**
- **CloudSpin**

Manage the NetApp ONTAP Backup Configuration

In Cohesity, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirement.

> **Note:** You cannot update the registered NetApp ONTAP Server and the assigned Storage Domain in the Protection Group settings. You cannot enable or disable the NetApp SnapDiff option on an existing Protection Group.

Add NetApp ONTAP volumes to the Protection Group

You can add new NetApp ONTAP volumes to the existing Protection Group for backup. The newly added volumes are backed up from the next protection run and it will be a full backup.

To add NetApp ONTAP volumes to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for NetApp ONTAP.
   For NetApp Snapdiff backup, select the NetApp SnapDiff-enabled Protection Group that you had created for NetApp ONTAP.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** field, click the **Edit** icon.
5. Select the NetApp ONTAP volumes you want to add to the Protection Group.
6. Click **Save Selection** > **Save**.

The newly added NetApp ONTAP volumes will be backed in the next scheduled protection run.

Remove NetApp ONTAP volumes from the Protection Group

From the **Edit Protection** page, you can remove NetApp ONTAP volumes from the Protection Group that you do not want to back up in the next protection run.

To remove NetApp ONTAP volumes from the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for NetApp ONTAP.
   For NetApp Snapdiff backup, select the NetApp SnapDiff-enabled Protection Group that you had created for NetApp ONTAP.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** field, click the **Edit** icon.
5. Unselect the NetApp ONTAP volumes that you want to remove from the Protection Group.
6. Click **Save Selection** > **Save**.

The removed NetApp ONTAP volumes will not be backed in the next scheduled protection run.

Enable Auto Protect

The Auto Protect option enables you to automatically protect the new NetApp ONTAP volumes that are added to the selected parent NetApp ONTAP server. However, you cannot enable auto-protect at the server-level containing both Read-Write volumes and Data-Protect volumes.

To enable auto protect:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for NetApp ONTAP.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** field, click **Edit Objects**.
5. Click the shield icon to enable Auto Protect.
6. Click **Save Selection** > **Save**.

When this option is enabled on the parent NetApp ONTAP server, all the NetApp ONTAP volumes that are added to the parent NetApp ONTAP server in the future are automatically added to the Protection Group and are protected from the next protection run.

For example, you create a Protection Group that backs up a NetApp ONTAP SVM. The Protection Group runs for two weeks and then a new volume is added to the NetApp ONTAP SVM. The next time the Protection Group runs, if the object hierarchy has been refreshed on the Cohesity cluster, the new volume is also backed up even though the new volume has not been explicitly selected to be included in the Protection Group. The object hierarchy is automatically refreshed every four hours. To manually refresh the object hierarchy, select **Data Protection > Sources**, find the source in the list, and click . To exclude an object from Auto Protect, click .

- Indicates an Auto Protected object.
- Excluded objects are not protected. The icon indicates that an ancestor of the object is Auto Protected but this object is explicitly excluded.

Edit Existing Protection Policy

You can edit the existing Protection Policy that is attached to the Protection Group based on your requirement. In the Protection Policy, you can edit the settings listed in the Create or Use an Existing Protection Policy.

> **Note:** You cannot enable or disable the NetApp SnapDiff option to an existing Protection Group.

To the policy settings:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for NetApp ONTAP.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Policy** field, click **Edit**.

   The Edit Policy page appears.
5. Edit the settings listed in the Create or Use an Existing Protection Policy and then click **Save**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

You can attach a new Protection Policy to your Protection Group. The new policy is applied to the Protection Group in the next scheduled protection run.

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for NetApp ONTAP.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, from the drop-down list in the **policy** field, select a new Protection Policy for the Protection Group.
5. Click **Save**.

Start an On-demand Protection Run

You can instantly start a protection run of the Protection Group that you have created to back up NetApp ONTAP volumes. It provides you options to back up all the objects or only selected objects in the Protection Group. If the policy associated with the Protection Group:

- Supports multiple backup types, you can select an incremental or full backup.
- Is configured with replication targets, you can select those targets.
- Is configured with archival targets, you can select those targets.

To start a protection run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for NetApp ONTAP.
3. Click the action icon next to the Protection Group and select **Run Now**.
4. In the pop-up window, perform the following:
    a. In the **Backup** drop-down list, select any one of the following:
        - **Backup all Objects in the Protection Group**
        - **Backup only selected Objects in the Protection Group**
    b. In the **Backup Type** drop-down list, select the backup type.
    c. In the Replicate section, select the replication target, the retention duration, and enable the **Replicate only fully successful runs** checkbox if you want to replicate the data only after a successful protection run.
    d. In the Archive section, select the archive target, the retention duration, and enable the **Archive only fully successful runs** checkbox if you want to archive the data only after a successful protection run
5. Click **Run Now**.

Pause Future Protection Runs

You can stop the protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for NetApp ONTAP.
3. Click the action icon next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run.

To resume a paused protection run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the action icon next to the Protection Group and select **Resume**.

Supplemental Terms for SnapDiff API Implementation

COHESITY, INC. (TOGETHER WITH ITS AFFILIATES, "**COHESITY**") AGREES TO SUPPLY AND/OR LICENSE CERTAIN OF SUBJECT IMPLEMENTATION TO YOUR BUSINESS OR ORGANIZATION ("**CUSTOMER**") ONLY IF (A) YOU REPRESENT AND WARRANT THAT YOU HAVE THE AUTHORITY TO LEGALLY BIND CUSTOMER AND (B) YOU ACCEPT AND AGREE ON BEHALF OF CUSTOMER TO BE BOUND BY ALL OF THE SUPPLEMENTAL TERMS (THIS "**SUPPLEMENTAL TERMS**", INCLUDING ALL DOCUMENTS INCORPORATED HEREIN BY REFERENCE), WHICH SHALL BE DEFINITIVELY EVIDENCED BY ANY ONE OF THE FOLLOWING MEANS: YOUR CLICKING THE "ACCEPT", "CONTINUE" OR A SIMILAR BUTTON, AS APPLICABLE; YOUR SIGNATURE ON A TANGIBLE COPY OF THIS LICENSE; YOUR INSTALLATION OR USE OF THE PRODUCTS AND/OR SOFTWARE; OR BY SUCH OTHER CONTRACT FORMATION MECHANISM AS MAY BE RECOGNIZED UNDER APPLICABLE LAW FROM TIME TO TIME. IF YOU DO NOT AGREE TO THE TERMS AND CONDITIONS IN THIS AGREEMENT, DO NOT COPY, INSTALL OR USE THE PRODUCT(S) OR ANY ASSOCIATED SOFTWARE. THESE SUPPLEMENTAL TERMS ARE IN ADDITION TO AND SUPPLEMENT THE TERMS AND CONDITIONS IN THE COHESITY EULA OR SIMILAR COMMERCIAL AGREEMENT AGREED TO BY COHESITY AND CUSTOMER WITH RESPECT TO COHESITY PRODUCTS AND SERVICES. THESE SUPPLEMENTAL TERMS APPLY ONLY WITH RESPECT TO THE SUBJECT IMPLEMENTATION.

Customer agrees not to, or authorize or assist a third party to:

1. decompile, disassemble, decrypt, extract, or otherwise reverse engineer or attempt to reconstruct, or discover any source code of the SnapDiff APIs or NetApp Format, including any underlying ideas, algorithms, API Keys or file or data formats of, or used in, the SnapDiff APIs, or any portion of the SnapDiff APIs as implemented in the Subject Implementation, by any means whatever; provided that the foregoing restriction shall not limit any activity that is required to be permitted under the applicable law in a specific jurisdiction; further provided, however, that if Customer wishes to exercise its rights to engage in activities that are permitted under the applicable law in a specific jurisdiction that otherwise would be prohibited by the foregoing restrictions, Customer will provide prompt written notice to Cohesity and provide Cohesity and its licensors with a reasonable amount of time in which to perform the activity and provide related results to the Licensee;
2. remove or conceal any product identification, copyright or other notices contained in or on the Subject Implementation;
3. publish or provide to a third party any results of benchmark tests run on the Subject Implementation, any portion of the Subject Implementation, without Cohesity's prior written consent;
4. disable, disrupt, circumvent, interfere with, or otherwise violate or impair the security of the Subject Implementation;
5. access any application, system, service, computer, data, account, or network without authorization using the Subject Implementation;

6. combine, remix, link against, transform, build upon, create a derivative work with, or otherwise use the Subject Implementation or otherwise such that the Subject Implementation or NetApp Format would be licensed under a license that requires the SnapDiff APIs, Subject Implementation, or any portion thereof to be (i) disclosed or distributed in source code form, or (ii) licensed under terms that allow any licensee to copy, create derivative works and distribute the software without any fee or cost;
7. allow SnapDiff APIs to be visible, discoverable, usable, accessible, or otherwise expose, either directly or indirectly, by any third party; or
8. display, reproduce, publish, sell, offer for sale, modify, or create a derivative work of any part of the Subject Implementation

Troubleshoot NetApp Protection

- If backing up a NetApp volume fails with the following error: An entity being protected was not found in the global entity hierarchy, this could have been caused because the volume was moved to a different aggregate.

  Workaround - Edit the Protection Group that protects the volume that was moved and select the moved volume for protection.

- Registering and backing up a NetApp volume as an NFS NAS mount point results in a larger backup size because all files inside the .snapshot directory are backed up.

  Workaround - Do one of the following:

  - Register a path to a snapshot on that NetApp volume
  - Register it as a NetApp source instead of a NAS mount point
  - In the Protection Group's settings configure the filter to skip the .snapshot directory
  - Disable the configuration on that NetApp volume to show the .snapshot directory

- For an incremental backup, if there is no snapshot created in the DP volume after the last snapshot that is used for the full or incremental backup, then the protection run fails with the following error message:

```
No new snapshot found to take backup. Last snapshot used for backup:
<snaphot_name> with create time: <create_time> for volume: <volume_
name> on vserver: <server_name>
```

- If the snapshot label specified in the protection group does not match with the snapshot label in the DP volume, then the protection run fails with the following error message:

```
No snapshot with label: home found in the volume: <volume_name> on
vserver: <server_name>. Cohesity discovers snapshots for DataProtect
```

```
volumes and uses existing snapshots for taking backups. Please verify
the labels for the snapshot provided.
```

- If the backup fails for a protection group that has **Snapshot Array Management** enabled with the following error message, ensure the Storage Array backing the DataStore in which the VM resides is registered with the Cohesity Cluster:

  ```
  VM cannot be backed up due to error: [kUnknownStorageDevice]: Storage
  array of the datastore is not registered.
  ```

- If you do not enable the **Snapshot Prefix** option while creating the Protection Group, then the backup of NetApp DP volume may fail with the following error.

  ```
  [kInvalidRequest]: Error: No new snapshot found in the volume: <volume_
  name> on  vserver: <vserver_name>. Cohesity discovers snapshots and
  uses existing snapshots for taking backups. Please verify the labels
  for the snapshot provided
  ```

  Workaround - If the Snapshot Prefix option is not enabled, then ensure that an appropriate older snapshots are available in the NetApp source.

Nutanix Files

Nutanix Files is a hardware and software-based solution for file storage and retrieval. You can configure Cohesity to back up and restore data on Nutanix Files arrays.

You can back up and restore Nutanix Files volumes using the Cohesity File-Runner backup method. The File-Runner tool identifies differences between two snapshot copies.

See:

Nutanix Files File-Runner Based Backups

Plan and Prepare for File-Runner Based Nutanix Files Backup

Nutanix Files File-Runner Based Backups

The backup and restoration of Nutanix Files volumes can be efficiently managed using the Cohesity File-Runner backup method. This approach is designed to optimize the process and ensure data integrity.

Cohesity File-Runner facilitates the backing up of Nutanix Files volumes by leveraging snapshots. The tool specifically identifies differences between two snapshot copies, allowing for incremental backups and minimizing redundancy.

Plan and Prepare for File-Runner Based Nutanix Files Backup

This topic provides information on the supported Nutanix Files versions and volumes, minimum permissions, and the prerequisites to register and protect Nutanix Files with

Cohesity cluster. For more information, see Register and Manage Nutanix Files Source.

Before registering Nutanix Files arrays with the Cohesity cluster and protecting volumes and data, verify the prerequisites in this section.

This is an Early Access feature. Contact your Cohesity account team to enable the feature.

Considerations

- Replication is not supported for 7.3.1.
- Backup of distributed shares or home directories is not supported in version 7.3.1.
- NFSv4.1 is not supported in 7.3.1.
- Prism central and Prism element are supported.

Required ports

Ensure the port 9440 is open for Nutanix Files.

Supported NFS and SMB versions

The following table lists the supported NFS and SMB versions for backup and restore:

Protocol	Version
NFS	V3
SMB	V3

Minimum Required Permissions

Before registering a Nutanix Files Cluster as the source type, ensure you have the following permissions:

- For Prism Central local user: Needs Files Admin permission.
- For Prism Element local user: Needs Cluster Admin permission.

Supported Nutanix Files Versions

Component	Version
Nutanix Prism Element	
FSM	5.1.1
File Server	5.1.1

Component	Version
Nutanix Prism Central	
Files Manager	5.1

Enable WORM

You must enable WORM (Write Once, Read Many) in the Nutanix Files clusters to perform restores.

Refer to the Nutanix Files documentation for details on enabling WORM in Nutanix Files clusters.

Register and Manage Nutanix Files Source

To protect your Nutanix Files data, you need to register your Nutanix Files clusters as a source on the Cohesity cluster. After registration, you can manage the source on the Cohesity cluster in the following ways:

- Update the Nutanix Files source configuration
- Refresh the source details
- Unregister the Nutanix Files source from the Cohesity cluster.

Register Nutanix Files as a Source

Before you register Nutanix Files as a source on the Cohesity cluster, ensure that you:

1. Review the requirements, considerations, and best practices.
2. Perform the prerequisite tasks.

For more information, see Plan and Prepare for File-Runner Based Nutanix Files Backup.

To register Nutanix Files as a source:

1. In the Cohesity Dashboard, select **Data Protection > Sources**.
2. Click **Register** on the top-right of the page and then select **NAS**.

   The Register NAS page appears.
3. From the NAS Source drop-down list, select **Nutanix Files**.
4. Enter the following information, and then click **Register**.

Field Name	Description
NAS Source	Select **Nutanix Files**.
Type	Select either **Prism Central** or **Prism Element**. Prism Element manages one Nutanix cluster, while Prism Central lets you control several clusters from one interface. A single Prism Central can contain multiple Prism Elements.
Host or IP Address	The Host or IP address of the Nutanix Files cluster to register.
Username	Username used to access the Nutanix Files cluster . Specify a user that has adequate privileges to perform actions on the Source. If you are providing a domain user account, then you must specify the user name in the following format: `fully_qualified_domain_name\username`. For example, `xydc.local\user1`. For more information, see Plan and Prepare for File-Runner Based Nutanix Files Backup **Note:** The username used to register the Nutanix Files cluster is case sensitive.
Password	Enter the password for the specified user.
Back Up SMB Volumes	Whether Nutanix Files will back up SMB volumes. If yes, provide the local or Active Directory user credentials that allow at least read access on the Nutanix Files cluster . **Note:** The user must have full control on the restore target during restore.
Filter IPs	Enable this option to filter the IP addresses of the Nutanix Files cluster. By filtering IP addresses, you can allow or deny the communication of the Cohesity cluster to specific IP addresses or subnets of the Nutanix Files cluster. To filter the IP addresses of the Nutanix Files cluster, select one of the following options: • **Allow IPs**: Select this option and specify the IP addresses of the Nutanix Files source through which the communication to the Cohesity cluster must happen. You can provide the IP addresses in a comma-separated list or in a CIDR format. • **Deny IPs**: Select this option and specify the IP addresses of the Nutanix Files source through which the communication to the Cohesity cluster must not happen. You can provide the IP addresses in a comma-separated list or in a CIDR format.

When registration finishes, a new entry appears on the Sources page. You can now create a Protection Group to backup Nutanix Files volumes. For more information, see Backup Nutanix Files Using File-Runner.

Update the Nutanix Files Source Configuration

You can update the Nutanix Files details that you had provided during the registration process with the latest Nutanix Files configuration.

To edit the Nutanix Files source configuration:

1. In the Cohesity Dashboard, select **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Nutanix Files source and select **Edit**.
3. In the Edit NAS page, update the respective configurations.
4. In the **Password** field, enter the password of the Nutanix Files user account, and then click **Update**.

Refresh the Nutanix Files Source

You can refresh the Nutanix Files configuration and fetch the latest changes on the Nutanix Files.

To refresh the Nutanix Files source configuration:

1. In the Cohesity Dashboard, select **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Nutanix Files source and select **Refresh**.

Unregister Nutanix Files Source

If you plan to stop taking backups of the Nutanix Files volumes, you can unregister the Nutanix Files source from the Cohesity cluster. Before you unregister, you must delete all the Protection Groups associated with the Nutanix Files cluster. For more information, see Delete the Protection Group.

To unregister the Nutanix Files cluster on the Cohesity cluster:

1. In the Cohesity Dashboard, select **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Nutanix Files source and select **Unregister**.
3. Click **Unregister**.

Backup Nutanix Files Using File-Runner

After you register the Nutanix Files cluster as a source on the Cohesity cluster, create a Protection Group to back up Nutanix Files. You can include one or more Nutanix Files NFS or SMB shares in a Protection Group and preserve ACLs on SMB shares.

Select Nutanix Files Volumes for Backup

Cohesity supports backing up Nutanix Files read-write (RW) volumes. The volume can be an NFS export or an SMB share. Based on the selected volume and protocol, you must provide additional details when creating a Protection Group.

Considerations:

- NFS only or SMB only volumes are supported. Mixed volumes are not supported.
- Supported versions of NFS and SMB both is version 3.

User Access Credentials to Back Up SMB Shares

To back up SMB shares of any volume type, you must provide the local or Active Directory user credentials that allow at least read access to the Nutanix Files SMB share. You can provide these credentials while registering the Nutanix Files cluster with the Cohesity cluster or later when creating the Protection Group. For more information, see Register and Manage Nutanix Files Source.

Protect Nutanix Files Using File-Runner Based Backup

In Cohesity, Nutanix Files volumes are protected using a Protection Group and a Protection Policy. A Protection Group uses the schedules and settings defined in the policy to determine when and how backups are captured, archived, or replicated.

A Protection Policy is a reusable set of settings that define how and when objects are protected and replicated. You can select which standard or custom policy to use when creating a Protection Group. For more information, see Manage Protection Policy.

This topic provides information on how to protect Nutanix Files volumes using a Protection Group and a Protection Policy.

Protect Read-Write volumes with Only SMB Share or NFS Export

You can protect Nutanix Files RW volumes with only SMB share or NFS export by creating a Protection Group.

To protect RW volumes with only SMB share or NFS export:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then select **NAS**.
3. Click **Add Objects** and from the **Registered Source** drop-down list, select the NAS source that contains the volumes you want to back up.

   You can also register a new source with the Cohesity cluster so you can protect it. For more information, see Register and Manage Nutanix Files Source.
4. From the Object list, select RW volumes of NFS exports or SMB shares. You can filter the list using the **Protection Status** drop-down. Using the **Protocol** drop-down, filter the list for only SMB or NFS shares.
5. Click **Continue**.
6. To back up SMB shares, provide the user access credentials if you have not provided when registering the Nutanix Files source.
7. In the **Protection Group** field, enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.

8. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, see Protect Nutanix Files Using File-Runner Based Backup.
9. Select the appropriate Storage Domain. For more information, see Manage Storage Domains.
10. If you want to change or configure any of the additional settings, then select **More Options** and perform the below steps or else, click **Protect**.
11. Optionally, from the **Protection Group** field, you can select an existing Protection Group. By selecting an existing Protection Group, the settings configured in the existing Protection Group will be applied to this Protection Group. To select an existing Protection Group, perform the following steps or else, go to step 13:
    a. From the **Protection Group** field, enable **Existing Group**.
    b. Select an existing Protection Group from the **Group** drop-down list.
    c. Click **Protect**.
12. In the **Start Time** field, the default time zone is the browser's time zone. You can change the time zone of the job by selecting a different time zone.
13. If you need to change any of the additional settings on the Protection Group page, click the down arrow icon next to **Additional Settings** and click **Edit** on the right. For more information, see Protect Nutanix Files Using File-Runner Based Backup.
14. Click **Protect**.

    Your new Protection Group is now active and running.

Additional Settings

Additional Settings

Additional Settings	Description
Pause Future Runs	Toggle on this option to stop protection runs of the Protection Group from executing. Once you enable this option, no protection runs will be scheduled for this Protection Group.
End Date	Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts prior to this date runs until completion even if it completes after this date.

Additional Settings	Description
QoS Policy	Select an appropriate quality of service (QoS) policy. **Note:** Cohesity recommends specifying **Backup HDD**, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Pre & Post Scripts	Toggle **Enable** to run scripts on a Unix server before and/or after a Protection Group runs. If configured, scripts are run every time an object (or entity) is backed by a protection run. For example, if there are five mount/shares that are backed up as part of the NAS Protection Group and the Pre Script is configured, then five instances of the Pre Script is executed in parallel. You can distinguish between the scripts that are run on the different objects (entities) using the `COHESITY_BACKUP_ENTITY` environment variable. The Cohesity cluster populates this environment variable with the name of the backed object (or entity).
Skip Files on Errors	Toggled on by default. The Protection Group continues to run even if it encounters errors on files, such as permissions errors. If files are skipped, the protection run details page indicates a warning status and provides additional information. If toggled off, the Protection Group stops when it encounters an error.

Additional Settings	Description
File DataLock	Toggle on this option to preserve the AccessTime of the files and folders of the selected volumes. The AccessTime provides the lock period of the files and folders that are applied when these files and folders are recovered to the Cohesity View. For more information on File DataLock, seeNAS File DataLock . Select one of the following **DataLock** modes: • **Compliance**: In this mode, files or folders cannot be deleted or modified during the retention period. After the lock expires, no user can modify the files or folders. However, a root user can delete the files and folders. Only a user with Data Security role can edit the File DataLock settings in the Compliance mode. • **Enterprise**: In this mode, files or folders cannot be modified by any user before or after the lock retention period expiration. However, a root user can delete the files or folders before or after the lock retention period. An admin user or a user with a Data Security role can edit the File DataLock settings in the Enterprise mode. This mode is useful for giving storage administrators additional control over the file. You can further configure the File DataLock settings to: • Set the lock period for the new files and folders created on the recovered Cohesity View Provide the following information to set the lock period for the new files and folders that will be created on the recovered Cohesity View. These settings are not applicable for the existing NAS source files and folders recovered on the Cohesity View. • **Default Lock Period**: Provide the time period during which the files should remain locked. When the time period ends, files can be deleted but not changed. By default, the files are locked forever. • **Autolock Files**: By enabling this option, the files are automatically locked if they are not modified in the time period you specify. By default, this option is disabled. • **Manually Lock Using**: Select when the files are to be locked: • **Read-Only**: Select this option to lock files when the file permission is set to read only, for example; by setting the Windows file properties attribute or using the Linux `chmod` command. By default, the files are locked when the file permission is set to read only. • **FutureATime**: Select this option to lock files when the last access time (atime) is set, for example, by using Windows `PowerShell` commands or the Linux touch command.

Additional Settings	Description
	Optionally you can set a **Minimum Retention** and/or a **Maximum Retention** period to ensure that a file's last access time cannot be set outside this period. A request to do so results in a permission denied error if manual locking mode is FutureATime. Otherwise, the request will be silently rejected and the file will be locked for the minimum retention duration. • Override the locking period of the existing files and folders recovered on the Cohesity View: The following option can be applied to all the existing files and folders that will be recovered on the Cohesity View. • **Override (Lock all files until a specific date)**: Enable this option and select a date to override the locking period of the existing files and folders. When you recover the files to the Cohesity View, Cohesity applies the farthest lock period between the override lock period you specify and the source file's lock period. For example; • The lock period of the source file is 09/09/2023 and the override lock period you specified is 09/08/2022. When you recover the file to the Cohesity View, then the lock period of the source file is applied to the recovered file, which is 09/09/2023. • The lock period of the source file is 09/09/2022 and the override lock period you specified is 09/08/2024. When you recover the file to the Cohesity View, then the override lock period you specified is applied to the recovered file, which is 09/08/2024. In **Compliance** mode, a user with Data Security privileges can extend the override date into the future, but no user can shorten the date. In **Enterprise** mode, a user with admin or Data Security privileges can extend or shorten the override date.

Additional Settings	Description
	Note: • You cannot enable or disable File DataLock once the Protection Group is created. • If you have disabled File DataLock while creating a Protection Group, then when you edit this Protection Group, the File DataLock option will not be displayed. • You can delete Protection Groups and snapshots having File DataLock enabled. File DataLock also preserves the ATimes of the hardlinks and symlinks.
Exclusions and Inclusions	Toggle on this option if you want to exclude or include locations. By creating exclusion and inclusion rules, you can limit the Protection Group to a specific set of files and directories and therefore minimize the disk space used to store the data. All the files and folders are included for by default for protection. For more information, seeExclusions and Inclusions for NAS Protection Group.
Indexing	This option is toggled on by default to index the data of the Protection Group. Indexing improves files and folders search. Cohesity performs incremental indexing where only the data that has changed since the previous snapshot is scanned and indexed.

Additional Settings	Description
Quiet Times	This option is available only if the selected policy has at least one quiet time period. Toggle the **Stop in-progress runs when quiet time starts** option to pause or abort the runs during quiet time. If this option is toggled off, after a protection run starts, execution continues even when the quiet time period specified for this Protection Group starts. However, a new protection run will not start during a quiet time period. • **Pause Runs** - Select this option to pause the currently executing protection runs and resume the runs when quiet time ends. • **Abort Runs** - Select this option to abort the currently executing protection runs when the quiet time period specified for the Protection Group starts. > **Note:** If the quiet time window for multiple protection runs is scheduled at the same time, then when the protection run is resumed, prioritization of the protection run does not work. 
Additional Settings	Description
Alerts	Select one or more of the following **Alerts On** settings if you want alerts to be created for the following triggers: • SLA Violation: Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts. • Failure: Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • Success: Create an informational alert when the Protection Group completes successfully. Emails are not sent when informational alerts are created. To send emails when alerts are triggered for the Protection Group, in the **Email Recipients** field, add the email addresses of the recipients.
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of jobs exceeds the ability to process jobs, this will be the priority of implementation of the jobs: a. High b. Medium c. Low
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks). • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. > **Note:** Users with similar SLAs can be grouped together and a custom policy and Protection Group can be created to achieve different SLAs.
Description	Enter a brief description about the Protection Group.

Create or Use an Existing Protection Policy

A Protection Policy is a reusable set of settings. It enables you to define how and when Nutanix Files data is protected and archived. A standard policy provides various settings that you can configure for a Protection Group.

Create a Protection Policy with the settings listed in the Protect Nutanix Files Using File-Runner Based Backup. For detailed instructions on how to create a Protection Policy, see Create or Edit a Standard Policy.

Policy Settings for Nutanix Files

The following table lists the applicable policy settings for Nutanix Files:

Field	Description
Primary Copy	Select **Local** from the drop-down to keep the primary copy data on the Cohesity cluster. Select any external target for performing CloudArchive Direct wherein the primary copy of the data is stored on the external targets. For more information, see CloudArchive Direct.
DataLock	If applicable, add a DataLock for compliance and regulatory requirements, to ensure that your protected data, including local backups, and archives, cannot be modified until the DataLock expiration. Once applied, a DataLocked Snapshot will be deleted only after its retention period expires. A DataLock prevents all users, including those who have the Data Security role in Cohesity, from modifying or deleting any Snapshots that were generated by theProtection Groups that use this Policy. Only users with the Data Security role can add, modify, or remove a DataLock from a Policy.
Scheduled Backup	Defines when backups are captured, how long they are retained and the type of backup to capture.
Extended Retention	Add this to retain a subset of snapshots (backups) for longer than defined by the protection schedule.
Retry Options	Use this option to customize the retry settings for capturing Snapshots. By default, Cohesity attempts to capture Snapshots three times before the Protection Group fails. The default time between retries is five minutes. You can customize the number of retries and how long to wait between each attempt.
Periodic full backup	Use this option to choose when to run a periodic full backup.
Quiet Times	Quiet Times defines time periods when new protection runs are not started. For example, you might want to configure hourly backups that run during weekdays but not on Saturday or Sunday. Quiet Times only prevents new protection runs from starting during the specified time period. The protection runs that started before the quiet time period will be dependent on the quiet time settings configured in the additional settings of the protection Group. For example, if a protection run starts at 12:45 AM on Saturday morning and there is a weekend quiet time period that starts at 1 AM on Saturday morning, the protection run will continue to run past 1 AM. No new protection runs are started during the quiet time period.

Field	Description
Archival	To add an archive schedule, click the archival icon from the floating menu.
Storage Array Snapshot	Select **Snapshot Array Snapshot** from the floating menu to manage snapshots of VMs stored in Nutanix Files NFS volumes. • **Every**: Specify how often the snapshots have to be taken. • **Retain for xx days**: Specify how long the snapshots are retained on the Nutanix Files NFS volume. Consider the following when you are enabling this option: • **Storage Array Snapshot** can be enabled only on new or existing Protection Policies with Scheduled Backup configured. • If **Archive** is enabled for a Protection Policy along with **Storage Array Snapshot**, archival will only work on the regular backups and not on the Storage Array Snapshots. • **Storage Array Snapshot** cannot be enabled with backup options such as **Continuous Data Protection**.

Use an Existing Protection Policy

You can use an existing Protection Policy protecting Nutanix Files. If you are selecting an existing protection policy, then the following options are ignored if they are already configured in the protection policy:

- **Log Backup (Databases)**
- **Continuous Data Protection**
- **Add BMR Backup (Physical Server)**
- **CloudSpin**

NAS File DataLock

Many organizations now rely on WORM (Write Once Read Many) data storage such as Nutanix Files, NetApp Snaplock, and Isilon Smartlock volumes to retain their files and folders in unmodified form for compliance and regulatory purposes and to protect the files from accidental deletion or modification.

When you backup these WORM-capable volumes to the Cohesity cluster, it is essential to have the ability to easily lock the files and folders of the volumes while protecting themselves from accidental or malicious attempts to delete or modify these files. The backup should also provide a strong guarantee for data non-mutability and non-erasability for a certain period of time.

This capability is achieved using Cohesity's File DataLock feature.

FileDataLock is a Cohesity feature that preserves the WORM attributes of any files and folders created in the Cohesity View. You can apply the File DataLock feature for NAS backup (NFS exports and SMB shares) while creating a NAS Protection Group.

With File DataLock enabled in a NAS Protection Group, Cohesity preserves the future AccessTime (ATime) of the files and folders. The AccessTime provides the lock period for files and folders. You can also override this lock period in the File DataLock settings of the NAS Protection Group. This lock period is applied to these files and folders when they are recovered to the Cohesity View. This prevents the users or administrator from modifying or deleting these locked files until the locking period expires.

You can also set lock periods for the new files and folders created on recovered Cohesity View in the File DataLock settings of the NAS Protection Group.

When you recover File DataLock enabled storage volumes to the Cohesity View, the View details page will display a lock icon for the files and folders having File DataLock.

File DataLock is supported for all types of NAS sources including NetApp 7-mode and is agnostic of the NAS protocol.

For information on how to enable File DataLock, see Protect NAS.

File DataLock Modes

You can use the File DataLock feature in one of the two modes:

- **Compliance mode**: The WORM files are protected at the disk level. This mode implements strict regulatory requirements for data retention and complies with SEC Rule 17a-4. In this mode, files and folders cannot be deleted or modified during the retention period. After the lock expires, no user can modify the files and folders. However, a root user can delete the files and folders. Only a user with a Data Security role can edit the File DataLock settings in the Compliance mode.
- **Enterprise mode**: The WORM files are protected at the file level. This mode does not implement strict regulatory requirements for data retention. In this mode, files and folders cannot be modified by any user before or after the lock retention period expiration. However, a root user can delete the files and folders during or after the lock retention period. An admin user or a user with the Data Security role can edit the File DataLock settings in the Enterprise mode

> **Note:** An admin user or a user with the Data Security role can edit the File DataLock settings and switch from the Enterprise mode to Compliance mode. But switching from Compliance mode to Enterprise mode is not supported.

Things to remember for File DataLock

- You cannot enable or disable File DataLock once the View is created.
- If you have disabled File DataLock while creating a Protection Group, then when you edit this Protection Group, the File DataLock option will not be displayed.
- You can delete Protection Groups and snapshots having File DataLock enabled.

  File DataLock also preserves the ATimes of the hardlinks and symlinks.
- **Recovery**
  - Recovering a File DataLock enabled backed-up volume as a Cohesity View will preserve ATimes and the locking period for the file.
  - Recovering a File DataLock enabled volume to the original location with 'Overwrite existing files/folder' as the recovery option will encounter an error if the files and folders are read-only. However, the ATime and other attributes of other files and folders of the source volumes are preserved.
  - Recovering a File DataLock enabled volume to an alternate NAS recovery will preserve ATimes and other attributes of files and folders of the source volumes.
  - Cloning a recovered View having File DataLock enabled will not inherit the File DataLock properties.
- **Replication**

  When you replicate to a remote Cohesity cluster, the File DataLock settings are also replicated.
- **Archival**

  File DataLock settings are preserved when you recover volume from an archived snapshot whose Protection Group has File Datalock enabled, to a Cohesity View.
- **Cloud Archive Direct**

  File DataLock settings are preserved when you recover from a Cloud ArchiveDirect snapshot whose Protection Group has File Datalock enabled, to a Cohesity View.

Exclusions and Inclusions for NAS Protection Group

In a NAS Protection Group, all the files and folders are included by default for data protection. While creating a Protection Group, you can toggle on **Exclusions and Inclusions** from the **Advanced Settings** options if you want to exclude or include locations. By creating the exclusion and inclusion rules, you can limit the Protection Group to a specific set of files and directories. As a result, you can minimize the disk space used to store the data.

> **Note:**
> - To add an exclusion or inclusion rule, you must prefix a forward slash (‘/’) or suffix an asterisk (‘*’) to the path or to a particular file within the protected object. For example, ‘**/test**’ or ‘***.txt**’.
> - In exclusion or inclusion rules, file names and folder names are case-sensitive, which means ‘**test.txt**’ and ‘**Test.txt**’ are considered separate files. Use the correct capitalization of file or folder names to ensure that the rules recognize your file or folder.

Add Inclusion

From the Additional Settings options on the Protection Group page, toggle on **Exclusions and Inclusions**. Click **Add Inclusion** to include a particular path or a particular file within the protected object.

For example, consider four directories - **test**, **test1**, **test2**, and **test3** under the protected object with path `/ifs/TestShare1/Folder1`. The table below lists the input types for an inclusion list of folders and their respective outcome:

Input	Outcome
/	Everything inside the protection path is backed up if exclusions are not defined.
/test	When the inclusion path is not suffixed by '/', Protection Group will include all folders starting from the protection path. In this example, /test will behave as /test* and Protection Group will include '**test**', '**test1**', '**test2**', and '**test3**' from the protection path for backup.
/test/	When the inclusion path is suffixed by '/', it will only include the specific folder. In this example, /test/ behaves as /test/* and Protection Group will only include '**test**' from the protection path for backup.

- Do not provide the folder name along with the backup path while including files and folders for a Protection Group. The backup path is considered by default. For example, `/ifs/TestShare1/Folder1/test` does not include any folder.
- If exclusions are defined, they will take precedence over inclusions.

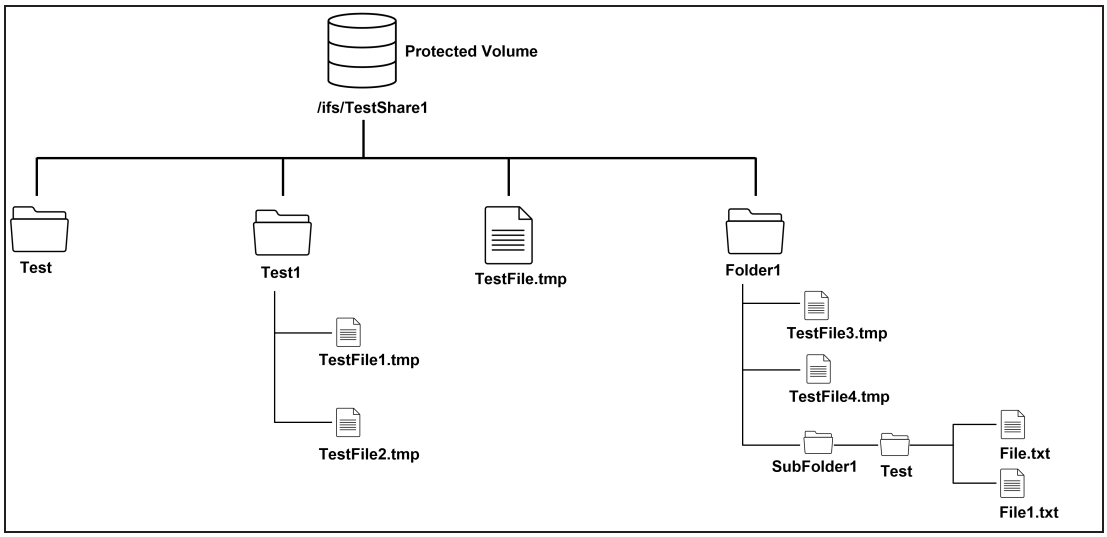
Add Exclusion

From the Additional Settings options on the Protection Group page, toggle on **Exclusions and Inclusions**. Click **Add Exclusion** to exclude a particular path or a particular file within the protected object. You can also specify regular expressions for excluding files in the format `regex:<regex pattern>`.

For example, consider there are three directories - **Test**, **Test1**, and **Folder1** and a file, **TestFile.tmp** under the protected object with path **/ifs/TestShare1**.

- The **Test1** folder has **TestFile1.tmp**, **TestFile2.tmp** files.
- The **Folder1** folder has **TestFile3.tmp**, **TestFile4.tmp files**, and **SubFolder1** which further has a **Test** folder with **File.txt**, **File1.txt** files in it.

The following figure illustrates the directory structure under the protected object with path **/ifs/TestShare1**.



The table below lists the input types for an exclusion list of folders and their respective outcome:

Input	Description	Outcome
/Test	When the exclusion path is not suffixed by '/', the Protection Group will exclude all files and folders with **Test** as the prefix. For exclusions, **/Test** behaves as **/Test***. **Note:** Exclusion will not be effective on the sub-directory level.	Excludes **Test** and **Test1** folders, and **TestFile1.tmp** file from the protection path. **TestFile3.tmp** and **TestFile4.tmp** files in the **Folder1** folder will not be excluded.

Input	Description	Outcome
/Test/	When the exclusion path is suffixed by '**/**', the Protection Group excludes only the files and folders with the name **Test**. For exclusions, **/Test/** behaves as **/Test/***. **Note:** Exclusion will not be effective on the sub-directory level.	Excludes the **Test** folder of the parent directory. The **Test** sub-folder in **/Folder1/SubFolder1** will not be excluded.
*/Test	Excludes all the files and directories with the name '**Test**'. **Note:** Exclusion will be effective on all levels of sub-directories.	Excludes the **Test** folder of the parent directory and the **Test** sub-folder in **/Folder1/SubFolder1**.
*.tmp	Excludes all the files that with '**.tmp**'. **Note:** Exclusion will be effective on all levels of sub-directories.	Excludes **TestFile.tmp**, **TestFile1.tmp**, **TestFile2.tmp**, **TestFile3.tmp**, **TestFile4.tmp** files.
regex:.*\.tmp	Excludes the files and folders with '**.tmp**'. **Note:** Exclusion will be effective on all levels of sub-directories.	Excludes **TestFile.tmp**, **TestFile1.tmp**, **TestFile2.tmp**, **TestFile3.tmp**, **TestFile4.tmp** files.
regex:/Folder1/.*/Test/.*\.txt$	Excludes all files with **.txt** extension from all the **Test** folders directory in **/Folder1/**.	Excludes **File.txt** and **File1.txt** files in the **/Folder1/SubFolder/Test** folder.

Note: Do not provide the folder name along with the backup path while excluding files and folders for a Protection Group. The backup path is considered by default. For example, `/ifs/TestShare1/Folder1/test` does not exclude any folder.

Cohesity automatically excludes the following NetApp system files:

- .vtoc_internal and .bplusvtoc_internal files
- .copy-offload directory and .tokens file

Considerations

Cohesity does not support inclusion or exclusion of paths in:

- an IsilonProtection Group with Changelist enabled.
- a NetApp SnapDiff-basedProtection Group.

Manage the Nutanix Files Backup Configuration

In Cohesity, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirement.

> **Note:** You cannot update the registered Nutanix Files cluster and the assigned Storage Domain in the Protection Group settings.

Add Nutanix Files volumes to the Protection Group

You can add new Nutanix Files volumes to the existing Protection Group for backup. The newly added volumes are backed up from the next protection run and it will be a full backup.

To add Nutanix Files volumes to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Nutanix Files.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** field, click the **Edit** icon.
5. Select the Nutanix Files volumes you want to add to the Protection Group.
6. Click **Save Selection** > **Save**.

The newly added Nutanix Files volumes will be backed in the next scheduled protection run.

Remove Nutanix Files volumes from the Protection Group

From the **Edit Protection** page, you can remove Nutanix Files volumes from the Protection Group that you do not want to back up in the next protection run.

To remove Nutanix Files volumes from the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Nutanix Files.
3. Click the action icon next to the Protection Group and select **Edit**.

4. On the **Edit Protection** page, in the **Object** field, click the **Edit** icon.
5. Unselect the Nutanix Files volumes that you want to remove from the Protection Group.
6. Click **Save Selection** > **Save**.

The removed Nutanix Files volumes will not be backed in the next scheduled protection run.

Enable Auto Protect

The Auto Protect option enables you to automatically protect the new Nutanix Files volumes that are added to the selected parent Nutanix Files cluster. However, you cannot enable auto-protect at the cluster-level containing Read-Write volumes.

To enable auto protect:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for NetApp ONTAP.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** field, click **Edit Objects**.
5. Click the shield icon to enable Auto Protect.
6. Click **Save Selection** > **Save**.

When this option is enabled on the parent Nutanix Files cluster, all the Nutanix Files volumes that are added to the parent Nutanix Files cluster in the future are automatically added to the Protection Group and are protected from the next protection run.

For example, you create a Protection Group that backs up a Nutanix Files cluster. The Protection Group runs for two weeks and then a new volume is added to the Nutanix Files cluster. The next time the Protection Group runs, if the object hierarchy has been refreshed on the Cohesity cluster, the new volume is also backed up even though the new volume has not been explicitly selected to be included in the Protection Group. The object hierarchy is automatically refreshed every four hours. To manually refresh the object hierarchy, select **Data Protection > Sources**, find the source in the list, and click . To exclude an object from Auto Protect, click .

- Indicates an Auto Protected object.
- Excluded objects are not protected. The icon indicates that an ancestor of the object is Auto Protected but this object is explicitly excluded.

Edit Existing Protection Policy

You can edit the existing Protection Policy that is attached to the Protection Group based on your requirement. In the Protection Policy, you can edit the settings listed in the Create or Use an Existing Protection Policy.

To the policy settings:

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for NetApp ONTAP.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Policy** field, click **Edit**.

   The Edit Policy page appears.
5. Edit the settings listed in the Create or Use an Existing Protection Policy and then click **Save**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

You can attach a new Protection Policy to your Protection Group. The new policy is applied to the Protection Group in the next scheduled protection run.

1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for NetApp ONTAP.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, from the drop-down list in the **policy** field, select a new Protection Policy for the Protection Group.
5. Click **Save**.

Start an On-demand Protection Run

You can instantly start a protection run of the Protection Group that you have created to back up Nutanix Files volumes. It provides you options to back up all the objects or only selected objects in the Protection Group. If the policy associated with the Protection Group:

- Supports multiple backup types, you can select an incremental or full backup.
- Is configured with archival targets, you can select those targets.

If the last protection run contains failed objects, you can backup only the failed objects.

To start a protection run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Nutanix Files.
3. Click the action icon next to the Protection Group and select **Run Now**.

4. In the pop-up window, perform the following:
    a. In the **Backup** drop-down list, select any one of the following:
        - **All objects in the protection group**
        - **All objects that failed last run**: Available when the last backup run contains failed objects.
        - **All objects that succeeded the last run**: Available when the last backup run does not contain failed objects.
        - **Selected objects in the protection run**
    b. In the **Backup Type** drop-down list, select the backup type.
    c. In the Archive section, select the archive target, and the retention duration. You can register an external target, if required.
5. Click **Run**.

Pause Protection Runs Instantly

You can instantly pause a protection run of the Protection Group that you have created to back up the Nutanix Files sources.

Perform the following steps to pause a currently executing protection run of a Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, click the Nutanix Files Protection Group that has been created.
3. Click the action icon next to the protection run and click **Pause Run**.

Pause Future Protection Runs

You can stop the protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Nutanix Files.
3. Click the action icon next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run.

To resume a paused protection run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.

3. Click the action icon next to the Protection Group and select **Resume**.

Delete the Protection Group

Cohesity provides the following ways to delete the Protection Group associated with Nutanix Files:

- **Delete Protection Group Only**: Delete only the Protection Group. Any local snapshots and or archived snapshots stored on the external targets that were captured by this Protection Group are not deleted
- **Delete Protection Group and Snapshots**: Delete the Protection Group and all Snapshots, any local Snapshots captured by this Protection Group and stored on this Cluster are deleted. In addition, any archived Snapshots stored on external targets that were captured by this Protection Group are also deleted.

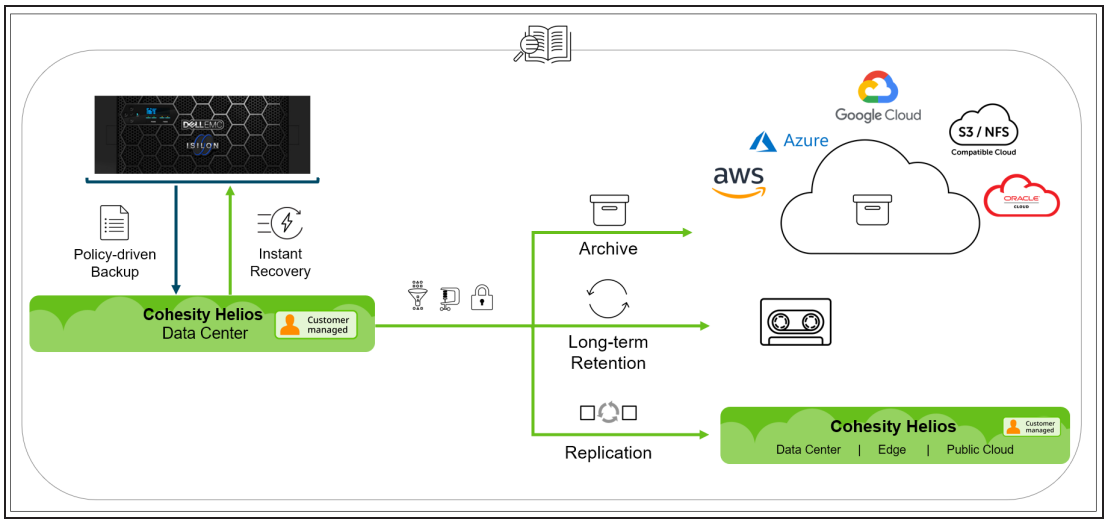
To delete the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Nutanix Files.
3. Click the action icon next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Delete Protection Group Only
    - Delete Protection Group and Snapshots

If the current Protection Group is archiving snapshots to an external target, you should cancel these archive tasks before deleting the Protection Group. For instructions, see Cancel Replication and Archive Copy Tasks of a Protection Group Run.

Dell EMC Isilon

Isilon is a network-attached storage platform offered by Dell EMC and provides a cluster-based storage array based on industry-standard hardware. Using the policy-based data protection solution from Cohesity, you can protect the data stored on Isilon. This section provides information on how to back up and recover Isilon data using Cohesity.



Plan and Prepare for Isilon Protection

Before you register your Isilon cluster with the Cohesity cluster and protect the volumes and data, ensure that:

- Cohesity supports the Isilon cluster versions and volumes you plan to protect.
- You have the minimum permissions required to register and manage your Isilon cluster.
- The required firewall ports are open to enable communication between the Cohesity cluster and the Isilon cluster.
- You meet the prerequisites to register and manage your Isilon cluster.
- You have reviewed and understood the considerations of Isilon cluster backup and recovery.

Support Matrix

Before you register your Isilon cluster with the Cohesity cluster, ensure that Cohesity supports the Isilon versions and volumes you want to protect. For more information, see Supported Software.

Supported NFS and SMB versions

The following table lists the supported NFS and SMB versions for backup:

Protocol	Version	Notes
NFS	NFSv3 NFSv4.1	NFS v4.1 Kerberos authentication is supported.
SMB	SMB v2.x, v3	

Minimum Permissions

The user account that will be used for registering the Isilon cluster with the Cohesity cluster does not require administrator privileges on the Isilon cluster. The user account only requires the following permissions necessary to back up and restore your Isilon data:

Access-level	Command	Description	Protocol
ReadOnly	Platform API	For access to Isilon's APIs.	SMB/NFS
	Auth	To verify users and passwords.	
	Cluster	To obtain cluster identity and settings.	
	Network	To obtain the network interfaces.	
	SMB	To read the settings in the SMB server.	
Read/Write	Job Engine	To read and write Changelist jobs.	
	Snapshot	To fetch, create, and delete snapshots for shares and exports.	
	NFS	To read and write settings to and from the NFS server.	

Ports Used for Communication

Ensure that TCP/UDP ports 300, 302, 304, 443, 445, 8080, 111, and 2049 are open in the firewall between the Cohesity cluster and your Isilon device. For more information, see Manage Firewall Ports.

Prerequisites

> **Note:** The sub-settings for Snapshot Self-Service are not mandatory. However, when the Global Visibility and Access is enabled, the sub-settings for NFS Settings, SMB Settings, and Local Settings are also enabled by default. These sub-settings for Snapshot Self-Service are not mandatory for Cohesity and can be disabled if you choose to do so.

Ensure to meet the following prerequisites to register and manage your Isilon cluster:

- Cohesity leverages SnapshotIQ to perform the backup of the Isilon source. Therefore, ensure to enable the SnapshotIQ license with the following settings on the Isilon cluster:

    - Enable Snapshot Service
    - Enable global visibility and access
- The user provided during the Isilon source registration must be added to the SMB shares as access with Read-Only permission.

Considerations

- The Cohesity Dashboard estimates the total size of protected and unprotected Isilon shares by multiplying the number of shares by about 3.5 GiB. Cohesity cannot determine the actual size because each share is a subdirectory of the root /ifs directory.
- For Isilon OneFS 9.2.x or earlier versions, the maximum filename length or full path length limits to 255 bytes.
- Root permissions are required to set the ACLs. To set the permissions, you can perform the following:
    - for the share that belongs to System Access Zone, add "Backup files from /ifs" and "Restore files to /ifs" privileges for the role to which the user or group belongs.
    - for non-System Access Zone, set the share permissions for the user as "Run as root".
- Cohesity recommends a first full and incremental forever backup approach to back up your NAS sources.
- When browsing files or folders for recovery, Cohesity does not display files or folders with an absolute path length exceeding approximately 3,500 characters. To recover these files or folders, select the parent directory.

Register and Manage Isilon Source

To protect your Isilon data, you must register your Isilon cluster as a source on the Cohesity cluster. After registration, you can manage the source on Cohesity in the following ways:

- Update the Isilon source configuration
- Refresh the source details
- Unregister the Isilon cluster source from the Cohesity cluster.

Register Isilon Cluster as a Source

Before you register an Isilon cluster as a source on the Cohesity cluster, ensure that you:

1. Review the requirements, considerations, and best practices.
2. Perform the prerequisite tasks.

For more information, see Plan and Prepare for Isilon Protection.

To register Isilon cluster as a source:

1. In the Cohesity Dashboard, select **Data Protection > Sources**.
2. Click **Register** on the top-right of the page and then select **NAS**.
   The Register NAS page appears.
3. From the NAS Source drop-down list, select **Isilon (Cluster)**.
4. Enter the following information and then click **Register**.

Field Name	Description
Host or IP Address	Provide the management IP address or hostname of the Isilon cluster.
Username	Provide the user account that you configured with the required permissions on the Isilon cluster. If you are providing a domain user account, then you must specify the user name in the following format: `fully_qualified_domain_name\username`. For example, `xydc.local\user1`.
Password	Provide the password of the user account.
Back Up SMB Volumes	If you want to protect Isilon SMB shares, provide the local or Active Directory user credentials that allow read access to the Isilon SMB share you want to back up. Ensure to provide the Active Directory user credentials in the `domain\user` format. **Note:** • You can assign the local or AD user to the built-in "BackupAdmin" role to allow the user to read the SMB data for backup without modifying the access control lists (ACLs). • To provide access at the share level, grant the "Run as root" and "Full Control" permissions at the share level.
Filter IPs	Enable this option to filter the IP addresses of the Isilon cluster. By filtering IP addresses, you can allow or deny the communication of the Cohesity cluster to specific IP addresses or subnets of the Isilon cluster. To filter the IP addresses of the Isilon cluster, select one of the following options: • **Allow IPs**: Select this option and specify the IP addresses of the Isilon source through which the communication to the Cohesity cluster must happen. You can provide the IP addresses in a comma-separated list or in a CIDR format. • **Deny IPs**: Select this option and specify the IP addresses of the Isilon source through which the communication to the Cohesity cluster must not happen. You can provide the IP addresses in a comma-separated list or in a CIDR format.

For more information, see Protect Dell EMC Isilon with Cohesity DataProtect.

When registration finishes, a new entry appears on the Sources page. You can now create a Protection Group to backup Isilon volumes. For more information, see Protect Isilon.

After registering the Isilon source, you can choose the **Configure** option in the **Source** to configure the **Static Network Pool** and **Dynamic Network Pool**, as well as the SmartConnect for each Isilon Access Zone.

Update the Isilon Cluster Source Configuration

You can update the Isilon cluster details that you provided during the registration process with the latest Isilon configuration.

To edit the Isilon cluster source configuration:

1. In the Cohesity Dashboard, select **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Isilon cluster source and select **Edit**.
3. In the Edit NAS page, update the respective configurations.
4. In the **Password** field, enter the password of the Isilon user account, and then click **Update**.

Refresh the Isilon cluster Source

You can refresh the Isilon cluster configuration and fetch the latest changes on the Isilon cluster.

To refresh the Isilon cluster source configuration:

1. In the Cohesity Dashboard, select **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Isilon cluster source and select **Refresh**.

Unregister Isilon cluster

If you plan to stop taking backups of the Isilon cluster volumes, you can unregister the Isilon cluster source from the Cohesity cluster. Before you unregister, you must delete all the Protection Groups associated with the Isilon cluster. For more information, see Delete the Protection Group

To unregister the Isilon cluster server on Cohesity cluster:

1. In the Cohesity Dashboard, select **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Isilon cluster source and select **Unregister**.
3. Click **Unregister**.

Isilon SmartConnect

Isilon SmartConnect is a feature that offers load balancing and failover capabilities for connections to an Isilon cluster. It effectively manages requests from multiple connections, manages DNS requests, and oversees multiple IP addresses.

SmartConnect is a licensed software module of the EMC Isilon OneFS, designed to enhance performance and availability by enabling intelligent client connection load balancing and failover support. If the Isilon cluster has SmartConnect enabled, it can be used for backup operations.

To utilize SmartConnect, you need to configure it after registering the Isilon source. You must register the Isilon Adapter Source using the SmartConnect IP (SIP), which provides multiple addresses for the Cohesity cluster to access

SmartConnect can be configured under **Cluster Management** > **Network Configuration**, where you can view or edit the subnet settings. Cohesity supports using the SmartConnect Fully Qualified Domain Name (FQDN) to discover and connect to the Isilon cluster.

Configure Isilon SmartConnect

To configure Isilon SmartConnect:

1. Navigate to **Data Protection > Sources**.
2. Select the registered Isilon source, click the 3 dots on the right, and click **Configure**.
3. On the **Configure Isilon Source** page, select the **Access Zone** you want to use.
4. From the **Static Network Pool**, select the desired Cohesity network pool to use for communicating with Isilon.
5. Enter or confirm the **SmartConnect FQDN** of the Isilon cluster.
6. Enable the **Use Smart Connect** option.
7. Click **Save**.

   The **SmartConnect FQDN** provided is used to do the backup.

Backup Isilon

After registering your Isilon cluster as a source on the Cohesity cluster, you can create a Protection Group to protect the Isilon volumes.

The volume can be of NFS export only, SMB share only, or of both NFS and SMB (mixed) type. To back up SMB shares of any volume type, you must provide the local or Active Directory user credentials that allow at least read access to the Isilon SMB share. You can provide these credentials while registering the Isilon cluster with the Cohesity cluster or later when creating the Protection Group. For more information, see, Register and Manage Isilon Source.

You can backup one or more Isilon NFS mount points, SMB shares, or mixed volumes in a Protection Group while preserving ACLs and Extended attributes on SMB.

Protect Isilon

In Cohesity, Isilon volumes are protected using a Protection Group and a Protection Policy. A Protection Group uses the schedules and settings defined in the policy to determine when

and how backups are captured, archived, or replicated.

A Protection Policy is a reusable set of settings that define how and when objects are protected and replicated. You can select which standard or custom policy to use when creating a Protection Group. For more information, see Manage Protection Policy.

You can protect Isilon volumes with only SMB share, NFS export, or the volumes that are exposed to both NFS export and SMB share (mixed volumes). For Isilon mixed volumes, Cohesity will back up both NFS POSIX ACLs and SMB access control lists (ACLs).

> **Note:** Cohesity recommends a first full and incremental forever backup approach to back up your NAS sources.

To protect Isilon volumes:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then select **NAS**.
3. Click **Add Objects** and from the **Registered Source** drop-down list, select the registered Isilon source that contains the volumes you want to back up.

   You can also register a new source with the Cohesity cluster so you can protect it. For more information, seeRegister and Manage Isilon Source.
4. From the **Objects** list, select Isilon volumes NFS exports, SMB shares, or the volumes that are exposed to both NFS and SMB protocols.
5. Click **Continue**.
6. To back up SMB shares, provide the user access credentials if you have not provided when registering the Isilon source.
7. If you have selected the volumes that are exposed to both NFS and SMB protocols, then select the backup preference mode of the volume you want to backup.
8. In the **Protection Group** field, enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.
9. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, see Create or Use an Existing Protection Policy.
10. Select the appropriate Storage Domain. For more information, see Manage Storage Domains.
11. If you want to change or configure any of the additional settings, then select **More Options** and perform the below steps or else, click **Protect**.
12. If you want to add the selected objects to an existing Protection Group, then perform the following steps or else, go to step 13:

a. From the **Protection Group** field, enableProtection Group **Existing Group**.

b. Select an existing one from the **Group** drop-down list.

c. Click **Protect**.

The objects will be protected based on the policy settings applied to the selected Protection Group.

13. In the **Start Time** field, specify the time to run the Protection Group. The default time zone is the browser's time zone.

> **Note:** This option is available only if the selected policy is set to Backup Daily.

14. If you need to change any of the additional settings on the Protection Group page, click the down arrow icon next to **Additional Settings** and click **Edit** on the right. For more information, see Additional Settings.

15. Click **Protect**.

Your new Protection Group is now active and running.

Additional Settings

Additional Settings	Description
End Date	Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts prior to this date runs until completion even if it completes after this date.

Additional Settings	Description
QoS Policy	Select an appropriate quality of service (QoS) policy. **Note:** Cohesity recommends specifying **Backup HDD**, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Pre & Post Scripts	Toggle **Enable** to run scripts on a Unix server before and/or after a Protection Group runs. If configured, scripts are run every time an object (or entity) is backed by a protection run. For example, if there are five mount/shares that are backed up as part of the NAS Protection Group and the Pre Script is configured, then five instances of the Pre Script are executed in parallel. You can distinguish between the scripts that are run on the different objects (entities) using the `COHESITY_BACKUP_ENTITY` environment variable. The Cohesity cluster populates this environment variable with the name of the backed object (or entity).
Skip Files on Errors	Toggled on by default. The Protection Group continues to run even if it encounters errors on files, such as permissions errors. If files are skipped, the protection run details page indicates a warning status and provides additional information. If toggled off, the Protection Group stops when it encounters an error.

Additional Settings	Description
Use Isilon Change Lists	Toggle on this option to use the vendor-native Change File Tracking (CFT) method for file discovery during an incremental backup. In this method, Cohesity leverages the Isilon CFT API to identify the delta between two snapshot copies. It reduces the time taken to discover the files and folders to backup. If this option is toggled off, Cohesity uses the Cohesity's built-in CFT method. In this method, Cohesity uses its internal File-Runner to discover the delta between two snapshot copies. By default, this option is disabled. > **Note:** Due to the limitations set by Isilon, only one change list can be run at a time. If the Protection Group contains multiple shares to back up, Isilon creates delta for each share serially.
Encryption	Toggle on this option to enable in-flight encryption of data that are backed up to the Cohesity cluster. This option is disabled by default. To use the encryption functionality for NFS volumes, you must join the Cohesity cluster to the active directory as the Kerberos server or add the Kerberos provider in the Cohesity cluster Access Management section. This option is disabled by default. > **Note:** Encrypting in-flight data will have a minor impact on the performance.

Additional Settings	Description
File DataLock	Toggle on this option to preserve the AccessTime of the files and folders of the selected volumes. The AccessTime provides the lock period of the files and folders that are applied when these files and folders are recovered to the Cohesity View. For more information on File DataLock, see NAS File DataLock. Select one of the following **DataLock** modes: • **Compliance**: In this mode, files or folders cannot be deleted or modified during the retention period. After the lock expires, no user can modify the files or folders. However, a root user can delete the files and folders. Only a user with the Data Security role can edit the File DataLock settings in the Compliance mode. • **Enterprise**: In this mode, files or folders cannot be modified by any user before or after the lock retention period expiration. However, a root user can delete the files or folders before or after the lock retention period. An admin user or a user with the Data Security role can edit the File DataLock settings in the Enterprise mode. This mode is useful for giving storage administrators additional control over the file. You can further configure the File DataLock settings to: • Set the lock period for the new files and folders created on the recovered Cohesity View Provide the following information to set the lock period for the new files and folders that will be created on the recovered Cohesity View. These settings are not applicable for the existing NAS source files and folders recovered on the Cohesity View. • **Default Lock Period**: Provide the time period during which the files should remain locked. When the time period ends, files can be deleted but not changed. By default, the files are locked forever. • **Autolock Files**: By enabling this option, the files are automatically locked if they are not modified in the time period you specify. By default, this option is disabled. • **Manally Lock Using**: Select when the files are to be locked: • **Read-Only**: Select this option to lock files when the file permission is set to read only, for example; by setting the Windows file properties attribute or using the Linux `chmod` command. By default, the files are locked when the file permission is set to read only. • **FutureATime**: Select this option to lock files when the last access time (atime) is set, for example, by using Windows `PowerShell` commands or the Linux touch command. Optionally you can set a **Minimum Retention** and/or a **Maximum Retention** period to ensure that a file's last access time cannot be set outside this period.

Additional Settings	Description
	A request to do so results in a permission denied error if manual locking mode is FutureATime. Otherwise, the request will be silently rejected and the file will be locked for the minimum retention duration. • Override the locking period of the existing files and folders recovered on the Cohesity View: The following option can be applied to all the existing files and folders that will be recovered on the Cohesity View. • **Override (Lock all files until a specific date)**: Enable this option and select a date to override the locking period of the existing files and folders. When you recover the files to the Cohesity View, Cohesity applies the farthest lock period between the override lock period you specify and the source file's lock period. For example; • The lock period of the source file is 09/09/2023 and the override lock period you specified is 09/08/2022. When you recover the file to the Cohesity View, then the lock period of the source file is applied to the recovered file, which is 09/09/2023. • The lock period of the source file is 09/09/2022 and the override lock period you specified is 09/08/2024. When you recover the file to the Cohesity View, then the override lock period you specified is applied to the recovered file, which is 09/08/2024. In **Compliance** mode, a user with the Data Security privileges can extend the override date into the future, but no user can shorten the date. In **Enterprise** mode, a user with admin or the Data Security privileges can extend or shorten the override date. **Note:** • You cannot enable or disable File DataLock once the Protection Group is created. • If you have disabled File DataLock while creating a Protection Group, then when you edit this Protection Group, the File DataLock option will not be displayed. • You can delete Protection Groups and snapshots having File DataLock enabled. File DataLock also preserves the ATimes of the hardlinks and symlinks.

Additional Settings	Description
Filter IPs	Toggle on option to filter the IP addresses of the Isilon cluster. By filtering IP addresses, you can allow or deny the communication of the Cohesity cluster to specific IP addresses or subnets of the Isilon cluster at the Protection Group level. To filter the IP addresses of the Isilon cluster, select one of the following options: • **Allow IPs**: Select this option and specify the IP addresses of the Isilon cluster source through which the communication to the Cohesity cluster must happen. You can provide the IP addresses in a comma-separated list or in a CIDR format. • **Deny IPs**: Select this option and specify the IP addresses of the Isilon cluster source through which the communication to the Cohesity cluster must not happen. You can provide the IP addresses in a comma-separated list or in a CIDR format. > **Note:** If you have specified the IP filtering at the source level also, then the IP filtering specified at the Protection Group level will take precedence over the IP filtering specified at the source level.
Exclusions and Inclusions	Toggle on this option if you want to exclude or include locations. By creating exclusion and inclusion rules, you can limit the Protection Group to a specific set of files and directories and therefore minimize the disk space used to store the data. All the files and folders are included for by default for protection. For more information, see Exclusions and Inclusions for NAS Protection Group. > **Note:** Cohesity does not support inclusion or exclusion of paths in an Isilon Protection Group with the **Use Isilon Change Lists** option enabled.
Indexing	This option is toggled on by default to index the data of the Protection Group. Indexing improves the files and folders search. Cohesity performs incremental indexing where only the data that has changed since the previous snapshot is scanned and indexed.

Additional Settings	Description
Quiet Times	This option is available only if the selected policy has at least one quiet time period. Toggle the **Stop in-progress runs when quiet time starts** option to pause or abort the runs during quiet time. If this option is toggled off, after a protection run starts, execution continues even when the quiet time period specified for this Protection Group starts. However, a new protection run will not start during a quiet time period. • **Pause Runs** - Select this option to pause the currently executing protection runs and resume the runs when quiet time ends. • **Abort Runs** - Select this option to abort the currently executing protection runs when the quiet time period specified for the Protection Group starts. > **Note:** If the quiet time window for multiple protection runs is scheduled at the same time, then when the protection run is resumed, prioritization of the protection run does not work.
Alerts	Select one or more of the following **Alerts On** settings if you want alerts to be created for the following triggers: • SLA Violation: Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts. • Failure: Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • Success: Create an informational alert when the Protection Group completes successfully. Emails are not sent when informational alerts are created. To send emails when alerts are triggered for the Protection Group, in the **Email Recipients** field, add the email addresses of the recipients.
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection run exceeds the ability to process the protection run, this will be the priority of implementation of the protection run: a. High b. Medium c. Low

Additional Settings	Description
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks). • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. **Note:** Users with similar SLAs can be grouped together and a custom policy and Protection Group can be created to achieve different SLAs.
Pause Future Runs	Toggle on this option to stop protection runs of the Protection Group from executing. Once you enable this option, no protection runs will be scheduled for this Protection Group.
Description	Enter a brief description about the Protection Group.

Create or Use an Existing Protection Policy

A Protection Policy is a reusable set of settings. It enables you to define how and when Isilon data is protected, replicated, and archived. A standard policy provides various settings that you can configure for a Protection Group.

Create a Protection Policy with the settings listed in the Policy Settings for Isilon. For detailed instructions on how to create a Protection Policy, see Create or Edit a Standard Policy.

Policy Settings for Isilon

The following table list the applicable policy settings for Isilon:

Field	Description
Primary Copy	Select **Local** from the drop-down to keep the primary copy data on the Cohesity cluster. Select any external target for performing CloudArchive Direct wherein the primary copy of the data is stored on the external targets. For more information, see CloudArchive Direct.

Field	Description
DataLock	If applicable, add a DataLock for compliance and regulatory requirements, to ensure that your protected data, including local backups, archives, and replication, cannot be modified until the DataLock expiration. Once applied, a DataLocked Snapshot will be deleted only after its retention period expires. A DataLock prevents all users, including those who have the Data Security role in Cohesity, from modifying or deleting any Snapshots that were generated by the Protection Groups that use this Policy. Only users with the Data Security role can add, modify, or remove a DataLock from a Policy.
Scheduled Backup	Defines when backups are captured, how long they are retained and the type of backup to capture.
Extended Retention	Add this to retain a subset of snapshots (backups) for longer than defined by the protection schedule.
Retry Options	Use this option to customize the retry settings for capturing Snapshots. By default, Cohesity attempts to capture Snapshots three times before the Protection Group fails. The default time between retries is five minutes. You can customize the number of retries and how long to wait between each attempt.
Periodic full backup	Use this option to choose when to run a periodic full backup.
Quiet Times	Quiet Times defines time periods when new protection runs are not started. For example, you might want to configure hourly backups that run during weekdays but not on Saturday or Sunday. Quiet Times only prevents new protection runs from starting during the specified time period. The protection runs that started before the quiet time period will be dependent on the quiet time settings configured in the additional settings of the protection Group. For example, if a protection run starts at 12:45 AM on Saturday morning and there is a weekend quiet time period that starts at 1 AM on Saturday morning, the protection run will continue to run past 1 AM. No new protection runs are started during the quiet time period.
Replication	To replicate snapshots to another, click the Replication icon from the floating menu. The copied snapshots are stored in the storage domain of the remote cluster. .
Archival	To add an archive schedule, click archival icon from the floating menu.

Use an Existing Protection Policy

You can use an existing Protection Policy protecting Isilon. If you are selecting an existing protection policy, then the following options are ignored if they are already configured in the protection policy:

- **Log Backup (Databases)**
- **Add BMR Backup (Physical Server)**
- **CloudSpin**

NAS File DataLock

Many organizations now rely on WORM (Write Once Read Many) data storage such as Nutanix Files, NetApp Snaplock, and Isilon Smartlock volumes to retain their files and folders in unmodified form for compliance and regulatory purposes and to protect the files from accidental deletion or modification.

When you backup these WORM-capable volumes to the Cohesity cluster, it is essential to have the ability to easily lock the files and folders of the volumes while protecting themselves from accidental or malicious attempts to delete or modify these files. The backup should also provide a strong guarantee for data non-mutability and non-erasability for a certain period of time.

This capability is achieved using Cohesity's File DataLock feature.

FileDataLock is a Cohesity feature that preserves the WORM attributes of any files and folders created in the Cohesity View. You can apply the File DataLock feature for NAS backup (NFS exports and SMB shares) while creating a NAS Protection Group.

With File DataLock enabled in a NAS Protection Group, Cohesity preserves the future AccessTime (ATime) of the files and folders. The AccessTime provides the lock period for files and folders. You can also override this lock period in the File DataLock settings of the NAS Protection Group. This lock period is applied to these files and folders when they are recovered to the Cohesity View. This prevents the users or administrator from modifying or deleting these locked files until the locking period expires.

You can also set lock periods for the new files and folders created on recovered Cohesity View in the File DataLock settings of the NAS Protection Group.

When you recover File DataLock enabled storage volumes to the Cohesity View, the View details page will display a lock icon for the files and folders having File DataLock.

File DataLock is supported for all types of NAS sources including NetApp 7-mode and is agnostic of the NAS protocol.

For information on how to enable File DataLock, see Protect NAS.

File DataLock Modes

You can use the File DataLock feature in one of the two modes:

- **Compliance mode**: The WORM files are protected at the disk level. This mode implements strict regulatory requirements for data retention and complies with SEC Rule 17a-4. In this mode, files and folders cannot be deleted or modified during the retention period. After the lock expires, no user can modify the files and folders. However, a root user can delete the files and folders. Only a user with a Data Security

role can edit the File DataLock settings in the Compliance mode.

- **Enterprise mode**: The WORM files are protected at the file level. This mode does not implement strict regulatory requirements for data retention. In this mode, files and folders cannot be modified by any user before or after the lock retention period expiration. However, a root user can delete the files and folders during or after the lock retention period. An admin user or a user with the Data Security role can edit the File DataLock settings in the Enterprise mode

> **Note:** An admin user or a user with the Data Security role can edit the File DataLock settings and switch from the Enterprise mode to Compliance mode. But switching from Compliance mode to Enterprise mode is not supported.

Things to remember for File DataLock

- You cannot enable or disable File DataLock once the View is created.
- If you have disabled File DataLock while creating a Protection Group, then when you edit this Protection Group, the File DataLock option will not be displayed.
- You can delete Protection Groups and snapshots having File DataLock enabled.

  File DataLock also preserves the ATimes of the hardlinks and symlinks.
- **Recovery**
  - Recovering a File DataLock enabled backed-up volume as a Cohesity View will preserve ATimes and the locking period for the file.
  - Recovering a File DataLock enabled volume to the original location with 'Overwrite existing files/folder' as the recovery option will encounter an error if the files and folders are read-only. However, the ATime and other attributes of other files and folders of the source volumes are preserved.
  - Recovering a File DataLock enabled volume to an alternate NAS recovery will preserve ATimes and other attributes of files and folders of the source volumes.
  - Cloning a recovered View having File DataLock enabled will not inherit the File DataLock properties.
- **Replication**

  When you replicate to a remote Cohesity cluster, the File DataLock settings are also replicated.
- **Archival**

  File DataLock settings are preserved when you recover volume from an archived snapshot whose Protection Group has File Datalock enabled, to a Cohesity View.
- **Cloud Archive Direct**

  File DataLock settings are preserved when you recover from a Cloud ArchiveDirect snapshot whose Protection Group has File Datalock enabled, to a Cohesity View.

Exclusions and Inclusions for NAS Protection Group

In a NAS Protection Group, all the files and folders are included by default for data protection. While creating a Protection Group, you can toggle on **Exclusions and Inclusions** from the **Advanced Settings** options if you want to exclude or include locations. By creating the exclusion and inclusion rules, you can limit the Protection Group to a specific set of files and directories. As a result, you can minimize the disk space used to store the data.

> **Note:**
> - To add an exclusion or inclusion rule, you must prefix a forward slash (‘/’) or suffix an asterisk (‘*’) to the path or to a particular file within the protected object. For example, ‘**/test**’ or ‘***.txt**’.
> - In exclusion or inclusion rules, file names and folder names are case-sensitive, which means ‘**test.txt**’ and ‘**Test.txt**’ are considered separate files. Use the correct capitalization of file or folder names to ensure that the rules recognize your file or folder.

Add Inclusion

From the Additional Settings options on the Protection Group page, toggle on **Exclusions and Inclusions**. Click **Add Inclusion** to include a particular path or a particular file within the protected object.

For example, consider four directories - **test**, **test1**, **test2**, and **test3** under the protected object with path `/ifs/TestShare1/Folder1`. The table below lists the input types for an inclusion list of folders and their respective outcome:

Input	Outcome
/	Everything inside the protection path is backed up if exclusions are not defined.
/test	When the inclusion path is not suffixed by '/', Protection Group will include all folders starting from the protection path. In this example, /test will behave as /test* and Protection Group will include '**test**', '**test1**', '**test2**', and '**test3**' from the protection path for backup.

Input	Outcome
/test/	When the inclusion path is suffixed by '/', it will only include the specific folder. In this example, /test/ behaves as /test/* and Protection Group will only include '**test**' from the protection path for backup.

- Do not provide the folder name along with the backup path while including files and folders for a Protection Group. The backup path is considered by default. For example, `/ifs/TestShare1/Folder1/test` does not include any folder.
- If exclusions are defined, they will take precedence over inclusions.

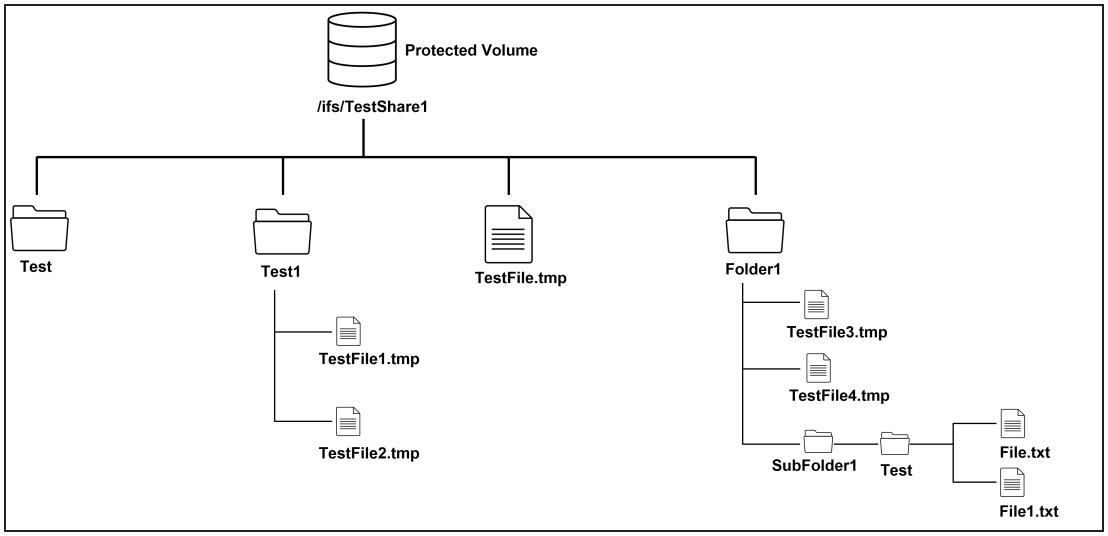
Add Exclusion

From the Additional Settings options on the Protection Group page, toggle on **Exclusions and Inclusions**. Click **Add Exclusion** to exclude a particular path or a particular file within the protected object. You can also specify regular expressions for excluding files in the format `regex:<regex pattern>`.

For example, consider there are three directories - **Test**, **Test1**, and **Folder1** and a file, **TestFile.tmp** under the protected object with path **/ifs/TestShare1**.

- The **Test1** folder has **TestFile1.tmp**, **TestFile2.tmp** files.
- The **Folder1** folder has **TestFile3.tmp**, **TestFile4.tmp files**, and **SubFolder1** which further has a **Test** folder with **File.txt**, **File1.txt** files in it.

The following figure illustrates the directory structure under the protected object with path **/ifs/TestShare1**.



The table below lists the input types for an exclusion list of folders and their respective outcome:

Input	Description	Outcome
/Test	When the exclusion path is not suffixed by '**/**', the Protection Group will exclude all files and folders with **Test** as the prefix. For exclusions, **/Test** behaves as **/Test***. **Note:** Exclusion will not be effective on the sub-directory level.	Excludes **Test** and **Test1** folders, and **TestFile1.tmp** file from the protection path. **TestFile3.tmp** and **TestFile4.tmp** files in the **Folder1** folder will not be excluded.
/Test/	When the exclusion path is suffixed by '**/**', the Protection Group excludes only the files and folders with the name **Test**. For exclusions, **/Test/** behaves as **/Test/***. **Note:** Exclusion will not be effective on the sub-directory level.	Excludes the **Test** folder of the parent directory. The **Test** sub-folder in **/Folder1/SubFolder1** will not be excluded.
*/Test	Excludes all the files and directories with the name '**Test**'. **Note:** Exclusion will be effective on all levels of sub-directories.	Excludes the **Test** folder of the parent directory and the **Test** sub-folder in **/Folder1/SubFolder1**.
*.tmp	Excludes all the files that with '**.tmp**'. **Note:** Exclusion will be effective on all levels of sub-directories.	Excludes **TestFile.tmp**, **TestFile1.tmp**, **TestFile2.tmp**, **TestFile3.tmp**, **TestFile4.tmp** files.
regex:.*\.tmp	Excludes the files and folders with '**.tmp**'. **Note:** Exclusion will be effective on all levels of sub-directories.	Excludes **TestFile.tmp**, **TestFile1.tmp**, **TestFile2.tmp**, **TestFile3.tmp**, **TestFile4.tmp** files.

Input	Description	Outcome
regex:/Folder1/.*/Test/.*\.txt$	Excludes all files with **.txt** extension from all the **Test** folders directory in **/Folder1/**.	Excludes **File.txt** and **File1.txt** files in the **/Folder1/SubFolder/Test** folder.

> **Note:** Do not provide the folder name along with the backup path while excluding files and folders for a Protection Group. The backup path is considered by default. For example, `/ifs/TestShare1/Folder1/test` does not exclude any folder.

Cohesity automatically excludes the following NetApp system files:

- .vtoc_internal and .bplusvtoc_internal files
- .copy-offload directory and .tokens file

Considerations

Cohesity does not support inclusion or exclusion of paths in:

- an IsilonProtection Group with Changelist enabled.
- a NetApp SnapDiff-basedProtection Group.

Manage the Isilon Backup Configuration

In Cohesity, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirement.

> **Note:** You cannot update the registered Isilon Server and the assigned Storage Domain in the Protection Group settings.

Add Isilon volumes to the Protection Group

You can add new Isilon volumes to the existing Protection Group for backup. The newly added volumes are backed up from the next protection run and it will be a full backup.

To add Isilon volumes to the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Isilon.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** field, click the **Edit** icon.

5. Select the Isilon volumes you want to add to the Protection Group.
6. Click **Save Selection** > **Save**.

The newly added Isilon volumes will be backed in the next scheduled protection run.

Remove Isilon volumes from the Protection Group

From the **Edit Protection** page, you can remove Isilon volumes from the Protection Group that you do not want to back up in the next protection run.

To remove Isilon volumes from the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Isilon.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** field, click the **Edit** icon.
5. Unselect the Isilon volumes that you want to remove from the Protection Group.
6. Click **Save Selection** > **Save**.

The removed Isilon volumes will not be backed in the next scheduled protection run.

Enable Auto Protect

The Auto Protect option enables you to automatically protect the new Isilon volumes that are added to the selected parent Isilon server. However, you cannot enable auto-protect at the cluster level containing both Read-Write volumes and Data-Protect volumes.

To enable auto protect:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Isilon.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** field, click the **Edit** icon.
5. Click the shield icon to enable Auto Protect.
6. Click **Save Selection** > **Save**.

When this option is enabled on the parent Isilon cluster, all the Isilon volumes that are added to the parent Isilon cluster in the future are automatically added to the Protection Group and are protected from the next protection run.

For example, you create a Protection Group that backs up an Isilon cluster. The Protection Group runs for two weeks and then a new volume is added to the Isilon cluster. The next time the Protection Group runs, if the object hierarchy has been refreshed on the Cohesity cluster, the new volume is also backed up even though the new volume has not been explicitly selected to be included in the Protection Group. The object hierarchy is automatically refreshed every four hours. To manually refresh the object hierarchy, select

Data Protection > Sources, find the source in the list, and click . To exclude an object from Auto Protect, click .

- Indicates an Auto Protected object.
- Excluded objects are not protected. The icon indicates that an ancestor of the object is Auto Protected but this object is explicitly excluded.

Edit Existing Protection Policy

You can edit the existing Protection Policy that is attached to the Protection Group based on your requirements. In the Protection Policy, you can edit the settings listed in the Create or Use an Existing Protection Policy.

To the policy settings:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Isilon.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Policy** field, click **Edit**.

   The Edit Policy page appears.
5. Edit the settings listed in the Create or Use an Existing Protection Policy and then click **Save**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

You can attach a new Protection Policy to your Protection Group. The new policy is applied to the Protection Group in the next scheduled protection run.

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Isilon.
3. Click the action icon next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, from the drop-down list in the **policy** field, select a new Protection Policy for the Protection Group.
5. Click **Save**.

Start an On-demand Protection Run

You can instantly start a protection run of the Protection Group that you have created to back up Isilon volumes. It provides you options to back up all the objects or only selected objects in the Protection Group. If the policy associated with the Protection Group:

- Supports multiple backup types, you can select an incremental or full backup.
- Is configured with replication targets, you can select those targets.

- Is configured with archival targets, you can select those targets.

To start a protection run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Isilon.
3. Click the action icon next to the Protection Group and select **Run Now**.
4. In the pop-up window, perform the following:
    a. In the **Backup** drop-down list, select any one of the following:
        - **Backup all Objects in the Protection Group**
        - **Backup only selected Objects in the Protection Group**
    b. In the **Backup Type** drop-down list, select the backup type.
    c. In the Replicate section, select the replication target, the retention duration, and enable the **Replicate only fully successful runs** checkbox if you want to replicate the data only after a successful protection run.
    d. In the Archive section, select the archive target, the retention duration, and enable the **Archive only fully successful runs** checkbox if you want to archive the data only after a successful protection run.
5. Click **Run Now**.

Pause Protection Runs Instantly

You can instantly pause a protection run of the Protection Group that you have created to back up the Isilon sources.

Perform the following steps to pause a currently executing protection run of a Protection Group:

1. In the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, click the Isilon Protection Group that has been created.
3. Click the action icon next to the protection run and click **Pause Run**.

Pause Future Protection Runs

You can stop the protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Isilon.
3. Click the action icon next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run.

To resume a paused protection run:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the action icon next to the Protection Group and select **Resume**.

Delete the Protection Group

Cohesity provides the following ways to delete the Protection Group associated with Isilon:

- **Delete Protection Group Only**: Delete only the Protection Group. Any local snapshots and or archived snapshots stored on the external targets that were captured by this Protection Group are not deleted
- **Delete Protection Group and Snapshots**: Delete the Protection Group and all Snapshots, any local Snapshots captured by this Protection Group and stored on this Cluster are deleted. In addition, any archived Snapshots stored on external targets that were captured by this Protection Group are also deleted.

To delete the Protection Group:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Isilon.
3. Click the action icon next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Delete Protection Group Only
    - Delete Protection Group and Snapshots

If the current Protection Group is replicating snapshots to a remote cluster or archiving snapshots to an external target, you should cancel these replication or archive tasks before deleting the Protection Group. For instructions, see Cancel Replication and Archive Copy Tasks of a Protection Group Run.

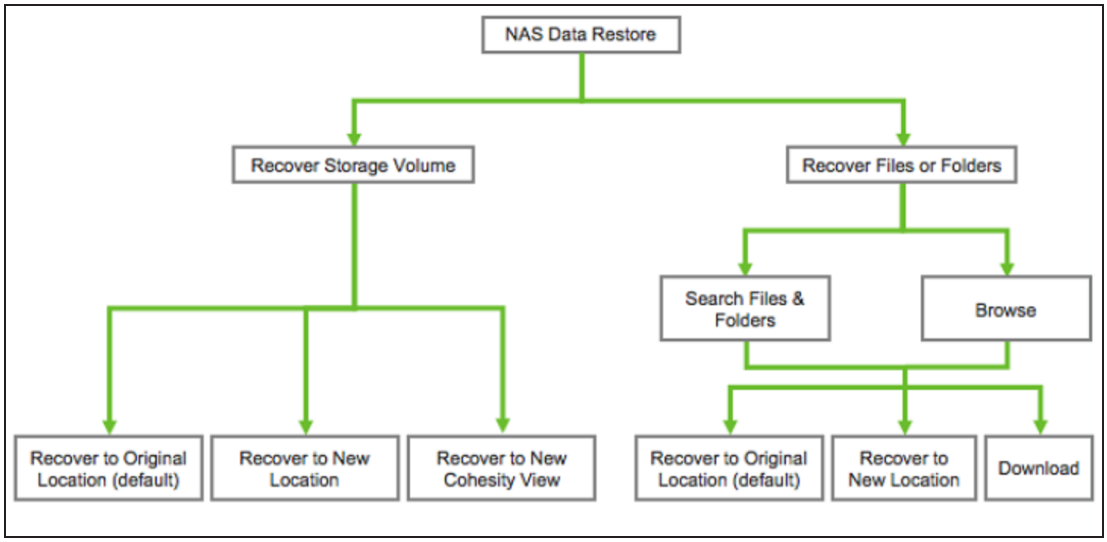
If the Protection Group is replicating to a remote cluster, the inactive job created on the remote cluster is not deleted. In addition, the snapshots that were replicated (copied) to the remote cluster by this job are not deleted. You can log in to the remote cluster to delete the snapshots and the inactive job.

Recover NAS Source

Cohesity recovers NAS data from snapshots of storage volumes created earlier by a Protection Group. Cohesity offers two levels of recovery granularity:

- Recover Storage Volume
- Recover Files or Folders

NAS volumes and files and folders can be recovered to their original location or to a newly specified location, which can be in the original source or a different NAS source. The following figure illustrates the phases and choices you encounter in a typical NAS data restore workflow.



Recover Storage Volume

Cohesity's recover storage volume capability allows you to select and restore specific NAS shares from any previous backup. Before you can recover storage volumes, ensure that snapshots of those volumes exist in the Protection Groups on your Cohesity cluster.

For more information, see Recover NAS Storage Volumes.

Recover Files and Folders

Cohesity’s recover files or folders capability allows you to search and recover specific files and whole folders from any previous NAS backup. Before you try to recover files or folders, ensure that snapshots of these files and folders appear on the Cohesity cluster in a Protection Group. For backed-up SMB volumes, the user account must have full control on the target as Cohesity uses that user to perform recovery.

Cohesity now allows the recovery of up to eight files or one folder from SnapDiff-based backups.

For more information, see Recover NAS Files or Folders.

Hardlink

A hardlink set consists of file references (hardlinks) with the same inode, pointing to the data's location on the filesystem.

For example, hardlinks can be created from file A such as B, C, D, and so on. All these files will be a part of the hardlink set.

You can restore the hardlinks to their original location or restore multiple directories containing common hardlinks. For more information, see Recover hardlinks.

Recover NAS Files or Folders

You can restore the files or folders to their original location or to a newly specified location, which can be within the original source or a different one, without losing the original permissions and attributes. For more information, see:

- Recover NAS Files or Folders to the Original Location
- Recover NAS Files or Folders to a New Location

You can also download specific files and folders directly from any snapshot that was created by a Cohesity Protection Group.

Before you try to recover files or folders, ensure that snapshots of these files and folders appear on the Cohesity cluster in a Protection Group. For backed-up SMB volumes, the user account must have full control on the target as Cohesity uses that user to perform recovery.

Recover NAS Files or Folders to the Original Location

To recover files and folders to the original NAS:

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Click **Recover** located at the top right of the page and then select **NAS > Files or Folders**.

   The Recover Files or Folders page appears.
3. Select any one of the following options to search for the file or folder:
   - **Files and Folders**: Allows you to search and recover files using file or folder names from any backup available on the Cohesity cluster.
   - **Browse or Specify Path for Search**: Allows you to search and recover files using the name of the source or Protection Group from any backup available on the Cohesity cluster.

If you select..	Then..
Files and Folders	1. Enter characters of the file name, path, or by specifying the wildcard character *. A list of items displays. You can optionally filter the search results by object type, source, object, Protection Group, Storage Domain, files only, or folders only. 2. From the list of search results, select the required files or folders to recover. 3. By default, the latest snapshot is selected for recovery. To recover from a different snapshot: > **Note:** The option to change the recovery point is not available if multiple items were selected for recovery. 1. From the selected list, mouse over the snapshot, and then click the **edit** icon. The Edit recovery point page appears. 2. By default, only the snapshots that are indexed are displayed. To display all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. 3. Select a date range and the snapshot point for recovery. 4. By default, the snapshot is recovered from the local cluster. You can also select the snapshot archived to the cloud (icon) by clicking this icon if available in the **Location** option. 5. When recovering from an archive, consider the following points: • The archive (external target) must be currently registered for the task to succeed. • (*Applies only for cloud archive incremental with periodic full*) Provisioned Capacity Units (PCU) are required for all file-level recoveries. Provisioned capacity ensures that your retrieval capacity for expedited retrievals is available when needed. Each unit of capacity guarantees that at least three expedited retrievals can be performed every five minutes and provides up to 150 MB/s of retrieval throughput. 4. Click **Select Recovery Point** and go to step 4.

If you select..	Then..
Browse	1. Enter the full or partial source or Protection Group name. You can optionally specify the wildcard character *. You can also optionally filter the search results by object type, source, object, Protection Group, Storage Domain. 2. From the list of search results, select the object whose files or folders are to be recovered. 3. By default, the latest snapshot is selected for recovery. To recover from a different snapshot, click the snapshots drop-down in the top-left corner and select the snapshot you need. 4. By default, only the files and folders that are indexed are displayed. To display all the available files and folders, toggle off the **Browse on Indexed Data** option. **Note:** • Changing the snapshot after selecting the items (files or folder) removes the selected items from the cart. • Enabling or disabling the **Browse on Indexed Data** option after selecting the items (files or folder) removes the selected items from the cart. • Deleted snapshots may be displayed as valid recovery points for a brief period until they are removed from the search index by a background process. 5. Browse to the file or folder that you want to recover by clicking a folder and subfolders. 6. Click **Save**. 7. After saving the selection, if you want to recover from a different snapshot or change the location from where the snapshot is recovered, perform the following steps: 1. From the selected list, mouse over the snapshot, and click the edit icon. The Edit recovery point page appears. 2. By default, only the snapshots that are indexed are displayed. To display all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. 3. Select a date range and the snapshot point for recovery.

If you select..	Then..
	4. By default, the snapshot is recovered from the local cluster. You can also select a snapshot archived to the cloud (icon) by clicking this icon if available in the **Location** option. When recovering from an archive, consider the following points: • The archive (external target) must be currently registered for the task to succeed. • (*Applies only for cloud archive incremental with periodic full*) Provisioned Capacity Units (PCU) are required for all file-level recoveries. Provisioned capacity ensures that your retrieval capacity for expedited retrievals is available when needed. Each unit of capacity guarantees that at least three expedited retrievals can be performed every five minutes and provides up to 150 MB/s of retrieval throughput. 8. Click **Select Recovery Point** and go to step 4.

4. Once you select the files and folder to recover, select one of the following options:
   - **Next Recover Option**: If you select this option, then continue with step 5 to configure the file recovery options.
   - **Download Files**: If you are recovering a single file, this option downloads the file to your browser's download folder. For all other selections, this creates a recovery task. When the task is completed, from the Recoveries page, click the task name and then click **Download Files** to download the generated zip file.

     Character replacement explanation for : and \ in file and directory names in zip files

     If the original file or directory name contains a ':' , it is replaced with '_COLON_' in the archive.
     Example:
     - The original name is "a:b" then the archived name is "a_COLON_b"
     - The original name is "a:b:c" then the archived name is "a_COLON_b_COLON_c"

     If the original file or directory name contains a '\', it is replaced with '_BACK_SLASH_' in the archive.
     Example:

- The original name is "x\y" then the archived name is "x_BACK_SLASH_y"
- The original name is "x\y\z" then the archived name is "x_BACK_SLASH_y_BACK_SLASH_z"

5. From the **Recover To**, select **Original Location** to recover the files or folders to the original source.
6. To recover to a different location in the original NAS, enable the **Recover to Alternate Path** option, and then provide the location to which the files or folders are to be recovered in the **Alternate Path** field. By default, the files and folders will be recovered to the original location.
7. Optional. Edit the default settings of the following **Recovery options**:
   - **Overwrite Existing File/Folder**: By default, this option is enabled to overwrite the existing files and folders. Disable the **Overwrite** option to create the files and folders in the specified location. Any duplicate files are skipped.

     Example for a Windows alternate location with **Overwrite** enabled and the target already exists:

     Files to be recovered: "C:\foo\1.txt", "C:\foo\test\1.txt", "C:\bar", "C:\foo\bar". Specified alternate location: "C:\restore". At the end of the copy, the target folder looks like this:

     - C:\restore\1.txt
     - C:\restore\cohesity<taskid>_0\1.txt
     - C:\restore\bar
     - C:\restore\cohesity<taskid>_1\bar

     If **Overwrite** is enabled, recovering a file to source when the file is in Fuse may cause the open file to be overwritten. Whether overwriting occurs depends on the application using the file.
   - **Continue on Error**: Enable this option if you want to continue the recovery even if one of the objects encounters an error. By default, this option is disabled and the recovery operation will fail if one of the objects encounters an error.
   - **Encryption**: Enable this option if you want the data to be encrypted in-flight during recovery. By default, this option is disabled. For more information on encryption, see NAS Solution Guide.
   - **Filter IPs**: Enable this option to filter the IP addresses of the NAS source. By filtering IP addresses, you can allow or deny the communication of the Cohesity cluster to specific IP addresses or subnets of the NAS source.
   - **Cluster Interface**: By default, the **Auto Select** option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option,

then select a configured interface group from the **Interface Group** drop-down.

- **Task Name**: Change the default name of the recovery task.

8. Click **Start Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Recover NAS Files or Folders to a New Location

To recover files and folders to a new NAS:

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Click **Recover** located at the top right of the page and then select **NAS > Files or Folders**.

   The Recover Files or Folders page appears.
3. Select any one of the following options to search for the file or folder:
   - **Files and Folders**: Allows you to search and recover files using file or folder names from any backup available on the Cohesity cluster.
   - **Browse or Specify Path for Search**: Allows you to search and recover files using the name of the source or Protection Group from any backup available on the Cohesity cluster.

If you select..	Then..
Files and Folders	1. Enter characters of the file name, path, or by specifying the wildcard character *. A list of items displays. You can optionally filter the search results by object type, source, object, Protection Group, Storage Domain, files only, or folders only. 2. From the list of search results, select the required files or folders to recover. 3. By default, the latest snapshot is selected for recovery. To recover from a different snapshot: **Note:** The option to change the recovery point is not available if multiple items were selected for recovery. 1. From the selected list, mouse over the snapshot, and then click the **edit** icon. The Edit recovery point page appears. 2. By default, only the snapshots that are indexed are displayed. To display all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. 3. Select a date range and the snapshot point for recovery. 4. By default, the snapshot is recovered from the local cluster. You can also select the snapshot archived to the cloud (icon) by clicking this icon if available in the **Location** option. 5. When recovering from an archive, consider the following points: • The archive (external target) must be currently registered for the task to succeed. • (*Applies only for cloud archive incremental with periodic full*) Provisioned Capacity Units (PCU) are required for all file-level recoveries. Provisioned capacity ensures that your retrieval capacity for expedited retrievals is available when needed. Each unit of capacity guarantees that at least three expedited retrievals can be performed every five minutes and provides up to 150 MB/s of retrieval throughput. 4. Click **Select Recovery Point** and go to step 4.

If you select..	Then..
Browse	1. Enter the full or partial source or Protection Group name. You can optionally specify the wildcard character *. You can also optionally filter the search results by object type, source, object, Protection Group, Storage Domain. 2. From the list of search results, select the object whose files or folders are to be recovered. 3. By default, the latest snapshot is selected for recovery. To recover from a different snapshot, click the snapshots drop-down in the top-left corner and select the snapshot you need. 4. By default, only the files and folders that are indexed are displayed. To display all the available files and folders, toggle off the **Browse on Indexed Data** option. **Note:** • Changing the snapshot after selecting the items (files or folder) removes the selected items from the cart. • Enabling or disabling the **Browse on Indexed Data** option after selecting the items (files or folder) removes the selected items from the cart. • Deleted snapshots may be displayed as valid recovery points for a brief period until they are removed from the search index by a background process. 5. Browse to the file or folder that you want to recover by clicking a folder and subfolders. 6. Click **Save**. 7. After saving the selection, if you want to recover from a different snapshot or change the location from where the snapshot is recovered, perform the following steps: 1. From the selected list, mouse over the snapshot, and click the edit icon. 2. The Edit recovery point page appears. 3. By default, only the snapshots that are indexed are displayed. To display all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. 4. Select a date range and the snapshot point for recovery. 5. By default, the snapshot is recovered from the local cluster. You can also select a snapshot archived to the cloud (icon) by clicking this icon if available in the **Location** option.

If you select..	Then..
	When recovering from an archive, consider the following points: • The archive (external target) must be currently registered for the task to succeed. • (*Applies only for cloud archive incremental with periodic full*) Provisioned Capacity Units (PCU) are required for all file-level recoveries. Provisioned capacity ensures that your retrieval capacity for expedited retrievals is available when needed. Each unit of capacity guarantees that at least three expedited retrievals can be performed every five minutes and provides up to 150 MB/s of retrieval throughput. 8. Click **Select Recovery Point** and go to step 4.

4. Once you select the files and folder to recover, select one of the following options:
   - **Next Recover Option**: If you select this option, then continue with step 5 to configure the file recovery options.
   - **Download Files**: If you are recovering a single file, this option downloads the file to your browser's download folder. For all other selections, this creates a recovery task. When the task is completed, from the Recoveries page, click the task name and then click **Download Files** to download the generated zip file.

     Character replacement explanation for : and \ in file and directory names in zip files

     If the original file or directory name contains a ':', it is replaced with '_COLON_' in the archive.
     Example:
     - The original name is "a:b" then the archived name is "a_COLON_b"
     - The original name is "a:b:c" then the archived name is "a_COLON_b_COLON_c"

     If the original file or directory name contains a '\', it is replaced with '_BACK_SLASH_' in the archive.
     Example:
     - The original name is "x\y" then the archived name is "x_BACK_SLASH_y"
     - The original name is "x\y\z" then the archived name is "x_BACK_SLASH_y_BACK_SLASH_z"

5. From the **Recover To**, select **New Location** to recover the files or folders to a new NAS source.
6. From the **Registered Source** drop-down menu, select a registered NAS source to which you want to recover the files and folders. You can also register a new source by clicking **Register Source** from the **Registered Source** drop-down menu.
7. From the **Volume** drop-down menu, select a volume to which you want to recover the files and folders.
8. In the **Path** field, enter the path where the files and folders will be recovered. By default, the files and folders will be recovered in the `/temp/recover-file-<month_date_time>` folder of the selected volume.
9. Optional. Edit the default settings of the following **Recovery options**:
   - **Overwrite Existing File/Folder**: By default, this option is enabled to overwrite the existing files and folders. Disable the **Overwrite** option to create the files and folders in the specified location. Any duplicate files are skipped.

     Example for a Windows alternate location with **Overwrite** enabled and the target already exists:

     Files to be recovered: "C:\foo\1.txt", "C:\foo\test\1.txt", "C:\bar", "C:\foo\bar". Specified alternate location: "C:\restore". At the end of the copy, the target folder looks like this:

     - C:\restore\1.txt
     - C:\restore\cohesity<taskid>_0\1.txt
     - C:\restore\bar
     - C:\restore\cohesity<taskid>_1\bar

     If **Overwrite** is enabled, recovering a file to source when the file is in Fuse may cause the open file to be overwritten. Whether overwriting occurs depends on the application using the file.

     > **Note:** For Pure Storage FlashBlade, the recovery of SMB data may fail if the files and folders being recovered have restrictive permissions. Cohesity recommends you either create folders or directories manually in the target location before initiating the recovery or use an SMB user with read/write permissions when registering the Pure Storage FlashBlade source.

   - **Continue on Error**: Enable this option if you want to continue the recovery even if one of the objects encounters an error. By default, this option is disabled and the recovery operation will fail if one of the objects encounters an error.

- **Encryption**: Enable this option if you want the data to be encrypted in-flight during recovery. By default, this option is disabled. For more information on encryption, see NAS Solution Guide.
- **Filter IPs**: Enable this option to filter the IP addresses of the NAS source. By filtering IP addresses, you can allow or deny the communication of the Cohesity cluster to specific IP addresses or subnets of the NAS source.
- **Cluster Interface**: By default, the **Auto Select** option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the **Interface Group** drop-down.
- **Task Name**: Change the default name of the recovery task.

10. Click **Start Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Recover NAS Storage Volumes

Cohesity provides the ability to recover storage volumes from a snapshot created earlier by a Protection Group. To learn more about recovering volumes, see About Recovering Storage Volumes.

Before you can recover storage volumes, snapshots of those volumes must exist on the Cohesity cluster. To create snapshots, create and run a Protection Group.

The options to recover storage volumes are as follows:

- Recover NAS Storage Volumes to the Original Location
- Recover NAS Storage Volumes to a New Location
- Recover NAS Storage Volumes as a Cohesity View

Recover NAS Storage Volumes to the Original Location

Before you can recover volumes, snapshots of those volumes must exist on the Cohesity cluster. To create snapshots, create and run a Protection Group.

To recover a storage volume to the original NAS location:

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Click on **Recover** located at the top right of the page and then select **NAS > Storage Volume**.

   The Storage Volumes page appears.
3. Search for the NAS volume that you want to recover by entering the characters of the volume name, the Protection Group name that protects the volume, or by specifying the wildcard character *.

   A list of NAS volume displays.

You can optionally filter the search results by source, Protection Group, Storage Domain, or date.

4. From the list of search results, select the volume you want to recover.

   By default, the latest snapshot is selected for recovery.

5. To recover from a different snapshot, mouse over the snapshot from the selected list, and then click the **edit** icon.

   The Edit recovery point for <Volume_name> page appears.

   > **Note:** In this workflow, deleted snapshots may be displayed as valid recovery points for a brief period until they are removed from the search index by a background process.

   By default, the option to select the snapshot is displayed in the **Timeline** mode. You can also choose to view the option in List mode by clicking the **List** tab in the top-right corner of the page.

   - To select a snapshot from the **Timeline** mode:
     a. From the **Choose a date** drop-down, select a date.

        The snapshots available on the selected date are displayed in blue dots on the timeline bar.

     b. Select the snapshot to be recovered by clicking the corresponding blue dot.

     c. By default, the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.

     d. Click **Select Recovery Point** and then go to step 6.
   - To select a snapshot from the **List** mode:
     a. Select the **List** tab from the top-right corner of the Edit recovery point for <Volume_name> page.

        By default, the page displays the snapshots available in the last month.

     b. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.

     c. Select the snapshots to be recovered.

d. By default, the snapshot is recovered from the local Cohesity cluster. You can also select snapshots archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.

e. Click **Select Recovery Point** and then go to step 6.

6. Click **Next: Recover Options**.
7. From the **Recover To** options, select **Original Location** to recover the volume to the original location.
8. Optional. Edit the default settings of the following **Recovery options**:
   - **Overwrite Existing File/Folder**: By default, this option is enabled to overwrite the existing files and folders. Disable this option to create the files and folders in the specified location. Any duplicate files are skipped.
   - **Preserve file/folder attributes**: By default, this option is enabled and the ACLs, permissions, and timestamps are preserved for all files and folders of the NAS volume. If you disable this option, then the ACLs and the permissions are not preserved. If recovering folders and files, folders receive new timestamps, but files retain their original timestamps. If recovering files only, files receive new timestamps.
   - **Continue on Error**: Enable this option if you want to continue recovery even if an error occurs during the recovery task. By default, this option is disabled and the recovery operation will fail if it encounters an error.
   - **Encryption**: Enable this option if you want the data to be encrypted in-flight during recovery. By default, this option is disabled. For more information on encryption, see NAS Solution Guide.
   - **Filter IPs**: Enable this option to filter the IP addresses of the NAS source. By filtering IP addresses, you can allow or deny the communication of the Cohesity cluster to specific IP addresses or subnets of the NAS source.

     To filter the IP addresses of the NAS source, select one of the following options:

     - **Allow IPs**: Select this option and specify the IP addresses of the NAS source through which the communication to the Cohesity cluster must happen. You can provide the IP addresses in a comma-separated list or in a CIDR format.
     - **Deny IPs**: Select this option and specify the IP addresses of the NAS source through which the communication to the Cohesity cluster.

> **Note:**
> If you have specified the IP filtering at the source-level also, then the IP filtering specified at the recovery task-level will take precedence over the IP filtering specified at the source-level.

- **Cluster interface**: By default, the **Auto Select** option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the **Interface Group** drop-down.
- **Task name**: Change the default name of the recovery task.

9. Click **Start Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Recover NAS Storage Volumes to a New Location

Before you can recover volumes to an alternate location as a new storage volume, snapshots of those volumes must exist on the Cohesity cluster. To create Snapshots, create and run a Protection Group.

To recover a storage volume to a new location:

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Click on **Recover** located at the top right of the page and then select **NAS > Storage Volume**.

   The Storage Volumes page appears.
3. Search for the NAS volume that you want to recover by entering the characters of the volume name, the Protection Group name that protects the volume, or by specifying the wildcard character *.

   A list of NAS volume displays.

   You can optionally filter the search results by source, Protection Group, Storage Domain, or date.
4. From the list of search results, select the volume you want to recover.

   By default, the latest snapshot is selected for recovery.
5. To recover from a different snapshot, mouse over the snapshot from the selected list, and then click the **edit** icon.

   The Edit recovery point for <Volume_name> page appears.

> **Note:** In this workflow, deleted snapshots may be displayed as valid recovery points for a brief period until they are removed from the search index by a background process.

By default, the option to select the snapshot is displayed in the **Timeline** mode. You can also choose to view the option in List mode by clicking the **List** tab in the top-right corner of the page.

- To select a snapshot from the **Timeline** mode:
  a. From the **Choose a date** drop-down, select a date.

     The snapshots available on the selected date are displayed in blue dots on the timeline bar.
  b. Select the snapshot to be recovered by clicking the corresponding blue dot.
  c. By default, the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.
  d. Click **Select Recovery Point** and then go to step 6.
- To select a snapshot from the **List** mode:
  a. Select the **List** tab from the top-right corner of the Edit recovery point for <Volume_name> page.

     By default, the page displays the snapshots available in the last month.
  b. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.
  c. Select the snapshots to be recovered.
  d. By default, the snapshot is recovered from the local Cohesity cluster. You can also select snapshots archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.
  e. Click **Select Recovery Point** and then go to step 6.

6. Click **Next: Recover Options**.
7. From the **Recover To** options, select **New Location** to recover the volume to an alternate location as a new storage volume.

8. From the **Registered Source** drop-down menu, select a registered NAS source to which you want to recover the NAS volume. You can also register a new NAS source by clicking **Register Source** from the Source drop-down menu.
9. From the **Target** drop-down menu, select a volume to which you want to recover the volume.
10. Optional. Edit the default settings of the following **Recovery options**:
    - **Overwrite Existing File/Folder**: By default, this option is enabled to overwrite the existing files and folders. Disable this option to create the files and folders in the specified location. Any duplicate files are skipped.
    - **Preserve file/folder attributes**: By default, this option is enabled and the ACLs, permissions, and timestamps are preserved for all files and folders of the NAS volume. If you disable this option, then the ACLs and the permissions are not preserved. If recovering folders and files, folders receive new timestamps, but files retain their original timestamps. If recovering files only, files receive new timestamps.
    - **Continue on Error**: Enable this option if you want to continue recovery even if an error occurs during the recovery task. By default, this option is disabled and the recovery operation will fail if it encounters an error.
    - **Encryption**: Enable this option if you want the data to be encrypted in-flight during recovery. By default, this option is disabled. For more information on encryption, see NAS Solution Guide.
    - **Filter IPs**: Enable this option to filter the IP addresses of the NAS source. By filtering IP addresses, you can allow or deny the communication of the Cohesity cluster to specific IP addresses or subnets of the NAS source.

      To filter the IP addresses of the NAS source, select one of the following options:
      - **Allow IPs**: Select this option and specify the IP addresses of the NAS source through which the communication to the Cohesity cluster must happen. You can provide the IP addresses in a comma-separated list or in a CIDR format.
      - **Deny IPs**: Select this option and specify the IP addresses of the NAS source through which the communication to the Cohesity cluster.

    > **Note:**
    > If you have specified the IP filtering at the source-level also, then the IP filtering specified at the recovery task-level will take precedence over the IP filtering specified at the source-level.

- **Cluster interface**: By default, the **Auto Select** option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the **Interface Group** drop-down.
- **Task name**: Change the default name of the recovery task.

11. Click **Start Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Recover NAS Storage Volumes as a Cohesity View

When recovering a NAS storage volume to a Cohesity View, Cohesity clones the volume's backed up data to a new Cohesity View within the Cohesity cluster and provides instant access to the data.

> **Note:** This workflow is not supported for NAS backups performed using the NFS4.1 protocol.

Before you can recover volumes, snapshots of those volumes must exist on the Cohesity cluster. To create Snapshots, create and run a Protection Group.

To recover a storage volume as a Cohesity View:

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Click on **Recover** located at the top right of the page and then select **NAS > Storage Volume**.

   The Storage Volumes page appears.
3. Search for the NAS volume that you want to recover by entering the characters of the volume name, the Protection Group name that protects the volume, or by specifying the wildcard character *.

   A list of NAS volume displays.

   You can optionally filter the search results by source, Protection Group, Storage Domain, or date.
4. From the list of search results, select the volume you want to recover.

   By default, the latest snapshot is selected for recovery.
5. To recover from a different snapshot, mouse over the snapshot from the selected list, and then click the **edit** icon.

   The Edit recovery point for <Volume_name> page appears.

> **Note:** In this workflow, deleted snapshots may be displayed as valid recovery points for a brief period until they are removed from the search index by a background process.

By default, the option to select the snapshot is displayed in the **Timeline** mode. You can also choose to view the option in List mode by clicking the **List** tab in the top-right corner of the page.

- To select a snapshot from the **Timeline** mode:
  a. From the **Choose a date** drop-down, select a date.

     The snapshots available on the selected date are displayed in blue dots on the timeline bar.
  b. Select the snapshot to be recovered by clicking the corresponding blue dot.
  c. By default, the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.
  d. Click **Select Recovery Point** and then go to step 6.
- To select a snapshot from the **List** mode:
  a. Select the **List** tab from the top-right corner of the Edit recovery point for <Volume_name> page.

     By default, the page displays the snapshots available in the last month.
  b. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.
  c. Select the snapshots to be recovered.
  d. By default, the snapshot is recovered from the local Cohesity cluster. You can also select snapshots archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.
  e. Click **Select Recovery Point** and then go to step 6.

6. Click **Next: Recover Options**.
7. From the **Recover To** options, select **New Cohesity View** to recover the volume to a new view within the Cohesity cluster.

8. Optional. In the **Name** field, change the default name of the new view where you want to recover the volume to. This cannot be an existing view name. Using UNIX special characters for the view name may cause the recovery to fail.
9. From the **QoS Policy** drop-down, select a QoS policy. Each Cohesity view is assigned a Quality of Service (QoS) Policy. A QoS Policy determines to which storage media it is written and the priority of I/O (when contention occurs). For details and recommendations, see QoS Policies for Cohesity Views.
10. Optional. Edit the default settings of the following **Recovery options**:
    a. **Cluster interface**: By default, the **Auto Select** option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the **Interface Group** drop-down.
    b. **Task name**: Change the default name of the recovery task.
11. Click **Start Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Once the recovery is complete, you must access or mount the View using SMB or NFS mount path to the system of your choice and then perform the desired operation with the recovered data.

To locate the mount point information, navigate to **Data Protection > Recoveries** and click the completed recovery task to view its results page. The **NFS Mount Path** for NFS systems and **SMB Mount Path** for Windows systems are displayed.

Recover hardlinks

A hardlink set consists of file references (hardlinks) with the same inode, pointing to the data's location on the filesystem.

You can restore the hardlinks to their original location or restore multiple directories containing common hardlinks.

Recover hardlinks to the original location

When recovering, you can enable or disable the "Overwrite" option. If the option is disabled, only the missing hardlinks from any hardlink set will be recreated after the restore. In this case, a new inode pointing to the backed-up version of the data will be created for the missing hardlink file, and all the other hardlinks to be restored will point to this inode. However, if the option is enabled, all hardlinks from any hardlink set are recreated after restoration, pointing to a new inode that points to the backed-up data version.

For example, let's say there is a hardlink set containing files from A to F, all of which are backed up. If we delete the hardlinks A, B, and C, and then restore to the original path with the “Overwrite” option disabled, a new inode will be created. This inode will point to a new backed-up version of the data, and hardlinks A, B, and C will be recreated and point to this new inode. The hardlinks D, E, and F will remain unchanged and have the original inode.

With the Overwrite option enabled, all files (A to F) will be recreated as new hardlinks, pointing to a new inode that contains the backed-up data version.

Recover multiple directories containing common hardlinks

If multiple folders are being restored, and they contain common hard links, each folder is restored independently. This means that a new inode is created for each hardlink set within a folder, pointing to a new backed-up version of the data. Any missing hardlinks are recreated, pointing to the new inodes of their respective folders.

Consider a scenario where directories A, B, and C have multiple hardlinks: A1 and A2 in A, B1 and B2 in B, and C1 and C2 in C, all pointing to the same file (with inode 100). With these hardlinks missing, if we restore only the directories A, B, and C instead of the entire volume, all these hard links will be recreated. The newly created A1 and A2 will point to a new inode (101), while B1 and B2 will point to a new inode (102), and C1 and C2 will point to a new inode (103). Each of these inodes will then reference separate backed-up versions of the data.

Replicate NAS Data

You can replicate Isilon data backup to the Cohesity cluster to another Cohesity cluster for disaster recovery use cases. For more details about replication, see Replication and Remote Access Setup.

Cohesity provides a policy-based replication solution for Isilon data. In the Protection Policy, you can specify the remote Cohesity cluster, define conditions for replication, specify the retention period of the data on the remote Cohesity cluster, and other parameters.

To replicate Isilon data to another Cohesity cluster:

1. Configure replication to another Cohesity cluster. For more details, see Replication and Remote Access Setup.
2. Edit the existing Protection Policy that you had created for backup or create a new Protection Policy for backup. Configure the replication settings as per your requirement. For more information, see Create or Edit a Standard Policy.
3. Run the Protection Group that you have created for Isilon based on your requirement or the replication settings will take effect in the next scheduled Protection Group run.

Archive NAS Data

Cohesity provides the option to store a copy of your data backed up onto the Cohesity cluster to a designated external target, such as tape or cloud storage for long-term retention purposes. The process of storing a copy of the data backed up on the Cohesity cluster to an external target is called Archival. For more information, see About Cloud Archival.

Cohesity provides a policy-based archival solution for NAS data. In the Protection Policy, you can define the archive schedule, select the external target, and specify the retention period of the data on the external target.

To archive NAS data:

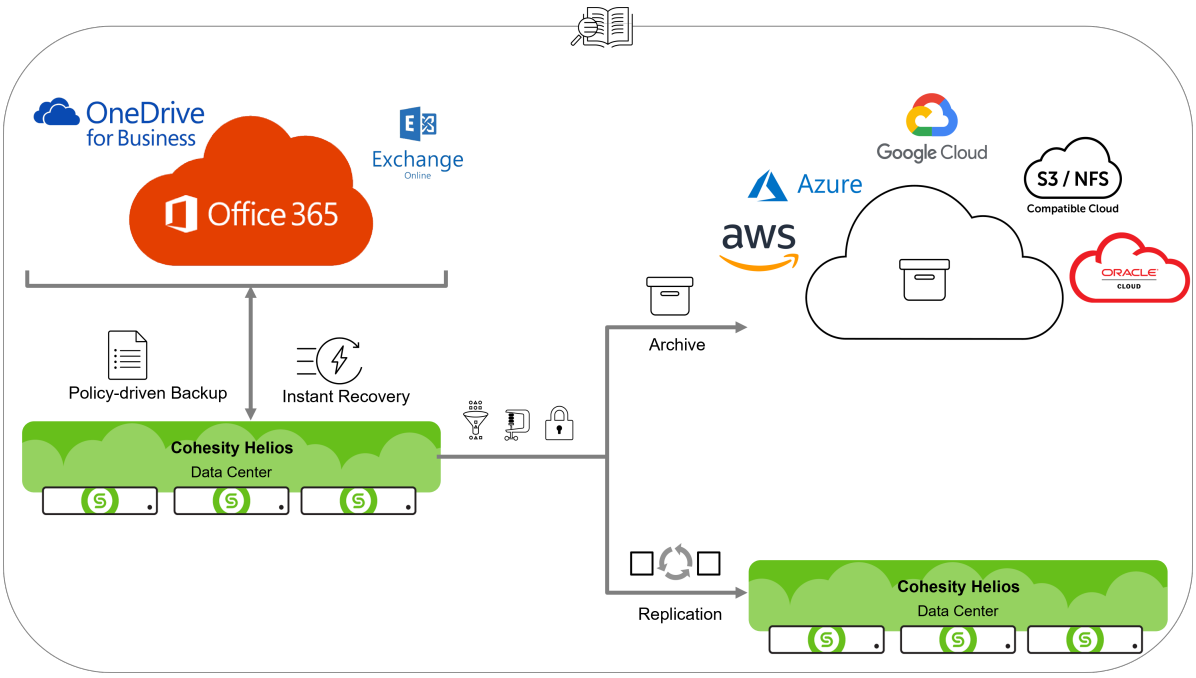
1. Register an external target. For more details, see Register an External Target.
2. Edit the existing Protection Policy that you had created for backup or if you are creating a new Protection Policy for backup. Configure the Archival settings as per your requirement. For more information, see **Step 14** in Create or Edit a Standard Policy.
3. Run the Protection Group that you have created for the respective NAS source based on your requirement or the Archival settings will take effect in the next scheduled Protection Group run.

Chapter 14: Microsoft 365

Microsoft 365 is a subscription service that bundles the traditional office productivity applications and delivers them as SaaS applications. Microsoft 365 includes Exchange Online, OneDrive for Business, SharePoint Online, Teams, and other applications. Cohesity provides enterprise-grade backup and recovery solutions for Microsoft 365.

Cohesity's software-defined platform provides simple, fast, and cost-effective data protection solution for the following Microsoft 365 applications:

- Exchange Online
- OneDrive for Business
- SharePoint Online
- Groups (Early Access)
- Microsoft Teams



Microsoft 365 Data Backup and Restore: Process Overview

This section provides a high-level overview of the steps required to protect data in your Microsoft 365 domain. These steps include completing the prerequisites, registering the Microsoft 365 domain as a source with Cohesity, performing backups, and restoring data when needed.

- **Complete the following prerequisites**:
  - Review and understand the supportability for Microsoft 365 backup and recovery workflows.
  - Review and understand the considerations and best practices for each application captured in its **Plan and Prepare** section.
  - Review the following general considerations:
    - When multiple clusters are deployed, ensure that the Microsoft 365 source is registered on all the clusters to avoid recovery failures.
    - Cohesity does not support Basic Auth for Microsoft 365 source registration.
  - Add Microsoft 365 Service User Account with Required Roles
  - Add a Custom Application for Cohesity in Microsoft Entra ID (Azure AD)
  - Assign Additional Permission for SharePoint Online
  - Configure Microsoft Organization Setting for Mailbox Size Reporting
  - Configure Firewall and Port Requirements
  - (Optional) Configure Windows Connector
  - Configure Enhance Backup of Large Microsoft 365 Data

  For more information, see Prerequisites.
- **Register your Microsoft 365 domain as a source in Cohesity** after completing the above prerequisites. You can register using either of the following methods:
  - Manual registration method
  - Express registration method

  Once the registration is complete, your Microsoft 365 domain is available as a source for the backup solution. You can then back up your Microsoft 365 domain data and restore it in case of data loss.
- **Perform backup**
- **Perform restore**

GCC High: Microsoft 365 Data Backup and Recovery

Cohesity supports the protection and recovery of Microsoft 365 in a U.S. Government Community Cloud High (GCC High) tenant. Consider the following points:

- Backup and recovery of Public Folders is not supported.
- Recovery of Private Channels is not supported.

Using Microsoft Graph APIs

By June 2026, Cohesity will migrate from Exchange Web Services (EWS) APIs to Microsoft Graph APIs to protect Microsoft 365 Applications. This is as per the Retirement of Exchange Web Services in Exchange Online announcement from Microsoft. For more information, see Deprecation of Exchange Web Services in Exchange Online.

Prerequisites

You must complete the following prerequisites to back up and restore data in your Microsoft 365 domain:

- Review and understand the supportability for Microsoft 365 backup and recovery workflows.
- Review and understand the considerations and best practices for each application captured in its **Plan and Prepare** section.
- Review the following general considerations:
  - When multiple clusters are deployed, ensure that the Microsoft 365 source is registered on all the clusters to avoid recovery failures.
  - Cohesity does not support Basic Auth for Microsoft 365 source registration.
- Add Microsoft 365 Service User Account with Required Roles
- Add a Custom Application for in Microsoft Entra ID (Azure AD)
- Assign Additional Permission for SharePoint Online
- Configure Microsoft Organization Setting for Mailbox Size Reporting
- Configure Firewall and Port Requirements
- (Optional) Configure Windows Connector
- Configure Enhance Backup of Large Microsoft 365 Data

Add Roles to Microsoft 365 Service User Account

To register your Microsoft 365 domain with Cohesity, you must have a service user account with the required roles. You can either create a new user account with the required roles or

assign the required roles to an existing account. To add the Microsoft 365 service user account, ensure the following requirements are met:

- The account must have a valid SharePoint license and a Mailbox license. A Microsoft 365 license is not required unless you plan to protect Public Folders. Assign the roles to the service user account as described in the following procedure.
- If you want to back up and restore Public Folders, the service user account must have the required root permissions

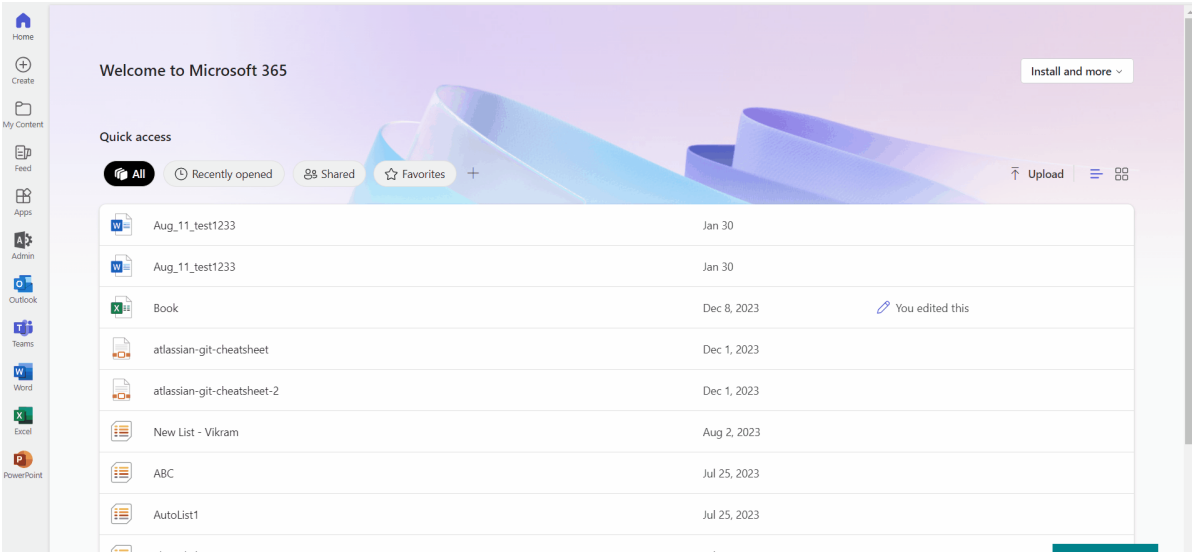
> **Important:** Ensure that multi-factor authentication is not enabled for the user account.

To add roles to the Microsoft 365 service user account:

1. Log in to Microsoft 365.
2. In the **Office 365** page, click **Admin**.
3. In the **Microsoft 365 admin center** page, select **Admin centers**, and then click **Exchange**.
4. Select **Roles** > **Admin roles**.
5. In the **Admin roles** page, click **Add role group**.
6. On the **Add role group** page , do the following:
    1. Under **Basics**, enter a **Name** and **Description** for the admin role and from the **Write scope** drop-down, select **Default** and click **Next**.
    2. Under **Permissions**, select the following and click **Next**:
        - `Mail Recipients`
        - `Mailbox Search`
        - `View-Only Configuration`
        - `View-Only Recipients`
    3. Under **Admins**, search and select the user account you plan to use to register the Microsoft 365 domain with CCohesity Platform, then click **Next**.
    4. Under **Review and finish**, review the configuration and click **Add role group**.
    5. After the role group is added, click **Done**.

       You are ready to update your Microsoft 365 Org setting for Mailbox size reporting.

Here is the GIFF you can refer to add roles to the Microsoft 365 service user account:



Add Required Public Folder Root Permissions for Microsoft 365 Service User Account

Your Microsoft 365 service user account must be configured with **Publishing Editor** root permission on `PublicFoldersRoot (IPM_SUBTREE)` for Cohesity to backup and recover public folders in Exchange Online.

To add the required root permissions to Microsoft 365 user account:

1. Log in to Microsoft 365.
2. In the **Exchange admin center**, select **public folders**.
3. In the **public folders** tab, click (**...**) menu and select **Root permissions**.
4. In the **public folder permissions** page, perform the following:
    1. In the **User** field, click **Browse** and select your Microsoft 365 user account.
    2. From the **Permission level** drop-down list, select **Publishing Editor**.
    3. Ensure that the following permissions are selected:
        - `Create items`
        - `Read items`
        - `Create subfolders`
        - `Edit own`
        - `Edit all`
        - `Folder visible`
        - `Delete own`
        - `Delete all`
    4. Click **Save**.

5. Select **Apply changes to this public folder and all its subfolders** and click **Save**.

Register Custom App in Microsoft Entra ID

To get started, you'll register a custom app below to add the necessary permissions.

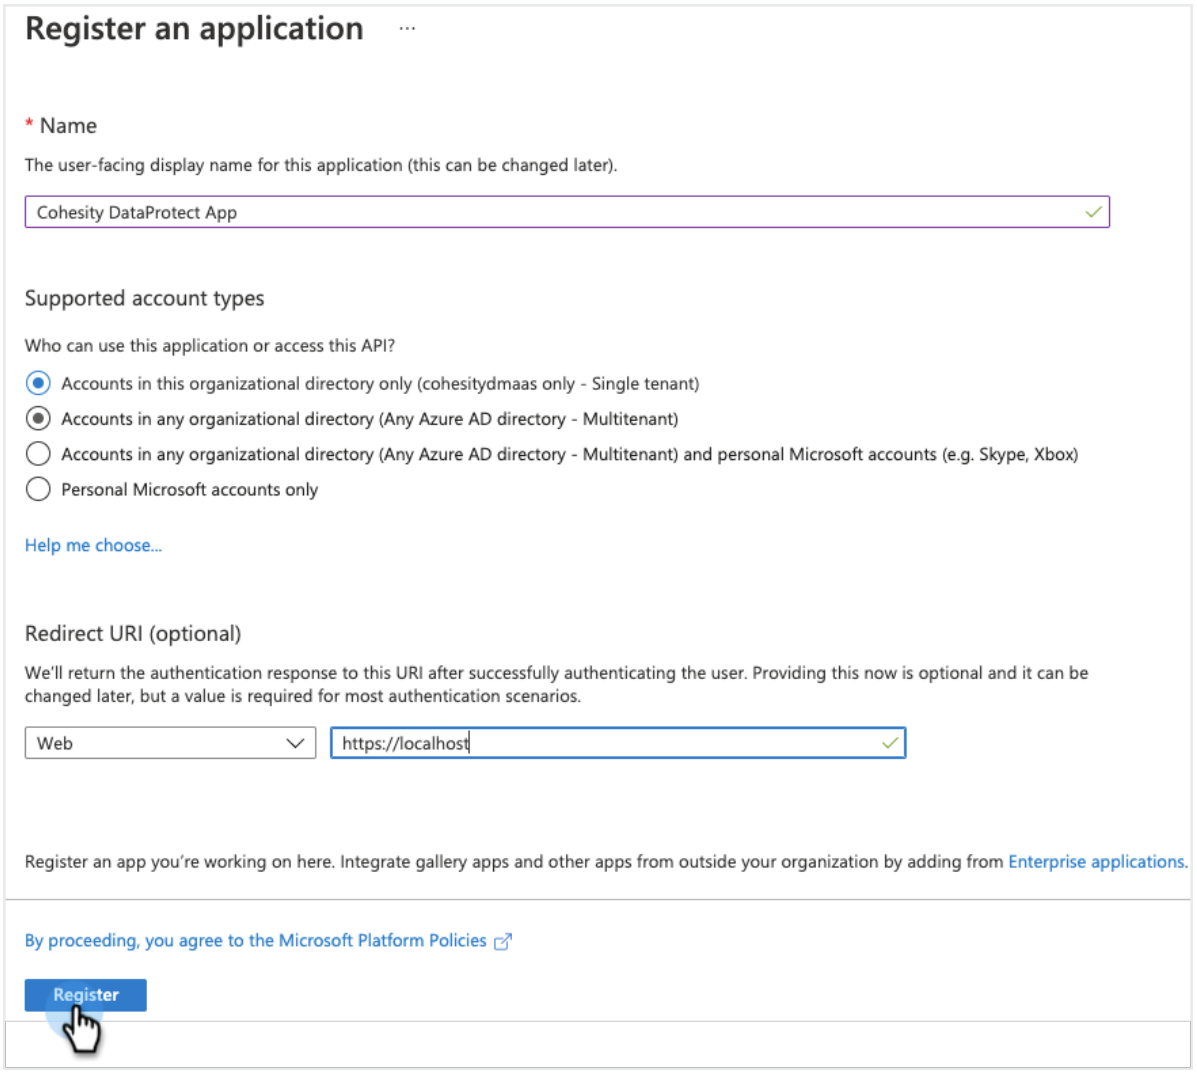
Go to the Azure portal, register a new app, add the permissions, and capture the App ID and Access Key. For more on registering and configuring apps in Microsoft Entra ID, see Register an application with the Microsoft identity platform and Configure a client application to access a web API in the Microsoft documentation.

> **Note:** Make sure that you make note of the App ID and Access Key while registering the app. You'll need them to register your Microsoft 365 domain as a source in Cohesity Platform.

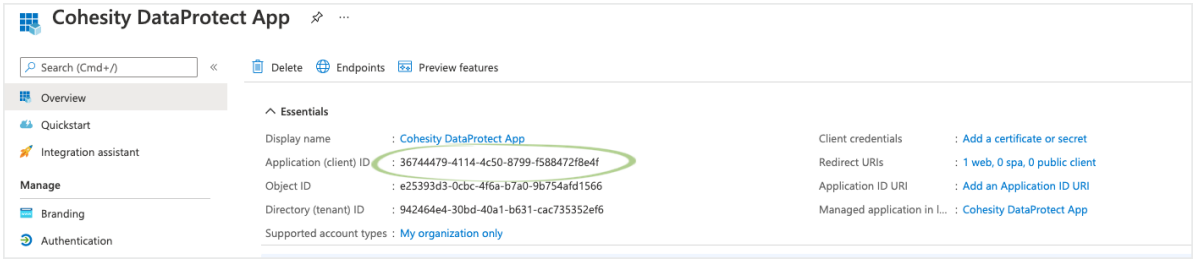
To register your custom app for Cohesity Platform:

1. Open Microsoft Entra ID
    1. To manage Microsoft Entra ID using the Azure Portal:
        1. Log in to the Azure portal with your Microsoft 365 administrator user credentials.
        2. Click the main menu (≡) in the top left corner and select **Microsoft Entra ID**.
    2. To manage Microsoft Entra ID using Microsoft 365:
        1. Log in to Microsoft 365.
        2. On the **Microsoft 365** page, click **Admin**.
        3. On the **Microsoft 365 admin center** page, select **Admin centers** and then click **Microsoft Entra**.
2. Create a new custom app.
    1. Under the **Manage** section, select **App Registrations**, then click **New Registration**. In the **Register an application** page:
        1. Enter a **Name** for your app.
        2. Select the **Supported account types** that can access the app,
        3. In the **Redirect URI** drop-down, select **Web** and enter `https://localhost`.

4. Click **Register**.



3. After the custom app has been created, click **Overview** and copy the **Application (client) ID**. You need to use **Application (client) ID** to register Microsoft 365 as a source in Cohesity Platform.



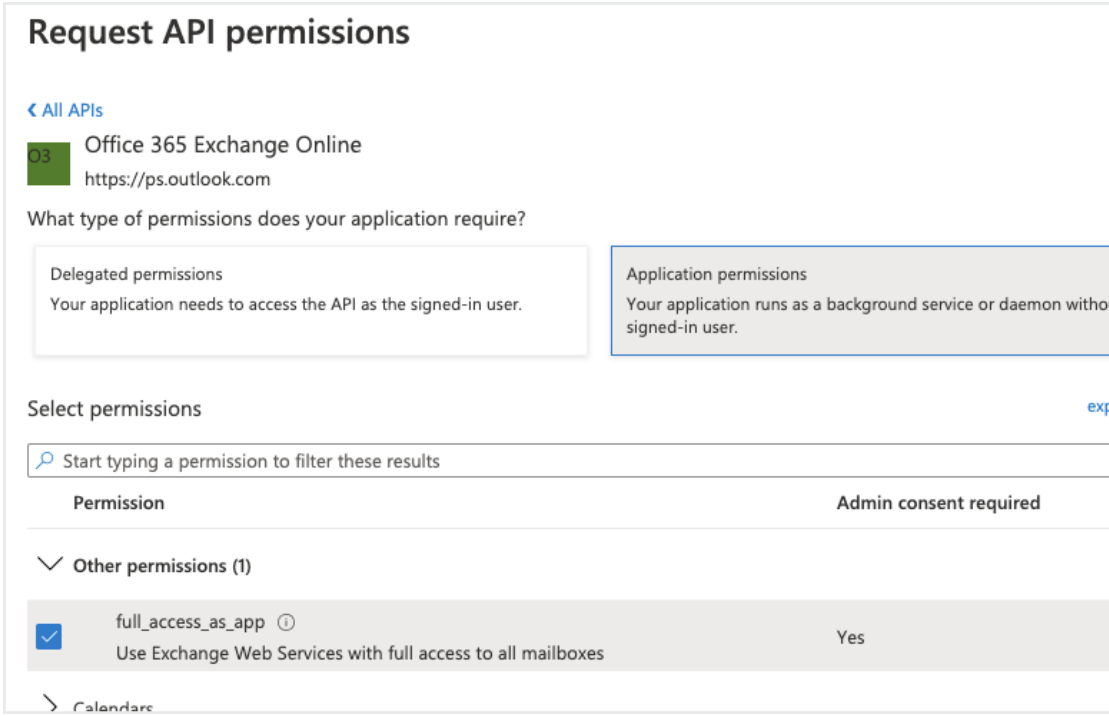
4. Add API permissions to the custom app:

1. **Add Oauth API permission** if the Microsoft 365 source tenant has OAuth enabled for secure communication:
    1. Under the **Manage** section, select **App Registrations** and click **Add a permission**.
    2. In the **Request API permissions** page, click the **APIs my organization uses tab**.
        a. In the search bar, enter **Office 365 Exchange Online** then **click the API**. (Use the complete app name.)

        b. In the Office 365 Exchange Online API, click **Application Permissions**.

        c. Under **Other Permissions**, select `full_access_as_app` to enable OAuth and click **Add Permissions**.

App Permissions	Permission Type	Mailboxes
full_access_as_app	Application	Y



2. Add Graph API permissions:
    1. Under the **Manage** section, select **App Registrations**, and then click **Add a permission**.
    2. In the **Request API permissions** page, select **Microsoft Graph API**.

    3. Click **Application Permissions** and add the permissions listed below for your Microsoft 365 application.

App Permissions	Permission Type	Mailboxes	OneDrive	SharePoint Online Sites	MS Teams
Channel.Create	Application	N/A	N/A	N/A	✓
Channel.ReadBasic.All	Application	N/A	N/A	N/A	✓
ChannelMember.ReadWrite.All	Application	N/A	N/A	N/A	✓
Directory.ReadWrite.All	Application	✓	✓	✓	✓
Files.ReadWrite.All	Application	N/A	✓	✓	✓
Group.Create	Application	N/A	N/A	N/A	✓
Group.ReadWrite.All	Application	N/A	✓	✓	✓
Reports.Read.All	Application	✓	✓	✓	✓
Sites.ReadWrite.All	Application	✓	✓	✓	✓
Sites.FullControl.All	Application	N/A	N/A	✓	✓
User.Read.All	Application	✓	✓	✓	✓
User.ReadWrite.All	Application	N/A	✓	✓	✓

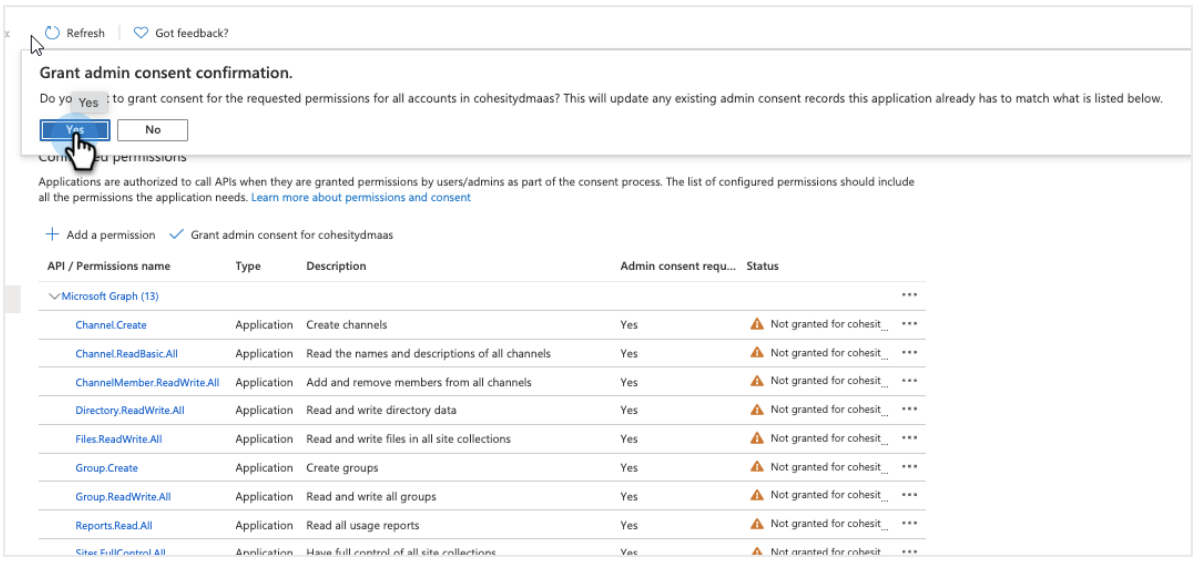
App Permissions	Permission Type	Mailboxes	OneDrive	SharePoint Online Sites	MS Teams
ChannelMessage.Read.All	Application	N/A	N/A	N/A	✓
Chat.Read.All	Application	✓	N/A	N/A	N/A
Mail.ReadWrite	Application	✓	N/A	N/A	N/A
MailboxSettings.Read	Application	✓	N/A	N/A	N/A

4. Click **Add permissions**.

3. Add SharePoint permissions to the custom app:
    1. Under the **Manage** section, select **App Registrations** and click **Add a permission**.
    2. In the **Request API permissions** page, select **SharePoint**. (If you don't see it, scroll further down.)
        a. Click **Delegated Permissions** and add the permissions listed below, then click **Add permissions**.
        b. Click **Application Permissions** and add the permissions listed below, then click **Add permissions**.

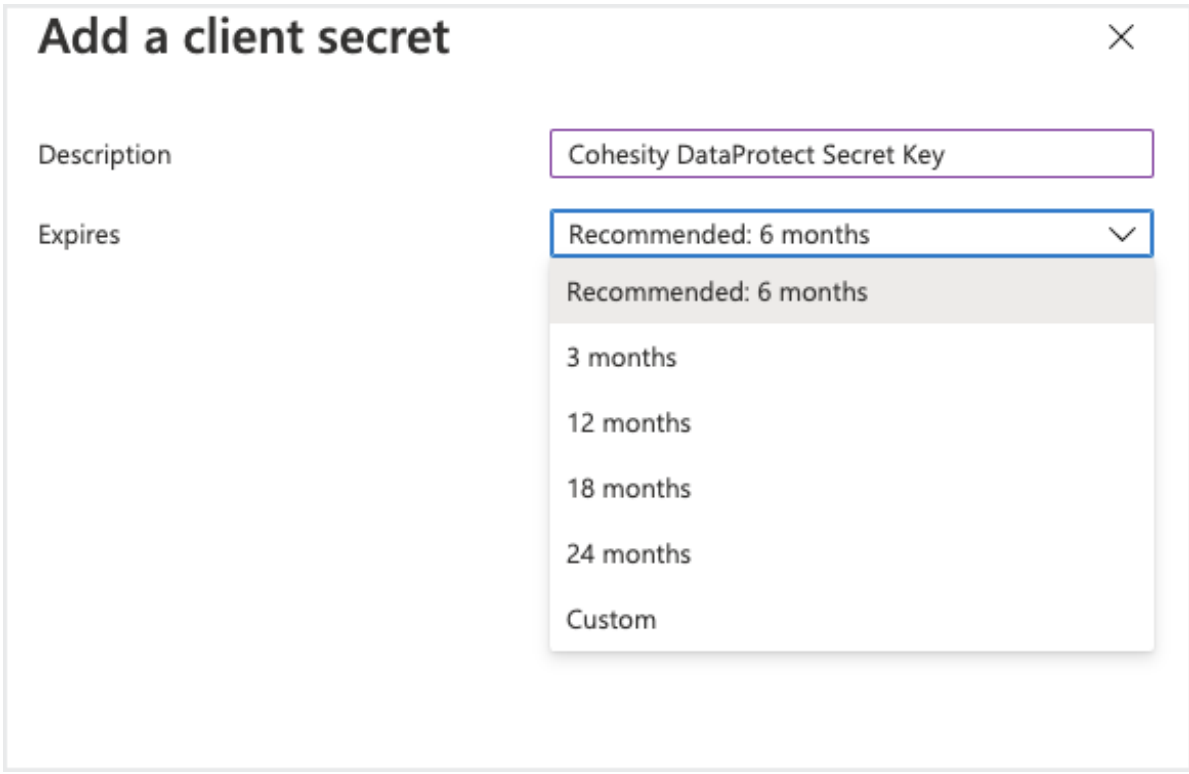
Permission Type	Permissions Name
Delegated	AllSites.FullControl
	AllSites.Manage
	AllSites.Read
	MyFiles.Read
	MyFiles.Write
	Sites.Search.All
	TermStore.ReadWrite.All
	User.ReadWrite.All
Application	Sites.FullControl.All
	Sites.Manage.All
	Sites.ReadWrite.All
	TermStore.ReadWrite.All
	User.ReadWrite.All

5. Grant admin consent for the API permissions.
    1. Under **Configured permissions**, click **Grant admin consent**.
    2. On the Grant admin consent confirmation, click **Yes**.

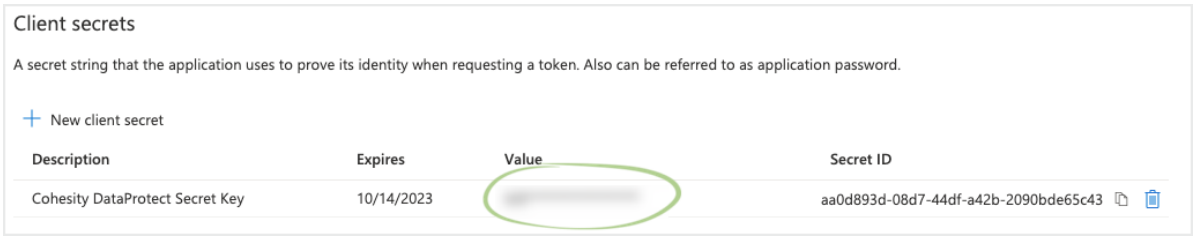


6. Create a new client secret that will be used to register Microsoft 365 as a source in Cohesity Platform.
    1. Under the **Manage** section, select **Certificates & secrets**.
        1. In the Client secrets section, click **New client secret**. Enter a **Description**.
        2. In the **Expires** drop-down, select how long the secret key will be valid.

3. Click **Add**.



2. Under **Client secrets**, click the **Copy** button next to the string under **VALUE**. You need the Value key of the client secret to register Microsoft 365 as a source in Cohesity Platform.
3. Store the Value key in a secure location. After you exit this page, you will not be able to see the Value key again. If you lose your value key, you will need to create a new client secret.



When you finish, your custom app should include the permissions as shown below:

API / Permissions name	Type	Description	Admin consent requ...	Status
Microsoft Graph (15)				
Channel.Create	Application	Create channels	Yes	Granted for Cohesity
Channel.ReadBasic.All	Application	Read the names and descriptions of all channels	Yes	Granted for Cohesity
ChannelMember.ReadWrite.A	Application	Add and remove members from all channels	Yes	Granted for Cohesity
ChannelMessage.Read.All	Application	Read all channel messages	Yes	Granted for Cohesity
Chat.Read.All	Application	Read all chat messages	Yes	Granted for Cohesity
Directory.ReadWrite.All	Application	Read and write directory data	Yes	Granted for Cohesity
Files.ReadWrite.All	Application	Read and write files in all site collections	Yes	Granted for Cohesity
Group.Create	Application	Create groups	Yes	Granted for Cohesity
Group.ReadWrite.All	Application	Read and write all groups	Yes	Granted for Cohesity
MailboxSettings.Read	Application	Read all user mailbox settings	Yes	Granted for Cohesity
Reports.Read.All	Application	Read all usage reports	Yes	Granted for Cohesity
Sites.FullControl.All	Application	Have full control of all site collections	Yes	Granted for Cohesity
Sites.ReadWrite.All	Application	Read and write items in all site collections	Yes	Granted for Cohesity
User.Read.All	Application	Read all users' full profiles	Yes	Granted for Cohesity
User.ReadWrite.All	Application	Read and write all users' full profiles	Yes	Granted for Cohesity
Office 365 Exchange Online (1)				
full_access_as_app	Application	Use Exchange Web Services with full access to all mailboxes	Yes	Granted for Cohesity
SharePoint (12)				
AllSites.FullControl	Delegated	Have full control of all site collections	Yes	Granted for Cohesity
AllSites.Manage	Delegated	Read and write items and lists in all site collections	No	Granted for Cohesity
MyFiles.Read	Delegated	Read user files	No	Granted for Cohesity
MyFiles.Write	Delegated	Read and write user files	No	Granted for Cohesity
Sites.FullControl.All	Application	Have full control of all site collections	Yes	Granted for Cohesity
Sites.Manage.All	Application	Read and write items and lists in all site collections	Yes	Granted for Cohesity
Sites.ReadWrite.All	Application	Read and write items in all site collections	Yes	Granted for Cohesity
Sites.Search.All	Delegated	Run search queries as a user	Yes	Granted for Cohesity
TermStore.ReadWrite.All	Application	Read and write managed metadata	Yes	Granted for Cohesity
TermStore.ReadWrite.All	Delegated	Read and write managed metadata	Yes	Granted for Cohesity
User.ReadWrite.All	Application	Read and write user profiles	Yes	Granted for Cohesity
User.ReadWrite.All	Delegated	Read and write user profiles	Yes	Granted for Cohesity

Set Additional Permissions for SharePoint Online

For SharePoint Online data protection, ensure that you set the required add-in permissions and tenant permissions below.

When you finish, your custom Azure app should include the permissions as shown below.

Add-In Permissions in SharePoint Online

Make sure that you assign the following add-in permissions to the custom app by configuring the tenant permissions. For more information, see Add-in permissions in SharePoint in the Microsoft documentation.

Scope URI	Required Rights
`http://sharepoint/content/tenant`	FullControl
`http://sharepoint/content/sitecollection`	FullControl
`http://sharepoint/content/sitecollection/web`	FullControl
`http://sharepoint/content/sitecollection/web/list`	FullControl
`http://sharepoint/taxonomy`	Read,Write

Tenant Permissions

After you have registered the custom app, configure the tenant permissions on the custom app.

To configure the tenant permissions:

1. Launch the **SharePoint Admin Center** using the URL: `https://<your-tenant>-admin.sharepoint.com/_layouts/15/AppInv.aspx`

   > **Note:** In the case of Multi-Geo tenants, for sites in a specific region (e.g., 'eur' for Europe), the URL for the SharePoint Admin Center changes accordingly. For instance, the URL for the domain `abcdef` and the region `eur` would be: `https://abcdefeur-admin.sharepoint.com/_layouts/15/AppInv.aspx`

2. In the **SharePoint Admin Center**, log in as the tenant admin.
3. In the **App ID and Title** section, perform the following:
   1. In the **App Id** field, enter the **AppID** of the custom app you have created and click **Lookup** to search for the custom app.
   2. In the **App Domain** field, enter www.localhost.com as the app domain.

      > **Important:** Do not enter any other string other than www.localhost.com in the **App Domain** field.

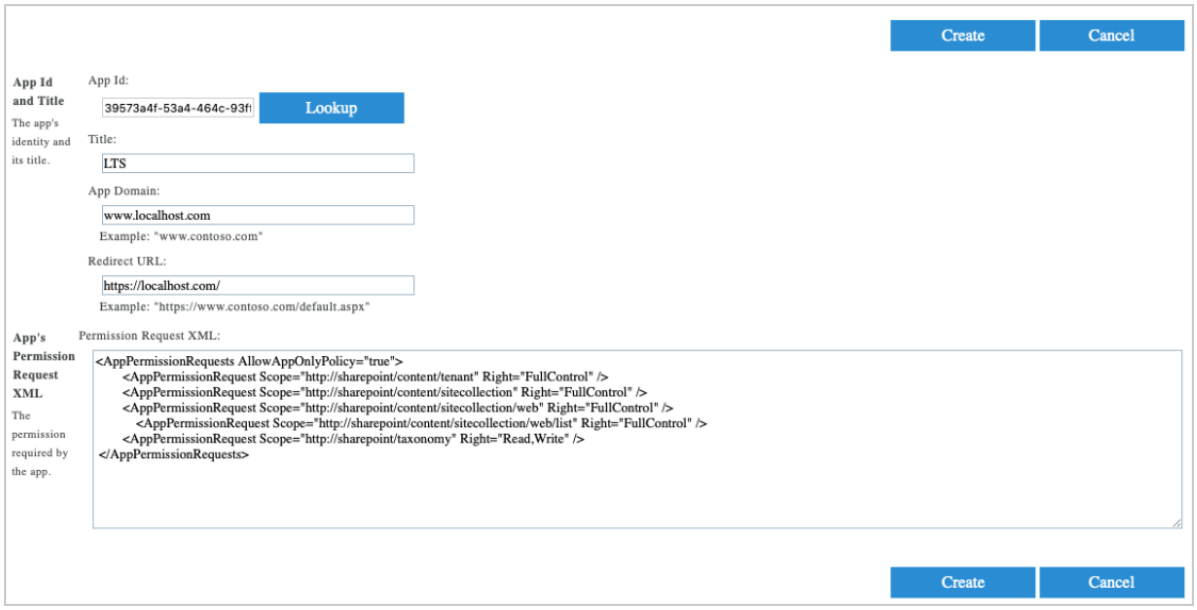
   3. In the **Redirect URL** field, enter https://localhost.com/ as the redirect URL.

> **Important:** Do not enter any other URL other than https://localhost.com/ in the **Redirect URL** field.

4. In the **Permission Request XML** field, enter the following values:

```
<AppPermissionRequests AllowAppOnlyPolicy="true">
<AppPermissionRequest Scope="http://sharepoint/content/tenant"
Right="FullControl" />
<AppPermissionRequest
Scope="http://sharepoint/content/sitecollection"
Right="FullControl" />
<AppPermissionRequest
Scope="http://sharepoint/content/sitecollection/web"
Right="FullControl" />
<AppPermissionRequest
Scope="http://sharepoint/content/sitecollection/web/list"
Right="FullControl" />
<AppPermissionRequest Scope="http://sharepoint/taxonomy"
Right="Read,Write" />
</AppPermissionRequests>
```

App Configuration for SharePoint Online



4. Click **Create**.
5. In the **Do you trust <app_title>?** page, perform the following:

a. From the drop-down, select **DO_NOT_DELETE_SPLIST_TENANTADMIN_AGGREGATED_SITECOLLECTIONS**.

b. click **Trust It**.

Important: If you have created your Microsoft 365 tenant on or after Sep 20, 2020, you must install SharePoint Online PowerShell. Using the global administrator account, run the following commands in an administrator PowerShell session:

```
Get-Module -Name Microsoft.Online.SharePoint.PowerShell -
ListAvailable | Select Name,Version
[Net.ServicePointManager]::SecurityProtocol =
[Net.SecurityProtocolType]::Tls12
Install-Module -Name Microsoft.Online.SharePoint.PowerShell -Scope
AllUsers
Connect-SPOService -Url 'https://<tenant>-admin.sharepoint.com'
Set-SPOTenant -DisableCustomAppAuthentication $False
```

Note: Custom scripts setting is not supported in SharePoint.

Install SharePoint Online PowerShell

If you have created your Microsoft 365 tenant on or after Sep 20, 2020, you must install SharePoint Online PowerShell. Using the Windows administrator account, install the SharePoint Online PowerShell.

To install SharePoint Online PowerShell:

1. Log on to the administrator PowerShell session.
2. Verify if the module, `Microsoft.Online.SharePoint.PowerShell` is already installed. Use the following command:

```
Get-Module -Name Microsoft.Online.SharePoint.PowerShell -ListAvailable
| Select Name,Version
```

3. If the module is not installed, use the following commands to install the module:

```
[Net.ServicePointManager]::SecurityProtocol =
[Net.SecurityProtocolType]::Tls12

Install-Module -Name Microsoft.Online.SharePoint.PowerShell -Scope
AllUsers
```

4. Connect to SharePoint Online using a global administrator account and enter the global administrator username and password when prompted. Use the following command:

```
Connect-SPOService -Url 'https://<tenant>-admin.sharepoint.com'
```

5. Enable PowerShell libraries to connect to SharePoint Online. Use the following command:

```
Set-SPOTenant -DisableCustomAppAuthentication $False
```

Enhance Backup of Large Microsoft 365 Data

When it comes to ingesting Microsoft 365 data, the size can vary from hundreds of terabytes (TBs) to a few petabytes (PBs) in some cases. One of the issues that may arise while performing the initial full backup of such large data is throttling from the Microsoft 365 APIs.

Cohesity recommends using only one application ID for Microsoft 365 backups. However, when you back up a large amount of data, using only one application ID may result in a prolonged ETA for the first full backup. Contact your Cohesity account team to determine the appropriate number of application IDs to optimize the performance while ensuring that the Microsoft Tenant Level Throttling limits are not exceeded, which may cause service failures for Microsoft 365.

After completing the first full backup, using multiple application IDs is not usually required. However, in certain situations, a single application ID may be inadequate. For guidance on the appropriate number of application IDs for incremental backups following the initial full backup, Contact your Cohesity account team.

Cohesity also supports Microsoft paid APIs to perform the first full backups faster. These APIs come with higher limits, ensuring the backups are performed faster at a higher API rate. The paid APIs are configured to be used in addition to the existing backup capacity allocated by Microsoft, rather than as a substitute, to help minimize additional costs.

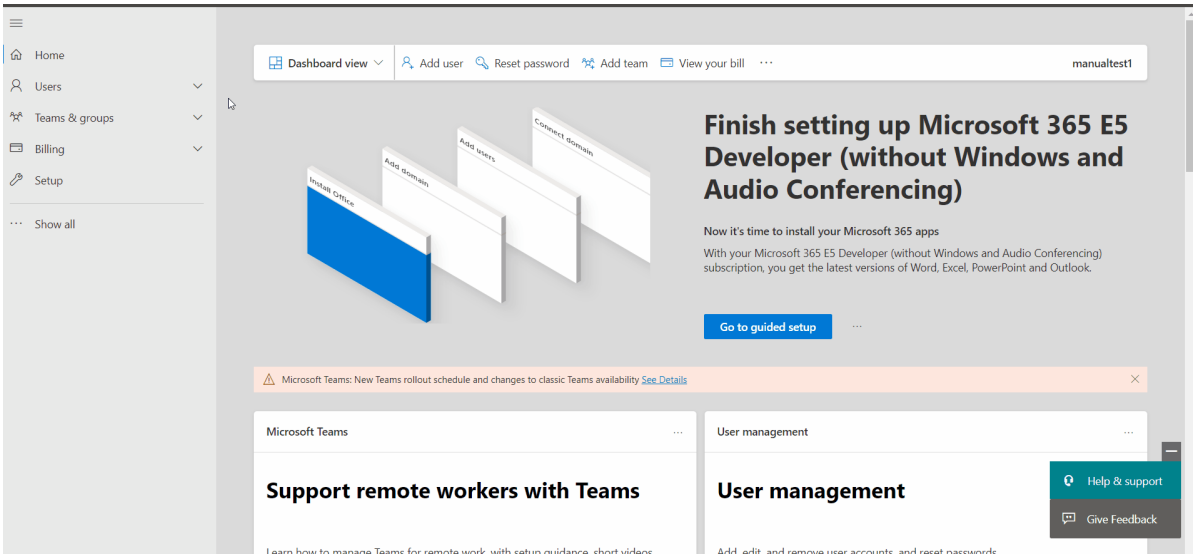
Update Microsoft Organization Setting for Mailbox Size Reporting

By default, Microsoft reports, using Graph API, display information as de-identified names for users, groups, and sites. However, for Mailbox size reporting to work in Cohesity, you need to have identifiable information in the Email activity reports. To do that, you need to disable de-identified names for users, groups, and sites in Microsoft 365 reports.

Update the following organization setting in your Microsoft 365 admin center:

1. Log in to your Microsoft 365 admin center as a Microsoft 365 tenant administrator.
2. Go to **Settings** > **Org settings** > **Services** > **Reports**.
3. In **Reports**, ensure the information is identifiable by deselecting **Display concealed user, group, and site names in all reports**.

4. Click **Save**.



To continue, if you are using:

- Cohesity's express registration for Microsoft 365 sources, you are ready to add those sources to Cohesity Platform.
- The manual registration for Microsoft 365 sources, you must first register your custom Azure app.

> **Note:** For SharePoint Online data protection, ensure that you also set the required add-in permissions and tenant permissions on the Azure application.

Firewall and Port Requirements for Microsoft 365 Protection

You must open specific ports in the firewall to allow the Cohesity cluster to protect Microsoft 365 application and the following table lists the required ports. For details on the Microsoft 365 endpoint URLs and IP address ranges, see Office 365 URLs and IP address ranges in Microsoft 365 documentation.

Port	Source	Target	Direction	Network Protocol	Usage
80/443	Cohesity cluster	Microsoft 365 Services	Outgoing	TCP	For Cohesity cluster to communicate with Microsoft Graph and the following service endpoints: • https://accounts.accesscontrol.windows.net • https://<tenant>.onmicrosoft.com • https://graph.microsoft.com/v1.0 • https://graph.microsoft.com/beta • https://outlook.office365.com • https://<tenant>.sharepoint.com • https://<tenant>-admin.sharepoint.com • https://<tenant>-my.sharepoint.com • login.microsoftonline.com
50051	Windows Proxy	Cohesity cluster	Bidirectional	TCP	Used for Cohesity Agent, on the Windows Proxy, and Agentless data transfer to the Cluster.
80/443	Windows Proxy	Microsoft 365 Services	Outgoing	TCP	For the Cohesity Agent to access the following SharePoint Online service endpoints: • https://accounts.accesscontrol.windows.net • https://<tenant>.onmicrosoft.com • https://<tenant>.sharepoint.com • https://<tenant>-admin.sharepoint.com • https://<tenant>-my.sharepoint.com

Set Up a Windows Connector for Microsoft 365

A Windows Connector is a Microsoft Windows VM that is required by the Cohesity cluster for downloading your backed-up mailboxes or email(s) in PST format.

You need to register a Windows Connector as a physical server source on Cohesity and connect it with your Microsoft 365 source. The following is the supported specification for the Windows Connector:

Specification	
Operating System	Microsoft Windows 10, 2016, 2019, or 2022.
vCPU	2
RAM	8 GB (minimum)
Disk	20 GB

Prerequisites

Ensure that:

- Cohesity Windows Agent is installed on Windows Connector.

  > **Note:** You do not have to install the Volume CBT or File CBT kernel drivers.

- Cohesity recommends that the Windows Connector is dedicated to Microsoft 365 data protection and is not part of any other workflows provided by Cohesity.
- The Windows Connector VM has internet connectivity.
- The Windows Connector VM is in English locale. Non-English locale is not supported.
- If your Cohesity cluster is joined to the Active Directory (AD) domain, ensure that the Windows Connector is also part of the AD domain.
- You exclude the following directory paths from Windows Security:
  - `C:\Program Files\Cohesity`
  - `C:\ProgramData\Cohesity`
  - `C:\Windows\Temp`
- You open specific ports in the firewall to allow data transfer between the Windows Connector and the Cohesity cluster. For information on the required ports, see Firewall and Port Requirements.

Points to note:

- A Windows Connector can be used for a maximum of five Microsoft 365 tenants.
- To download your backed-up mailboxes or email(s) in PST format, ensure that you have installed Microsoft Outlook 64-bit version on the Windows Connector. From your Microsoft 365 homepage, you can install Office. For detailed instructions, see Microsoft Documentation on Office installation. After you have installed the Microsoft Outlook 64-bit version, ensure that you restart the Cohesity Windows Agent. To restart the Cohesity Windows Agent, use the command-line or PowerShell as

administrator and run the following commands:

```
net stop cohesityagent

net start cohesityagent
```

Register a Windows Connector as a Physical Server Source

To register a Windows Connector as a physical server source on Cohesity, see Register or Edit a Physical Server.

> **Note:** After registering a Windows Connector as a physical server source on Cohesity, make sure to toggle on **Use Windows Connector** when registering or updating the Microsoft 365 source.

Microsoft 365 Certificate Based Authentication

Cohesity supports Certificate-Based Authentication (CBA) when registering Microsoft 365 applications. This feature allows you to authenticate with an X.509 certificate against the Public Key Infrastructure (PKI) and provides phishing resistant authentication.

> **Note:** This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

Prerequisites

- Ensure that you create a certificate via API and upload it to Azure. Contact your Cohesity account team to generate and download certificates via API.
- Registering Microsoft 365 applications using Certificate-Based Authentication (CBA) requires additional permissions. To upload certificates to Azure, the apps require self-ownership. The **Application.ReadWrite.OwnedBy** permission is required for an app to set itself as an owner. For more details, see Microsoft Graph permissions reference.

Considerations

- An error may occur if you select a certificate that has not been uploaded to the app in Azure.
- Certificates generated by Cohesity have one year of expiry. By default, Cohesity attempts to rotate the certificates 60 days before the expiry and displays alerts/warnings 45 days before the expiry. These timelines are configurable.
- When importing custom certificates, the certificates must be uploaded (via express or manual registration) on the app before clicking Register in the UI, which will otherwise cause the registration to fail.

- When migrating apps to CBA using manual registration, the following error may occur: "Insufficient privileges to complete the operation". Ensure that the app being migrated includes OwnedBy permission. The app being migrated must be an owner of itself.

Create Cohesity Managed Certificate

To create a Cohesity managed certificate:

1. Navigate to **Sources** and select **Register > Microsoft 365**.
2. Choose the **Microsoft 365 Applications** to discover.
3. In the **Account Credentials** section, enter the Microsoft 365 **Username** and **Password**.

   Toggle ***on*** the **Enable OAuth** option. Ensure that you added the required permission, for more information, see Use OAuth for Microsoft 365 Backups.
4. Adding multiple Microsoft 365 service accounts using the **Additional Service Accounts** section requires OAuth disabled, as Microsoft has enabled OAuth by default, ignore adding multiple Microsoft 365 service accounts.
5. Select the **Authentication Option** as *Certificate* to authenticate applications using Microsoft Entra Certificate-Based Authentication (CBA). For more information, see Microsoft Entra Certificate-Based Authentication.
6. Enter the number of Azure applications you want to create based on your requirements and click **Create**.

   > **Note:** By default, one Azure application will be created. To better manage Microsoft 365 throttling, Cohesity recommends at least two Azure apps.
7. In the **Add Azure Application** form, copy the device code and click the **Microsoft Azure App** link to open the Microsoft Azure App authorization service in a new tab.

   If you prefer to create your Azure apps manually, see Manual Registration for Microsoft 365 Sources.
8. Paste the copied code in the **Microsoft Azure App** authorization service and click **Next**.
9. Log in to Microsoft Azure, enter the **Username** and **Password** of your Microsoft 365 account and click **Sign in**.

   > **Note:** Ensure that your Microsoft 365 account has global administrator access.

10. Follow the instructions to complete the authorization on the Microsoft Azure portal. Then, wait for Microsoft Azure Authorization to complete. During this process, the Cohesity managed certificates will be created and then the Azure apps will be created.
11. Once completed, the **App IDs** and the **Associated Certificates** will be listed in the **Azure Applications** section.
12. Click **Register**.

The certificates created will be available in the Certificate Store.

> **Note:** Contact your Cohesity account team to generate and download certificates via API.

Migrate Existing Apps to Certificate-Based Authentication

To migrate your existing apps from App Secret-based authentication to Certificate-based authentication:

1. Navigate to **Sources** and select **Register > Microsoft 365**.
2. Choose the **Microsoft 365 Applications** to discover.
3. In the **Account Credentials** section, enter the Microsoft 365 **Username** and **Password**.

   > **Note:** Toggle ***on*** the **Enable OAuth** option. Ensure that you added the required permission, for more information, see Use OAuth for Microsoft 365 Backups.

4. Adding multiple Microsoft 365 service accounts using the **Additional Service Accounts** section requires OAuth disabled, as Microsoft has enabled OAuth by default, ignore adding multiple Microsoft 365 service accounts.
5. Select the **Authentication Option** as ***Certificate*** to authenticate applications using Microsoft Entra Certificate-Based Authentication (CBA). For more information, see Microsoft Entra Certificate-Based Authentication.
6. Enter the number of Azure applications you want to create based on your requirements and click **Create**.

   > **Note:** By default, two Azure applications will be created. To better manage Microsoft 365 throttling, Cohesity recommends at least two Azure apps.

7. Click **Migrate Existing Apps**. You can also attach certificates directly into your Azure app in the Azure portal, but this can take much longer time.

8. In the **Register Microsoft 365 Source** page, copy the device code and click the **Microsoft Azure App** link to open the Microsoft Azure App authorization service in a new tab.
9. Paste the copied code in the **Microsoft Azure App** authorization service and click **Next**.
10. Log in to Microsoft Azure, enter the **Username** and **Password** of your Microsoft 365 account and click Sign in.

    > **Note:** Ensure that your Microsoft 365 account has global administrator access.

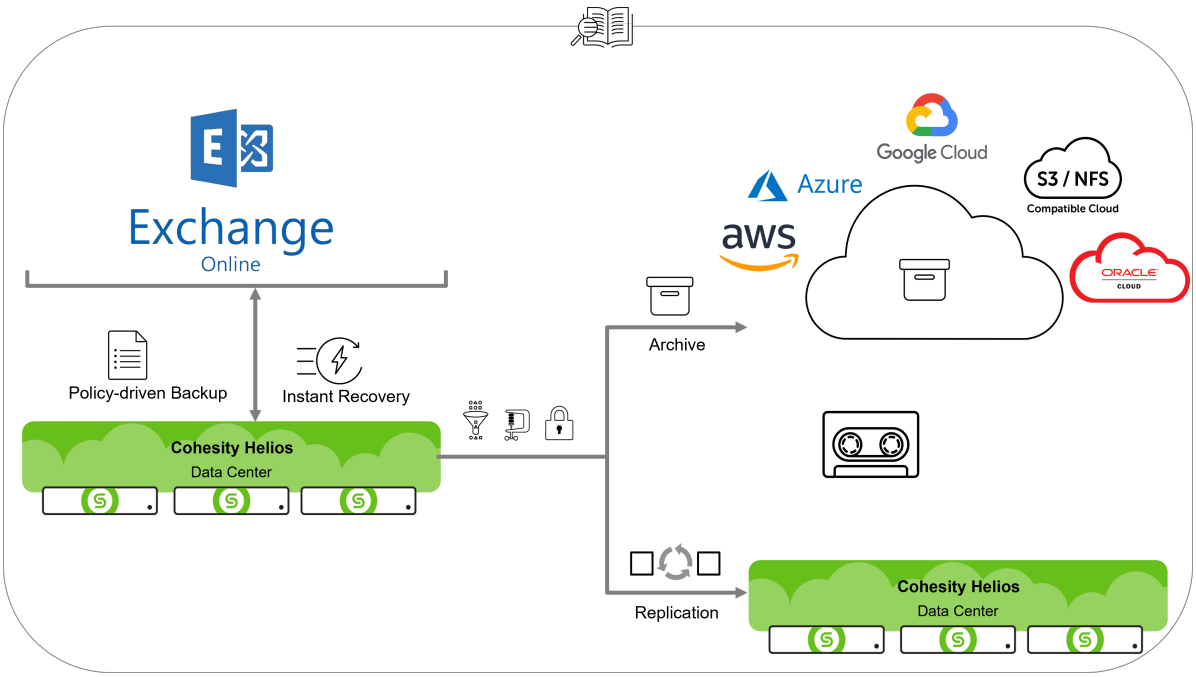
11. Follow the instructions to complete the authorization on the Microsoft Azure portal. Then, wait for Microsoft Azure Authorization to complete. During this process, the Cohesity managed certificates will be created and then the Azure apps will be created.
12. Once completed, the **App IDs** and the **Associated Certificates** will be listed in the **Azure Applications** section.
13. Click **Register**.
    The source authentication method will be migrated from App Secret-based to Certificate-based authentication.

For more information on certificates, see Certificates.

> **Note:** This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

Exchange Online Mailboxes

Microsoft Exchange Online is a SaaS application that is bundled in your Microsoft 365 subscription service. It is a hosted messaging solution that delivers the capabilities of Microsoft Exchange Server as a cloud-based service. It gives users access to email, calendar, contacts, and tasks from PCs, the web, and mobile devices. Using the policy-based data protection solution from Cohesity, you can protect Exchange Online data on Microsoft 365.



Plan and Prepare for Mailbox Protection

Before you register your Microsoft 365 domain with Cohesity to protect Microsoft 365 data, ensure:

- You have completed all the prerequisites.
- You have reviewed and understood the considerations and best practices.

> **Note:** Save this value in a safe location. You need this value to register Microsoft 365 as a source on Cohesity.

Considerations

Considerations

Review and understand the following considerations before you protect your Microsoft 365 Exchange Online data:

- Recovery can be performed at the mailbox, folder, or item level. Currently, recovery at the Protection Group level is not supported.
- Recovery of items in the same mailbox from different recovery points is not supported in the same recovery task. You need to create different recovery tasks for different recovery points.
- If the email already exists at the destination during the recovery workflow, the email will be updated

- The backup or recovery of Mailboxes, OneDrives, SharePoint Online Sites, and MS Teams are executed in parallel as long as there are enough resources on the Cohesity cluster. However, the backup or recovery operations are serialized for the Mailboxes and OneDrives that belong to the same user, and the operations execute in first-in-first-out order.

  For example, if the backup of a user's mailbox is in progress, then the backup of the user's OneDrive starts only after the backup of the mailbox completes.
- Converted-shared mailboxes are not backed up by default. To enable backup of converted-shared mailboxes, contact Cohesity Support.
- The Retirement of RBAC Application Impersonation in Exchange Online has no known impact on the Microsoft 365 Exchange Online Mailboxes, Teams, and Groups protection workflow on the Cohesity cluster.
- By default, the Conversation History/Team Chat folder is excluded during the Exchange Online backup.
- Following the Microsoft changes for EWS APIs, Cohesity no longer backs up mailbox items of the type **IPM.Teams.SkypeMessage**. For more details, see the KB Article.
- Exchange Online Mailboxes protection is supported only for users present on Azure AD and not for users on the on-premises Active Directory.
- Exchange Online Mailboxes protection is:

  Supported for:

  - Users present in Azure AD
  - Hybrid setup with users present on Azure AD

  Not supported for:

  - Users on on-premises Active Directory
  - Users natively on on-premise Active Directory that are synchronized to Azure AD
- Microsoft 365 items with only special characters will not be listed in granular search. The item name must contain at least one alphanumeric character to be listed in the search result.
- Cohesity supports protecting 100k Microsoft 365 objects. This includes the following:
  - Objects on individual applications, for example, 100k Mailboxes.
  - Objects on combined applications, for example, 50k Mailboxes, 30k Teams, and 20k Groups.

  Validations will be displayed when backing up more than 7500 objects and recovering more than 5000 objects.

> **Note:** This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

- In Recoverable Items:
  - Only Deletions, Purges, Discovery Holds, and SubstrateHolds folders are currently supported.

    SubstrateHolds is an Controlled Availability feature. Contact your Cohesity account team to enable the feature.
  - Audits, Calendar Logging, and Versions folders are not supported.

    This is an Early Access feature. Contact your Cohesity account team to enable the feature.
- Backup and download of the following is not supported:
  - Self-message (messages sent to self)
  - Saved or pinned messages property in the conversation
  - Meeting recordings metadata from private chats
  - Emojis and Stickers
- Restoration at the protection group level is not supported for Microsoft 365.
- Recovery for items in the same mailbox from different recovery points is not supported in the same recovery task. You need to create different recovery tasks for different recovery points.
- If the size of the mailbox is large, then exporting the mailbox to PST format takes longer duration.
- The exported PST of the mailbox or the email is valid for 72 hours. Ensure that you download the PST file within 72 hours of the recovery task completion.
- PST recovery of emails with more than 2000 recipients is not supported.
- The Cohesity cluster and connector must be a member of the same or any trusted AD for PST recovery.

Best Practices

To protect your Microsoft 365 data, Cohesity recommends the following best practices:

- Set **Retry Options** to **1**, as the Microsoft 365 connector already has the retry mechanism handling failed requests. There is no need to increase the value for this setting in the Cohesity Protection Policy.
- Use **Auto-Protect** to avoid adding new users to the Protection Group manually.
- Avoid adding the same users in multiple Protection Groups.

For the workflows supported by Exchange Online, see Microsoft 365 Workflows.

Register and Manage Microsoft 365 Exchange Online Mailboxes

To start protecting Microsoft 365 applications, you need to register the Microsoft 365 domain as a source in Cohesity.

Cohesity uses the Microsoft Graph API for object discovery, backup, and recovery in Microsoft 365. Cohesity uses an Azure application created and registered on the Azure portal with the necessary permissions to use the Graph API. You can either let Cohesity create the Azure application or manually enter Azure application details while registering your Microsoft 365 domain as a source in Cohesity.

Express Registration for Microsoft 365 Sources

Before you register your Microsoft 365 domain, ensure that you have:

- Added roles to the Microsoft 365 user account.
- Updated your Microsoft Organization setting for Mailbox size reporting.

To register your Microsoft 365 domain:

1. Navigate to **Sources** and select **Register** > **Microsoft 365**.
2. Choose **Mailbox** as the **Microsoft 365 Applications** to discover.

   > **Note:**
   > If the Private Chats and Teams Posts option is enabled under the Mailbox and Teams apps respectively, the Private Chats and Teams Posts will be backed up along with the corresponding Users and Teams respectively.

   > **Note:** This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

3. In the **Account Credentials** section, enter the Microsoft 365 **Username** and **Password**.

   > **Note:** Toggle ***on*** the **Enable OAuth** option. Ensure that you added the required permission, for more information, see Plan and Prepare for Mailbox Protection.

4. Adding multiple Microsoft 365 service accounts using the **Additional Service Accounts** section requires OAuth disabled, as Microsoft has enabled OAuth by default, ignore adding multiple Microsoft 365 service accounts.

5. In the **Azure Applications** section, enter the number of Azure applications you want to create based on your requirements and click **Create**.

   > **Note:** By default, two Azure applications will be created. To better manage Microsoft 365 throttling, Cohesity recommends at least two Azure apps.

6. In the **Add Azure Application** form, copy the device code and click the **Microsoft Azure App** link to open the Microsoft Azure App authorization service in a new tab.

   > **Note:** If you prefer to create your Azure apps manually, see Manual Registration for Microsoft 365 Sources.

7. Paste the copied code in the **Microsoft Azure App** authorization service and click **Next**.
8. Log in to Microsoft Azure, enter the **Username** and **Password** of your Microsoft 365 account and click **Sign in**.

   > **Note:** Ensure that your Microsoft 365 account has a global administrator access.

9. Follow the instructions to complete the authorization on the Microsoft Azure portal. Then, wait for Microsoft Azure Authorization to complete.
10. Optional. To enable exporting and downloading mailboxes or email(s) in PST format, toggle on **Use Windows Connector** and specify the hostname (FQDN) or server IP of the Windows Connector added as a Physical server. For more information, see Set Up a Windows Connector.
11. Click **Register**.

Manual Registration for Microsoft 365 Sources

Before you register Office 365 as a source on Cohesity, ensure that you:

- Review the requirements, considerations, and best practices.
- Perform the prerequisite tasks.

For more information, see Plan and Prepare for Mailbox Protection.

To register your Microsoft 365 domain:

1. Navigate to **Sources** and select **Register** > **Microsoft 365**.
2. Choose **Mailbox** as the **Microsoft 365 Applications** to discover.

> **Note:**
> If the Private Chats and Teams Posts option is enabled under the Mailbox and Teams apps respectively, the Private Chats and Teams Posts will be backed up along with the corresponding Users and Teams respectively.

> **Note:** This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

3. In the **Account Credentials** section, enter the Microsoft 365 **Username** and **Password**.

> **Note:** Toggle ***on*** the **Enable OAuth** option. Ensure that you added the required permission, for more information, see Plan and Prepare for Mailbox Protection.

4. Adding multiple Microsoft 365 service accounts using the **Additional Service Accounts** section requires OAuth disabled, as Microsoft has enabled OAuth by default, ignore adding multiple Microsoft 365 service accounts.
5. In the **Azure Applications** section, enter the number of Azure applications you want to create based on your requirements and click **Create**.

> **Note:** By default, two Azure applications will be created. To better manage Microsoft 365 throttling, Cohesity recommends at least two Azure apps.

6. In the **Add Azure Application** form, click the **You can also add Azure App manually** link.
   - For **Certificate** authentication, the **App ID** and the **Associated Certificate** of your custom Azure app will be populated. You can select the **Associated Certificate** from the list of certificates present in your certificate store or Create Cohesity Managed Certificate.

     > **Note:** This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

   - For **App Secret** authentication, the **App ID** and **App Secret Key** of your custom Azure app will be populated.

> **Note:** You can add multiple Azure apps for a Microsoft 365 source to load balance your backup and restore operations. Click **+** to add multiple Azure apps. When you do, ensure that you provide the valid **App ID** and **App Secret Key**.

To migrate the existing apps from App Secret to Certificate authentication method, see Migrate Existing Apps to Certificate-Based Authentication.

7. Optional. To enable exporting and downloading mailboxes or email(s) in PST format, toggle on **Use Windows Connector** and specify the hostname (FQDN) or server IP of the Windows Connector added as a Physical server. For more information, see Set Up a Windows Connector for Microsoft 365.
8. Click **Register**.

Manage Microsoft 365 Source Registration

After registering your Microsoft 365 domain as a source, you can:

- Update the Microsoft 365 source configuration.
- Refresh the source details.
- Unregister the Microsoft 365 domain from Cohesity.

Update the Microsoft 365 Source Configuration

After registering your Microsoft 365 source on Cohesity, you might have changed the Microsoft 365 domain configuration by:

- Changing the credentials of Microsoft 365 user account credentials.
- Updating the app secret by adding more permissions to the custom app.
- Creating a new app ID.
- Configure the Windows Proxy to enable export and download of your backed-up mailboxes or email(s) in PST format.

You can update the Microsoft 365 details provided during the registration process with the latest Microsoft 365 configuration details.

To edit the Microsoft 365 source configuration:.

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Microsoft 365 source and select **Edit**.
3. On the **Update Microsoft 365 Source** page, update the required configurations.
4. Click **Register**.

Refresh the Microsoft 365 Source

You can refresh the Microsoft 365 domain configuration and fetch the latest changes on the Microsoft 365 domain.

To refresh the Microsoft 365 Source Configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Microsoft 365 source and select **Refresh**.

Unregister the Microsoft 365 Domain

If you plan to stop taking the backup of your Microsoft 365 domain, you can unregister the Microsoft 365 source from the Cohesity Cluster.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the Microsoft 365 source.

To unregister the Microsoft 365 domain:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Microsoft 365 source and select **Unregister**.

Backup Exchange Online Mailboxes

Exchange Online mailboxes are protected using a Protection Group and a Protection Policy. A Protection Group enables you to select and group the objects that you want to back up. It uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured and replicated.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. Also, for Disaster Recovery, you can add replication for the Protection Group using the Protection Policy. You can select which standard or custom policy to use when creating a Protection Group. For more information, see Manage Protection Policy.

To protect Exchange Online mailboxes:

1. Do one of the following:
    - On the **Dashboards** page, from the drop-down at the top of the page, select **Data Protection** and do one of the following:
        - If there is no existing Protection Group, click **Start Data Protection** > **Microsoft 365** > **Mailbox**.
        - Click **Protect** > **Microsoft 365** > **Mailbox**.

- Select **Data Protection > Protection**. Click **Protect** on the top-right of the page and then select **Microsoft 365** > **Mailbox**.
- Select **Data Protection > Sources**. Click the actions menu (⋮) next to the Microsoft 365 source and then select **Protect Mailbox**.

2. In the **New Protection** pop-up, do one of the following:
   - Protect the mailbox by specifying a subset of options such as objects, protection group and policy by clicking the edit icon corresponding to the following options:
     i. **Add Objects**: Select the registered Microsoft 365 source or click **Register Source** to register a Microsoft 365 account. From the **Users** list, select the users you plan to back up.
     ii. **Protection Group**: Specify a name for the Protection Group.
     iii. **Policy**: Select an existing policy or click **Create Policy** to create a new protection policy.
     iv. **Storage Domain**: Select the appropriate storage domain.

     > **Note:** This option is visible on the **New Protection** pop-up only if there is more than one storage domain.

     v. Click **Protect**.
   - To protect the mailbox by specifying all the options, click **More Options**.
3. From the **Source** drop-down list, select the registered Microsoft 365 source or click **Register Source** to register a Microsoft 365 source. For more information, see Register and Manage Microsoft 365 Exchange Online Mailboxes.
4. From the **Users** list, select the users that you plan to backup and click **Save Selection**.

   > **Note:** You can use the advanced filters that are available to search and find users based on user attributes. Also, you can click the shield icon to enable Auto Protect. For more information on Auto Protect, see Enable or Disable Auto Protect.

5. In the **Protection Group** section, do one of the following:
   - Select **New Group** to create a new Protection Group. In the **Protection Name** field, enter a name from the Protection Group.

- Select **Existing Group** to use the settings of an existing Protection Group. From the **Group** list, select an existing Protection Group and click **Protect**.

6. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, Create or Use an Existing Protection Policy.
7. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains.
8. After selecting a Storage Domain, if you need to change any of the advanced settings on the **New Microsoft 365 Protection Group** page, scroll down and click **Edit** on the right. For more information, see Advanced Settings.
9. Click **Protect**.

   Your Exchange Online Data Protection is now active and running.

Advanced Settings

Advance Settings	Description
Start Time	Available only if the selected policy is set to Backup Daily. Indicates when the protection run should start. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
End Time	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts prior to this date runs until completion even if it completes after this date.
QoS Policy	Select an appropriate quality of service (QoS) policy. **Note:** Cohesity recommends specifying **Backup HDD**, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy.

Advance Settings	Description
Exclusion List	Select the folders that you plan to exclude from the backup or click **Add** to add custom folders that you want to exclude from the backup. **Note:** Exclusion list is not supported for Public Folders.
Indexing	By default, indexing is enabled. **Note:** Indexing is mandatory for granular restore of an Exchange Online mailbox , such as restoring a folder or restoring an email. For more information, see Recover Mailbox .
Alerts and Priority	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts.
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs
Email Recipients	You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection run.

Advance Settings	Description
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks). > **Note:** Users with similar SLAs can be grouped together and a custom policy and Protection Group can be created to achieve different SLAs.
Description	**Optional**. Enter a brief description about the Protection Group.

Create or Use an Existing Protection Policy

Create a Protection Policy with the settings listed in the Policy Settings for Exchange Online. For detailed instructions on how to create a Protection Policy, see Create or Edit a Standard Policy.

Policy Settings for Exchange Online

The following table lists the applicable policy settings for Exchange Online:

Field	Description
DataLock	Add a DataLock for compliance and regulatory requirement. This ensures that your protected data, including local backups, archives, and replication, cannot be modified until the DataLock expiration. Once applied, a DataLocked Snapshot will be deleted only after its retention period expires. A DataLock prevents all users from modifying or deleting any Snapshots that were generated by the protection runs that use this Policy. The users include those who have the Data Security role in Cohesity as well. > **Note:** Only users with the Data Security role can add, modify, or remove a DataLock from a Policy.

Field	Description
Scheduled Backup	Defines when backups are captured, how long they are retained, and the type of backup to capture.
Extended Retention	Add this to retain a subset of snapshots (backups) for longer duration than defined by the protection schedule.
Retry Options	Use this option to customize the retry settings for capturing Snapshots. By default, Cohesity attempts to capture Snapshots three times before the protection run fails. The default time between retries is thirty minutes. You can customize the number of retries and how long to wait between each attempt. **Note:** Set **Retry Options** to **1**, as the Microsoft 365 connector already has the retry mechanism handling the failed requests. There is no need to increase the value for this setting in the Protection Policy.
Quiet Times	Quiet Times define time periods when new protection runs are not started. For example, you might want to configure hourly backups that run during weekdays but not on Saturdays or Sundays. Quiet Times only prevent new protection runs from starting during the specified time period. The protection runs that started before the quiet time period are not affected and will continue to run. For example, if a protection run starts at 12:45 AM on Saturday morning and there is a weekend quiet time period that starts at 1 AM on Saturday morning, the protection run will continue to run past 1 AM. No new protection runs are started during the quiet time period.
Replication	Replicate snapshots to another Cohesity cluster.

Use an Existing Protection Policy

You can edit an existing Protection Policy and configure it with applicable policy settings for Exchange Online. In this case, all the policy settings apart from the settings applicable to Exchange Online are ignored.

To use and existing Protection Policy:

1. Navigate to **Data Protection > Policies**.
2. On the **Policies** page, select the policy that you plan to edit.
3. On the **Policy Details** page, click **Edit** and configure the applicable policy settings for Exchange Online. For information on the applicable policy settings, see Policy Settings for Exchange Online.
4. Click **Save**.

The updated policy settings are applied to the Protection Group in the next protection run.

Manage the Exchange Online Backup Configuration

In Cohesity, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirement.

> **Note:** You cannot update the registered Microsoft 365 domain and the assigned Storage Domain in the Protection Group settings.

Add Mailboxes to the Protection Group

You can add new mailboxes to the existing Protection Group for backup. The newly added mailbox is backed up from the next protection run and it will be a full backup for the newly added user.

To add mailboxes to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Exchange Online.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Microsoft 365 - Mailbox** page, click ✎ in the **Users** section.
5. From the **Users** list, select the mailboxes that you plan to add to the backup and click **Save Selection**.
6. Click **Save**.

Remove Mailboxes from the Protection Group

You can remove mailboxes from the Protection Group that you do not want to back up in the next protection run. When you remove a user from the protection group, incremental backup of the user's mailbox is not performed from the next protection run. The existing backup for the user is preserved until the snapshot expires.

To remove mailboxes from the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Exchange Online.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Microsoft 365 - Mailbox** page, click ✎ in the **Users** section.
5. From the **Users** list, unselect the mailboxes that you want to remove from the Protection Group and click **Save Selection**.
6. Click **Save**.

Enable or Disable Auto Protect

The Auto Protect option enables you to automatically protect the new mailboxes that are added to Microsoft 365.

When the Auto Protect option is enabled:

- All the mailboxes that are added to Microsoft 365 in the future are automatically added to the Protection Group and are protected from the next protection run.
- All the mailboxes that are removed from Microsoft 365 in the future are automatically removed from the Protection Group and are not protected from the next protection run. The existing backup for the user is preserved until the snapshot expires.

When the Auto Protect option is disabled, you need to manually:

- Add newly onboarded users on Microsoft 365 to the Protection Group.
- Remove existing users that are offboarded on Microsoft 365 from the Protection Group. The existing backups of the users are preserved until the snapshot expires.

To enable or disable Auto Protect:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Exchange Online.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Microsoft 365 - Mailbox** page, click ✎ in the **Users** section.
5. From the **User** list, click the icon to enable or disable Auto Protect and click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group in the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Exchange Online.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.

4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Protect**.

Start an On-demand Protection Run

You can manually start a protection run of the Protection Group that you have created to back up Exchange Online. It provides you with options to:

- Back up all the objects or only selected objects in the Protection Group.
- Select an incremental or full backup.
- Add replication.

To start a protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Exchange Online.
3. Click the actions menu (⋮) next to the Protection Group and select **Run Now**.
4. In the pop-up window, perform the following:
    1. In the **Backup** drop-down list, select any one of the following:
        - Backup all Objects in the Protection Group
        - Backup only selected Objects in the Protection Group
    2. In the **Backup Type** drop-down list, select the backup type.
    3. Optional. In the **Replicate** section, select the replication target and the retention duration or click **Add** to add the replication target and the retention duration. Also, select **Replicate only fully successful runs** to replicate the data only from the completed protection runs.
    4. Optional. In the **Archive** section, click **Add** to add the external target to which you want to archive the data and the retention duration. Also, select **Archive only fully successful runs** to archive the data only from the completed protection runs.
5. Click **Backup Now**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Exchange Online.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups, local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group, the reclaimed storage space details will not be displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Exchange Online.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:

- **Delete Protection Group Only**
- **Delete Protection Group and Snapshots**

Recover Mailbox

You can recover Exchange Online data using Cohesity at various granularities, such as at the mailbox, folder, and email level. You can recover to the same location, alternate location, or across Microsoft 365 domains. Also, you can download the offline copy of the mailboxes or emails in PST file format.

> **Note:** To download backed-up mailboxes or email(s) in PST format, you need to register a Windows Connector as a physical server source on Cohesity and connect it with your Microsoft 365 source. For more information, Set Up a Windows Connector.

Recover Mailboxes

To recover mailboxes, you can search through the backups by using username or using a string pattern in the username for the mailbox that you plan to recover and then start the recover operation.

> **Note:** You can use * character to list all the mailboxes.

To recover mailboxes:

1. Navigate to **Data Protection > Recoveries**. Click **Recover** on the top-right of the page and then select **Microsoft 365** > **Mailboxes** as the recovery source.
2. On the **New Recovery Microsoft 365 - Mailbox** page, in the **Recovery Type**, select **Entire Mailbox**.
3. Search the user mailbox to be recovered, select the mailboxes you need, and click **Continue**.
4. Based on your requirements, select any one of the following options:

Options	Description
Original Location	To recover data to the same mailbox from which it was backed up.

Options	Description
New Location	To recover data to an alternate location in a different Microsoft 365 domain. Select a **Registered Source** and the **Target Mailbox**, and specify the **Folder name** to which you plan to recover. **Note:** • Both the Microsoft 365 domains must be registered as sources with the same Cohesity cluster. For more details, see Register and Manage Microsoft 365 Exchange Online Mailboxes. • If a folder with the specified name does not exist, Cohesity creates the folder and recovers the data to it.
Export as PST	To export a backed-up mailbox as a PST file, you must provide a password for the exported PST file. **Note:** • Once the recovery task is completed, the exported PST file is valid for 72 hours. Ensure that you download the PST within 72 hours. For more information, seeRecover Mailbox . • The PST export process might take a few minutes or hours depending on the size of the mailbox.
On-prem Exchange Server	To recover data to an on-prem Exchange Server created via API. You can select the required on-prem Exchange Server from the drop-down list. **Note:** This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

5. Select your Recovery Options:
    1. **Continue on Error.** Enable to complete the recovery task even if errors occur when recovering Mailboxes.
    2. **Task Name.** Change the default name of the recovery task.
    3. **Selective Recovery.** Toggle ON the **Recover within specified timeframe** option to filter the Mailbox items to be recovered.

Under **Include items in recovery**, select the required items:

- Mails
- Calendars
- Contacts, Tasks, and Notes.

You can also **recover data of the last specific days prior to the selected snapshot**.

> **Note:**
> - All upcoming calendar events will be recovered.
> - Any calendar events that were scheduled or received in the selected time frame will be recovered.
> - Contacts, Tasks, and Notes will be fully recovered unaffected by the days selected.

This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

6. Click **Recover** to start the recover operation.

Recover Mailbox Items

You can recover the mailbox items such as individual emails, folders, calendar items, contacts, notes, or tasks from the backed-up mailboxes.

Recover Emails

To recover specific emails:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** on the top-right of the page and then select **Microsoft 365** > **Mailboxes**.
3. On the **New Recovery Microsoft 365 - Mailbox** page, in the **Recovery Type**, select **Search Mailbox Items**.
4. From the **Item Type** drop-down list, select **Emails**.
5. To search for emails, enter the * wildcard character in the search bar, or enter text with a matching subject to find a specific email, and then select the emails to recover from the search results.
   Or click **Advanced Search** and use the following filters to search for specific emails:

Filters	Description
Subject	Subject line in the email.
From	Mail sender email address.
To	Mail recipient email address. Use a comma or space separator to enter multiple addresses.
Date Range	Using the calendar, select a specific date range to search the emails.
Email Type	Select one of the email types: • All Emails • Only emails with attachments • Only emails without attachments
cc	The email address in the Cc: line of the email. Use a comma or space separator to enter multiple addresses.
bcc	The email address in the Bcc: line of the email. Use a comma or space separator to enter multiple addresses.
Search in Folder	Search for the email within the specified folder. For example, Inbox, Drafts, and so on. Use a comma or space separator to enter multiple folder names.

6. Select the items that are to be restored.
7. To use a different recovery point, click the **Edit** icon on the tile. Find the recovery point you need and click **Select Recovery Point**.
8. Click **Next: Recover Options**.
9. From the **Recover To** section, select one of the following options based on your requirements:

Recover To options	Description
Original Location	To recover data to the same mailbox from which it was backed up.

Recover To options	Description
New Location	To recover data to a different Microsoft 365 mailbox. Do the following: • Select the required **Registered Source** from the list. Both the Microsoft 365 domains must be registered as sources with the same Cohesity cluster. For more details, see Register and Manage Microsoft 365 Exchange Online Mailboxes • Select the **Target Mailbox** and specify the **Folder name** to which you want to recover the data. If a folder with the specified name does not exist, Cohesity creates the folder and recovers the data to it.
Download as PST	To download the required email as a PST file. To enhance security, you can set a password for the downloaded PST file. Once the recovery task is completed, the exported PST file is valid for 7 days. Ensure that you download the PST within 7 days. For more information, seeRecover Mailbox .
On-prem Exchange Server	To recover data to an on-prem Exchange Server created via API. You can select the required on-prem Exchange Server from the drop-down list. **Note:** This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

10. Select your **Recovery Options**:
    - **Continue on Error**. Enable to recover even if errors occur when recovering Mailboxes. For example, if one of the emails cannot be recovered, Cohesity will still attempt to recover the other selected emails.
    - **Task Name**. Change the default name of the recovery task.
11. Click **Recover**.
    The system creates a separate recovery task as needed. A sequential suffix number is added to each recovery task name. You can monitor and track these recovery tasks individually on the **Recoveries** page.

Recover Calendar Items

With this procedure you can recover specific calendar items from a protected Microsoft 365 mailbox.

To recover specific calendar items:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** on the top-right of the page and then select **Microsoft 365** > **Mailboxes**.
3. On the **New Recovery Microsoft 365 - Mailbox** page, in the **Recovery Type**, select **Search Mailbox Items**.
4. From the **Item Type** drop-down list, select **Calendars**.
5. To search for emails, enter the * wildcard character in the search bar, or enter text with a matching subject to find a specific email, and then select the emails to recover from the search results.
   Or click **Advanced Search** and use the following filters to search for specific emails:

Filters	Description
Subject of Event	Subject line in the calendar invite.
Organizer	The email address of the event organizer.
Invitee	Event recipients' email addresses. Use a comma or space separator to enter multiple addresses.
Invitation Date	Using the calendar, select a specific date range to search the calendar invites.

6. Select the items that are to be restored.
7. To use a different Recovery Point, click the Edit icon on the tile. Find the recovery point you need and click **Select Recovery Point**.
8. Click **Next: Recover Options**.
9. From the **Recover To** section, select one of the following options based on your requirements:

Recover To options	Description
Original Location	To recover data to the same mailbox from which it was backed up.

Recover To options	Description
New Location	To recover data to a different Microsoft 365 mailbox. Do the following: • Select the required **Registered Source** from the list. Both the Microsoft 365 domains must be registered as sources with the same Cohesity cluster. For more details, see Register and Manage Microsoft 365 Exchange Online Mailboxes • Select the **Target Mailbox** and specify the **Folder name** to which you want to recover the data. If a folder with the specified name does not exist, Cohesity creates the folder and recovers the data to it.
Download as PST	To download the required email as a PST file. To enhance security, you can set a password for the downloaded PST file. Once the recovery task is completed, the exported PST file is valid for 7 days. Ensure that you download the PST within 7 days. For more information, seeRecover Mailbox .
On-prem Exchange Server	To recover data to an on-prem Exchange Server created via API. You can select the required on-prem Exchange Server from the drop-down list. **Note:** This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

10. Select your **Recovery Options**:
    - **Continue on Error**. Enable to recover even if errors occur when recovering Mailboxes. For example, if one of the emails cannot be recovered, Cohesitywill still attempt to recover the other selected emails.
    - **Task Name**. Change the default name of the recovery task.
11. Click **Recover**.
    The system creates a separate recovery task as needed. A sequential suffix number is added to each recovery task name. You can monitor and track these recovery tasks individually on the **Recoveries** page.

Recover Contacts

To recover specific contacts:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** on the top-right of the page and then select **Microsoft 365** > **Mailboxes**.

3. On the **New Recovery Microsoft 365 - Mailbox** page, in the **Recovery Type**, select **Search Mailbox Items**.
4. From the **Item Type** drop-down list, select **Contacts**.
5. To search for emails, enter the * wildcard character in the search bar, or enter text with a matching subject to find a specific email, and then select the emails to recover from the search results.
   Or click **Advanced Search** and use the following filters to search for specific emails:

Filters	Description
First Name	The first name of the contact.
Last Name	The last name of the contact.
Email Address	The email address of the contact.

6. Select the items that are to be restored.
7. To use a different Recovery Point, click the Edit icon on the tile. Find the recovery point you need and click **Select Recovery Point**.
8. Click **Next: Recover Options**.
9. From the **Recover To** section, select one of the following options based on your requirements:

Recover To options	Description
Original Location	To recover data to the same mailbox from which it was backed up.

Recover To options	Description
New Location	To recover data to a different Microsoft 365 mailbox. Do the following: • Select the required **Registered Source** from the list. Both the Microsoft 365 domains must be registered as sources with the same Cohesity cluster. For more details, see Register and Manage Microsoft 365 Exchange Online Mailboxes • Select the **Target Mailbox** and specify the **Folder nam**e to which you want to recover the data. If a folder with the specified name does not exist, Cohesity creates the folder and recovers the data to it.
Download as PST	To download the required email as a PST file. To enhance security, you can set a password for the downloaded PST file. Once the recovery task is completed, the exported PST file is valid for 7 days. Ensure that you download the PST within 7 days. For more information, seeRecover Mailbox .
On-prem Exchange Server	To recover data to an on-prem Exchange Server created via API. You can select the required on-prem Exchange Server from the drop-down list. **Note:** This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

10. Select your **Recovery Options**:
    - **Continue on Error**. Enable to recover even if errors occur when recovering Mailboxes. For example, if one of the emails cannot be recovered, Cohesity will still attempt to recover the other selected emails.
    - **Task Name**. Change the default name of the recovery task.
11. Click **Recover**.
    The system creates a separate recovery task as needed. A sequential suffix number is added to each recovery task name. You can monitor and track these recovery tasks individually on the **Recoveries** page.

Recover Notes

To recover specific notes:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** on the top-right of the page and then select **Microsoft 365** > **Mailboxes**.

3. On the **New Recovery Microsoft 365 - Mailbox** page, in the **Recovery Type**, select **Search Mailbox Items**.
4. From the **Item Type** drop-down list, select **Notes**.
5. To search for emails, enter the * wildcard character in the search bar, or enter text with a matching subject to find a specific email, and then select the emails to recover from the search results.
   Or click **Advanced Search** and use the following filters to search for specific emails:

Filters	Description
Subject	The subject of the note.
Creation Date	Using the calendar, select a specific date range to search the notes based on the creation date.
Modification Date	Using the calendar, select a specific date range to search the notes based on the modification date.

6. Select the items that are to be restored.
7. To use a different Recovery Point, click the Edit icon on the tile. Find the recovery point you need and click **Select Recovery Point**.
8. Click **Next: Recover Options**.
9. From the **Recover To** section, select one of the following options based on your requirements:

Recover To options	Description
Original Location	To recover data to the same mailbox from which it was backed up.

Recover To options	Description
New Location	To recover data to a different Microsoft 365 mailbox. Do the following: • Select the required **Registered Source** from the list. Both the Microsoft 365 domains must be registered as sources with the same Cohesity cluster. For more details, see Register and Manage Microsoft 365 Exchange Online Mailboxes • Select the **Target Mailbox** and specify the **Folder nam**e to which you want to recover the data. If a folder with the specified name does not exist, Cohesity creates the folder and recovers the data to it.
Download as PST	To download the required email as a PST file. To enhance security, you can set a password for the downloaded PST file. Once the recovery task is completed, the exported PST file is valid for 7 days. Ensure that you download the PST within 7 days. For more information, seeRecover Mailbox .
On-prem Exchange Server	To recover data to an on-prem Exchange Server created via API. You can select the required on-prem Exchange Server from the drop-down list. **Note:** This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

10. Select your **Recovery Options**:
    - **Continue on Error**. Enable to recover even if errors occur when recovering Mailboxes. For example, if one of the emails cannot be recovered, Cohesity will still attempt to recover the other selected emails.
    - **Task Name**. Change the default name of the recovery task.
11. Click **Recover**.
    The system creates a separate recovery task as needed. A sequential suffix number is added to each recovery task name. You can monitor and track these recovery tasks individually on the **Recoveries** page.

Recover Tasks

To recover specific tasks:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** on the top-right of the page and then select **Microsoft 365** > **Mailboxes**.

3. On the **New Recovery Microsoft 365 - Mailbox** page, in the **Recovery Type**, select **Search Mailbox Items**.
4. From the **Item Type** drop-down list, select **Tasks**.
5. To search for emails, enter the * wildcard character in the search bar, or enter text with a matching subject to find a specific email, and then select the emails to recover from the search results.
   Or click **Advanced Search** and use the following filters to search for specific emails:

Filters	Description
Subject	The subject of the task.
Creation Date	Using the calendar, select a specific date range to search the tasks based on their creation date.
Due Date	Using the calendar, select a specific date range to search the tasks based on their due date.
Status	The status of the task.

6. Select the items that are to be restored.
7. To use a different Recovery Point, click the Edit icon on the tile. Find the recovery point you need and click **Select Recovery Point**.
8. Click **Next: Recover Options**.
9. From the **Recover To** section, select one of the following options based on your requirements:

Recover To options	Description
Original Location	To recover data to the same mailbox from which it was backed up.

Recover To options	Description
New Location	To recover data to a different Microsoft 365 mailbox. Do the following: • Select the required **Registered Source** from the list. Both the Microsoft 365 domains must be registered as sources with the same Cohesity cluster. For more details, see Register and Manage Microsoft 365 Exchange Online Mailboxes • Select the **Target Mailbox** and specify the **Folder nam**e to which you want to recover the data. If a folder with the specified name does not exist, Cohesity creates the folder and recovers the data to it.
Download as PST	To download the required email as a PST file. To enhance security, you can set a password for the downloaded PST file. Once the recovery task is completed, the exported PST file is valid for 7 days. Ensure that you download the PST within 7 days. For more information, seeRecover Mailbox .
On-prem Exchange Server	To recover data to an on-prem Exchange Server created via API. You can select the required on-prem Exchange Server from the drop-down list. **Note:** This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

10. Select your **Recovery Options**:
    - **Continue on Error**. Enable to recover even if errors occur when recovering Mailboxes. For example, if one of the emails cannot be recovered, Cohesity will still attempt to recover the other selected emails.
    - **Task Name**. Change the default name of the recovery task.
11. Click **Recover**.
    The system creates a separate recovery task as needed. A sequential suffix number is added to each recovery task name. You can monitor and track these recovery tasks individually on the **Recoveries** page.

Recover Emails and Folders

To recover emails and folders, you need to search through the backups for the email or folders using the following search filters:

Search Filters	Description
From	Mail sender email address
To	Mail recipient email address
Subject	Subject line for the email
Folder Name	Folder name which needs to be recoverd
Start Date	Time interval
End Date	
Only show Emails with Attachments	Search only the emails with attachments
Only show Folders	Search only the folders
Cc	The user email address that was added as a cc in the email
Bcc	The user email address that was added as bcc in the email
Microsoft 365 Server	From the drop-down list, select the Microsoft 365 server.
Mailbox	From the drop-down list, select the mailboxes from which you want to recover the emails or folders.
Protection Group	From the drop-down list, select the Protection Group.

Once the search yields the desired result, select the mail or folder you plan to recover and start the recover operation.

To recover emails and folders:

1. Navigate to **Protection** > **Recoveries**. Click the plus icon (**+**) on the top-right of the page and then select **Microsoft 365** as the recovery source.
2. On the **New Recovery Microsoft 365 - Mailbox** page, in the **Recovery Type**, select **Emails & Email Folders**.
3. Search the emails or folders using the search filter, click **Search**.
4. Select the mailbox from the results, and click **Continue**.
5. Based on your requirements, select any one of the following options:

Options	Description
Original Location	To recover data to the same mailbox from which it was backed up.
New Location	To recover data to an alternate location in a different Microsoft 365 domain. Select a **Registered Source** and the **Target Mailbox**, and specify the **Folder name** to which you plan to recover. **Note:** • Both the Microsoft 365 domains must be registered as sources with the same Cohesity cluster. For more details, see Register and Manage Microsoft 365 Exchange Online Mailboxes. • If a folder with the specified name does not exist, Cohesity creates the folder and recovers the data to it.
Export as PST	To export the backed-up email(s) or mailbox folder(s) as a PST file, you must provide a password for the exported PST file. **Note:** • Once the recovery task is completed, the exported PST file is valid for 72 hours. Ensure that you download the PST within 72 hours. For more information, see Download the Exported Email or Mailbox Folder PST File. • The PST export process might take a few minutes or hours depending on the size of the mailbox.
On-prem Exchange Server	To recover data to an on-prem Exchange Server created via API. You can select the required on-prem Exchange Server from the drop-down list. **Note:** This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

6. Select your Recovery Options:
   i. **Continue on Error.** Enable to complete the recovery task even if errors occur when recovering Mailboxes.
   ii. **Task Name.** Change the default name of the recovery task.

iii. **Selective Recovery.** Toggle ON the **Recover within specified timeframe** option to filter the Mailbox items to be recovered.

Under **Include items in recovery**, select the required items:

- Mails
- Calendars
- Contacts, Tasks, and Notes.

You can also **recover data of the last specific days prior to the selected snapshot**.

> **Note:**
> - All upcoming calendar events will be recovered.
> - Any calendar events that were scheduled or received in the selected time frame will be recovered.
> - Contacts, Tasks, and Notes will be fully recovered unaffected by the days selected.

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

7. Click **Start Recovery** to start the recover operation.

Download the Exported Mailbox PST File

After the recovery task is completed, within 72 hours you can download the exported PST file of the mailbox that you choose to recover.

To download the PST file:

1. Navigate to **Protection** > **Recoveries**.
2. Locate and click on the recovery task from which you want to download the exported PST file.
3. Click **Download Files**.

The PST file is downloaded to your local system.

> **Note:** If the PST file is protected with a password, you must contact the admin user and obtain the password to open the downloaded PST file.

Download the Exported Email or Mailbox Folder PST File

After the recovery task is completed, within 72 hours you can download the exported PST file of the email(s) that you choose to recover.

To download the PST file:

1. Navigate to **Data Protection > Recoveries**.
2. Locate and click on the recovery task from which you want to download the exported PST file.
3. Click **Download Files**.

The PST file is downloaded to your local system.

Download Private Chats

To download the Private Chats of a user:

1. Navigate to **Sources**.
2. Click on the required **Source** and click the **Mailbox** tab.
3. Select **Show All** > **Protected** and use the other filters, search box, and views at the top to narrow your search.
4. Click the **Actions** menu next to the object and click **Download Private Chats**.
5. In the **Download Private Chats** page, select the required snapshot, provide the task name, and click **Recover**.

   > **Note:** Attachments in the Private Chats will not be downloaded.

6. Click the View Progress button in the pop-up message or click the **Activity** menu.
7. Once the recovery is successful, click Download. The Private Chats will be downloaded.

> **Note:** This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

Archive Mailbox Data

Cohesity enables you to archive the Exchange Online Mailboxes data to a designated external target, such as tape or cloud storage. For more details about external targets, see Manage External Targets.

It provides a policy-based archival solution for Exchange Online Mailboxes data. In the Protection Policy, you can define the archive schedule, select the external target, and specify the retention period of the data on the external target.

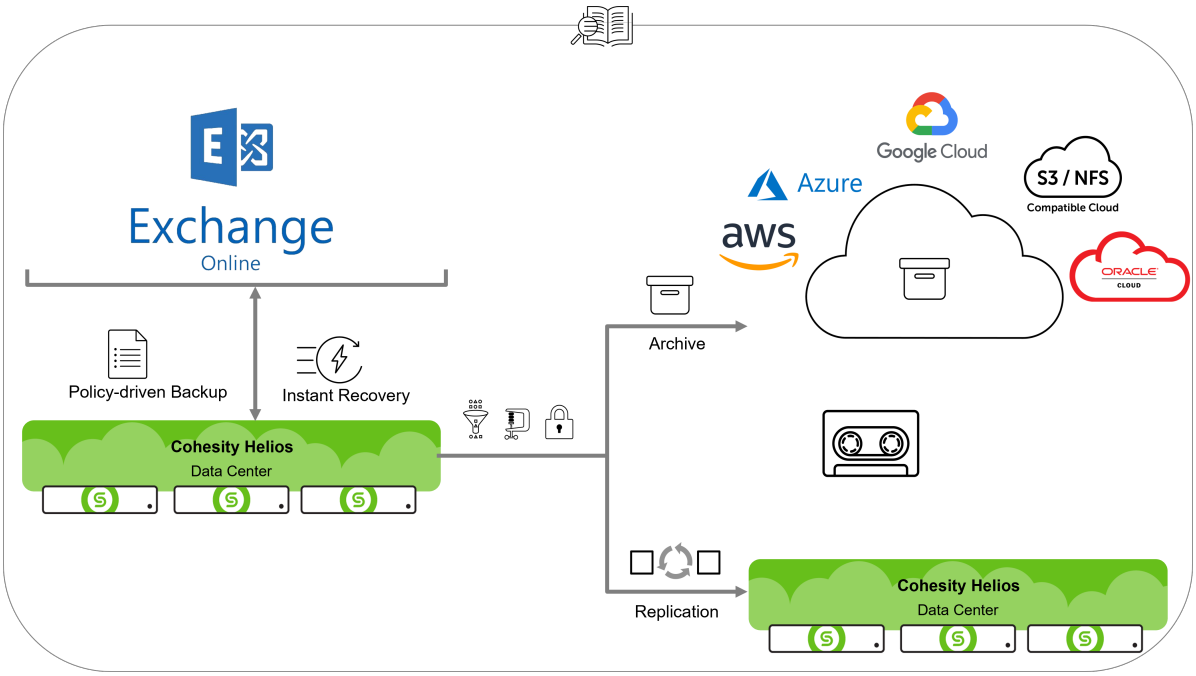
> **Note:** CloudRetrieve is not supported.

To archive Exchange Online Mailboxes data:

1. Register an external target. For more details, see Register an External Target.
2. Edit the existing Protection Policy that you had created for backup or if you are creating a new Protection Policy for backup. Configure the Archival settings as per your requirement. For more information, see **Step 18** in Create or Edit a Standard Policy.
3. Run the Protection Group that you have created for Exchange Online Mailboxes based on your requirement or the Archival settings will take effect in the next scheduled Protection Group run.

Exchange Online Public Folders

Cohesity enables data protection of Microsoft Exchange Online. Cohesity provides a policy-based data protection solution for protecting Microsoft Exchange Online Public Folders on Microsoft 365.



Plan and Prepare for Public Folders Protection

Before you register your Microsoft 365 domain with Cohesity to protect Microsoft 365 data, ensure:

- You have completed all the prerequisites.
- You have reviewed and understood the considerations and best practices.
- An Exchange Online license with a mailbox provisioned.
- A default Public folder mailbox configured (preferably Primary).

Considerations

Review and understand the following considerations before you protect your Exchange Online public folder data:

- For public folder backups, if you move a subfolder from one root folder to another root folder, a full backup of the subfolder will be performed in the next run.
- Exclusion list is not supported for Public Folders Protection Group.
- Suppose a newly added folder at any location in the folder hierarchy does not have the required permissions mentioned in Plan and Prepare for Public Folders Protection. The folder, including its subfolders, is not discoverable and hence will not be backed up by Cohesity.
- Microsoft does not support OAuth for Public Folders and backups will fail if you have enabled OAuth for Exchange Online backup.
- Restoring the public folder or content of the public folder from the backup to an alternate location in a different Microsoft 365 domain is not supported.
- Public Folders are not supported in Government Community Cloud (GCC) High.
- Microsoft 365 items with only special characters will not be listed in granular search. The item name must contain at least one alphanumeric character to be listed in the search result.

Best Practices

To protect your Microsoft 365 data, Cohesity recommends the following best practices:

- Set **Retry Options** to **1**, as the Microsoft 365 connector already has the retry mechanism handling failed requests. There is no need to increase the value for this setting in the Cohesity Protection Policy.
- Use **Auto-Protect** to avoid adding new users to the Protection Group manually.
- Avoid adding the same users in multiple Protection Groups.

For the workflows supported by Public Folders, see Microsoft 365 Workflows.

Register and Manage Microsoft 365 Exchange Online Public Folders

To start protecting Microsoft 365 applications, you need to register the Microsoft 365 domain as a source in Cohesity.

Cohesity uses the Microsoft Graph API for object discovery, backup, and recovery in Microsoft 365. Cohesity uses an Azure application created and registered on the Azure

portal with the necessary permissions to use the Graph API. You can either let Cohesity create the Azure application or Manual Registration for Microsoft 365 Sources details while registering your Microsoft 365 domain as a source in Cohesity.

Express Registration for Microsoft 365 Sources

Before you register Office 365 as a source on Cohesity, ensure that you:

- Review the requirements, considerations, and best practices.
- Perform the prerequisite tasks.

For more information, see Plan and Prepare for Public Folders Protection.

To register your Microsoft 365 domain:

1. Navigate to **Sources** and select **Register** > **Microsoft 365**.
2. Choose **Public Folders** as the **Microsoft 365 Applications** to discover.
3. In the **Account Credentials** section, enter the Microsoft 365 **Username** and **Password**.

   > **Note:** Toggle ***on*** the **Enable OAuth** option. Ensure that you added the required permission, for more information, see Plan and Prepare for Public Folders Protection.

4. Adding multiple Microsoft 365 service accounts using the **Additional Service Accounts** section requires OAuth disabled, as Microsoft has enabled OAuth by default, ignore adding multiple Microsoft 365 service accounts.
5. In the **Azure Applications** section, enter the number of Azure applications you want to create based on your requirements and click **Create**.

   > **Note:** By default, two Azure applications will be created. To better manage Microsoft 365 throttling, Cohesity recommends at least two Azure apps.

6. In the **Add Azure Application** form, copy the device code and click the **Microsoft Azure App** link to open the Microsoft Azure App authorization service in a new tab.

   > **Note:** If you prefer to create your Azure apps manually, see Manual Registration for Microsoft 365 Sources.

7. Paste the copied code in the **Microsoft Azure App authorization** service and click **Next**.

8. Log in to Microsoft Azure, enter the **Username** and **Password** of your Microsoft 365 account and click **Sign in**.

   > **Note:** Ensure that your Microsoft 365 account has a global administrator access.

9. Follow the instructions to complete the authorization on the Microsoft Azure portal. Then, wait for Microsoft Azure Authorization to complete.
10. Optional. Toggle on **Use Windows Connector** and specify the hostname (FQDN) or server IP of the Windows Connector. The **Use Windows Connector** option is applicable only if you want to protect SharePoint Online data or to export and download mailboxes or email(s) in PST format. For more information, see Set Up a Windows Connector for Microsoft 365.
11. Click **Register**.

Manual Registration for Microsoft 365 Sources

Before you register Office 365 as a source on Cohesity, ensure that you:

- Review the requirements, considerations, and best practices.
- Perform the prerequisite tasks.

For more information, see Plan and Prepare for Public Folders Protection.

To register your Microsoft 365 domain:

1. Navigate to **Sources** and select **Register** > **Microsoft 365**.
2. Choose **Public Folders** as the **Microsoft 365 Applications** to discover.
3. In the **Account Credentials** section, enter the Microsoft 365 **Username** and **Password**.

   > **Note:** Toggle ***on*** the **Enable OAuth** option. Ensure that you added the required permission, for more information, see Plan and Prepare for Public Folders Protection.

4. Adding multiple Microsoft 365 service accounts using the **Additional Service Accounts** section requires OAuth disabled, as Microsoft has enabled OAuth by default, ignore adding multiple Microsoft 365 service accounts.
5. In the **Azure Applications** section, enter the number of Azure applications you want to create based on your requirements and click **Create**.

> **Note:** By default, two Azure applications will be created. To better manage Microsoft 365 throttling, Cohesity recommends at least two Azure apps.

6. In the **Add Azure Application** form, click the **You can also add Azure App manually** link.
   - For **Certificate** authentication, the **App ID** and the **Associated Certificate** of your custom Azure app will be populated. You can select the **Associated Certificate** from the list of certificates present in your certificate store or Create Cohesity Managed Certificate.

     > **Note:** This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

   - For **App Secret** authentication, the **App ID** and **App Secret Key** of your custom Azure app will be populated.

   > **Note:** You can add multiple Azure apps for a Microsoft 365 source to load balance your backup and restore operations. Click **+** to add multiple Azure apps. When you do, ensure that you provide the valid **App ID** and **App Secret Key**.

   To migrate the existing apps from App Secret to Certificate authentication method, see Migrate Existing Apps to Certificate-Based Authentication.
7. Optional. Toggle on **Use Windows Connector** and specify the hostname (FQDN) or server IP of the Windows Connector. The **Use Windows Connector** option is applicable only if you want to protect SharePoint Online data or to export and download mailboxes or email(s) in PST format. For more information, see Set Up a Windows Connector for Microsoft 365.
8. Click **Register**.

Manage Microsoft 365 Source Registration

After registering your Microsoft 365 domain as a source, you can:

- Update the Microsoft 365 source configuration.
- Refresh the source details.
- Unregister the Microsoft 365 domain from Cohesity.

Update the Microsoft 365 Source Configuration

After registering your Microsoft 365 source on Cohesity, you might have changed the Microsoft 365 domain configuration by:

- Changing the credentials of Microsoft 365 user account credentials.
- Updating the app secret by adding more permissions to the custom app.
- Creating a new app ID.

You can update the Microsoft 365 details provided during the registration process with the latest Microsoft 365 configuration details.

To edit the Microsoft 365 source configuration:.

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Microsoft 365 source and select **Edit**.
3. On the **Update Microsoft 365 Source** page, update the required configurations.
4. Click **Register**.

Refresh the Microsoft 365 Source

You can refresh the Microsoft 365 domain configuration and fetch the latest changes on the Microsoft 365 domain.

To refresh the Microsoft 365 Source Configuration:

1. Navigate to **Data Protection** > **Sources**.
2. Click the actions menu (⋮) next to the Microsoft 365 source and select **Refresh**.

Unregister the Microsoft 365 Domain

If you plan to stop taking the backup of your Microsoft 365 domain, you can unregister the Microsoft 365 source from Cohesity.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the Microsoft 365 source.

To unregister the Microsoft 365 domain:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Microsoft 365 source and select **Unregister**.

Backup Exchange Online Public Folders

Exchange Online pubic folders are protected using a Protection Group and a Protection Policy. A Protection Group enables you to select and group the objects that you want to back up. It uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured and replicated.

A Protection Policy is a group of settings that define the type of backup, backup schedule, and backup snapshot retention. Also, for Disaster Recovery, you can add replication for the

Protection Group using the Protection Policy. You can select which standard or custom policy to use when creating a Protection Group. For more information, see Manage Protection Policy.

To protect Exchange Online public folders:

1. Do one of the following:
   - On the **Dashboards** page, from the drop-down at the top of the page, select **Data Protection** and do one of the following:
     - If there is no existing Protection Group, click **Start Data Protection** > **Microsoft 365** > **Public Folder**.
     - Click **Protect** > **Microsoft 365** > **Public Folder**.
   - Select **Data Protection > Protection**. Click **Protect** on the top-right of the page and then select **Microsoft 365** > **Public Folder**.
   - Select **Data Protection > Sources**. Click the actions menu (⋮) next to the Microsoft 365 source and then select **Protect Public Folders**.
2. In the **New Protection** pop-up, do one of the following:
   - Protect the public folder by specifying a subset of options such as objects, protection group and policy by clicking the edit icon corresponding to the following options:
     i. **Add Objects**: Select the registered Microsoft 365 source or click **Register Source** to register a Microsoft 365 account. In the **Public Folders** section, select the public folder(s) from the Root Public Folder List that you plan to back up.
     ii. **Protection Group**: Specify a name for the Protection Group.
     iii. **Policy**: Select an existing policy or click **Create Policy** to create a new protection policy.
     iv. **Storage Domain**: Select the appropriate storage domain.

     > **Note:** This option is visible on the **New Protection** pop-up only if there is more than one storage domain.

     v. Click **Protect**.
   - To protect the public folder by specifying all the options, click **More Options**.
3. From the **Source** drop-down list, select the registered Microsoft 365 source or click **Register Source** to register a Microsoft 365 source. For more information, see Register and Manage Microsoft 365 Exchange Online Public Folders.

4. In the **Public Folders** section, under **Objects**, select the public folder(s) from the **Root Public Folder List** that you plan to backup and click **Save Selection**.

   > **Note:** You can use the advanced filters that are available to find the public folders or search for the public folder using the folder name. Also, you can click the shield icon to enable Auto Protect. For more information on Auto Protect, see Enable or Disable Auto Protect.

5. In the **Protection Group** section, do one of the following:
   - Select **New Group** to create a new Protection Group. In the **Protection Name** field, enter a name from the Protection Group.
   - Select **Existing Group** to use the settings of an existing Protection Group. From the **Group** list, select an existing Protection Group and click **Protect**.
6. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, Create or Use an Existing Protection Policy.
7. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains.
8. After selecting a Storage Domain, if you need to change any of the advanced settings on the **New Office365 Protection Group** page, scroll down and click **Edit** on the right. For more information, see Advanced Settings.
9. Click **Protect**.

   Your Exchange Online Data Protection is now active and running.

Advanced Settings

Advance Settings	Description
Start Time	Available only if the selected policy is set to Backup Daily. Indicates when the protection run should start. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
End Time	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts prior to this date runs until completion even if it completes after this date.

Advance Settings	Description
QoS Policy	Select an appropriate quality of service (QoS) policy. **Note:** Cohesity recommends specifying **Backup HDD**, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy.
Exclusion List	Select the folders that you plan to exclude from the backup or click **Add** to add custom folders that you want to exclude from the backup. **Note:** Exclusion list is not supported for Public Folders.
Indexing	By default, indexing is enabled. **Note:** Indexing is mandatory for granular restore of an Exchange Online mailbox , such as restoring a folder or restoring an email. For more information, see Recover Mailbox .
Alerts and Priority	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts.

Advance Settings	Description
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs
Email Recipients	You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection run.
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks). **Note:** Users with similar SLAs can be grouped together and a custom policy and Protection Group can be created to achieve different SLAs.
Description	**Optional**. Enter a brief description about the Protection Group.

Create or Use an Existing Protection Policy

Create a Protection Policy with the settings listed in the Policy Settings for Exchange Online. For detailed instructions on how to create a Protection Policy, see Create or Edit a Standard Policy.

Policy Settings for Exchange Online

The following table lists the applicable policy settings for Exchange Online:

Field	Description
DataLock	Add a DataLock for compliance and regulatory requirement. This ensures that your protected data, including local backups, archives, and replication, cannot be modified until the DataLock expiration. Once applied, a DataLocked Snapshot will be deleted only after its retention period expires. A DataLock prevents all users from modifying or deleting any Snapshots that were generated by the protection runs that use this Policy. The users include those who have the Data Security role in Cohesity as well. > **Note:** Only users with the Data Security role can add, modify, or remove a DataLock from a Policy.
Scheduled Backup	Defines when backups are captured, how long they are retained, and the type of backup to capture.
Extended Retention	Add this to retain a subset of snapshots (backups) for longer duration than defined by the protection schedule.
Retry Options	Use this option to customize the retry settings for capturing Snapshots. By default, Cohesity attempts to capture Snapshots three times before the protection run fails. The default time between retries is thirty minutes. You can customize the number of retries and how long to wait between each attempt. > **Note:** Set **Retry Options** to **1**, as the Microsoft 365 connector already has the retry mechanism handling the failed requests. There is no need to increase the value for this setting in the Protection Policy.
Quiet Times	Quiet Times define time periods when new protection runs are not started. For example, you might want to configure hourly backups that run during weekdays but not on Saturdays or Sundays. Quiet Times only prevent new protection runs from starting during the specified time period. The protection runs that started before the quiet time period are not affected and will continue to run. For example, if a protection run starts at 12:45 AM on Saturday morning and there is a weekend quiet time period that starts at 1 AM on Saturday morning, the protection run will continue to run past 1 AM. No new protection runs are started during the quiet time period.
Replication	Replicate snapshots to another Cohesity cluster.

Use an Existing Protection Policy

You can edit an existing Protection Policy and configure it with applicable policy settings for Exchange Online. In this case, all the policy settings apart from the settings applicable to Exchange Online are ignored.

To use an existing Protection Policy:

1. Navigate to **Data Protection > Policies**.
2. On the **Policies** page, select the policy that you plan to edit.
3. On the **Policy Details** page, click **Edit** and configure the applicable policy settings for Exchange Online. For information on the applicable policy settings, see Policy Settings for Exchange Online.
4. Click **Save**.

The updated policy settings are applied to the Protection Group in the next protection run.

Manage Public Folder Backup Configuration

A backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

> **Note:** You cannot update the registered Microsoft 365 domain and the assigned Storage Domain in the Protection Group settings.

Add Public Folders to the Protection Group

You can add new public folders to the existing Protection Group for backup. The newly added public folder is backed up from the next protection run and it will be a full backup for the newly added public folder.

To add public folders to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Exchange Online.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ in the **Public Folders** section.
5. In the **Objects** section, select the public folders that you want to add to the backup and click **Save Selection**.
6. Click **Save**.

Remove Public Folders From the Protection Group

You can remove public folder(s) from the Protection Group that you do not want to backup in the next protection run. When you remove a public folder from the protection group, incremental backup of the contents in the public folder is not performed from the next protection run. The existing backup for the public folder is preserved until the snapshot expires.

To remove public folders from the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Exchange Online.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ in the **Public Folders** section.
5. In the **Objects** section, select the public folders that you want to remove from the backup and click **Save Selection**.
6. Click **Save**.

Enable or Disable Auto Protect

The Auto Protect option enables you to automatically protect the new public folder(s) that are added to Microsoft 365.

When the Auto Protect option is enabled:

- All the public folders that are added to Microsoft 365 in the future are automatically added to the Protection Group and are protected from the next protection run.
- All the public folders that are removed from Microsoft 365 in the future are automatically removed from the Protection Group and are not protected from the next protection run. The existing backups for the public folder are preserved until the snapshot expires.

When the Auto Protect option is disabled, you need to manually:

- Add newly onboarded public folder on Microsoft 365 to the Protection Group.
- Remove existing public folders that are offboarded on Microsoft 365 from the Protection Group. The existing backups of the public folders are preserved until the snapshot expires.

To enable or disable Auto Protect:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Exchange Online.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, click ✎ in the **Public Folders** section.
5. In the **Objects** section, click the icon to enable or disable Auto Protect and click **Save Selection**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group in the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Exchange Online.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Protect**.

Start an On-demand Protection Run

You can manually start a protection run of the Protection Group that you have created to back up Exchange Online. It provides you with options to:

- Back up all the objects or only selected objects in the Protection Group.
- Select an incremental or full backup.
- Add replication.

To start a protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Exchange Online.
3. Click the actions menu (⋮) next to the Protection Group and select **Run Now**.
4. In the pop-up window, perform the following:
    1. In the **Backup** drop-down list, select any one of the following:
        - Backup all Objects in the Protection Group
        - Backup only selected Objects in the Protection Group
    2. In the **Backup Type** drop-down list, select the backup type.
    3. Optional. In the **Replicate** section, select the replication target and the retention duration or click **Add** to add the replication target and the retention duration.
5. Click **Backup Now**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Exchange Online.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups, local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group, the reclaimed storage space details will not be displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Exchange Online.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
   - **Delete Protection Group Only**
   - **Delete Protection Group and Snapshots**

Recover Public Folders

You can restore Exchange Online public folders data using Cohesity at various granularities, such as at the public folder and folder contents level. You can restore to the same location or to an alternate location.

Restore Public Folders

To restore public folders, you can search for the public folder(s) through the backups by the public folder name or substring in the name of the public folder.

> **Note:** You can use the * character to list all the public folders.

To restore public folder(s):

1. Navigate to **Data Protection > Recoveries**. Click **Recover** on the top-right of the page and then select **Microsoft 365** > **Public Folder** as the recovery source.
2. In the **Recovery Type** section, select **Entire Public Folders**.
3. Search the public folder(s) using the partial name of the root public folder or use * character to list all the public folders. Also, you use the available advanced filters to narrow down on the public folder(s) that you plan to recover. Select the public folder (s) you need, and click **Next:Recover Options**.
4. In the **Recover To** section, based on your requirements, select any one of the following options:

Options	Description
Original Location	To restore the public folder to the same location from which it was backed up.

Options	Description
New Location	**Alternate location in the same Microsoft 365 domain**: Choose the **Root Public Folder** to which data needs to be restored and also define the **Path** in the public folder where you plan to restore the data.

5. In the **Recovery Options** section, perform the following:
    1. Toggle on **Continue on Error** to continue the recovery process even if errors occur while recovering the public folder(s).
    2. In the **Task Name** field, enter a name for the recovery task.
6. Click **Start Recovery** to start the restore operation.

Restore Public Folder Contents

To restore the contents of a public folder, you need to search for the contents of the public folder through the backups using the following item types and search filters:

Item Type	Search Criteria
Event	Subject
Contacts	Display Name
Emails & Posts	Subject
Subfolders	Folder Name
Tasks	Subject
Journals	Subject
Notes	Subject

Once the search yields the desired result, select the mail or folder you plan to restore and start the restore operation.

To restore emails and folders:

1. Navigate to **Data Protection > Recoveries**. Click **Recover** on the top-right of the page and then select **Microsoft 365** > **Public Folder** as the recovery source.
2. In the **Recovery Type** section, select **Folder Contents**.
3. Search for the public folder contents using **Item Type** and search filters. Also, you use the available advanced filters to narrow down on the public folder content from

the search results. Select the public folder content that you need, and click **Next:Recover Options**.

> **Note:** You cannot select the items across Protection Group, Storage Domain and Office365 domain.

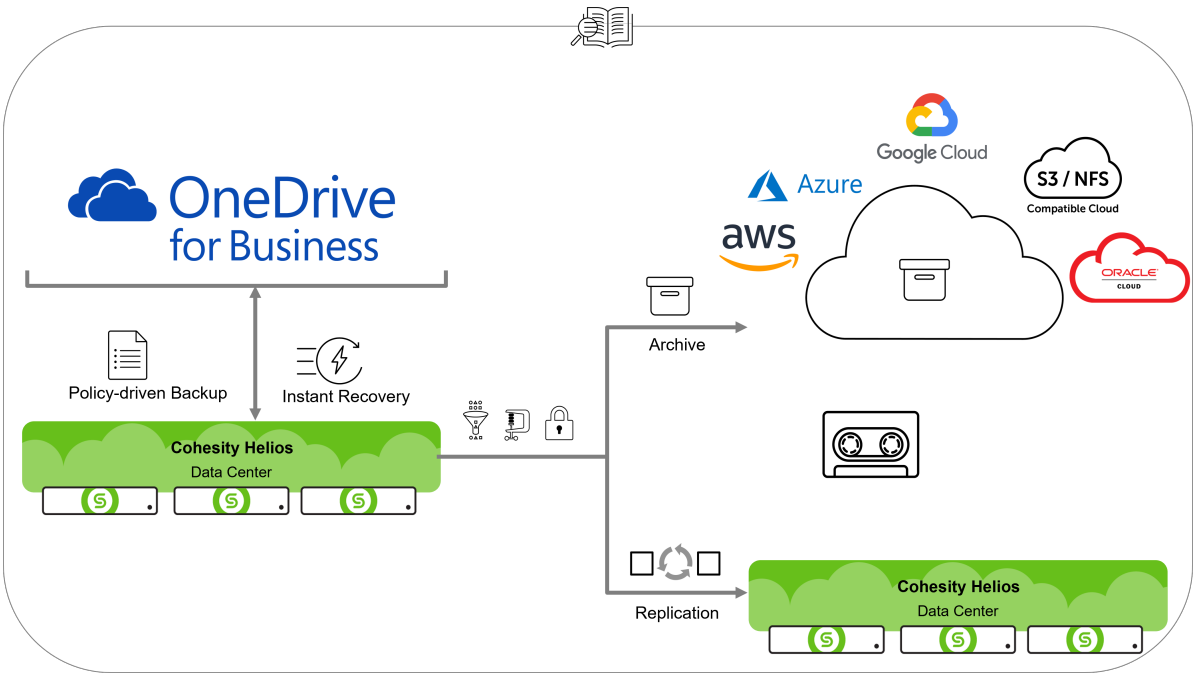
4. In the **Recover To** section, based on your requirements, select any one of the following options:

Options	Description
Original Location	To restore the public folder content to the same location from which it was backed up.
New Location	**Alternate location in the same Microsoft 365 domain**: Choose the **Root Public Folder** to which data needs to be restored and also define the **Path** in the public folder where you plan to restore the public folder content.

5. In the **Recovery Options** section, perform the following:
    1. Toggle on **Continue on Error** to continue the recovery process even if errors occur while recovering the public folder(s).
    2. In the **Task Name** field, enter a name for the recovery task.
6. Click **Start Recovery** to start the restore operation.

OneDrive for Business

OneDrive for Business is a SaaS application that is bundled in your Microsoft 365 subscription service. It is an intelligent files app for Microsoft 365 connecting you to all your files so you can share and work together from anywhere while protecting your work. It enables you to easily store, access, and discover your individual and shared work files in Microsoft 365. Using the policy-based data protection solution from Cohesity, you can protect OneDrive for Business data on Microsoft 365.



Plan and Prepare for OneDrive Protection

Before you register your Microsoft 365 domain with Cohesity to protect Microsoft data, ensure:

- You have completed all the prerequisites.
- You have reviewed and understood the considerations and best practices.

Considerations

- Backup and restore of OneNote files in the OneDrive are not supported.
- Backup and recovery of the Recycle Bin in OneDrive is not supported.
- Backup of the mailbox and the OneDrive for an individual user happens sequentially. However, backup of mailboxes and OneDrive belonging to different users may happen in parallel.
- The backup or recovery of Mailboxes, OneDrives, SharePoint Online Sites, and MS Teams are executed in parallel as long as there are enough resources on the Cohesity cluster. However, the backup or recovery operations are serialized for the Mailboxes and OneDrives that belong to the same user, and the operations execute in the first-in-first-out order.

  For example, if the backup of a user's mailbox is in progress, then the backup of the user's OneDrive starts only after the backup of the mailbox completes.
- The user list containing users with protected mailboxes shows as protected when creating a Protection Group for OneDrive and vice-versa.

- OneDrive protection is supported only for users present on Azure AD or Hybrid setup with users present on Azure AD and not for users on the on-premises Active Directory.
- File/folder permissions with no role will not be recovered since Microsoft does not allow adding such permissions via Graph APIs. For example, no role will be assigned when a Restricted View permission is added to a user from Advanced Setting.
- OneDrive does not support item permissions from applications and devices.
- Microsoft 365 items with only special characters will not be listed in granular search. The item name must contain at least one alphanumeric character to be listed in the search result.
- Permissions are recovered only at file level and not folder level.
- If more than 50 thousand files are present, the permissions are recovered only for 50 thousand files (there is no option to identify these files in advance).
- Sharing links permissions are not recovered.
- Cohesity supports protecting 100k Microsoft 365 objects. This includes the following:
  - Objects on individual applications, for example, 100k Teams.
  - Objects on combined applications, for example, 50k Teams, 30k Mailboxes, and 20k Groups.

  Validations will be displayed when backing up more than 7500 objects and recovering more than 5000 objects.

  > **Note:** This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

Preservation Hold Library

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

- Recovering shared permissions for files in the Preservation Hold Library (PHL) drive is not supported.
- PHL data can only be recovered using full OneDrive recovery. Granular level recovery is not supported for the PHL data.
- Data from PHL is not searchable.

Best Practices

To protect your OneDrive for Business data, Cohesity recommends the following best practices:

- Set **Retry Options** to **1**, as the Microsoft 365 connector already has the retry mechanism handling failed requests. There is no need to increase the value for this setting in the Cohesity Protection Policy.
- Use **Auto Protect** to avoid adding new users to the Protection Group manually.
- Avoid adding the same users in multiple Protection Groups.

For the workflows supported by OneDrive, see Microsoft 365 Workflows.

Register and Manage Microsoft 365 OneDrive

To start protecting Microsoft 365 applications, you need to register the Microsoft 365 domain as a source in Cohesity.

Cohesity uses the Microsoft Graph API for object discovery, backup, and recovery in Microsoft 365. Cohesity uses an Azure application that is created and registered on the Azure portal with the necessary permissions to use the Graph API. You can either let Cohesity create the Azure application or manually enter Azure application details while registering your Microsoft 365 domain as a source in Cohesity.

Express Registration for Microsoft 365 Sources

Before you register Office 365 as a source on Cohesity, ensure that you:

- Review the requirements, considerations, and best practices.
- Perform the prerequisite tasks.

For more information, see Plan and Prepare for OneDrive Protection.

To register your Microsoft 365 domain:

1. Navigate to **Sources** and select **Register** > **Microsoft 365**.
2. Choose **OneDrive** as the **Microsoft 365 Applications** to discover.
3. In the **Account Credentials** section, enter the Microsoft 365 **Username** and **Password**.

   > **Note:** Toggle ***on*** the **Enable OAuth** option. Ensure that you added the required permission, for more information, see Plan and Prepare for OneDrive Protection.

4. Adding multiple Microsoft 365 service accounts using the **Additional Service Accounts** section requires OAuth disabled, as Microsoft has enabled OAuth by default, ignore adding multiple Microsoft 365 service accounts.
5. In the **Azure Applications** section, enter the number of Azure applications you want to create based on your requirements and click **Create**.

> **Note:** By default, two Azure applications will be created. To better manage Microsoft 365 throttling, Cohesity recommends at least two Azure apps.

6. In the **Add Azure Application** form, copy the device code and click the **Microsoft Azure App** link to open the Microsoft Azure App authorization service in a new tab.

> **Note:** If you prefer to create your Azure apps manually, see Manual Registration for Microsoft 365 Sources.

7. Paste the copied code in the **Microsoft Azure App authorization** service and click **Next**.
8. Log in to Microsoft Azure, enter the **Username** and **Password** of your Microsoft 365 account and click **Sign in**.

> **Note:** Ensure that your Microsoft 365 account has a global administrator access.

9. Follow the instructions to complete the authorization on the Microsoft Azure portal. Then, wait for Microsoft Azure Authorization to complete.
10. Optional. Toggle on **Use Windows Connector** and specify the hostname (FQDN) or server IP of the Windows Connector. The **Use Windows Connector** option is applicable only if you want to protect SharePoint Online data or to export and download mailboxes or email(s) in PST format. For more information, see Set Up a Windows Connector for Microsoft 365.
11. Click **Register**.

Manual Registration for Microsoft 365 Sources

Before you register Office 365 as a source on Cohesity, ensure that you:

- Review the requirements, considerations, and best practices.
- Perform the prerequisite tasks.

For more information, see Plan and Prepare for OneDrive Protection.

To register your Microsoft 365 domain:

1. Navigate to **Sources** and select **Register** > **Microsoft 365**.
2. Choose **OneDrive** as the **Microsoft 365 Applications** to discover.
3. In the **Account Credentials** section, enter the Microsoft 365 **Username** and **Password**.

> **Note:** Toggle ***on*** the **Enable OAuth** option. Ensure that you added the required permission, for more information, see Plan and Prepare for OneDrive Protection.

4. Adding multiple Microsoft 365 service accounts using the **Additional Service Accounts** section requires OAuth disabled, as Microsoft has enabled OAuth by default, ignore adding multiple Microsoft 365 service accounts.
5. In the **Azure Applications** section, enter the number of Azure applications you want to create based on your requirements and click **Create**.

   > **Note:** By default, two Azure applications will be created. To better manage Microsoft 365 throttling, Cohesity recommends at least two Azure apps.

6. In the **Add Azure Application** form, click the **You can also add Azure App manually** link.
   - For **Certificate** authentication, the **App ID** and the **Associated Certificate** of your custom Azure app will be populated. You can select the **Associated Certificate** from the list of certificates present in your certificate store or Create Cohesity Managed Certificate.

     > **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

   - For **App Secret** authentication, the **App ID** and **App Secret Key** of your custom Azure app will be populated.

   > **Note:** You can add multiple Azure apps for a Microsoft 365 source to load balance your backup and restore operations. Click **+** to add multiple Azure apps. When you do, ensure that you provide the valid **App ID** and **App Secret Key**.

   To migrate the existing apps from App Secret to Certificate authentication method, see Migrate Existing Apps to Certificate-Based Authentication.
7. Optional. Toggle on **Use Windows Connector** and specify the hostname (FQDN) or server IP of the Windows Connector. The **Use Windows Connector** option is applicable only if you want to protect SharePoint Online data or to export and download mailboxes or email(s) in PST format. For more information, see Set Up a Windows Connector for Microsoft 365.

8. Click **Register**.

Manage Microsoft 365 Source Registration

After registering your Microsoft 365 domain as a source, you can:

- Update the Microsoft 365 source configuration.
- Refresh the source details.
- Unregister the Microsoft 365 domain from Cohesity.

Update the Microsoft 365 Source Configuration

After registering your Microsoft 365 source on Cohesity, you might have changed the Microsoft 365 domain configuration by:

- Changing the credentials of Microsoft 365 user account credentials.
- Updating the app secret by adding more permissions to the custom app.
- Creating a new app ID.

You can update the Microsoft 365 details provided during the registration process with the latest Microsoft 365 configuration details.

To edit the Microsoft 365 source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Microsoft 365 source and select **Edit**.
3. On the **Update Microsoft 365 Source** page, update the required configurations.
4. Click **Register**.

Refresh the Microsoft 365 Source

You can refresh the Microsoft 365 domain configuration and fetch the latest changes on the Microsoft 365 domain.

To refresh the Microsoft 365 Source Configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Microsoft 365 source and select **Refresh**.

Unregister the Microsoft 365 Domain

If you plan to stop taking the backup of your Microsoft 365 domain, you can unregister the Microsoft 365 source from Cohesity.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the Microsoft 365 source.

To unregister the Microsoft 365 domain:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Microsoft 365 source and select **Unregister**.

Backup OneDrive for Business

OneDrive for Business is protected using a Protection Group and a Protection Policy. A Protection Group enables you to select and group the objects that you want to back up. It uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured and replicated.

A Protection Policy is a group of settings that define the type of backup, backup schedule and backup snapshot retention. Also, for Disaster Recovery, you can add replication for the Protection Group using the Protection Policy. You can select which standard or custom policy to use when creating a Protection Group. For more details, see Manage Protection Policy.

To protect OneDrive for Business:

1. Do one of the following:
   - On the **Dashboards page**, from the drop-down at the top of the page, select **Data Protection** and do one of the following:
     - If there is no existing Protection Group, click **Start Data Protection** > **Microsoft 365** > **OneDrive**.
     - Click **Protect** > **Microsoft 365** > **OneDrive**.
   - Select **Data Protection > Protection**. Click **Protect** on the top-right of the page and then select **Microsoft 365** > **OneDrive**.
   - Select **Data Protection > Sources**. Click the actions menu (⋮) next to the Microsoft 365 source and then select **Protect OneDrive**.
2. In the **New Protection** pop-up, do one of the following:
   - Protect OneDrive by specifying a subset of options such as objects, protection group and policy by clicking the edit icon corresponding to the following options:
     i. **Add Objects**: Select the registered Microsoft 365 source or click **Register Source** to register a Microsoft 365 account. From the **Users** list, select the users you plan to back up.
     ii. **Protection Group**: Specify a name for the Protection Group.
     iii. **Policy:** Select an existing policy or click **Create Policy** to create a new protection policy.
     iv. **Storage Domain**: Select the appropriate storage domain.

> **Note:** This option is visible on the **New Protection** pop-up only if there is more than one storage domain.

v. Click **Protect**.

- To protect OneDrive by specifying all the options, click **More Options**.

3. From the **Source** drop-down list, select the registered Microsoft 365 source or click **Register Source** to register a Microsoft 365 source. For more information, see Register and Manage Microsoft 365 OneDrive.
4. From the **Users** list, select the users that you plan to backup and click **Save Selection**.

> **Note:** You can use the advanced filters that are available to search and find users based on user attributes. Also, you can click the shield icon to enable Auto Protect. For more information on Auto Protect, see Enable or Disable Auto Protect.

5. In the **Protection Group** section, do one of the following:
   - Select **New Group** to create a new Protection Group. In the **Protection Name** field, enter a name from the Protection Group.
   - Select **Existing Group** to use the settings of an existing Protection Group. From the **Group** list, select an existing Protection Group and click **Protect**.
6. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, see Create or Use an Existing Protection Policy.
7. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains.
8. After selecting a Storage Domain, if you need to change any of the advanced settings on the **New Office365 Protection Group** page, scroll down and click **Edit** on the right. For more information, see Advanced Settings.
9. Click **Protect**.

   Your OneDrive for Business Data Protection is now active and running.

Advanced Settings

Advance Settings	Description
Start Time	Available only if the selected policy is set to Backup Daily. Indicates when the protection run should start. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
End Time	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
QoS Policy	Select an appropriate quality of service (QoS) policy. QoS policies are designed for workloads such as backups, which keep a lot of IOs outstanding. We recommend one of the following: • **Backup Target HDD (Default)**: This policy assumes higher latency is OK and the workload will get high throughput if it issues a lot of writes in parallel. The data lands on hard disks if it is sequential and on SSDs if it is random writes. • **Backup Target SSD**: With this policy, both sequential and random IOs land on SSDs, but the IOs are not treated as high-priority IOs and we assume the workload keeps lots of IOs outstanding. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Exclusion List	Select the paths that you plan to exclude from the backup.
Protect Preservation Hold Library	Enable **Protect Preservation Hold Library** (PHL) to protect the Preservation Hold Library which is used to store the files needed for compliance reasons. For more information, see Retention for OneDrive. > **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.
Indexing	By default, indexing is enabled. > **Note:** Indexing is mandatory to search for files or folders in a OneDrive.

Advance Settings	Description
Alerts and Priority	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts.
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the protection runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs
Email Recipients	You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection run.
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks). > **Note:** Users with similar SLAs can be grouped together and a custom policy and Protection Group can be created to achieve different SLAs.
Description	**Optional**. Enter a brief description about the Protection Group.

Create or Use an Existing Protection Policy

A Protection Policy is a reusable set of settings. It enables you to define how and when OneDrive data is protected and replicated. A standard policy provides various settings that you can configure for a Protection Group.

Create a Protection Policy with the settings listed in the Policy Settings for OneDrive. For detailed instructions on how to create a Protection Policy, see Create or Edit a Standard Policy.

Policy Settings for OneDrive

The following table lists the applicable policy settings for OneDrive:

Field	Description
DataLock	Add a DataLock for compliance and regulatory requirement. This ensures that your protected data, including local backups, archives, and replication, cannot be modified until the DataLock expiration. Once applied, a DataLocked Snapshot will be deleted only after its retention period expires. A DataLock prevents all users from modifying or deleting any Snapshots that were generated by the protection runs that use this Policy. The users include those who have the Data Security role in Cohesity as well. > **Note:** Only users with the Data Security role can add, modify, or remove a DataLock from a Policy.
Scheduled Backup	Defines when backups are captured, how long they are retained, and the type of backup to capture.
Extended Retention	Add this to retain a subset of snapshots (backups) for longer duration than defined by the protection schedule.
Retry Options	Use this option to customize the retry settings for capturing Snapshots. By default, Cohesity attempts to capture Snapshots three times before the protection run fails. The default time between retries is thirty minutes. You can customize the number of retries and how long to wait between each attempt. > **Note:** Set **Retry Options** to **1**, as the Microsoft 365 connector already has the retry mechanism handling the failed requests. There is no need to increase the value for this setting in the Protection Policy.

Field	Description
Quiet Times	Quiet Times define time periods when new protection runs are not started. For example, you might want to configure hourly backups that run during weekdays but not on Saturdays or Sundays. Quiet Times only prevent new protection runs from starting during the specified time period. The protection runs that started before the quiet time period are not affected and will continue to run. For example, if a protection run starts at 12:45 AM on Saturday morning and there is a weekend quiet time period that starts at 1 AM on Saturday morning, the protection run will continue to run past 1 AM. No new protection runs are started during the quiet time period.
Replication	Replicate snapshots to another Cohesity cluster.

Use an Existing Protection Policy

You can edit an existing Protection Policy and configure it with the applicable policy settings for OneDrive. In this case, all the policy settings apart from the settings applicable to OneDrive are ignored.

To use the Protection Policy:

1. Navigate to **Data Protection > Policies**.
2. On the **Policies** page, select the policy that you plan to edit.
3. On the **Policy Details** page, click **Edit** and configure the applicable policy settings for OneDrive. For information on the applicable policy settings, see Policy Settings for OneDrive.
4. Click **Save**.

The updated policy settings are applied to the Protection Group in the next protection run.

Manage the OneDrive Backup Configuration

A backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

> **Note:** You cannot update the registered Microsoft 365 domain and the assigned Storage Domain in the Protection Group settings.

Add OneDrives to the Protection Group

You can add new OneDrives to the Protection Group for backup. The newly added OneDrive is backed up from the next protection run and it will be a full backup for the newly added user.

To add OneDrives to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for OneDrive.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Microsoft 365 - OneDrive** page, click ✎ in the **Users** section.
5. From the **User** list, select the OneDrives that you plan to add to the backup and click **Save Selection**.
6. Click **Save**.

Remove OneDrives from the Protection Group

You can remove OneDrive from the Protection Group that you do not want to back up in the next protection run. When you remove a user from the protection group, incremental backup of the OneDrive is not performed from the next protection run. The existing backup for the user is preserved until the snapshot expires.

To remove OneDrives from the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for OneDrive.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Microsoft 365 - OneDrive** page, click ✎ in the **Users** section.
5. From the **User** list, unselect the OneDrives that you want to remove from the Protection Group and click **Save Selection**.
6. Click **Save**.

Enable or Disable Auto Protect

The Auto Protect option enables you to automatically protect the new OneDrives that are added to Microsoft 365.

When the Auto Protect option is enabled:

- All the OneDrives that are added to Microsoft 365 in the future are automatically added to the Protection Group and are protected from the next protection run.
- All the OneDrives that are removed from Microsoft 365 in the future are automatically removed from the Protection Group and are not protected from the next protection run. The existing backup for the user is preserved until the snapshot expires.

When the Auto Protect option is disabled, you need to manually:

- Add newly onboarded users on Microsoft 365 to the Protection Group.
- Remove existing users that are offboarded on Microsoft 365 from the Protection Group. The existing backups of the users are preserved until the snapshot expires.

To enable or disable Auto Protect:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for OneDrive.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Microsoft 365 - OneDrive** page, click ✎ in the **Users** section.
5. From the **User** list, click the **shield** icon to enable or disable Auto Protect.
6. Click **Protect**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for OneDrive.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Start an On-demand Protection Run

You can manually start a protection run of the Protection Group that you have created to back up OneDrive. It provides you with options to:

- Back up all the objects or only selected objects in the Protection Group.
- Select an incremental or full backup.
- Add replication.

To start a protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for OneDrive.
3. Click the actions menu (⋮) next to the Protection Group and select **Run Now**.

4. In the pop-up window, perform the following:
    1. In the **Backup** drop-down list, select any one of the following:
        - Backup all Objects in the Protection Group
        - Backup only selected Objects in the Protection Group
    2. In the **Backup Type** drop-down list, select the backup type.
    3. Optional. In the **Replicate** section, select the replication target and the retention duration or click **Add** to add the replication target and the retention duration. Also, select **Replicate only fully successful runs** to replicate the data only from the completed protection runs.
    4. Optional. In the **Archive** section, click **Add** to add the external target to which you want to archive the data and the retention duration. Also, select **Archive only fully successful runs** to archive the data only from the completed protection runs.
5. Click **Backup Now**.

Pause Future Protection Runs

You can pause future protection runs for the Protection Group. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for OneDrive.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired then a full backup is triggered

To resume a paused protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

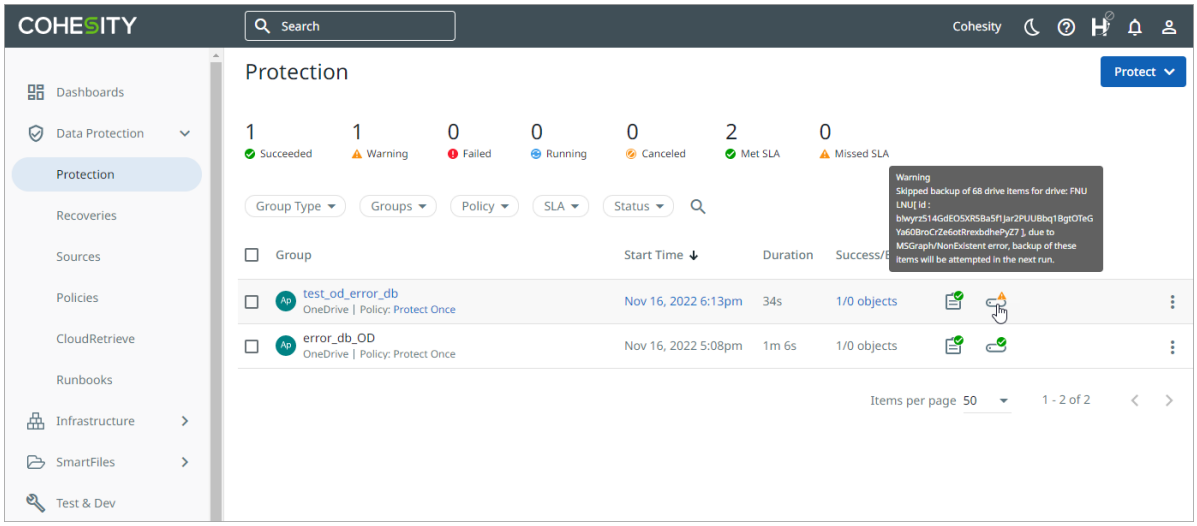
Download Error Report for a Protection Run

You can now download a list of errors encountered during the OneDrive protection run. Once the protection run is finished and if any files are skipped or have encountered errors, the protection run status is shown as **Warning**. You can download a report that lists the files that are skipped or have encountered errors.

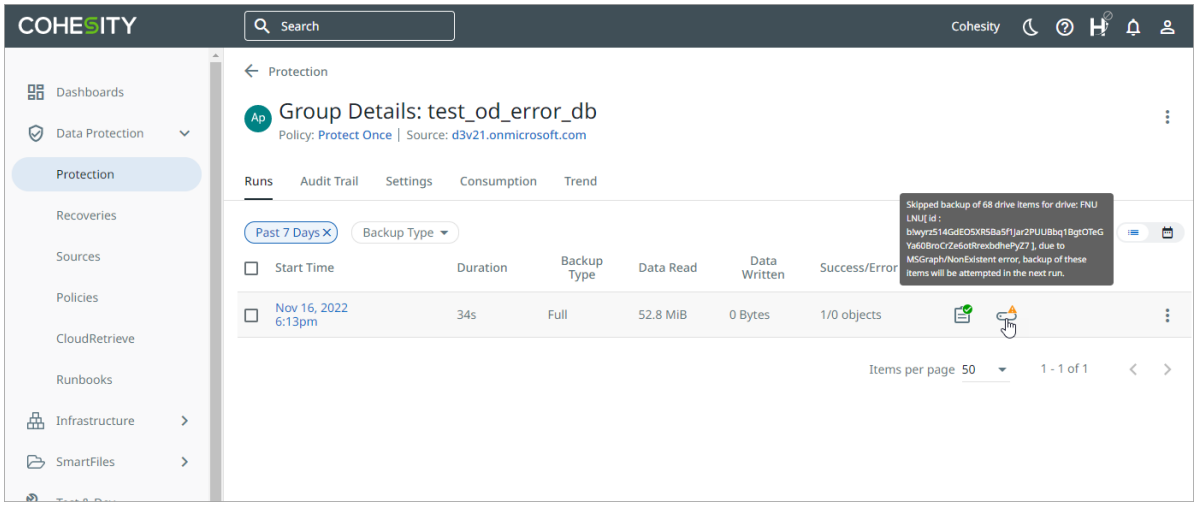
> **Note:** The files skipped or encountered errors are re-tried for the backup in the following protection run.

To download the report:

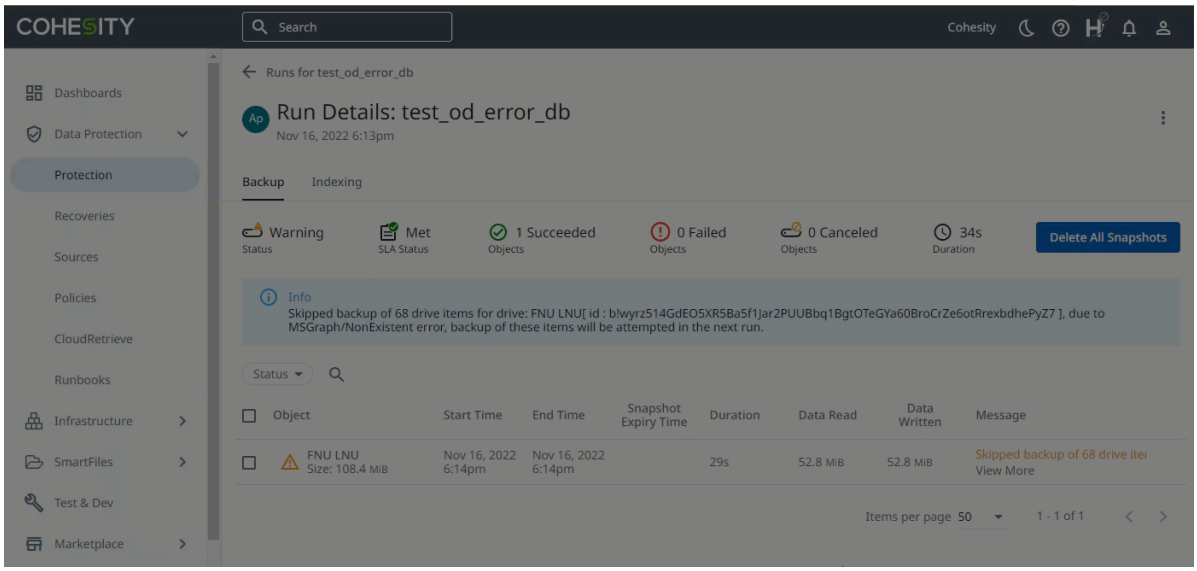
1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select a OneDrive Protection Group with an icon in the **Status** column.



3. In the **Group Details** page, select the protection run with the icon in the **Status** column.



4. On the **Run Details** page, select **view more** to view the list of errors for the protection run and click **Download Error Logs**.



This will download all the error logs in a CSV file format.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for OneDrive.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:

- Delete Protection Group Only
- Delete Protection Group and Snapshots

Recover OneDrive

You can restore OneDrive for Business data at various granularities, such as at the drive, folder, and file levels. You can restore to the same OneDrive or to a different OneDrive, in the same or a different Microsoft 365 domain.

Restore OneDrive

To restore OneDrive, you need to search through the backups by username or Protection Group name of the OneDrive that you plan to restore and then start the restore operation.

To restore OneDrive:

1. Navigate to **Data Protection > Recoveries**. Click **Recover** on the top-right of the page and then select **Microsoft 365** > **OneDrive** as the recovery source.
2. On the **New Recovery Microsoft 365 - OneDrive** page, in the **Recovery Type**, select **Entire OneDrive**.
3. Search using the user or protection group name, select the user OneDrive you need to restore, and click **Next: Recover Options**.
4. Under **Recover To**, based on your requirements, select one of the following options:

Options	Description
Original Location	Restore data to the same OneDrive from which it was backed up. **Note:** If the files and folders being restored already exist in the folder, the file is restored as the latest version.

Options	Description
New Location	**An alternate folder within the same drive**: Choose the same **Registered Source**, select the **Target OneDrive** as the source user drive and keep the default Folder name or provide the **Folder** name to which the file should be restored.
	Alternate location in the same Microsoft 365 domain: Choose the same **Registered Source**, select the **Target OneDrive** and provide the **Folder** name to which the file should be restored.
	Alternate location in a different Microsoft 365 domain: Choose the target **Registered Source**, select the **Target OneDrive** and provide the **Folder** name to which the file should be restored. > **Note:** Both the Microsoft 365 domains must be registered as sources with the same Cohesity cluster. For more information, see Register and Manage Microsoft 365 Exchange Online Mailboxes.

5. Select your **Recovery Options**:
   - **Continue on Error**. Enable to recover even if errors occur when recovering OneDrive(s). For example, if one of the OneDrives cannot be recovered, Cohesity will still attempt to recover the other selected OneDrive.
   - **Task Name**. Change the default name of the recovery task.
6. Click **Recover**.

Restore Files and Folders

To restore files or folders, you can either search for the files/folders or browse through the backups using the user OneDrive name and then select the file or folder that you plan to restore.

To restore files and folders:

1. Navigate to **Data Protection > Recoveries**. Click **Recover** on the top-right of the page and then select **Microsoft 365** as the recovery source.
2. On the New Recovery Microsoft 365 - OneDrive page, in the Recovery Type, select any one of the following tabs to search for the file or folder:
   - **Browse OneDrive and Recover**. You can browse the individual user OneDrive to navigate and select the files or folders to be restored.
   - **Search Files and Recover**. You can use the global search to find the files and folders that need to be restored.
3. If you plan to browse and recover, do the following:

1. In the **Recovery Type** section, select **Browse OneDrive and Recover**.
2. Search for the username and click the username or click **Browse** to browse the drive for the user.
3. Select the file or folder you plan to restore. Do any one of the following based on your requirements:
   - To recover the file(s) or folder(s), click **Next**.
   - To download the file(s) or folder(s), click **Download Files**.

     A new recovery task is created to download the file(s) or folder(s). When the task completes, from the Recoveries page, click the task name and then click Download Files to download the generated zip file.

     > **Note:**
     > - You cannot download empty folders.
     > - A recovery task is not created if you download a single file. Instead, the file is directly downloaded from the browser.
4. Click **Next: Recover Options**.

4. If you plan to search and recover, do the following:
   1. In the **Recovery Type** section, select **Search Files and Recover**.
   2. Search for the file or folder name you plan to recover or Click **Advanced Search** and select **Both**, **Files**, or **Folder** and search based on the available filters and click **Apply**.
   3. Select the file or folder you plan to restore and Click **Next: Recover Options**.
5. Under **Recover To**, based on your requirements, select one of the following options:

Options	Description
Original Location	Restore data to the same OneDrive from which it was backed up. **Note:** If the file being restored already exists in the folder, the file is restored as the latest version.

Options	Description
Restore OneDrive items to an alternate location	**An alternate folder within the same drive**: Choose the same **Registered Source**, select the **Target OneDrive** as the source user drive and keep the default **Folder** name or provide the **Folder** name to which the file should be restored.
	Alternate location in the same Microsoft 365 domain: Choose the same **Registered Source**, select the **Target OneDrive** and provide the **Folder** name to which the file should be restored.
	Alternate location in a different Microsoft 365 domain: Choose the target **Registered Source**, select the **Target OneDrive** and provide the **Folder** name to which the file should be restored. > **Note:** Both the Microsoft 365 domains must be registered as sources with the same Cohesity cluster. For more information, see Register and Manage Microsoft 365 Exchange Online Mailboxes.

6. Select your **Recovery Options**:
   - **Continue on Error**. Enable to recover even if errors occur when recovering OneDrive(s). For example, if one of the OneDrives cannot be recovered, Cohesity will still attempt to recover the other selected OneDrive.
   - **Include Preservation Hold Library**. Enable to recover the Preservation Hold Library that is part of the Cohesity snapshot.

     Recovering the Preservation Hold Library (PHL) data may increase the recovery time substantially since it contains a large amount of data. The recovery fails if sufficient space is not available in the target location.

     > **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

   - **Task Name**. Change the default name of the recovery task.
7. Click **Recover**.

Archive OneDrive Data

Cohesity enables you to archive the OneDrive for Business data to a designated external target, such as tape or cloud storage. For more details about external targets, see Manage External Targets .

It provides a policy-based archival solution for OneDrive for Business data. In the Protection Policy, you can define the archive schedule, select the external target, and specify the retention period of the data on the external target.

> **Note:** CloudRetrieve is not supported.

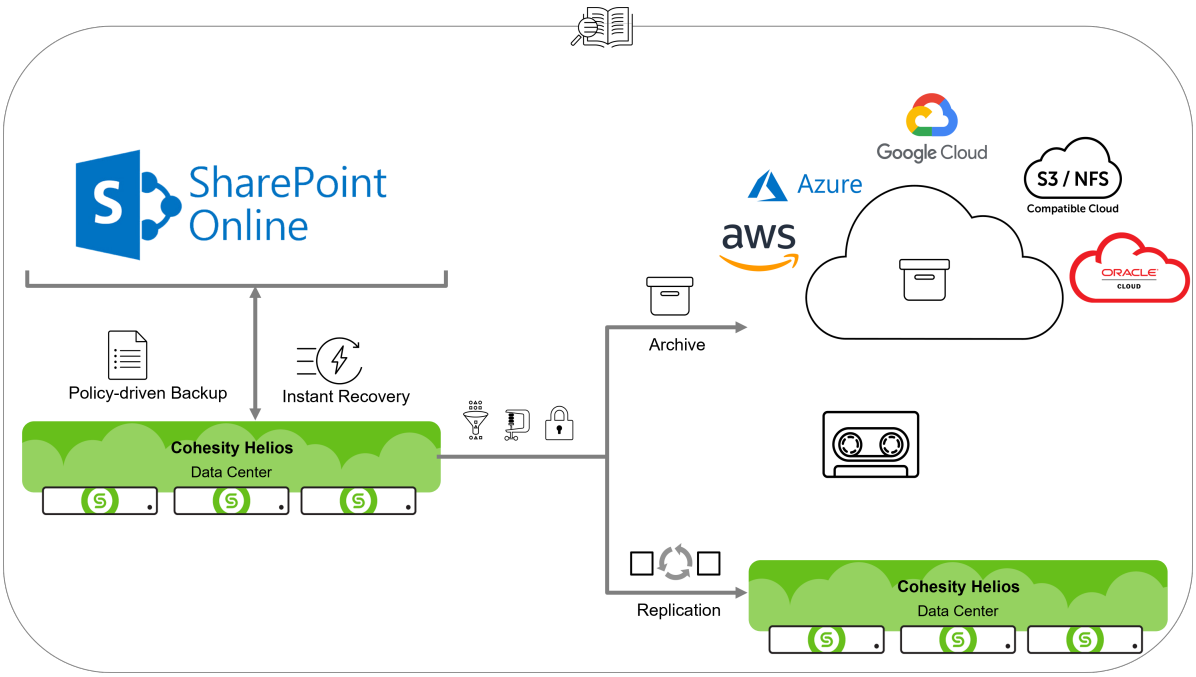
To archive OneDrive for Business data:

1. Register an external target. For more details, see Register an External Target.
2. Edit the existing Protection Policy that you had created for backup or if you are creating a new Protection Policy for backup. Configure the Archival settings as per your requirement. For more information, see **Step 13** in Create or Edit a Standard Policy.
3. Run the Protection Group that you have created for OneDrive for Business based on your requirement or the Archival settings will take effect in the next scheduled Protection Group run.

SharePoint Online

SharePoint Online is a SaaS application bundled with the Microsoft 365 service. It provides an extensive range of collaborative and creative capabilities enabling organizations to share, manage, and access information from almost any device.

Using the policy-based data protection solution from Cohesity, you can back up and recover the SharePoint Online site templates. Thus enabling you to backup and recover the SharePoint Online sites or subsites and their contents such as document libraries, lists, view, and so on.



Site Tagging

SharePoint Online sites are containers that are used to store and organize information in SharePoint. Sites can be standalone or can be associated with Groups and Teams referred to as Groups sites and Teams sites respectively. The Site Tagging option categorizes the sites and tags them to their respective containers.

> **Note:** Any Site that is tagged as a Group or Team will not be visible in the Sites section and these sites will be protected through the corresponding Group or Team protection.

Plan and Prepare for SharePoint Protection

Before you register your Microsoft 365 domain with Cohesity to protect Microsoft 365 data, ensure:

- You have completed all the prerequisites.
- You have reviewed and understood the considerations and best practices.

Considerations

> **Important:** Microsoft has retired Azure ACS (Access Control Service) for Microsoft 365 on November 1, 2024. As a result, the backup and recovery workflow for SharePoint sites in Microsoft 365 tenants created after this date may encounter issues and fail. This change affects newly created Microsoft 365 tenants only; existing Microsoft 365 tenants remain unaffected. If you experience issues or require assistance, contact Cohesity Support for guidance and potential workarounds.

- Only the list schema is backed up as part of the SharePoint online backup. The list items are not part of the SharePoint online backup.
- Backup and restore of OneNote files associated with the SharePoint Online sites are not supported.
- Document libraries enabled with the ForceCheckout option are not restored.
- Restore of sites with Out of the box (OOTB) modern theme or composed look is not supported.
- Backup and restore of sites or subsites URLs with non-ANSI characters are not supported.
- Restore of a site collection is not supported if the site URL has changed after the backup.
- In a document library, the documents in the initial version v1.0 and checked-out are not backed up.
- File/folder permissions with no role will not be recovered since Microsoft does not allow adding such permissions via Graph APIs. For example, no role will be assigned when a Restricted View permission is added to a user from Advanced Setting.
- SharePoint sites that are archived or locked will not be backed up and the source discovery may complete early due to these locked sites. Contact your Cohesity account team to configure the cluster to ignore the locked sites during discovery.
- The following template types are not supported:
    - Custom Workflow Process
    - Workflow History
    - Project Tasks
    - Public Workflows External List
- Microsoft 365 items with only special characters will not be listed in granular search. The item name must contain at least one alphanumeric character to be listed in the search result.

- Recovery of Content Type Hub SharePoint Online sites is not supported.
- From the recovery workflow, you cannot download an empty folder.
- The system discovers and protects the SharePoint Online sites created in the central storage location of your Microsoft 365 tenant.
- SharePoint Online sites created in satellite storage locations of your Microsoft 365 tenant can be discovered and protected. You can recover to the same tenant and same location or an alternate tenant and default location. For more details, see Multi-Geo Capabilities in SharePoint Online.

  > **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

- Cohesity currently does not support Geo-Stretched Microsoft 365 tenants.
- Custom scripts setting is not supported in SharePoint.
- Granular recovery of Team and Group sites is not supported when Site Tagging is enabled.
- During SharePoint granular recovery, you cannot browse or download files from the document libraries that contain a slash (/) in its name. As a workaround, you can perform a full recovery.
- Recovering shared permissions for files in the PHL drive is not supported.

  > **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

- Data from PHL is not searchable.
- Microsoft 365 Backup Storage service is supported for SharePoint Online.

  > **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

- For SharePoint recoveries larger than 1TB, you must adjust the quotas to allow for up to 25TB on the SharePoint recovery for it to function properly. Without this adjustment, the recovery process may fail due to size constraints.
- During the recovery process:
  - The original sharing link is not restored. Instead, a new sharing link with similar settings is created.

    - Passwords associated with sharing links, if set, are not restored.
- Recovery of docx, pptx, xlsx in system docslib is not supported.
- Teams and Groups Sites cannot be recovered directly. The site must be pre-created if backed up from the Sites tab.
- Site tagging can be enabled by default. Sites tagged to Teams or Groups can be directly protected during SharePoint protection if Teams or Groups workflow is not enabled. This ensures that no Teams Sites or Groups Sites are missed during recovery.

  > **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

- Recovery always creates a new version. The actual creation time and owner details of the file are not recovered. The current time is displayed as the creation/modification time and the SharePoint app is displayed as the owner/modifier.
- Backup and recovery of custom headers (columns) in SharePoint Online Document Libraries and Lists is supported.

  > **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

Best Practices

To protect your SharePoint Online data, Cohesity recommends the following best practices:

- In the Protection Policy, set **Retry Options** to **2** or **3**, with a small interval between the retry attempts.
- Use **Auto Protect** to automatically include the newly added sites on SharePoint Online to the Protection Group.
- Avoid adding the same sites in multiple Protection Groups.

For the workflows supported by SharePoint Online, see Microsoft 365 Workflows.

Register and Manage Microsoft 365 SharePoint

To start protecting Microsoft 365 applications, you need to register the Microsoft 365 domain as a source in Cohesity.

Cohesity uses the Microsoft Graph API for object discovery, backup, and recovery in Microsoft 365. Cohesity uses an Azure application that is created and registered on the Azure portal with the necessary permissions to use the Graph API. You can either let

Cohesity create the Azure application or manually enter Azure application details while registering your Microsoft 365 domain as a source in Cohesity.

Express Registration for Microsoft 365 Sources

Before you register Office 365 as a source on Cohesity, ensure that you:

- Review the requirements, considerations, and best practices.
- Perform the prerequisite tasks.

For more information, see Plan and Prepare for SharePoint Protection.

To register your Microsoft 365 domain:

1. Navigate to **Sources** and select **Register** > **Microsoft 365**.
2. Choose **Sites** as the **Microsoft 365 Applications** to discover.
3. In the **Account Credentials** section, enter the Microsoft 365 **Username** and **Password**.

   > **Note:** Toggle ***on*** the **Enable OAuth** option. Ensure that you added the required permission, for more information, see Plan and Prepare for SharePoint Protection.

4. Adding multiple Microsoft 365 service accounts using the **Additional Service Accounts** section requires OAuth disabled, as Microsoft has enabled OAuth by default, ignore adding multiple Microsoft 365 service accounts.
5. In the **Azure Applications** section, enter the number of Azure applications you want to create based on your requirements and click **Create**.

   > **Note:** By default, two Azure applications will be created. To better manage Microsoft 365 throttling, Cohesity recommends at least two Azure apps.

6. In the **Add Azure Application** form, copy the device code and click the **Microsoft Azure App** link to open the Microsoft Azure App authorization service in a new tab.

   > **Note:** If you prefer to create your Azure apps manually, see Manual Registration for Microsoft 365 Sources.

7. Paste the copied code in the **Microsoft Azure App authorization** service and click **Next**.
8. Log in to Microsoft Azure, enter the **Username** and **Password** of your Microsoft 365 account and click **Sign in**.

> **Note:** Ensure that your Microsoft 365 account has a global administrator access.

9. Follow the instructions to complete the authorization on the Microsoft Azure portal. Then, wait for Microsoft Azure Authorization to complete.
10. Toggle on **Use Windows Connector** and specify the hostname (FQDN) or server IP of the Windows Connector added as a Physical server. For more information, see Set Up a Windows Connector for Microsoft 365.

> **Note:** A Windows Connector is mandatory for SharePoint Online data protection. If you plan only to protect SharePoint Online document libraries then you do not require the Windows Connector.

11. Click **Register**.

Manual Registration for Microsoft 365 Sources

Before you register Office 365 as a source on Cohesity, ensure that you:

- Review the requirements, considerations, and best practices.
- Perform the prerequisite tasks.

For more information, see Plan and Prepare for OneDrive Protection.

To register your Microsoft 365 domain:

1. Navigate to **Sources** and select **Register** > **Microsoft 365**.
2. Choose **Sites** as the **Microsoft 365 Applications** to discover.
3. In the **Account Credentials** section, enter the Microsoft 365 **Username** and **Password**.

> **Note:** Toggle ***on*** the **Enable OAuth** option. Ensure that you added the required permission, for more information, see Plan and Prepare for OneDrive Protection.

4. Adding multiple Microsoft 365 service accounts using the **Additional Service Accounts** section requires OAuth disabled, as Microsoft has enabled OAuth by default, ignore adding multiple Microsoft 365 service accounts.
5. In the **Azure Applications** section, enter the number of Azure applications you want to create based on your requirements and click **Create**.

> **Note:** By default, two Azure applications will be created. To better manage Microsoft 365 throttling, Cohesity recommends at least two Azure apps.

6. In the **Add Azure Application** form, click the **You can also add Azure App manually** link.
   - For **Certificate** authentication, the **App ID** and the **Associated Certificate** of your custom Azure app will be populated. You can select the **Associated Certificate** from the list of certificates present in your certificate store or Create Cohesity Managed Certificate.

     > **Note:** This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

   - For **App Secret** authentication, the **App ID** and **App Secret Key** of your custom Azure app will be populated.

   > **Note:** You can add multiple Azure apps for a Microsoft 365 source to load balance your backup and restore operations. Click **+** to add multiple Azure apps. When you do, ensure that you provide the valid **App ID** and **App Secret Key**.

   To migrate the existing apps from App Secret to Certificate authentication method, see Migrate Existing Apps to Certificate-Based Authentication.
7. Optional. To enable exporting and downloading mailboxes or email(s) in PST format, toggle on **Use Windows Connector** and specify the hostname (FQDN) or server IP of the Windows Connector added as a Physical server. For more information, see Set Up a Windows Connector for Microsoft 365.
8. Click **Register**.

Manage Microsoft 365 Source Registration

After registering your Microsoft 365 domain as a source, you can:

- Update the Microsoft 365 source configuration.
- Refresh the source details.
- Unregister the Microsoft 365 domain from Cohesity.

Update the Microsoft 365 Source Configuration

After registering your Microsoft 365 source on Cohesity, you might have changed the Microsoft 365 domain configuration by:

- Changing the credentials of Microsoft 365 user account credentials.
- Updating the app secret by adding more permissions to the custom app.
- Creating a new app ID.

You can update the Microsoft 365 details provided during the registration process with the latest Microsoft 365 configuration details.

To edit the Microsoft 365 source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Microsoft 365 source and select **Edit**.
3. On the **Update Microsoft 365 Source** page, update the required configurations.
4. Click **Register**.

Refresh the Microsoft 365 Source

You can refresh the Microsoft 365 domain configuration and fetch the latest changes on the Microsoft 365 domain.

To refresh the Microsoft 365 Source Configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Microsoft 365 source and select **Refresh**.

Unregister the Microsoft 365 Domain

If you plan to stop taking the backup of your Microsoft 365 domain, you can unregister the Microsoft 365 source from Cohesity.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the Microsoft 365 source.

To unregister the Microsoft 365 domain:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Microsoft 365 source and select **Unregister**.

Backup SharePoint Online

SharePoint Online is protected using a Protection Group and a Protection Policy. A Protection Group enables you to select the objects that you want to back up. It uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured and replicated.

A Protection Policy is a reusable list of settings that define the type of backup, backup schedule, and backup snapshot retention. Also, for Disaster Recovery, you can add

replication for the Protection Group using the Protection Policy. You can select which standard or custom policy to use when creating a Protection Group. For more details, see Manage Protection Policy.

> **Note:** SharePoint Online sites associated with Microsoft 365 Groups or modern Microsoft 365 Teams are protected as part of their dedicated workflows. For more information, Groups and Teams.

To protect SharePoint Online sites:

1. Do one of the following:
    - On the **Dashboards** page, from the drop-down at the top of the page, select **Data Protection** and do one of the following:
        - If there is no existing Protection Group, click **Start Data Protection** > **Microsoft 365** > **Sites**.
        - Click **Protect** > **Microsoft 365** > **Sites**.
    - Select **Data Protection > Protection**. Click **Protect** on the top-right of the page and then select **Microsoft 365** > **Sites**.
    - Select **Data Protection > Sources**. Click the actions menu (⋮) next to the Microsoft 365 source and then select **Protect SharePoint Online**.
2. In the **New Protection** pop-up, do one of the following:
    - Protect the sites by specifying a subset of options such as objects, protection group and policy by clicking the edit icon corresponding to the following options:
        i. **Add Objects**: Select the registered Microsoft 365 source or click **Register Source** to register a Microsoft 365 account. From the **Sites** list, select the sites or subsites that you plan to back up.
        ii. **Protection Group**: Specify a name for the Protection Group.
        iii. **Policy**: Select an existing policy or click **Create Policy** to create a new protection policy.
        iv. **Storage Domain**: Select the appropriate storage domain.

        > **Note:** This option is visible on the **New Protection** pop-up only if there is more than one storage domain.

        v. Click **Protect**.
    - To protect sites by specifying all the options, click **More Options**.

3. From the **Source** drop-down list, select the registered Microsoft 365 source or click **Register Source** to register a Microsoft 365 source. For more information, see Register and Manage Microsoft 365 SharePoint.
4. From the **Sites** list, select the sites or subsites that you plan to backup and click Save Selection or click the icon to enable Auto Protect at the domain level or site level. For more information on Auto Protect, see Enable or Disable Auto Protect.
5. In the **Protection Group** section, do one of the following:
   - Select **New Group** to create a new Protection Group. In the **Protection Name** field, enter a name from the Protection Group.
   - Select **Existing Group** to use the settings of an existing Protection Group. From the **Group** list, select an existing Protection Group and click **Protect**.
6. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, Create or Use an Existing Protection Policy.
7. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains.
8. After selecting a Storage Domain, if you need to change any of the advanced settings on the **Microsoft 365 - SharePoint Online** page, scroll down and click **Edit** on the right. For more information, see Advanced Settings.
9. Click **Protect**.

   Your SharePoint Online Data Protection is now active and running.

Advanced Settings

Advance Settings	Description
Start Time	Available only if the selected policy is set to Backup Daily. Indicates when the protection run should start. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
End Time	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts prior to this date runs until completion even if it completes after this date.

Advance Settings	Description
QoS Policy	Select an appropriate quality of service (QoS) policy. **Note:** Cohesity recommends specifying **Backup HDD**, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy.
Exclusion List	Select the folders that you plan to exclude from the backup or click **Add** to add custom folders that you want to exclude from the backup. **Note:** Exclusion list is not supported for Public Folders.
Indexing	By default, indexing is enabled. **Note:** Indexing is mandatory for granular restore of an Exchange Online mailbox , such as restoring a folder or restoring an email. For more information, see Recover Mailbox .
Alerts and Priority	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts.

Advance Settings	Description
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs
Email Recipients	You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection run.
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks). **Note:** Users with similar SLAs can be grouped together and a custom policy and Protection Group can be created to achieve different SLAs.
Description	**Optional**. Enter a brief description about the Protection Group.

Create or Use an Existing Protection Policy

Create a Protection Policy with the settings listed in the Policy Settings for SharePoint Online. For detailed instructions on how to create a Protection Policy, see Create or Edit a Standard Policy.

Policy Settings for SharePoint Online

The following table lists the applicable policy settings for SharePoint Online:

Field	Description
DataLock	Add a DataLock for compliance and regulatory requirement. This ensures that your protected data, including local backups, archives, and replication, cannot be modified until the DataLock expiration. Once applied, a DataLocked Snapshot will be deleted only after its retention period expires. A DataLock prevents all users from modifying or deleting any Snapshots that were generated by the protection runs that use this Policy. The users include those who have the Data Security role in Cohesity as well. > **Note:** Only users with the Data Security role can add, modify, or remove a DataLock from a Policy.
Scheduled Backup	Defines when backups are captured, how long they are retained, and the type of backup to capture.
Extended Retention	Add this to retain a subset of snapshots (backups) for longer duration than defined by the protection schedule.
Retry Options	Use this option to customize the retry settings for capturing Snapshots. By default, Cohesity attempts to capture Snapshots three times before the protection run fails. The default time between retries is thirty minutes. You can customize the number of retries and how long to wait between each attempt. > **Note:** Set **Retry Options** to **1**, as the Microsoft 365 connector already has the retry mechanism handling the failed requests. There is no need to increase the value for this setting in the Protection Policy.
Quiet Times	Quiet Times define time periods when new protection runs are not started. For example, you might want to configure hourly backups that run during weekdays but not on Saturdays or Sundays. Quiet Times only prevent new protection runs from starting during the specified time period. The protection runs that started before the quiet time period are not affected and will continue to run. For example, if a protection run starts at 12:45 AM on Saturday morning and there is a weekend quiet time period that starts at 1 AM on Saturday morning, the protection run will continue to run past 1 AM. No new protection runs are started during the quiet time period.
Replication	Replicate snapshots to another Cohesity cluster.

Use an Existing Protection Policy

You can edit an existing Protection Policy and configure it with applicable policy settings for SharePoint Online. In this case, all the policy settings apart from the settings applicable to SharePoint Online are ignored.

To use an existing Protection Policy:

1. Navigate to **Data Protection > Policies**.
2. On the **Policies** page, select the policy that you plan to edit.
3. On the **Policy Details** page, click **Edit** and configure the applicable policy settings for SharePoint Online. For information on the applicable policy settings, see Policy Settings for SharePoint Online.
4. Click **Save**.

The updated policy settings are applied to the Protection Group in the next protection run.

Manage the SharePoint Online Backup Configuration

A backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

> **Note:** You cannot update the registered Microsoft 365 domain and the assigned Storage Domain in the Protection Group settings.

Add Sites or Subsites to the Protection Group

You can add a new SharePoint Online site(s) or subsite(s) to the Protection Group for backup. The newly added sites or subsites are backed up from the next protection run, and it will be a full backup for the recently added user.

To add Sites or Subsites to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for OneDrive.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Microsoft 365 - SharePoint Online** page, click ✎ in the **Users** section.
5. From the **Sites** list, select the sites or subsites that you plan to add to the backup and click **Save Selection**.

   > **Note:** If you select a site with subsites, automatically, the subsites are selected for the protection run.

6. Click **Save**.

Remove Sites or Subsites from the Protection Group

You can remove the SharePoint Online site(s) or subsite(s) from the Protection Group that you do not want to back up in the next protection run. When you remove a site from the protection group, the site's incremental backup is not performed from the future protection run. The existing backup for the site is preserved until the snapshot expires.

To remove Sites or Subsites from the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for OneDrive.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Microsoft 365 - SharePoint Online** page, click ✎ in the **Users** section.
5. From the **Sites** list, unselect the sites or subsites that you plan to remove from the backup and click **Save Selection**.
6. Click **Save**.

Enable or Disable Auto Protect

The Auto Protect option enables you to automatically protect the new sites that are added to Microsoft 365.

When the Auto Protect option is enabled:

- All the sites that are added to SharePoint Online in the future are automatically added to the Protection Group and are protected from the next protection run.
- All the sites that are removed from SharePoint Online in the future are automatically removed from the Protection Group and are not protected from the next protection run. The existing backup for the site is preserved until the snapshot expires.

When the Auto Protect option is disabled, you need to manually:

- Add newly onboarded sites on SharePoint Online to the Protection Group.
- Remove existing sites that are offboarded on SharePoint Online from the Protection Group. The existing backups of the sites are preserved until the snapshot expires.

To enable or disable Auto Protect:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for OneDrive.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Microsoft 365 - SharePoint Online** page, click ✎ in the **Users** section.
5. From the **Sites** list, click the 🛡 icon in the domain level or site level to enable or disable Auto Protect and click **Save Selection**.
6. Click **Protect**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for OneDrive.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Start an On-demand Protection Run

You can manually start a protection run of the Protection Group that you have created to back up SharePoint Online sites. It provides you with options to:

- Back up all the objects or only selected objects in the Protection Group.
- Select an incremental or full backup.
- Add replication.

To start a protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for SharePoint Online.
3. Click the actions menu (⋮) next to the Protection Group and select **Run Now**.
4. In the pop-up window, perform the following:
    1. In the **Backup** drop-down list, select any one of the following:
        - Backup all Objects in the Protection Group
        - Backup only selected Objects in the Protection Group
    2. In the **Backup Type** drop-down list, select the backup type.
    3. Optional. In the **Replicate** section, select the replication target and the retention duration.
5. Click **Backup Now**.

Pause Future Protection Runs

You can pause future protection runs for the Protection Group. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for SharePoint Online.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired then a full backup is triggered

To resume a paused protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

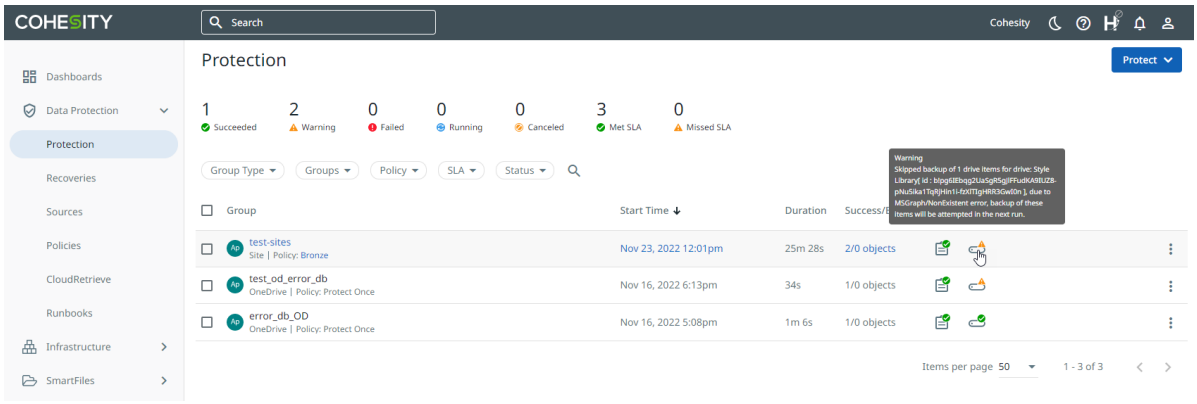
Download Error Report for a Protection Run

You can now download a list of errors encountered during the SharePoint Site protection run. Once the protection run is finished and if any files are skipped or have encountered errors, the protection run status is shown as **Warning**. You can download a report that lists the files that are skipped or have encountered errors.

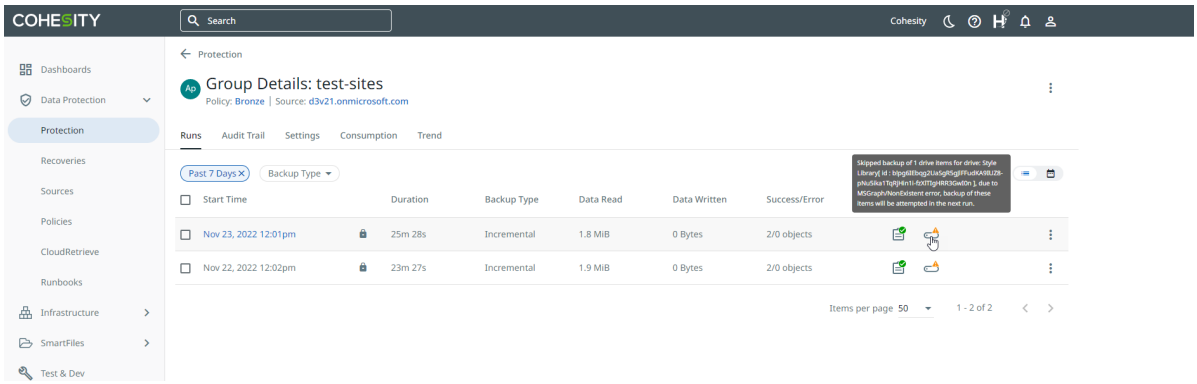
> **Note:** The files skipped or encountered errors are re-tried for the backup in the following protection run.

To download the report:

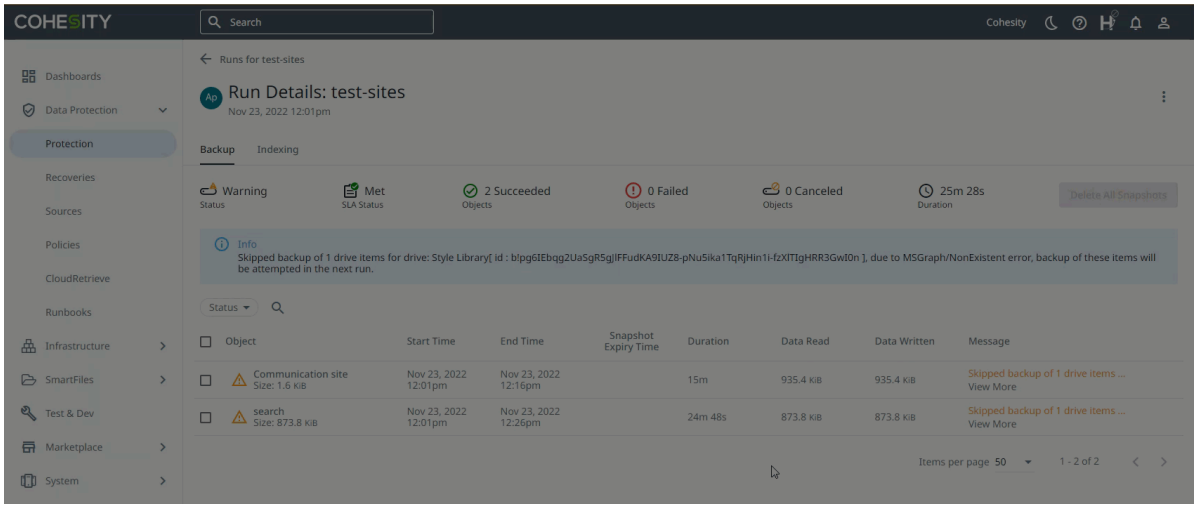
1. Navigate to **Data Protection** > **Protection**.
2. On the **Protection** page, select a SharePoint Site Protection Group with an icon in the **Status** column.



3. In the **Group Details** page, select the protection run with the icon in the **Status** column.



4. On the **Run Details** page, select view more to view the list of errors for the protection run and click **Download Error Logs**.



This will download all the error logs in a CSV file format.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group and Snapshots, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for SharePoint Online.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
   - Delete Protection Group Only
   - Delete Protection Group and Snapshots

Recover SharePoint

You can restore the document library on a SharePoint Online Site at various granularities, such as the document library, folder, and file levels. You can restore to the same SharePoint location or a different SharePoint location, in the same or a different Microsoft 365 domain.

Restore Sites

To restore sites, you need to search through the backups by the site name or Protection Group name of the Site that you plan to restore and then start the restore operation.

You can also restore the subsites of a site collection. Search for site collection (root site) using the site collection name or its relative site URL, for example, `/sites/myroot`. If the site collection is part of a single backup snapshot, you can select the subsites in the site collection, and the subsites are restored in their original order.

> **Note:** Ensure that you have configured the tenant with the required permissions for recovery. For more information, see Plan and Prepare for SharePoint Protection.

To restore sites:

1. Navigate to **Data Protection > Recoveries**. Click **Recover** on the top-right of the page and then select **Microsoft 365** > **Sites** as the recovery source.
2. On the **New Recovery Microsoft 365 - SharePoint Online** page, under the **Recovery Type** section, click **Entire Site**.
3. Search using the site name or protection group name, select the site(s) that you plan to restore, and click **Next: Recover Options**.
4. Under **Recover To**, based on your requirements, select one of the following options:

Options	Description
Original Location	Click **Recover** to restore data to the same SharePoint site from which it was backed up.
New Location	**Alternate site in the same Microsoft 365 domain**: Choose the **Site** to which the document libraries need to be restored.
	Alternate site in a different Microsoft 365 domain: Choose the **Microsoft 365 Server** to which the site needs to be restored. > **Note:** Both the Microsoft 365 domains must be registered as sources with the same Cohesity cluster. For more information, see Register and Manage Microsoft 365 SharePoint.

5. Select the **Recovery Options**:
   - **Continue on Error**. Enable to recover even if errors occur when recovering SharePoint Online sites. For example, if one of the sites cannot be recovered, Cohesity will still attempt to recover the other selected sites.
   - **Include Preservation Hold Library**. Enable to recover the Preservation Hold Library that is part of the Cohesity snapshot. Recovering the Preservation Hold Library data may increase the recovery time substantially as it can include a large amount of data. The recovery will fail if the Target Location does not have sufficient space.
     This is a Controlled Availability feature. Contact your Cohesity account team to

enable the feature.

- **Task Name**. Change the default name of the recovery task.

6. Click **Recover** to start the restore operation.

Restore Document Libraries and Files

To restore document libraries or files, you can either search for the files/document libraries or browse through the backups using the site name and then select the file or document library that you plan to restore.

> **Note:** When you restore a deleted SharePoint site, the associated document libraries are automatically restored as well.

To restore files and document library:

1. Navigate to **Data Protection > Recoveries**. Click **Recover** on the top-right of the page and then select **Microsoft 365** > **Sites** as the recovery source.
2. On the **New Recovery Microsoft 365 - SharePoint Online** page, under the **Recovery Type** section, select any one of the following to search for the file or folder:
   - **Browse Site and Recover**. You can browse the individual site to navigate and select the files/document library to be restored.
   - **Search Files and Recover**. You can use the global search to find the files and document libraries that need to be restored.
3. If you plan to browse and recover, do the following:
   1. In the **Recovery Type** section, select **Browse Site and Recover**.
   2. Search for the site name and click the site name to browse the site.
   3. Select the file or document library you plan to restore. Do any one of the following based on your requirements:
      - To recover the file(s) or document library(s), click **Next**.
      - To download the file(s) or document library(s), click **Download Files**.

        A new recovery task is created to download the file(s) or document library (s). When the task is completed, from the **Recoveries** page, click the task name and then click **Download Files** to download the generated zip file.

> **Note:**
> - You cannot download empty folders.
> - A recovery task is not created, if you download a single file. Instead the file is directly downloaded from the browser.

4. Click **Next: Recover Options**.

4. If you plan to search and recover, do the following:
    1. In the **Recovery Type** section, select **Search Files and Recover**.
    2. Search for the file or document libraries you plan to recover or click **Advanced Search** and select **Both**, **Files**, or **Folder** and search based on the available filters and click **Apply**.
    3. Click **Next: Recover Options**.
5. Under **Recover To**, based on your requirements, select one of the following options:

Options	Description
Original Location	Click **Recover** to restore data to the same SharePoint site from which it was backed up. **Note:** If the file being restored already exists in the document library, the file is restored as the latest version.

Options	Description
New Location	**An alternate document library within the same site**: Choose the target **Document Library** that is the same as the source site and keep the existing document library name or provide the document library name to which the file should be restored.
	Alternate location in a different Microsoft 365 domain: Choose the **Microsoft 365 Server** to which data needs to be restored and then specify the **Document Library** to which the data needs to be restored. > **Note:** Both the Microsoft 365 domains must be registered as sources with the same Cohesity cluster. For more information, see Register and Manage Microsoft 365 SharePoint.

6. Click **Recover** to start the restore operation.

Groups

Microsoft 365 groups are used for collaboration between users, both inside and outside your company. With each Microsoft 365 group, members get a group email and shared workspace for conversations, files, and calendar events, and a planner.

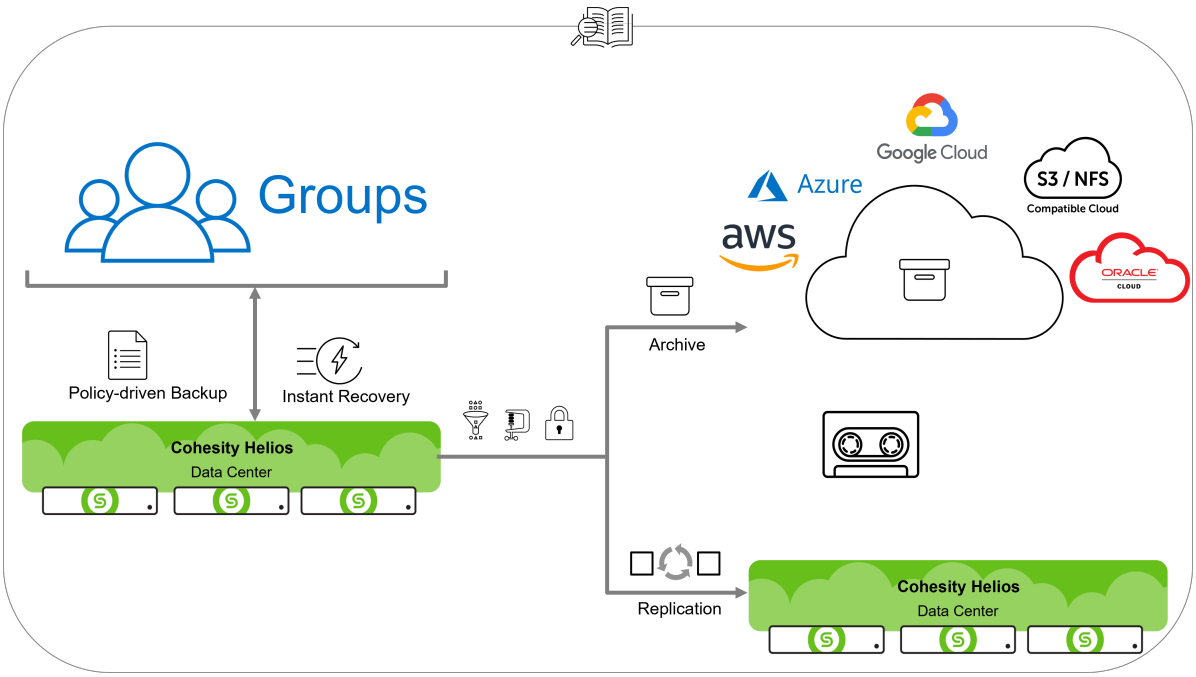
Using the policy-based data protection solution from Cohesity, you can backup and recover Unified Groups data in Microsoft 365.

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

The following are the data backed by Cohesity for Microsoft 365 Groups:

- Shared Outlook Inbox
- Shared Calendars
- Shared SharePoint Document Library

> **Important:** Mail-enabled security groups, security groups, and distribution lists are not supported.



Plan and Prepare for Groups Protection

Before you register your Microsoft 365 domain with Cohesity to protect Microsoft 365 data, ensure:

- You have completed all the prerequisites.
- You have reviewed and understood the considerations and best practices.

Considerations

- Restoring to an alternate Microsoft 365 domain is not supported.
- Using a Group recovery job, you can only restore only one Group.
- Recovering system document libraries (libraries that are present in the Group site by default - Site Assets, Style Library, Documents, and Form Templates) is not supported. You can recover only the non-system document libraries in a Group site.

  > **Note:** Files associated with Private Channels in Teams saved under the Documents library can be protected and recovered.

- Cohesity does not support Groups data protection in a multitenant environment.
- Groups must have owners for the backups to function properly.
- File/folder permissions with no role will not be recovered since Microsoft does not allow adding such permissions via Graph APIs. For example, no role will be assigned when a Restricted View permission is added to a user from Advanced Setting.

- Microsoft 365 items with only special characters will not be listed in granular search. The item name must contain at least one alphanumeric character to be listed in the search result.

Best Practices

To protect your SharePoint Online data, Cohesity recommends the following best practices:

- In the Protection Policy, set **Retry Options** to **2** or **3**, with a small interval between the retry attempts.
- Use **Auto Protect** to automatically include the newly added sites on SharePoint Online to the Protection Group.
- Avoid adding the same sites in multiple Protection Groups.

For the workflows supported by Groups, see Microsoft 365 Workflows.

Register and Manage Microsoft 365 Groups

To start protecting Microsoft 365 applications, you need to register the Microsoft 365 domain as a source in Cohesity.

Cohesity uses the Microsoft Graph API for object discovery, backup, and recovery in Microsoft 365. Cohesity uses an Azure application that is created and registered on the Azure portal with the necessary permissions to use the Graph API. You can either let Cohesity create the Azure application or manually enter Azure application details while registering your Microsoft 365 domain as a source in Cohesity.

Express Registration for Microsoft 365 Sources

Before you register Office 365 as a source on Cohesity, ensure that you:

- Review the requirements, considerations, and best practices.
- Perform the prerequisite tasks.

For more information, see Plan and Prepare for Groups Protection.

To register your Microsoft 365 domain:

1. Navigate to **Sources** and select **Register** > **Microsoft 365**.
2. Choose **Groups** as the Microsoft 365 Applications to discover.
3. In the **Account Credentials** section, enter the Microsoft 365 **Username** and **Password**.

> **Note:** Toggle ***on*** the **Enable OAuth** option. Ensure that you added the required permission, for more information, see Plan and Prepare for Groups Protection.

4. Adding multiple Microsoft 365 service accounts using the **Additional Service Accounts** section requires OAuth disabled, as Microsoft has enabled OAuth by default, ignore adding multiple Microsoft 365 service accounts.
5. In the **Azure Applications** section, enter the number of Azure applications you want to create based on your requirements and click **Create**.

   > **Note:** By default, two Azure applications will be created. To better manage Microsoft 365 throttling, Cohesity recommends at least two Azure apps.

6. In the **Add Azure Application** form, copy the device code and click the **Microsoft Azure App** link to open the Microsoft Azure App authorization service in a new tab.

   > **Note:** If you prefer to create your Azure apps manually, see Manual Registration for Microsoft 365 Sources.

7. Paste the copied code in the **Microsoft Azure App authorization** service and click Next.
8. Log in to Microsoft Azure, enter the **Username** and **Password** of your Microsoft 365 account and click **Sign in**.

   > **Note:** Ensure that your Microsoft 365 account has global administrator access.

9. Follow the instructions to complete the authorization on the Microsoft Azure portal. Then, wait for Microsoft Azure Authorization to complete.
10. Optional. Toggle on **Use Windows Connector** and specify the hostname (FQDN) or server IP of the Windows Connector added as a Physical server.

    > **Note:** If you are protecting only MS Groups data, then the Use Windows Proxy option is not applicable. For more information, see Set Up a Windows Connector for Microsoft 365.

11. Click **Register**.

Manual Registration for Microsoft 365 Sources

Before you register Office 365 as a source on Cohesity, ensure that you:

- Review the requirements, considerations, and best practices.
- Perform the prerequisite tasks.

For more information, see Plan and Prepare for Groups Protection.

To register your Microsoft 365 domain:

1. Navigate to **Sources** and select **Register** > **Microsoft 365**.
2. Choose **Groups** as the **Microsoft 365 Applications** to discover.
3. Adding multiple Microsoft 365 service accounts using the **Additional Service Accounts** section requires OAuth disabled, as Microsoft has enabled OAuth by default, ignore adding multiple Microsoft 365 service accounts.
4. In the **Azure Applications** section, enter the number of Azure applications you want to create based on your requirements and click **Create**.

   > **Note:** By default, two Azure applications will be created. To better manage Microsoft 365 throttling, Cohesity recommends at least two Azure apps.

5. In the **Add Azure Application** form, click the **You can also add Azure App manually** link.
   - For **Certificate** authentication, the **App ID** and the **Associated Certificate** of your custom Azure app will be populated. You can select the **Associated Certificate** from the list of certificates present in your certificate store or Create Cohesity Managed Certificate.

     > **Note:** This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

   - For **App Secret** authentication, the **App ID** and **App Secret Key** of your custom Azure app will be populated.

   > **Note:** You can add multiple Azure apps for a Microsoft 365 source to load balance your backup and restore operations. Click **+** to add multiple Azure apps. When you do, ensure that you provide the valid **App ID** and **App Secret Key**.

   To migrate the existing apps from App Secret to Certificate authentication method, see Migrate Existing Apps to Certificate-Based Authentication.
6. Optional. Toggle on **Use Windows Connector** and specify the hostname (FQDN) or server IP of the Windows Connector added as a Physical server.

> **Note:** If you are protecting only MS Groups data, then the Use Windows Proxy option is not applicable. For more information, see Set Up a Windows Connector for Microsoft 365.

7. Click **Register**.

Manage Microsoft 365 Source Registration

After registering your Microsoft 365 domain as a source, you can:

- Update the Microsoft 365 source configuration.
- Refresh the source details.
- Unregister the Microsoft 365 domain from Cohesity.

Update the Microsoft 365 Source Configuration

After registering your Microsoft 365 source on Cohesity, you might have changed the Microsoft 365 domain configuration by:

- Changing the credentials of Microsoft 365 user account credentials.
- Updating the app secret by adding more permissions to the custom app.
- Creating a new app ID.

You can update the Microsoft 365 details provided during the registration process with the latest Microsoft 365 configuration details.

To edit the Microsoft 365 source configuration:.

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Microsoft 365 source and select **Edit**.
3. On the **Update Microsoft 365 Source** page, update the required configurations.
4. Click **Register**.

Refresh the Microsoft 365 Source

You can refresh the Microsoft 365 domain configuration and fetch the latest changes on the Microsoft 365 domain.

To refresh the Microsoft 365 Source Configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Microsoft 365 source and select **Refresh**.

Unregister the Microsoft 365 Domain

If you plan to stop taking the backup of your Microsoft 365 domain, you can unregister the Microsoft 365 source from Cohesity.
=======

If you plan to stop taking the backup of your Microsoft 365 domain, you can unregister the Microsoft 365 source from the Cohesity Cluster.
>>>>>>> [7.0]Fix for the rebranding comments.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the Microsoft 365 source.

To unregister the Microsoft 365 domain:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Microsoft 365 source and select **Unregister**.

Backup Microsoft 365 Groups

Microsoft 365 Groups data is protected using a Protection Group and a Protection Policy. A Protection Group enables you to select the objects that you want to back up. It uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured and replicated.

A Protection Policy is a reusable list of settings that define the type of backup, backup schedule, and backup snapshot retention. Also, for Disaster Recovery, you can add replication for the Protection Group using the Protection Policy. You can select which standard or custom policy to use when creating a Protection Group. For more details, see Manage Protection Policy.

To protect Microsoft 365 Groups:

1. Do one of the following:
   - On the **Dashboards** page, from the drop-down at the top of the page, select **Data Protection** and do one of the following:
     - If there is no existing Protection Group, click **Start Data Protection** > **Microsoft 365** > **Group**.
     - Click **Protect** > **Microsoft 365** > **Group**.
   - Select **Data Protection > Protection**. Click **Protect** on the top-right of the page and then select **Microsoft 365** > **Group**.
   - Select **Data Protection > Sources**. Click the actions menu (⋮) next to the Microsoft 365 source and then select **Protect Group**.
2. In the **New Protection** pop-up, do one of the following:
   - Protect Group by specifying a subset of options such as objects, protection group and policy by clicking the edit icon corresponding to the following

options:

i. **Add Objects**: Select the registered Microsoft 365 source or click **Register Source** to register a Microsoft 365 account. From the **Group** list, select the group(s) that you plan to back up.

ii. **Protection Group**: Specify a name for the Protection Group.

iii. **Policy**: Select an existing policy or click **Create Policy** to create a new protection policy.

iv. **Storage Domain**: Select the appropriate storage domain.

> **Note:** This option is visible on the **New Protection** pop-up only if there is more than one storage domain.

v. Click **Protect**.

- To protect Teams by specifying all the options, click **More Options**.

3. From the **Source** drop-down list, select the registered Microsoft 365 source or click **Register Source** to register a Microsoft 365 source. For more information, see Register and Manage Microsoft 365 Groups.
4. From the **Groups** list, select the group(s) that you plan to back up or click the icon to enable Auto Protect at the domain level. For more information on Auto Protect, see Enable or Disable Auto Protect.
5. In the **Protection Group** section, do one of the following:
   - Select **New Group** to create a new Protection Group. In the **Protection Name** field, enter a name from the Protection Group.
   - Select **Existing Group** to use the settings of an existing Protection Group. From the **Group** list, select an existing Protection Group and click **Protect**.
6. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, Create or Use an Existing Protection Policy.
7. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains.
8. After selecting a Storage Domain, if you need to change any of the advanced settings on the **Microsoft 365 - Groups** page, scroll down and click **Edit** on the right. For more information, see Advanced Settings.
9. Click **Protect**.

   Your Microsoft 365 Groups Data Protection is now active and running.

Advanced Settings

Advance Settings	Description
Start Time	Available only if the selected policy is set to Backup Daily. Indicates when the protection run should start. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
End Time	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts prior to this date runs until completion even if it completes after this date.
QoS Policy	Select an appropriate quality of service (QoS) policy. **Note:** Cohesity recommends specifying **Backup HDD**, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Indexing	By default, indexing is enabled.

Advance Settings	Description
Alerts and Priority	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts.
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs
Email Recipients	You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection run.
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks). > **Note:** Users with similar SLAs can be grouped together and a custom policy and Protection Group can be created to achieve different SLAs.
Description	**Optional**. Enter a brief description about the Protection Group.

Create or Use an Existing Protection Policy

Create a Protection Policy with the settings listed in the Policy Settings for Microsoft 365 Groups. For detailed instructions on how to create a Protection Policy, see Create or Edit a Standard Policy.

Policy Settings for Microsoft 365 Groups

The following table lists the applicable policy settings for Microsoft 365 Groups:

Field	Description
DataLock	Add a DataLock for compliance and regulatory requirement. This ensures that your protected data, including local backups, archives, and replication, cannot be modified until the DataLock expiration. Once applied, a DataLocked Snapshot will be deleted only after its retention period expires. A DataLock prevents all users from modifying or deleting any Snapshots that were generated by the protection runs that use this Policy. The users include those who have the Data Security role in Cohesity as well. > **Note:** Only users with the Data Security role can add, modify, or remove a DataLock from a Policy.
Scheduled Backup	Defines when backups are captured, how long they are retained, and the type of backup to capture.
Extended Retention	Add this to retain a subset of snapshots (backups) for longer duration than defined by the protection schedule.
Retry Options	Use this option to customize the retry settings for capturing Snapshots. By default, Cohesity attempts to capture Snapshots three times before the protection run fails. The default time between retries is thirty minutes. You can customize the number of retries and how long to wait between each attempt. > **Note:** Set **Retry Options** to **1**, as the Microsoft 365 connector already has the retry mechanism handling the failed requests. There is no need to increase the value for this setting in the Protection Policy.

Field	Description
Quiet Times	Quiet Times define time periods when new protection runs are not started. For example, you might want to configure hourly backups that run during weekdays but not on Saturdays or Sundays. Quiet Times only prevent new protection runs from starting during the specified time period. The protection runs that started before the quiet time period are not affected and will continue to run. For example, if a protection run starts at 12:45 AM on Saturday morning and there is a weekend quiet time period that starts at 1 AM on Saturday morning, the protection run will continue to run past 1 AM. No new protection runs are started during the quiet time period.
Replication	Replicate snapshots to another Cohesity cluster.

Use an Existing Protection Policy

You can edit an existing Protection Policy and configure it with applicable policy settings for Microsoft 365 Groups. In this case, all the policy settings apart from the settings applicable to Microsoft 365 Groups are ignored.

To use an existing Protection Policy:

1. Navigate to **Data Protection > Policies**.
2. On the **Policies** page, select the policy that you plan to edit.
3. On the **Policy Details** page, click **Edit** and configure the applicable policy settings for Microsoft 365 Groups. For information on the applicable policy settings, see Policy Settings for Microsoft 365 Groups.
4. Click **Save**.

The updated policy settings are applied to the Protection Group in the next protection run.

Manage Groups Backup Configuration

A backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

> **Note:** You cannot update the registered Microsoft 365 domain and the assigned Storage Domain in the Protection Group settings.

Add Microsoft 365 Groups to the Protection Group

You can add a new Microsoft 365 Groups to the Protection Group for backup. The newly added Microsoft 365 Groups are backed up from the next protection run, and it will be a full backup for the recently added user.

To add Microsoft 365 Groups to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for OneDrive.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Microsoft 365 - Groups** page, click ✎ .
5. From the **Groups** list, select the Microsoft 365 Groups that you plan to add to the backup and click **Save Selection**.
6. Click **Save**.

Remove Microsoft 365 Groups from the Protection Group

You can remove the Microsoft 365 Groups from the Protection Group that you do not want to back up in the next protection run. When you remove a site from the protection group, the site's incremental backup is not performed from the future protection run. The existing backup for the site is preserved until the snapshot expires.

To remove Microsoft 365 Groups from the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for OneDrive.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Microsoft 365 - Groups** page, click ✎ .
5. From the **Groups** list, unselect the Microsoft 365 Groups that you plan to remove from the backup and click **Save Selection**.
6. Click **Save**.

Enable or Disable Auto Protect

The Auto Protect option enables you to automatically protect the new sites that are added to Microsoft 365.

When the Auto Protect option is enabled:

- All the groups that are added to Microsoft 365 in the future are automatically added to the Protection Group and are protected from the next protection run.
- All the Groups that are removed from Microsoft 365 in the future are automatically removed from the Protection Group and are not protected from the next protection run. The existing backups for the user are preserved until the snapshot expires.

When the Auto Protect option is disabled, you need to manually:

- Add newly onboarded groups on Microsoft 365 to the Protection Group.
- Remove existing groups that are offboarded on Microsoft 365 from the Protection Group. The existing backups of the users are preserved until the snapshot expires.

To enable or disable Auto Protect:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for OneDrive.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Microsoft 365 - Groups** page, click ✎ .
5. From the **Groups** list, click the shield icon in the domain level to enable or disable Auto Protect and click **Save Selection**.
6. Click **Protect**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for OneDrive.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Start an On-demand Protection Run

You can manually start a protection run of the Protection Group that you have created to back up Microsoft 365 Groups. It provides you options to:

- Back up all the objects or only selected objects in the Protection Group.
- Select an incremental or full backup.
- Add replication.

To start a protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Microsoft 365 Groups.
3. Click the actions menu (⋮) next to the Protection Group and select **Run Now**.
4. In the pop-up window, perform the following:
    1. In the **Backup** drop-down list, select any one of the following:
        - Backup all Objects in the Protection Group
        - Backup only selected Objects in the Protection Group
    2. In the **Backup Type** drop-down list, select the backup type.
    3. Optional. In the **Replicate** section, select the replication target and the retention duration.
5. Click **Backup Now**.

Pause Future Protection Runs

You can pause future protection runs for the Protection Group. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Microsoft 365 Groups.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired then a full backup is triggered

To resume a paused protection run:

1. Navigate to > **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group and Snapshots, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity cluster.

To delete the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Microsoft 365 Groups.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Delete Protection Group Only
    - Delete Protection Group and Snapshots

Recover Groups

You can restore Microsoft 365 Group data using Cohesity. In the same Microsoft 365 domain, you can restore data to the same Microsoft 365 Group, to an alternate Microsoft 365 Group, or to a new Microsoft 365 Group.

Points to note:

- If you're restoring a Microsoft 365 Group that does exist in the Microsoft 365 domain, Cohesity creates a new Microsoft 365 Group with the metadata and data from the backup snapshot.
- If you restore to an existing Microsoft 365 Group, the group resources in the existing Microsoft 365 Group are overwritten or appended with the restored data. The following table details the group resources that are overwritten or appended:

Restore Behaviour	Group Resource Type
Appended	members
	owners
	mails (data)
Overwritten	hideFromAddressLists
	hideFromOutlookClients
	displayName
	visibility
	securityEnabled
	description
	theme

To restore Microsoft 365 Groups, you can search through the backups by group name or using a string pattern in the group name that you plan to restore and then start the restore operation.

> **Note:** You use * character to list all the groups.

You can restore the Microsoft 365 Group data to:

- The same Microsoft 365 Group
- A different Microsoft 365 Group in the same Microsoft 365 domain
- A new Microsoft 365 Group in the same Microsoft 365 domain.

To restore Microsoft 365 Groups:

1. Navigate to **Data Protection > Recoveries**. Click **Recover** on the top-right of the page and then select **Microsoft 365** > **Groups** as the recovery source.
2. Search and select the Microsoft 365 Group you need, and click **Next:Recover Options**.
3. Under **Recover To**, select any one of the following options:

Options	Description
Original Location	**Recover to the same Microsoft 365 Group**: To restore data to the same group from which it was backed up.
New Location	**Alternate Microsoft 365 Group in the same Microsoft 365 domain:**: Enter the **Group Name** to which the data needs to be restored. **Note:** If the **Group Name** (display name or nickname) matches an existing group, the data is restored to the existing group. If not, Cohesity creates a new group and restores the data in it.

4. Under **Recovery Options**, perform the following:
   - Enable the **Continue on Error** option if you want to continue the recovery even if one of the objects encounters an error. By default, this option is disabled and the recovery operation will fail if one of the objects encounters an error.
   - In the **Task Name** field, enter the name of the recovery task, if you want to change the default recovery task name.
5. Click **Start Recovery** to start the restore operation.

Recover Groups Items

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

After you protect the Groups in your domain, you can recover the following Group items:

- Group Mailbox items, such as Group emails, mailbox folders, and calendar items.
- Group Site items, such as, document libraries.

> **Important:** Before you can recover a Group's items, you need to set up Microsoft 365 Groups protection with Indexing enabled.

Recover Groups Mailbox Items

To recover a Groups Mailbox items:

1. In **DataProtect**, go to **Sources** to set up your recovery task.
2. Click on the **Source** name and select the **Group** tab.

3. Above the tree, select **Show All** > **Protected**.
4. Find the Group you need and click the **Recover Groups Items** button on that row to open the **New Recovery** form.
5. On the **New Recovery Microsoft 365 - Groups** page, in the **Recovery Type**, select **Search Group's Mailbox Items**.
6. From the **Item Type** drop-down, do the following:
   - Select **Emails & Folders** and use the global search to find the emails and folders that needs to be restored.
   - Select **Calendars** and use the global search to find the calendar item that needs to be restored.

   Click **Next: Recover Options** to return to the form.
7. Under **Recover To**, select **Original Location** or **New Location**.
   - If you choose **New Location**, select a **Registered Source** and the **Target MS Group**.
   - Click **Download as PST** to export the backed-up email(s), mailbox folder(s), or calendar items as a PST file. To enhance security, enable **Password Protection** under **Recovery Options** and set a password for the exported PST file.

     A new recovery task is created to download the PST file. When the task is completed, from the Activity page, click the task name and then click Download Files to download the generated zip file.
8. Select your Recovery Options:
   - **Continue on Error**. Enable to recover even if errors occur when recovering Groups. For example, if one of the Groups cannot be recovered, Cohesity will still attempt to recover the other selected Groups.
   - **Task Name**. Change the default name of the recovery task.
   - **Password Protection**. Enable to add a password for the exported PST file.
9. Click **Start Recovery**.

Recover Groups Site Items

To recover a Groups Site items:

1. In **DataProtect**, go to **Sources** to set up your recovery task.
2. Click on the **Source** name and select the **Group** tab.
3. Above the tree, select **Show All** > **Protected**.
4. Find the Group you need and click the **Recover Groups Items** button on that row to open the **New Recovery** form.

5. On the **New Recovery Microsoft 365 - Groups** page, in the **Recovery Type**, select **Search Group's Site Items**.
6. Search and select the Group Site items you need, and click **Next: Recover Options**.
7. Under **Recover To**, select **Original Location** or **New Location**.
    - If you choose **New Location**, select a **Registered Source** and the **Target MS Group**. Then, enter the name of the **Document Library**.
    - Click **Download** to download the Group Site item.

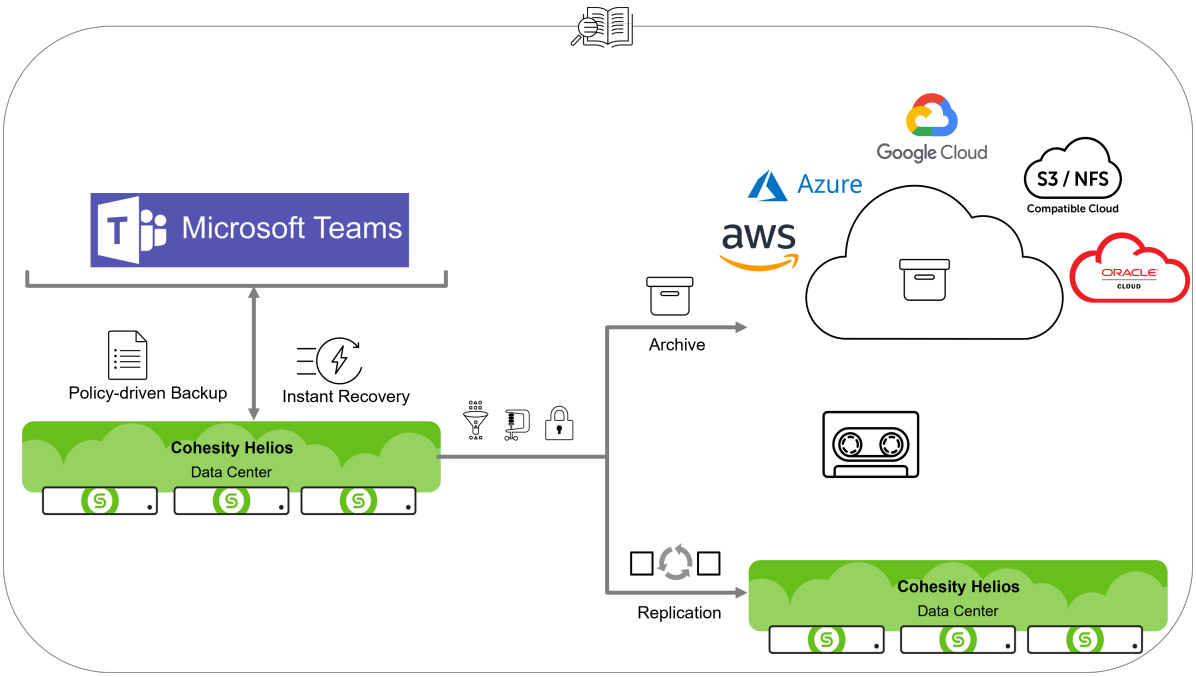
      A new recovery task is created to download the Group Site item(s). When the task is completed, from the **Activity** page, click the task name and then click **Download Files** to download the generated zip file.
8. Select your Recovery Options:
    - **Continue on Error**. Enable to recover even if errors occur when recovering Groups. For example, if one of the Groups cannot be recovered, Cohesity will still attempt to recover the other selected Groups.
    - **Restore Original Owner Member**. Enable to restore the original owner member as part of the recovery.
    - **Additional Group Owner**. Enable to add additional group owners to the recovered Group.
    - **Task Name**. Change the default name of the recovery task.
9. Click **Start Recovery**.

Teams

Microsoft Teams is a collaboration solution provided by Microsoft that is bundled with the Microsoft 365 service. For more information, see Microsoft documentation. Using the policy-based data protection solution from Cohesity, you can backup and recover Teams data in Microsoft 365.

The following are the data backed by Cohesity for Microsoft 365 Teams:

- Standard (public) channels
    - Files associated with these channels
    - Conversations/post associated with these channels
- Private channels
    - Files associated with these channels
    - Conversations/post associated with these channels
- Group mailboxes associated with the Teams



Plan and Prepare for Teams Protection

Before you register your Microsoft 365 domain with Cohesity to protect Microsoft 365 data, ensure:

- You have completed all the prerequisites.
- You have reviewed and understood the considerations and best practices.

Considerations

- A Team must have at least one owner with a license and login-enabled for that owner.
- Alternate restore of multiple Teams is not supported. But, you can recover multiple Teams to the original Microsoft 365 domain.
- Restoring deleted private channels or private channels in a deleted team to the original location is not supported.
- Private channels are not restored as a part of the alternate restore.
- Recovery of the following Team data is not supported:
    - Channel Tabs
    - Team Apps
    - Team Site Templates
    - Team Site Lists

    - Public or Private Channel conversations or posts
    - Files that belong to system document libraries.
- Downloading of Conversations/Posts in channels is supported.
- Backup and download of the following is not supported:
    - Self-message (messages sent to self)
    - Saved or pinned Posts property in the conversation
    - Meeting recordings metadata
    - Shared Channels
    - Emojis and Stickers
- Recovery of system document libraries—those that are included by default in a Team site, such as Site Assets, Style Library, Documents, and Form Templates—is not supported. Only non-system document libraries within a Team site can be recovered. Additionally, restoring Team site templates is not supported. The original appearance and configuration of the Team site will not be restored; instead, the new Team site will be created using Microsoft's default template.
- Backup and restore of OneNote files associated with the Teams are not supported.
- If the private channel members are deleted from the channel but are still part of the Team or changed from owner to member, the private channel members are restored. However, if a member has changed to the owner, the change is retained after the restoration.
- The entities protected for Teams include the SharePoint sites associated with the Team.
- New Teams Channels created as part of the restore are created with the suffix: `_coh<uniqueint>`. Where `_coh` is appended to the channel name, and `uniqueint` is a random integer value.
- A new Team is created when you restore the deleted Teams to their Original Location. If the restore fails, you need to clean up the newly created team manually.
- Restoration fails if the group properties are not updated appropriately during restoration. In this case, you need to retry the restore.
- For alternate search and restore of Teams files, the new Teams Channels created as target Team Channels will be public channels.
- Cohesity does not support Teams data protection in a multitenant environment.
- Suppose folders such as Feeds, Sync Issues, Legacy Archive Journals, Outbound, Managed Folders, Files, Yammer Root, Clutter, MeContact, and Archive, are not already present. In that case, these folders are skipped during restore.
- Backup and recovery of channel tabs are not supported.

- File/folder permissions with no role will not be recovered since Microsoft does not allow adding such permissions via Graph APIs. For example, no role will be assigned when a Restricted View permission is added to a user from Advanced Setting.
- Microsoft 365 items with only special characters will not be listed in granular search. The item name must contain at least one alphanumeric character to be listed in the search result.
- Recovery of Private Channels is not supported in GCC High.
- Protection of Teams Chat is not chargeable.

Best Practices

To protect your Microsoft 365 Teams data, Cohesity recommends the following best practices:

- In the Protection Policy, set **Retry Options** to **2** or **3**, with a small interval between the retry attempts.
- Use **Auto Protect** to automatically include the newly added sites on Microsoft 365 Teams to the Protection Group.
- Avoid adding the same sites in multiple Protection Groups.

For the workflows supported by Teams, see Microsoft 365 Workflows.

Register and Manage Microsoft 365 Teams

To start protecting Microsoft 365 applications, you need to register the Microsoft 365 domain as a source in Cohesity.

Cohesity uses the Microsoft Graph API for object discovery, backup, and recovery in Microsoft 365. Cohesity uses an Azure application created and registered on the Azure portal with the necessary permissions to use the Graph API. You can either let Cohesity create the Azure application or manually enter Azure application details while registering your Microsoft 365 domain as a source in Cohesity.

Express Registration for Microsoft 365 Sources

Before you register Office 365 as a source on Cohesity, ensure that you:

- Review the requirements, considerations, and best practices.
- Perform the prerequisite tasks.

For more information, see Plan and Prepare for Teams Protection.

To register your Microsoft 365 domain:

1. Navigate to **Sources** and select **Register** > **Microsoft 365**.
2. Choose **Teams** as the **Microsoft 365 Application** to discover.

> **Note:**
> If the Private Chats and Teams Posts option is enabled under the Mailbox and Teams apps respectively, the Private Chats and Teams Posts will be backed up along with the corresponding Users and Teams respectively.

> **Note:** This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

3. In the **Account Credentials** section, enter the Microsoft 365 **Username** and **Password**.

> **Note:** Toggle ***on*** the **Enable OAuth** option. Ensure that you added the required permission, for more information, see Plan and Prepare for Teams Protection.

4. Adding multiple Microsoft 365 service accounts using the **Additional Service Accounts** section requires OAuth disabled, as Microsoft has enabled OAuth by default, ignore adding multiple Microsoft 365 service accounts.
5. In the **Azure Applications** section, enter the number of Azure applications you want to create based on your requirements and click **Create**.

> **Note:** By default, two Azure applications will be created. To better manage Microsoft 365 throttling, Cohesity recommends at least two Azure apps.

6. In the **Add Azure Application** form, copy the device code and click the **Microsoft Azure App** link to open the Microsoft Azure App authorization service in a new tab.

> **Note:** If you prefer to create your Azure apps manually, see Manual Registration for Microsoft 365 Sources.

7. Paste the copied code in the **Microsoft Azure App authorization** service and click **Next**.
8. Log in to Microsoft Azure, enter the **Username** and **Password** of your Microsoft 365 account and click **Sign in**.

> **Note:** Ensure that your Microsoft 365 account has a global administrator access.

9. Follow the instructions to complete the authorization on the Microsoft Azure portal. Then, wait for Microsoft Azure Authorization to complete.
10. Optional. Toggle on **Use Windows Connector** and specify the hostname (FQDN) or server IP of the Windows Connector added as a Physical server.

> **Note:** If you are protecting only Microsoft 365 Teams data, then the Use Windows Proxy option is not applicable. For more information, see Set Up a Windows Connector for Microsoft 365.

11. Click **Register**.

Manual Registration for Microsoft 365 Sources

Before you register Office 365 as a source on Cohesity, ensure that you:

- Review the requirements, considerations, and best practices.
- Perform the prerequisite tasks.

For more information, see Plan and Prepare for Teams Protection.

To register your Microsoft 365 domain:

1. Navigate to **Sources** and select **Register** > **Microsoft 365**.
2. Choose **Teams** as the **Microsoft 365 Application** to discover.

> **Note:**
> If the Private Chats and Teams Posts option is enabled under the Mailbox and Teams apps respectively, the Private Chats and Teams Posts will be backed up along with the corresponding Users and Teams respectively.

> **Note:** This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

3. In the **Account Credentials** section, enter the Microsoft 365 **Username** and **Password**.

> **Note:**
> - Ensure that login is enabled for the user account.
> - The **Enable OAuth** option is applicable only if you want to protect both Exchange Online and SharePoint Online data. If you are protecting only SharePoint Online data, then this option is not applicable.

4. In the **Azure Applications** section, enter the number of Azure applications you want to create based on your requirements and click **Create**.

   > **Note:** By default, two Azure applications will be created. To better manage Microsoft 365 throttling, Cohesity recommends at least two Azure apps.

5. In the **Add Azure Application** form, click the **You can also add Azure App manually** link.
   - For **Certificate** authentication, the **App ID** and the **Associated Certificate** of your custom Azure app will be populated. You can select the **Associated Certificate** from the list of certificates present in your certificate store or Create Cohesity Managed Certificate.

     > **Note:** This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

   - For **App Secret** authentication, the **App ID** and **App Secret Key** of your custom Azure app will be populated.

   > **Note:** You can add multiple Azure apps for a Microsoft 365 source to load balance your backup and restore operations. Click **+** to add multiple Azure apps. When you do, ensure that you provide the valid **App ID** and **App Secret Key**.

   To migrate the existing apps from App Secret to Certificate authentication method, see Migrate Existing Apps to Certificate-Based Authentication.

6. Optional. Toggle on **Use Windows Connector** and specify the hostname (FQDN) or server IP of the Windows Connector added as a Physical server.

> **Note:** If you are protecting only Microsoft 365 Teams data, then the Use Windows Proxy option is not applicable. For more information, see Set Up a Windows Connector for Microsoft 365.

7. Click **Register**.

Manage Microsoft 365 Source Registration

After registering your Microsoft 365 domain as a source, you can:

- Update the Microsoft 365 source configuration.
- Refresh the source details.
- Unregister the Microsoft 365 domain from Cohesity.

Update the Microsoft 365 Source Configuration

After registering your Microsoft 365 source on Cohesity, you might have changed the Microsoft 365 domain configuration by:

- Changing the credentials of Microsoft 365 user account credentials.
- Updating the app secret by adding more permissions to the custom app.
- Creating a new app ID.

You can update the Microsoft 365 details provided during the registration process with the latest Microsoft 365 configuration details.

To edit the Microsoft 365 source configuration:.

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Microsoft 365 source and select **Edit**.
3. In the **Update Microsoft 365 Source** page, update the required configurations.
4. Click **Register**.

Refresh the Microsoft 365 Source

You can refresh the Microsoft 365 domain configuration and fetch the latest changes on the Microsoft 365 domain.

To refresh the Microsoft 365 Source Configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Microsoft 365 source and select **Refresh**.

Unregister the Microsoft 365 Domain

If you plan to stop taking the backup of your Microsoft 365 domain, you can unregister the Microsoft 365 source from Cohesity.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the Microsoft 365 source.

To unregister the Microsoft 365 domain:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Microsoft 365 source and select **Unregister**.

Backup Microsoft 365 Teams

Microsoft 365 Teams data is protected using a Protection Group and a Protection Policy. A Protection Group enables you to select the objects that you want to back up. It uses the schedules and settings defined in the Protection Policy to determine when and how backups are captured and replicated.

A Protection Policy is a reusable list of settings that define the type of backup, backup schedule, and backup snapshot retention. Also, for Disaster Recovery, you can add replication for the Protection Group using the Protection Policy. You can select which standard or custom policy to use when creating a Protection Group. For more details, see Manage Protection Policy.

To protect Microsoft 365 Teams:

1. Do one of the following:
   - On the **Dashboards** page, from the drop-down at the top of the page, select **Data Protection** and do one of the following:
     - If there is no existing Protection Group, click **Start Data Protection** > **Microsoft 365** > **Teams**.
     - Click **Protect** > **Microsoft 365** > **Teams**.
   - Select **Data Protection > Protection**. Click **Protect** on the top-right of the page and then select **Microsoft 365** > **Teams**.
   - Select **Data Protection > Sources**. Click the actions menu (⋮) next to the Microsoft 365 source and then select **Protect Teams**.
2. In the **New Protection** pop-up, do one of the following:
   - Protect Teams by specifying a subset of options such as objects, protection group and policy by clicking the edit icon corresponding to the following options:
     i. **Add Objects**: Select the registered Microsoft 365 source or click **Register Source** to register a Microsoft 365 account. From the **Teams**

list, select the Team(s) that you plan to back up.

ii. **Protection Group**: Specify a name for the Protection Group.

iii. **Policy**: Select an existing policy or click **Create Policy** to create a new protection policy.

iv. **Storage Domain**: Select the appropriate storage domain.

> **Note:** This option is visible on the **New Protection** pop-up only if there is more than one storage domain.

v. Click **Protect**.

- To protect Teams by specifying all the options, click **More Options**.

3. From the **Source** drop-down list, select the registered Microsoft 365 source or click **Register Source** to register a Microsoft 365 source. For more information, see Register and Manage Microsoft 365 Teams.
4. From the **Teams** list, select the Team(s) that you plan to back up or click the icon to enable Auto Protect at the domain level. For more information on Auto Protect, see Enable or Disable Auto Protect.
5. In the **Protection Group** section, do one of the following:
   - Select **New Group** to create a new Protection Group. In the **Protection Name** field, enter a name from the Protection Group.
   - Select **Existing Group** to use the settings of an existing Protection Group. From the **Group** list, select an existing Protection Group and click **Protect**.
6. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, Create or Use an Existing Protection Policy.
7. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains.
8. After selecting a Storage Domain, if you need to change any of the advanced settings on the **Microsoft 365 - Teams** page, scroll down and click **Edit** on the right. For more information, see Advanced Settings.
9. Click **Protect**.

   Your Microsoft 365 Teams Data Protection is now active and running.

Advanced Settings

Advance Settings	Description
Start Time	Available only if the selected policy is set to Backup Daily. Indicates when the protection run should start. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
End Time	**Optional**. Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts prior to this date runs until completion even if it completes after this date.
QoS Policy	Select an appropriate quality of service (QoS) policy. **Note:** Cohesity recommends specifying **Backup HDD**, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Indexing	By default, indexing is enabled. **Note:** Only the channels of the Microsoft 365 Teams are indexed.

Advance Settings	Description
Alerts and Priority	**Optional**. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts.
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs
Email Recipients	You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection run.
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks). > **Note:** Users with similar SLAs can be grouped together and a custom policy and Protection Group can be created to achieve different SLAs.
Description	**Optional**. Enter a brief description about the Protection Group.

Create or Use an Existing Protection Policy

Create a Protection Policy with the settings listed in the Policy Settings for Microsoft 365 Teams. For detailed instructions on how to create a Protection Policy, see Create or Edit a Standard Policy.

Policy Settings for Microsoft 365 Teams

The following table lists the applicable policy settings for Microsoft 365 Teams:

Field	Description
DataLock	Add a DataLock for compliance and regulatory requirements. This ensures that your protected data, including local backups, archives, and replication, cannot be modified until the DataLock expiration. Once applied, a DataLocked Snapshot will be deleted only after its retention period expires. A DataLock prevents all users from modifying or deleting any Snapshots that were generated by the protection runs that use this Policy. The users include those who have the Data Security role in Cohesity as well. > **Note:** Only users with the Data Security role can add, modify, or remove a DataLock from a Policy.
Scheduled Backup	Defines when backups are captured, how long they are retained, and the type of backup to capture.
Extended Retention	Add this to retain a subset of snapshots (backups) for longer duration than defined by the protection schedule.
Retry Options	Use this option to customize the retry settings for capturing Snapshots. By default, Cohesity attempts to capture Snapshots three times before the protection run fails. The default time between retries is thirty minutes. You can customize the number of retries and how long to wait between each attempt. > **Note:** Set **Retry Options** to **1**, as the Microsoft 365 connector already has the retry mechanism handling the failed requests. There is no need to increase the value for this setting in the Protection Policy.
Quiet Times	Quiet Times define time periods when new protection runs are not started. For example, you might want to configure hourly backups that run during weekdays but not on Saturdays or Sundays. Quiet Times only prevent new protection runs from starting during the specified time period. The protection runs that started before the quiet time period are not affected and will continue to run. For example, if a protection run starts at 12:45 AM on Saturday morning and there is a weekend quiet time period that starts at 1 AM on Saturday morning, the protection run will continue to run past 1 AM. No new protection runs are started during the quiet time period.

Use an Existing Protection Policy

You can edit an existing Protection Policy and configure it with applicable policy settings for Microsoft 365 Teams. In this case, all the policy settings apart from the settings applicable to Microsoft 365 Teams are ignored.

To use an existing Protection Policy:

1. Navigate to **Data Protection > Policies**.
2. On the **Policies** page, select the policy that you plan to edit.
3. On the **Policy Details** page, click **Edit** and configure the applicable policy settings for Microsoft 365 Teams. For information on the applicable policy settings, see Policy Settings for Microsoft 365 Teams.
4. Click **Save**.

The updated policy settings are applied to the Protection Group in the next protection run.

Manage Teams Backup Configuration

A backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

> **Note:** You cannot update the registered Microsoft 365 domain and the assigned Storage Domain in the Protection Group settings.

Add Microsoft 365 Teams to the Protection Group

You can add a new Microsoft 365 Teams to the Protection Group for backup. The newly added Microsoft 365 Teams are backed up from the next protection run, and it will be a full backup for the recently added user.

To add Microsoft 365 Teams to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for OneDrive.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Microsoft 365 - Teams** page, click ✎ .
5. From the **Teams** list, select the Microsoft 365 Teams that you plan to add to the backup and click **Save Selection**.
6. Click **Save**.

Remove Microsoft 365 Teams from the Protection Group

You can remove the Microsoft 365 Teams from the Protection Group that you do not want to back up in the next protection run. When you remove a site from the protection group, the

site's incremental backup is not performed from the future protection run. The existing backup for the site is preserved until the snapshot expires.

To remove Microsoft 365 Teams from the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for OneDrive.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Microsoft 365 - Teams** page, click ✎ .
5. From the **Teams** list, unselect the Microsoft 365 Teams that you plan to remove from the backup and click **Save Selection**.
6. Click **Save**.

Enable or Disable Auto Protect

The Auto Protect option enables you to automatically protect the new sites that are added to Microsoft 365.

When the Auto Protect option is enabled:

- All the Teams that are added to Microsoft 365 in the future are automatically added to the Protection Group and are protected from the next protection run.
- All the Teams that are removed from Microsoft 365 in the future are automatically removed from the Protection Group and are not protected from the next protection run. The existing backups for the user are preserved until the snapshot expires.

When the Auto Protect option is disabled, you need to manually:

- Add newly onboarded Teams on Microsoft 365 to the Protection Group.
- Remove existing Teams that are offboarded on Microsoft 365 from the Protection Group. The existing backups of the users are preserved until the snapshot expires.

To enable or disable Auto Protect:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for OneDrive.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Microsoft 365 - Teams** page, click ✎ .
5. From the **Groups** list, click the A icon in the domain level to enable or disable Auto Protect and click **Save Selection**.
6. Click **Protect**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for OneDrive.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Start an On-demand Protection Run

You can manually start a protection run of the Protection Group that you have created to back up Microsoft 365 Teams. It provides you with options to:

- Back up all the objects or only selected objects in the Protection Group.
- Select an incremental or full backup.

To start a protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Microsoft 365 Teams.
3. Click the actions menu (⋮) next to the Protection Group and select **Run Now**.
4. In the pop-up window, perform the following:
    1. In the **Backup** drop-down list, select any one of the following:
        - Backup all Objects in the Protection Group
        - Backup only selected Objects in the Protection Group
    2. In the **Backup Type** drop-down list, select the backup type.
5. Click **Backup Now**.

Pause Future Protection Runs

You can pause future protection runs for the Protection Group. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Microsoft 365 Teams.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired then a full backup is triggered

To resume a paused protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

> **Note:** After deleting the Protection Group and Snapshots, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Cluster.

To delete the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Microsoft 365 Teams.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:

- Delete Protection Group Only
- Delete Protection Group and Snapshots

Replicate Microsoft 365 Data

Cohesity enables you to replicate Microsoft 365 data to another Cohesity cluster for disaster recovery use cases. For more details about replication, see Replication and Remote Access Setup.

Cohesity provides a policy-based replication solution for Microsoft 365 data. In the Protection Policy, you can specify the remote Cohesity cluster, define conditions for replication, specify the retention period of the data on the remote Cohesity cluster, and other parameters.

To replicate Microsoft 365 data to another Cohesity cluster:

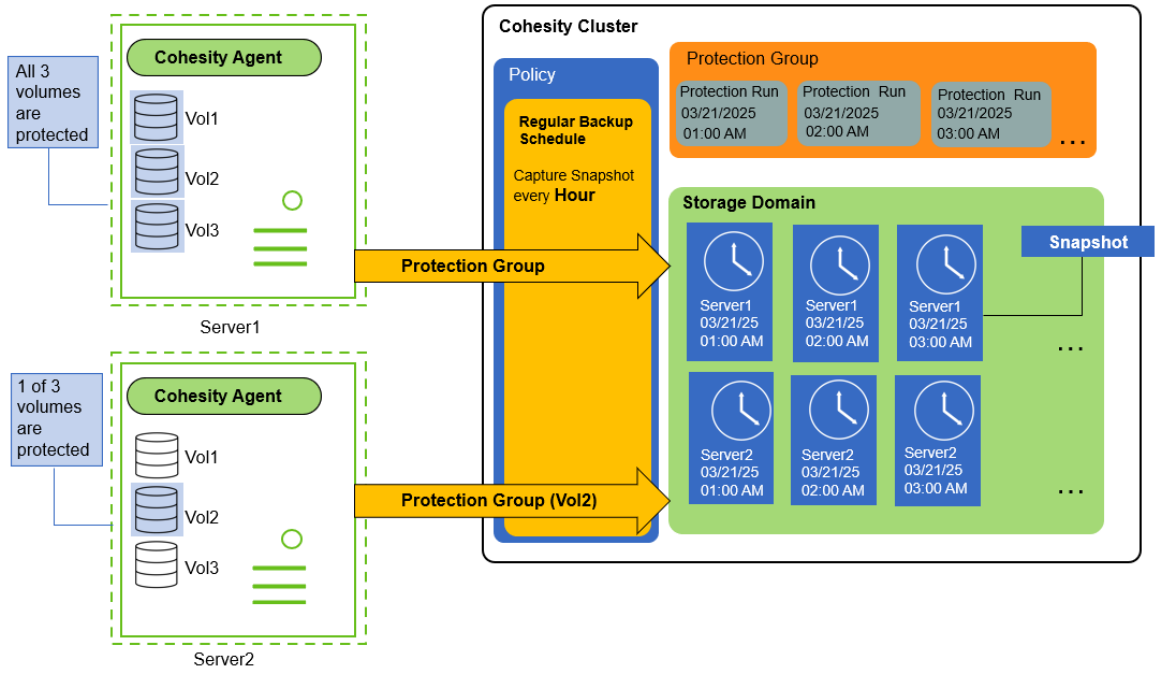
1. Configure replication to another Cohesity cluster. For more details, see Replication and Remote Access Setup.
2. Edit the existing Protection Policy that you had created for backup or create a new Protection Policy for backup. Configure the replication settings as per your requirement. For more information, see Create or Edit a Standard Policy.
3. Run the Protection Group that you have created for Microsoft Exchange Online or OneDrive based on your requirement or the replication settings will take effect in the next scheduled Protection Group run.

Chapter 15: Physical Servers

After installing the Cohesity Agent on a physical Server and registering it with the Cohesity cluster, the Cohesity cluster can use a block-based or file-based Protection Group to back up the physical Server. Protection Groups can run repetitively on a schedule.

To learn more about the relationship between Protection Groups and Policies, see Manage Protection Policy. For instructions on how to back up Physical Servers, see Manage Protection Groups.

For example, you could create a block-based Protection Group with a protection schedule that backs up all the critical Servers every hour as represented by the *Critical* Protection Group in the following figure.



During a Protection Group Run, Snapshots of the Servers are saved on the Cohesity cluster with a date and time stamp.

For instructions on how to back up Physical Servers, see Add or Edit a Protection Group for Physical Servers.

Plan and Prepare for Physical Server Protection

This topic provides information on minimum permissions, prerequisites and considerations to protect physical servers with the Cohesity cluster.

Minimum Permissions

Ensure you have the required minimum permissions to register physical servers as a source with the Cohesity, and to perform backup and recovery. For more information, see Ensure Adequate Privileges for Cohesity on the Source.

Minimum Agent Requirements

Operating System	Minimum CPU	Minimum memory	Free Disk Space	Software Requirement
Linux	1 core	300 MB	400 MB	nfs-utils, rsync, lsof, wget
Debian/Ubuntu	1 core	300 MB	400 MB	nfs-utils, rsync, lsof, wget
SLES/openSUSE	1 core	300 MB	400 MB	nfs-utils, rsync, lsof, wget, libcap-progs
RHEL/CentOS/OEL	1 core	300 MB	400 MB	nfs-utils, rsync, lsof, wget
Solaris	0.5 core	1.5 GB	100 MB	Java 1.8, sudo
AIX	0.25 core	1 GB	100 MB	Java 1.8, sudo
HP-UX	1 core	1 GB	100 MB	Java 1.8, sudo

Support Matrix

Before you register your physical servers with the Cohesity cluster, ensure that Cohesity supports the physical server versions. For more information, see Supported Software

Ports Used for Communication

Ensure all necessary ports are open in the firewall between the Cohesity cluster and physical servers. For more information, see Manage Firewall Ports.

Prerequisites and Considerations

Physical Server Protection

Prerequisites

- The Cohesity Agent running on the hosts should be Cohesity version 6.2 onwards.
- If physical servers are behind NAT, add the NAT server's IP address to the Cohesity cluster's subnets specified in the allowlist.

Physical Server - Generic Considerations

- Making a disk offline and then online triggers a full backup for Simple, Striped and Spanned volumes. Mirrored volumes are not affected.
- Recovering a file or instantly mounting volumes from an AD-joined Cohesity cluster to a server that does not belong to that AD domain is not supported.
- Instant volume mounting does not currently support using drive letters on the target physical Server. Volumes are under C:\CohesityMounts\... for Windows and /opt/cohesity/agent/mount_paths/vol_mounts/….. for Linux systems.
- You cannot add different types of physical servers (Windows, Linux) in a single Protection Group as the supported features of Cohesity Data Cloud are different for different physical servers.
- Cohesity supports recovery only from physical server to physical server. Recovering physical server to VM and vice-versa is not supported.
- Cohesity supports recovering files and folders from Linux to Linux, AIX to AIX, and Solaris to Solaris only. Recovering files and folders from one operating system to another is not supported. For example, recovering files and folders from Linux to AIX or Solaris is not supported.
- After creating a directive file-based Protection Group for a physical server, you can simultaneously trigger more than one protection run of the Protection Group to backup only a specific set of files and folders in each run. However, you cannot simultaneously trigger multiple protection runs to back up the same file or folder.
- When browsing files or folders for recovery, Cohesity does not display files or folders with an absolute path length exceeding approximately 3,500 characters. To recover these files or folders, select the parent directory.
- Due to variations across operating systems and file systems, sparse files may not be detected accurately. In such scenarios, they’ll be backed up as regular files, with

relevant updates in pulse logs.

- When sparse files are detected and processed during backups and recoveries, the amount of data processed during backups and recoveries will reflect the non-zero content. This is likely to differ from previous backups or recoveries where sparse files were processed as normal files.

Windows - Considerations

- When performing a recovery for a Windows physical server, if deduplication functionality is enabled for the backed-up data (files, folders, volumes, or mount volumes), the target machine should have deduplication functionality enabled by default, or the recovery jobs would fail.
- Recovery of deduplicated volume from archival is not supported for Windows physical servers.
- For file and folder recoveries to Windows machines, if the machine is apart of an AD Domain then the Cohesity Cluster must be joined to the same AD domain. The only alternative is to disable **SMB Security** in **Cohesity Views Global Settings** and allow Guest login on the Windows machine.
- Windows file-based backup does not support the following:
  - Backup and recovery of encrypted files (EFS) and alternate data streams (ADS).
  - Backup of symbolic links within a symbolic link pointing to the NAS target.
- A subsequent Full (No CBT) backup would also occur after a machine restart unless it is an intentional restart of a Windows physical server with the Capture Incremental After Server Restart option toggled on.
- You cannot add different types of physical servers (Windows, Linux) in a single Protection Group as the supported features of Cohesity Data Cloud are different for different physical servers.
- Source-side deduplication is not supported in Windows 2008 R2 servers.
- By default, VSS writers are not used for Windows file-based protection. This can be controlled using the crash-consistent backup settings. For more information, see Protecting a Physical Server (File-based).
- To avoid antivirus scans on the Cohesity folder saved on the `C:` drive, place it under the exclusion of the antivirus software.

Linux

Prerequisites

- To use the Linux PowerPC, Linux on z/Architecture or Linux on ARM (aarch64) agent, the following prerequisites are required:

- Java Runtime Environment (JRE) 8+ (JRE 8, 11, 17)
- Minimum free space of 102400KB is required in /var and /usr directories
- Minimum memory of 2GB is recommended

Considerations

- For block-based backups, the Cohesity Linux agent uses LVM snapshots to back up volumes. LVM does not support any consistency across volumes, so snapshots of different volumes, even in the same backup run, will have slightly different point in time snapshot timestamps.
- Linux block-based backup does not support CBT (Changed Block Tracking). Therefore, every incremental backup is a full backup.
- For block-based backup of the Linux server, Cohesity does not support thin-pool configurations, which allows snapshots to be created outside the volume group.
- For block-based backup of the Linux server, Cohesity supports snapshot creation only inside the same volume group. If there is no space within the same volume group, block-based backup of the Linux server will fail.
- For SLES 11 SP4, the Linux agent is supported for the root user only.
- Linux PowerPC supports only file-based backups.
- Linux PowerPC supports only RPM-based installation.
- Linux on PowerPC, z/Architecture, and ARM (aarch64) supports only file-based backups.
- Linux on PowerPC, z/Architecture, and ARM (aarch64) supports only RPM-based installation.

AIX

Prerequisites

- To use the AIX agent (Java based), Java Runtime Environment (JRE) 8 needs to be installed on the source system.
- AIX agent (Java based) being installed should be a higher version than the existing version of GoAgent.
- Install 64-bit version 8 of IBM-supported AIX compatible Java.
- 1.5 GB of free RAM (at run time) to account for JRE overhead.
- Sudo package must be installed.
- Latest version of Bash must be installed. For more information, see AIX Toolbox for Linux Applications.
- Java Agent must be installed as the Root user.

Considerations

- Only file-based Protection Groups are supported.
- The mount point used for Oracle DB cloning is not persistent across reboots. To resolve this issue, manually update the **/etc/filesystem** file using any editor and update the mount path information.
- IVM (Instant Volume Mount) is not supported.
- The AIX physical server does not support the following:
  - Source-side deduplication
  - AIX clustering
  - AIX version earlier than 6.1
  - Power HA
  - JFS2-based snapshots
  - Veritas Cluster Server
  - BMR
  - Workload partitions (WPARs).

Red Hat High Availability (Pacemaker) Cluster

Considerations

- Pacemaker version 2.1 or higher with PCS is supported.
- Only resources of class ocf, provider heartbeat, type IpAddr2, and Filesystem are supported.
- The Cohesity agent must be installed on all nodes belonging to the cluster. If any additional node is added to the cluster at a later stage, the agent should be installed on it as well.
- It is expected that Filesystem resources are active on the same node where the IpAddr2 resource is running. Cohesity itself assumes no coupling between IpAddr2 and Filesystem resources.
- Backup and recovery are supported only if the agent is installed as the root user.
- If failover happens during the backup run, there may be a few files missed in the run. Explicit failover detection and handling can be enabled by contacting Cohesity Support.

Veritas Cluster Server (VCS)

Prerequisites

- One node in the VCS cluster must be active and the other nodes must be passive.
- Each node in the VCS cluster must have its own service group and each service requires access to all the shared volumes.

- The same version of the Cohesity Linux Agent must be installed on all the nodes in the VCS cluster.
- The following commands must exist on all the nodes in the VCS cluster:
  - whereis hares
  - whereis hagrp
  - whereis hasys
  - whereis haclus
  - whereis lltconfig

  If the command output returns the path of the command, the command is present on the node.

Considerations

- Only file-based backup and recovery of the VCS cluster running on a physical server is supported.
- Only active-passive VCS cluster configuration is supported (active-active configuration is not supported).
- If you are upgrading Cohesity Linux Agents of the VCS cluster from the Cohesity cluster using the VIP, then only the Agent on the node to which the VIP is pointing will be upgraded. Other nodes can be upgraded by one of the following methods:
  - Add individual nodes to the Cohesity cluster as a physical server and upgrade the Cohesity Linux Agent.
  - Do failover of VIP to other nodes and then upgrade the Cohesity Linux Agent.
  - Install fresh Agents on other nodes.
- To protect a VCS cluster shared disk, use VIPs to register the VCS cluster. To protect local disks, register the VCS nodes with their Private IPs.
- If a failover happens during backup, then the backup of some files might be skipped. These skipped files will be backed up in the next Protection Group run.
- If the failover takes more than 10 minutes, then the Protection Group run might fail.
- If a failover happens during the restore, the maximum delay permitted is 10 minutes. If the failover is more than 10 minutes, the restore will fail.
- If you mount a volume to a VIP using the Instant Volume Mount capability, and perform a failover followed by a teardown, then the teardown might fail, and the node's VIP will be orphaned.

Solaris

Prerequisites

- Java Agent must be deployed on the server.
- Physical source should be installed with Java version 8.

Considerations

- Block-based, BMR, Source side dedupe and volume recovery are not supported for Solaris.
- Solaris Zones in Solaris x86_64 are not supported.

HP-UX

Considerations

- Cohesity supports only file-based backup and restores on HP-UX servers.
- Cohesity does not support block-based, BMR, and source side dedupe backups on HP-UX servers.

Register or Edit a Physical Server

Before registering a physical server with the Cohesity cluster, you must download and install the Cohesity agent on each server you plan to register.

Overview

1. Download the Cohesity agent to the physical server.
2. Install the agent on the physical server.

   Instructions for silent installation on Windows servers are available here: Silently Install the Cohesity Agent on Windows Physical Servers.
3. Register the physical server with the Cohesity cluster.

Download and Install the Agent

Installing the agent on a physical server allows it to be registered as a source with the Cohesity cluster.

1. Select **Data Protection > Sources**.
2. Click **Download Cohesity Agent**.
3. Follow the installation instructions for the corresponding agent operating system:

   Windows Agent

   1. Ensure the agent has been downloaded to the server you want to protect.
   2. As an administrator with local system privileges on that server, run the executable with **Run as administrator** and complete the installation wizard.

      Install the **Volume CBT (Changed Block Tracker)** component to perform incremental backups. Installing this component requires a reboot. Without a

reboot, only full backups can be performed. Not installing this component means only full backups can be performed.

> **Note:**
> The Cohesity Volume CBT driver creates the **Cohesity_Bitmap.cty** file at the root of each volume. There are multiple ways to backup Windows physical server but the **Cohesity_Bitmap.cty** file will be available on the system only if the Volume CBT driver is installed. This file is used to maintain the CBT data for incremental block-based backups across Windows server reboots.
>
> Do not move or delete the "**.cty**" file.

The **File System CBT (Changed Block Tracker)** component is required for MS SQL file-based protection.

3. The agent starts automatically.

> **Note:** This installation does not require a restart. You can wait until a normal maintenance window (such as a Patch Tuesday) to restart. However, until you do, some Protection Groups that depend on Volume CBT will run in full backup mode.

Linux Agent

The Cohesity Linux agent is now available with different installer packages, providing support on multiple Linux distributions. The following table lists the installer packages and Linux distributions on which the installer package is supported.

Installer package	Linux distribution
(Default) RPM	RHEL and its derivative
SUSE RPM	SUSE
Script Installer	All supported Linux operating systems

Linux agent has dependencies on the following packages, which must be installed on the Linux server:

Command/Package	Linux distribution				
	RHEL	SUSE	CentOS	Ubuntu	Debian
rsync	rsync	rsync	rsync	rsync	rsync
mount	mount	mount	mount	mount	mount
lsof	lsof	lsof	lsof	lsof	lsof
umount	umount	umount	umount	umount	umount
cp	cp	cp	cp	cp	cp
chown	chown	chown	chown	chown	chown
chmod	chmod	chmod	chmod	chmod	chmod
mkdir	mkdir	mkdir	mkdir	mkdir	mkdir
rm	rm	rm	rm	rm	rm
tee	tee	tee	tee	tee	tee
hostname	hostname	hostname	hostname	hostname	hostname
stat	stat	stat	stat	stat	stat
blkid	blkid	blkid	blkid	blkid	blkid
ls	ls	ls	ls	ls	ls
losetup	losetup	losetup	losetup	losetup	losetup
dmsetup	dmsetup	dmsetup	dmsetup	dmsetup	dmsetup
timeout	timeout	timeout	timeout	timeout	timeout
lvs	lvs	lvs	lvs	lvs	lvs
vgs	vgs	vgs	vgs	vgs	vgs

Command/Package	Linux distribution				
	RHEL	SUSE	CentOS	Ubuntu	Debian
lvcreate	lvcreate	lvcreate	lvcreate	lvcreate	lvcreate
lvremove	lvremove	lvremove	lvremove	lvremove	lvremove
lvchange	lvchange	lvchange	lvchange	lvchange	lvchange
libpcap-progs	null	libpcap-progs	null	null	null
nfs-utils **Note:** Required for Instant Volume Mount, file-folder recovery from block-based backup and VMware backup.	nfs-utils	nfs-utils	nfs-utils	nfs-utils	nfs-utils
wget	wget	wget	wget	wget	wget

Installing the Linux agent as an LDAP user is supported.

Install RPM, Debian or SUSE RPM Installer Package

The following table explains the action to be performed for installing the RPM, Debian or SUSE installer package:

> **Note:** In the following commands, replace the Cohesity agent version with the desired agent version.

Action	How to
Download the Agent installer	From the Download Agents window, based on your Linux distribution, select **RPM**, **Debian**, or **SUSE RPM** and download it to the server you want to protect.
Navigate to the downloaded directory	As the root user with local system privileges on that server, change the directory to the location of the installer package.
Install the Custom certificates	**LINUX** If you are using a Cohesity certificate then run the following commands to install the user certificate followed by agent installation: `export ENFORCE_USE_CUSTOM_CERTS=true && export AGENT_CERT_FILE=<path-to-agent-certificate-in-Cohesity-format>`
Install the Agent	Run the following command depending on the installer package: • RPM: `rpm -i el-cohesity-agent-7.3.1-1.x86_64.rpm` or `yum localinstall ./el-cohesityagent-7.3.1-1.x86_64.rpm` • Debian: `dpkg -i cohesity-agent_7.3.1-1_amd64.deb` • SUSE RPM: `rpm -i cohesity-agent-7.3.1-1.x86_64.rpm`
Install the agent as root user	Run the executable file with the following command syntax: `/<path_to_installer_file> -- --install -c 0 -S root -G root` Followings are the command options in details: 1. **-S** this is the user to run the agent, specify root. 2. **-G** this is the group permission the Agent will use for files and directories installed by the agent, specify root. 3. **-c** this boolean switch controls if the OS user and group should be created. 0 means do not create the OS user and group, 1 means the agent installation will create the specified OS user and group. (When choose to run with the root user, specify '-c 0' as 'root' already exists)

Action	How to

Install the agent as non-root user	To start the service as a non-root user, create a new user or use an existing user with sudo permission and run the following command:
	• RPM: `export COHESITYUSER=<username> ; rpm -i el-cohesity-agent-7.3.1-1.x86_64`
	• Debian: `COHESITYUSER=<username> dpkg -i cohesity-agent_7.3.1-1_amd64`
	• SUSE RPM: `export COHESITYUSER=<username> rpm -i cohesity-agent-7.3.1-1.x86_64`
	Where, *<username>* is the user name with sudo permission.
	Note:
	By default, the installation uses the root user permission for all the files, and the service is started as root. Therefore, it is required to add non-root users to the sudoers list by making the following changes in the `/etc/sudoers` file:
	`<user_name> ALL=(ALL) NOPASSWD:ALL`
	`Defaults:<user_name> !requiretty`
	An example of the sudoers file is as given below:
	dgoble ALL=(ALL) NOPASSWD:ALL
	Defaults:dgoble !requiretty
	cohbackup ALL=(ALL) NOPASSWD:ALL
	Defaults:cohbackup !requiretty

Action	How to

	Note:
	You can add sudo privileges for non-root users using the syntax given below:
	`<user_name> ALL=(ALL) NOPASSWD:/path/to/command1, /path/to/command2, /path/to/command3`
	Remove `NOPASSWD` from the command above if you do not want to authenticate every sudo commands with password.
	The example below shows the sudo commands for user cohesityagent:
	`cohesityagent ALL=NOPASSWD: /bin/mount,/bin/umount,/bin/chmod,/bin/chown,/bin/hostname,/bin/mkdir,/bin/rm,/usr/bin/tee,/usr/bin/stat,/bin/cp,/bin/sed,/usr/bin/touch,/sbin/blkid,/usr/bin/lsof,/bin/ls,/sbin/losetup,/sbin/dmsetup,/usr/bin/rsync,/usr/bin/timeout,/usr/bin/getfacl,/usr/bin/setfacl, /tmp/installer_ch_cohesity_linux_agent,/home/cohesityagent/installer,/home/cohesityagent/cohesityagent/data/agent/tmp/installer_ch_cohesity_linux_agent,/bin/systemctl,/home/cohesityagent/cohesityagent/software/crux/bin/cohesity_linux_agent.sh`
	The actual paths for each command may vary in each system. Cohesity keeps adding or removing commands across releases.

Location	• Installation directory: `/opt/cohesity` • Log file: `/var/log/cohesity`

Install script installer package

The following table explains the action to be performed for installing the script installer package:

> **Note:** In the following commands, replace the Cohesity agent version with the desired agent version.

Action	How to
Download the Agent installer	From the Download Agents window, based on your Linux distribution, select **Script Installer** and download it to the server you want to protect.
Navigate to the downloaded directory	As the root user with local system privileges on that server, change the directory to the location of the installer package. For SLES 11 SP4, installing the agent as the root user is required.
Make the installer executable	Make the installer executable, for example: `chmod +x cohesity_agent_7.3.1_linux_x64_installer`
Install the Agent	Run the executable: `sudo /cohesity_agent_6.6.0d_u2_linux_x64_installer – --install`
Location	• Installation directory: `/home/<username>/cohesityagent` or `/root/cohesityagent` • Log file: `/home/cohesityagent/cohesityagent/logs` **Note:** You can specify the option `-log-dir <installtion_path>` to specify the directory path where the agent logs will be saved. If this option is not provided, the logs will be saved in the default path

Install Cohesity Agent for Linux PowerPC

> **Note:** To use the Linux PowerPC agent (Java based), Java Runtime Environment (JRE) 8 needs to be installed on the source system.

The following section explains the action to be performed for installing the Linux PowerPC Agent as a ROOT user:

1. Select **Data Protection** > **Sources**.
2. Click **Download Cohesity Agent**.
3. From the **Download Agents** window, select **PowerPC** and download it to the server you want to protect.
4. Change the directory to the location of the installer package and run the following command to install the rpm based installer package for PowerPC

distribution:

```
cohesity-java-agent-7.0.1-1.ppc64le.rpm
```

The agent will be installed in the following directory `/opt/cohesity` and the logs files can be found in `/var/log/cohesity`.

5. To uninstall the agent, run the following command:

```
rpm -e cohesity-java-agent
```

For information about all Cohesity Linux agent installer options, see Linux Script Installer Options.

The agent starts after installation completes.

Agent startup behavior following a machine reboot:

- CentOS and RedHat (distributions with the "systemd" init system) - The agent starts automatically.
- Ubuntu (distributions with the "upstart" init system) - The agent starts automatically.

If a Linux server's `/etc/sudoers` file is managed by a deployment engine such as Chef, Puppet or others, this could impact Cohesity cluster's interaction with servers that have the Linux agent installed. Take the corresponding actions below:

Agent Installation - User type	Action required

As default cohesityagent user	The Cohesity Linux agent is installed using the cohesityagent user by default. For default installations, the cohesityagent is created by the installer. During installation, the installer updates the `/etc/sudoers` file to allow cohesityagent sudo and no-tty sudo access. Ensure the following settings in the /etc/sudoers file for the cohesityagent user are preserved:
	`cohesityagent ALL=(ALL) NOPASSWD:ALL`
	`Defaults:cohesityagent !requiretty`
	An example of the sudoers file is as given below:
	#includedir /etc/sudoers.d
	dgoble ALL=(ALL) NOPASSWD:ALL
	cohbackup ALL=(ALL) NOPASSWD:ALL
	Defaults:cohbackup !requiretty

As non default user, example foo	Ensure the above settings in the `/etc/sudoers` file for the foo user are preserved by replacing the occurrences of cohesityagent with foo.

Agent Installation - User type	Action required
As root user	No changes required

Install Cohesity Agent for Linux on z/Architecture

> **Note:** To use the Linux on z/Architecture agent (Java-based), Java Runtime Environment (JRE) 8+ (JRE 8, 11, 17) needs to be installed on the source system.

The following section explains the action to be performed for installing the Linux on z/Architecture Agent as a ROOT user:

1. Select **Data Protection** > **Sources**.
2. Click **Download Cohesity Agent**.
3. From the **Download Agents** window, select **s390x** and download it to the server you want to protect.
4. Change the directory to the location of the installer package and run the following command to install the rpm based installer package for z/Architecture distribution:

   ```
   rpm -i cohesity-java-agent-0.0.0-1.s390x.rpm
   ```

   The agent will be installed in the following directory `/opt/cohesity` and the logs files can be found in `/var/log/cohesity`.
5. To uninstall the agent, run the following command:

   ```
   rpm -e cohesity-java-agent
   ```

Install Cohesity Agent for Linux on on ARM (aarch64)

> **Note:** To use the Linux on on ARM (aarch64) agent (Java-based), Java Runtime Environment (JRE) 8+ (JRE 8, 11, 17) needs to be installed on the source system.

The following section explains the action to be performed for installing the Linux on on ARM (aarch64) Agent as a ROOT user:

1. Select **Data Protection** > **Sources**.
2. Click **Download Cohesity Agent**.
3. From the **Download Agents** window, select **aarch64** and download it to the server you want to protect.
4. Change the directory to the location of the installer package and run the following command to install the rpm based installer package for z/Architecture distribution:

   ```
   rpm -i cohesity-java-agent-7.3.1-1.aarch64.rpm
   ```

   The agent will be installed in the following directory `/opt/cohesity` and the logs files can be found in `/var/log/cohesity`.
5. To uninstall the agent, run the following command:

   ```
   rpm -e cohesity-java-agent
   ```

cohesity_linux_agent.sh

The table lists how `cohesity_linux_agent.sh` interacts with various `init` systems to issue `start/stop/status` commands.

If Cohesity does not detect any of the `init` systems, the installer uses the **undetected** `init` system commands.

init system	Commands

systemd	`sudo systemctl start cohesity-agent`
	`sudo systemctl stop cohesity-agent`
	`sudo systemctl status cohesity-agent`

upstart	`sudo initctl start cohesity-agent`
	`sudo initctl stop cohesity-agent`
	`sudo initctl status cohesity-agent`

SysV	`sudo /etc/init.d/cohesity-agent start`
	`sudo /etc/init.d/cohesity-agent stop`
	`sudo /etc/init.d/cohesity-agent status`

undetected	`sudo /etc/init.d/cohesity-agent start`
	`sudo /etc/init.d/cohesity-agent stop`
	`sudo /etc/init.d/cohesity-agent status`

AIX Agent

For Cohesity support information, see Supported Software.

1. Download the Cohesity Java Agent package (a **.bff** file) from Cohesity Package Download. Ensure the Java Agent is on the AIX server you want to protect.
2. Log in to the AIX server as a root user and run the following command to install the package:

   ```
   installp -ad <path_to_downloaded_agent_package> all
   ```

   For example:

   ```
   installp -ad cohesity_agent_6.6_aix_java.bff all
   ```

   The Cohesity Java Agent starts automatically. Now you can register the server with the Cohesity cluster. Reboot is not required. The Cohesity Java Agent starts after any future reboots.

Solaris Agent

1. Obtain the Cohesity Solaris agent package. Download the Solaris 10 agent here.
2. Run the following command to install the package:

   ```
   sudo /usr/sbin/pkgadd -d <cohesity_agent_file_path>
   ```

   If sudo is not installed, install the package as the root user.

   The agent starts automatically. Now you can register the server with the Cohesity cluster. Reboot is not required. The agent starts after any future reboots.

HP-UX Agent

You can download the Cohesity agent installer from the Cohesity UI or manually download the agent from the Cohesity Package Download and install the agent using CLI. For more information on installing HP-UX agent, see Install and Manage the Agent on HP-UX Servers.

4. Open the following ports on the server:
   - TCP port 50051 for backup operations (incoming)
   - NFS ports 111 and 2049 for restore operations on a Linux server (outgoing)
   - SMB port 445 for restore operations on a Windows server (outgoing)

Register a Physical Server with the Cohesity cluster

Registering a physical server makes its content eligible to be protected or backed up on the Cohesity cluster.

> **Note:** Selecting an Interface Group is not relevant when registering a physical server, despite the option being present on the Physical Server registration page on the Cohesity cluster.

1. Select **Data Protection > Sources**.

   Click **Register > Physical Server.**
2. Specify the hostname (FQDN) or server IP (IPv4 or IPv6) of the server to register. Cohesity recommends using the FQDN.
3. Click **Register**.

   When registration finishes, a new entry appears in the physical section on the Sources page.

> **Note:** You can register a Windows physical server on multiple Cohesity cluster. In a Cohesity cluster failover scenario, when the primary Cohesity cluster goes down, you can use the secondary Cohesity cluster to backup the file/folder on the physical server. However, you cannot register a Windows physical server as an MS SQL server on multiple Cohesity cluster. For more information, Contact Cohesity Support.

Register Veritas Cluster Server (VCS) on Cohesity cluster

To protect VCS, you must first register VCS as a physical server on Cohesity cluster using VCS VIP.

> **Note:**
> - You can register a VCS VIP on multiple Cohesity clusters. For more information, Contact Cohesity Support.
>
>   This is an Early Access feature. Contact Cohesity Support to enable the feature.

Red Hat High Availability (Pacemaker) Cluster

To protect the Red Hat High Availability (Pacemaker) Cluster, you must first register it as a physical server on the Cohesity cluster using the VIP address.

Manage Physical Servers

Re-register Cohesity Agent (Windows or Linux)

The re-register functionality on the Cohesity cluster allows you to save the agent settings on the cluster and enables you to perform an agent re-registration with the same settings when required.

With re-registration, the existing file-based protection job would continue to work with the new agent without any intervention. However, the block-based protection job may need to be modified if specific volumes under the job have changed before re-registration.

> **Note:**
> - For block-based protection jobs, the first backup after re-registration will be a full backup.
> - Re-register functionality is currently supported for Windows and Linux servers.
> - During agent re-registration, you must use one of these options, **Apply settings for the agent preserved on Cohesity UI** or **Preserve setting during uninstallation of an agent from the server**.

1. Select **Data Protection** > **Sources**.
2. Navigate in the source hierarchy to the Windows or Linux server you want to re-register, mouse over its actions menu, and click **Re-register**.
3. Click **Apply the Settings for the agent preserved on the <date and time>** checkbox if you want to restore the server settings.

   If this checkbox is not selected, then the settings saved on the cluster are not applied to the newly registered agent.

   > **Note:** During agent uninstallation of a Cohesity Windows or Linux agent, there is an option to preserve settings in the Windows registry or config file for Linux. If you had selected the **Preserve Settings** option during the uninstall process then deselect the above option during the reregistration workflow.

4. Click **Re-register**.

Upgrade Agent on a Physical Server

This option is clickable if an agent upgrade is available for the server. If an agent upgrade is requested while backup jobs or recover tasks are active, the upgrade starts after the jobs and tasks finish.

1. Navigate to **Data Protection > Sources**.
2. Navigate the source hierarchy to the server, mouse over its actions menu and click **Upgrade Agent**.
3. Click **OK**.

Edit Physical Server Registration

1. Navigate to **Data Protection > Sources**.
2. Navigate the source hierarchy to the server, mouse over its actions menu and click **Edit**.
3. Edit the desired information.
4. Click **Update Server**.

Unregister Physical Server from the Cluster

1. Navigate to **Data Protection > Sources**.
2. Navigate the source hierarchy to the server, mouse over its actions menu and click **Unregister**.
3. Click **Unregister**.

Network Bandwidth and CPU Throttling for Physical Server

You can throttle the network bandwidth and CPU on the Windows and Linux physical servers registered with the Cohesity cluster. Network throttling optimizes the data transfer rate from the server to the Cohesity cluster when a Protection Group is run. CPU throttling optimizes the CPU capacity utilized when a Protection Group with source-side deduplication is run on the server.

Supported Servers

The following table lists the physical servers supporting networking bandwidth and CPU throttling.

Operating System	Network Bandwidth Throttling	CPU Throttling
Windows	Yes	Yes*
Linux	Yes	No

* CPU throttling is supported on Windows 2012 R2 and later versions.

> **Note:** The network bandwidth and CPU throttling do not apply to the CBMR.

Enable Network Bandwidth and CPU Throttling

To enable network and CPU throttling, you must first register the physical server as a source and then edit the registered source to enable the options for network bandwidth and CPU throttling:

1. Select **Data Protection > Sources**.
2. Navigate the hierarchy to the registered physical server source for which you want to enable network bandwidth and CPU throttling.

   > **Note:** The edit server page appears.

3. Enable the **Throttle Network Bandwidth** option and in the **Throttle to** field, specify the maximum data transfer rate from the server to the Cohesity cluster.

   To schedule network bandwidth throttling for specific days and time durations:

   1. Click **Add**.
   2. From the **On** field, select the days during which you want to optimize the network bandwidth.
   3. In the **Start Time** and **End Time** duration fields, specify the time duration for throttling.
   4. In the **Throttle to** field, specify the maximum data transfer rate from the server to the Cohesity cluster.
   5. To configure multiple schedules for throttling, click **+** and repeat steps b to d.

      Example: If you want to limit the data transfer rate to **100 MB/S** on **Mondays** and **Wednesdays** from **12.00 to 16.00**, then from the **On** field, select **M** and **W**, set the **Start Time** as **12.00**, **End Time** as **16.00**, and in the **Throttle to** field, enter **100** as the throttling rate.

      > **Note:** For the days and duration for which you have not scheduled the network bandwidth throttling, Cohesity will take the throttling value specified at the server level.

4. Enable the **Throttle CPU** option and in the **Throttle to** field, specify the maximum CPU capacity (in percentage) of the server that Cohesity cluster backup runs with source-side deduplication enabled can utilize.

> **Note:** CPU throttling is only applied when the protection run has source-side deduplication enabled.

5. Click **Save**.

Add or Edit a Protection Group for Physical Servers

In Cohesity Data Cloud, Protection Groups use Protection Policies. Protection Policies reflect the backup and archival frequency, and retention requirements for each Protection Run. A Protection Group defines operational requirements, such as which source objects to protect, the Protection Policy to use, and operational considerations like indexing, exclusions and inclusions, and more.

A Protection Group that protects physical servers captures snapshots which are required for the following tasks:

- Recover files
- Instant volume mount
- Replicate snapshots
- Archive snapshots

> **Tip:**
> You can also watch the following video to know more about Protection Groups:
>
> - Data Protection: Protection Groups

Supported Workflows

For more information about the supported workflows on protection groups for physical servers (either Block-based or File-based), refer to Physical Server Workflows.

Before you begin

When you create a Protection Group, you can select an existing source, policy, or storage domain. You can also create them while creating the Protection Group. However, you might find it easier to create them prior to creating the Protection Group, as described in the following topics.

- Register or Edit a Physical Server
- Create or Edit a Standard Policy
- Create or Edit Storage Domains

Compare Block-Based and File-Based Backup Methods

Cohesity offers two distinct approaches for physical server backups: Block-based and File-based. While both methods serve the purpose of safeguarding critical data, understanding their differences is essential for choosing the most suitable backup strategy for your organization's needs.

Cohesity Facet	Cohesity Block-based Physical Server Backups	Cohesity File-based Physical Server Backups
Granularity	Operates at the disk block level, capturing modified or new data blocks.	Operates at the file level, preserving entire files for backup and recovery.
Speed and Performance	Enables faster backup and recovery times by tracking changes at the block level and transferring only modified data blocks.	Offers straightforward backup and recovery operations, relying on the identification and preservation of entire files.
Optimized Storage Efficiency	Significantly reduces storage requirements by capturing only the changed data blocks.	File-based backups rely on deduplication within the storage domain for optimization. It provides file-level accessibility, allowing selective recovery.
Simplicity and Familiarity	Requires familiarity with block-level operations.	Follows traditional file-level backup approaches that administrators are accustomed to.
Flexibility and Accessibility	Focuses on individual data blocks, enabling more granular and incremental backups.	Ensures the accessibility of individual files and directories, simplifying selective recovery.
Metadata and Indexing	Relies on metadata which is available once indexing occurs after the backup is complete.	Includes comprehensive metadata and indexing capabilities for quick search and file location.
Dependencies	Block-based backups depend on the volume CBT driver on Windows and LVM snapshots in Linux.	No dependency in the case of file-based backups.
Supported Configurations	Block-based backups are supported with specific file systems (NTFS for Windows, small group for Linux x64).	File-based backups are less restrictive and can work with a wider range of filesystems and operating systems (AIX etc)
Supported Recoveries	Block-based allows for IVM recovery,	File-based only allows for File-level recovery.
Source Backup	Block-based backup allows only one backup against one Source	File-based backup allows multiple backups to be configured against one Source.

In summary, Cohesity provides two distinct methodologies for physical server backups: Block-based and File-based. While Block-based backups excel in speed, efficiency, and granularity at the disk block level, File-based backups offer simplicity, flexibility, and file-level accessibility. Choosing the appropriate backup method depends on your organization's specific requirements, data protection goals, and recovery objectives.

The decision between Cohesity's Block-based and File-based Physical Server backups should be based on factors such as backup speed, storage efficiency, data granularity, ease of recovery, and the desired level of accessibility.

By understanding the differences between the two backup approaches, organizations can effectively leverage the backup functionality to enhance their data protection strategies to optimize their overall businesses.

To add or edit a Protection Group for Physical Server

Once you have registered your physical server as a source, you're ready to use Cohesity Data Cloud to protect it.

You can either perform Block-based or File-based backups for the physical servers.

- Performing a Block-based Backup
- Performing a File-based Backup

> **Important:** Cohesity recommends not to run backup and restore protection groups in parallel on the same physical server path.

Protect a Physical Server (File-based)

To add or edit a Protection Group for Physical Server:

1. Select **Data Protection > Protection** and do one of the following:
   a. To create a Protection Group— Click **Protect** on the top-right of the page and select **Physical Server** > **File-based**.
   b. To edit a Protection Group—Click the action icon (⋮) next to the Protection Group and select **Edit**.
2. In the **New Protection** pop-up, do one of the following:
   a. Click **Add Objects** and select the Servers to protect.

      You can also register a new source with the Cohesity cluster so you can protect it.
   b. Select the physical servers to protect. By default, all Servers are excluded as indicated by the unselected check box. A selected check box (☑) indicates

the Server is selected to be protected.

You can optionally filter the Servers table.

- In the search field, enter part of the Server name.
- Select an option from the **Filter** drop-down:
  - **Unprotected**—Displays Servers that are not protected by any Protection Groups in the Cohesity cluster—not protected by Cohesity.
  - **Protected by Cohesity**—Displays Servers that are protected by any Protection Groups in the Cohesity cluster.
  - **Protected by this Job**—Displays Servers that are currently selected to be backed up by this Protection Group. (This option is available only when editing an existing Job.)

Selecting the check box adjacent to Servers selects all of the filtered servers.

The graphical representations are described below.

- An unchecked box indicates the Object is excluded from any Protection Group.

  A shield indicates the Object is already protected by another Protection Group. A Windows physical Server cannot be protected by a new protection group unless you remove it from the current protection group.

- A checked box indicates the Object will be protected by the current Protection Group.

- Click the icon to see details about the object.
- If the object name is in red, it is inaccessible, invalid, or orphaned. If the object is in one of the specified states when the Protection Group runs, no snapshot is created. If the object becomes accessible, a snapshot is created the next time the Protection Group runs.

c. You can select either Windows, VCS, Solaris, Red Hat High Availability (Pacemaker) Cluster, or AIX physical object. Click the edit icon next to the selected server and use one of the following methods to define the file or a folder path in a file-based protection group for the selected object (Windows, VCS, Solaris, or AIX):

> **Note:**
> - When backing up sparse files, consider the following:
>
> Due to variations across operating systems and file systems, sparse files may not be detected accurately. In such scenarios, they'll be backed up as regular files, with relevant updates in pulse logs.
>
> When sparse files are detected and processed during backups and recoveries, the amount of data processed during backups and recoveries will reflect the non-zero content. This is likely to differ from previous backups or recoveries where sparse files were processed as normal files.

Options	Descriptions
Follow symlink NAS target (applies only to **Windows file-based** backup)	> **Note:** Share user and Cohesity agent login user must be part of the "Domain Admin" group to use option. Enable this option if you want to back up the symbolic link pointing to the NAS target. You can create a symbolic link on the Windows server by running the following command: `mklink /d /<link> /<target>` Where **<link>** specifies the name of the symbolic link that is being created. **<target>** specifies the path (relative or absolute) that the new symbolic link refers to. > **Note:** > - Cohesity does not support the backup of symbolic links within a symbolic link. > - As the symbolic link points to a remote machine, the backup process will be slower than usual. Specify at least one path for each Server you want to protect. By default, all files in the `/ root or c:\` directory are backed up.

Options	Descriptions
All Volumes	Use this option to protect all the local volumes on the specific host. If you select this option, the system dynamically enumerates all the local volumes present during the backup protection group run and protects them. **Note:** In Windows, local volumes are the volumes listed in the "Disk Management" utility of the Windows host. If you choose to use the Add Exclusions functionality when using this option, you can either specify: • Individual files or folders within a volume by specifying the fully qualified path names • Individual files or folders across all the volumes using the wildcards • Entire volumes by defining the volume path If the exclusion path is not present at the time of a backup run, the system ignores this entry and proceeds to the next. This option overrides any exclusion path specified as global exclude. **Example** If you specify `/mnt/banapps/` as a global exclude path but the local mount points are `/mnt/banapps/ar_techsis_views` and `/mnt/banapps/common`, then all the files and folders inside these local mount points will be included. If you want the Protection Group to exclude all the local mount points inside `/mnt/banapps/`, then you can either add these local mount points as explicit exclude paths or choose a normal backup and then give "/" as the include path, and `/mnt/banapps/` as the exclude path. Add Exclusions You can use this option to add exclusion entries for Individual files and folders and Protect all local volumes. For more information, see Add Exclusions.
Directive File	The directive file defines the locations of the files and folders that you can back up in a protection group. Specify the file path of the directive file (meta-file) on the source while adding it to a protection group. For more information, see Directive File Backup. **Note:** Applies only to **Windows, AIX, and Linux** servers file-based backup

Options	Descriptions
Specify Directories	**Nested Mount Points to Skip** Based on the Physical server type you want to protect, select the mount points to skip. For Windows Physical Server: Skip Nested Mount Points: Enable this option if you do not want to backup the volumes that are mounted to a subfolder within the selected directory structure. By default, this option is enabled. **For Linux Physical Server**: Nested mount point types to skip: From the drop-down list, select the mount point types that you do not want to back up. By default, the mount point types autofs and nfs on the server are selected. **Inclusions** During File-based Physical Server Backups, all files and directories under the parent directory specified in the Include path of a Protection Group are protected by the Cohesity Cluster. **Add Exclusion** You can use this option to add exclusion entries for Individual files and folders and Protect all local volumes. For more information, see Add Exclusions. **Add Path** Click Add Path to protect an additional path and then click Save. For the Cohesity cluster version below 6.6.0d_u3, after an initial full backup of a cluster, if a parent directory is added, there is a probability of unaltered files going missing in the latest snapshot. This issue is fixed in Cohesity version 6.6.0d_u3 and later. However, Cohesity recommends running at least one full backup after the upgrade. For more information, see Incremental forever backups with parent directory addition.

3. **Protection Group**: To enter a new name for the protection group, select **New Group** and enter the group name in the **Group Name** field. To use an existing protection group name, select **Existing Group** and select an existing group name from the **Group** drop-down list.
4. **Policy**: Select an existing protection policy or create a new one by selecting **New Policy**.
5. **Storage Domain**: Select an existing storage domain or create a new one by selecting **New Storage Domain**.

> **Note:** Once you create a Protection Group, you cannot change the Storage Domain you selected for that job.

6. **Start Time**: Available only if the selected policy is set to Backup Daily. Indicates when the Protection Group should run. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting.
7. Click **More options** if you want to change or configure any of the additional settings.

Setting	Description
Pause Future Runs	Toggle this option to stop the protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.
End Date	Optional. Toggle on and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
QoS Policy	Select an appropriate quality of service (QoS) policy. **Note:** Cohesity recommends specifying a Backup HDD, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups. • **Backup Auto**: (Applicable only for C6K Platform) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy.

Setting	Description
Cancel Runs at Quiet Time Start	Available only if the selected policy has at least one quiet time period. Toggle it on to specify that all currently executing protection runs should abort if a quiet time period specified for the Protection Group starts. By default this toggle is off, which means after a protection run starts, it continues to execute even when a quiet time period specified for this protection run starts. However, a new protection run will not start during a quiet time period.
Pre and Post Scripts	Edit this option to run scripts on the protected server before and/or after a Protection Group runs. If configured, the scripts are run every time an object is backed up by a Protection Group run. For configuration details, see Configure Pre & Post Scripts.
Crash Consistent Backups (applies only to **Windows file-based** backup)	Toggle on this option to read files from the snapshots of volumes on which the files (that need backup) are residing before the Protection Group is executed. Optionally, you can enable **Continue with non-consistent backup in case of failure** option to resume the backup in case the crash consistent backups fail. Crash Consistent backup settings are enabled by default for block-based backup jobs. For file-based backups, this setting is off by default but can be enabled from the Cluster UI. User preferences are taken into account.
Source-Side Deduplication	Toggle on to enable source-side deduplication for all the servers that are part of the Protection Group. Source-side deduplication is not supported on Windows 2008 R2 servers. For more information, see Source-Side Deduplication for Physical Server. Toggle on Source Side Deduplication, click Add Exclusions and select the hostname (IP address) to be excluded from the deduplication protection group. **Note:** The dedupe parameter must be enabled on the storage domains associated with the Linux and Windows servers.

Setting	Description
Cache Optimization	This feature applies only to AIX, Linux (x86_64), PPC, Solaris (SPARC & x86) and HPUX file-based backups. Cache Optimization is a modified source dedup functionality that offers optimized backup performance on the Cohesity cluster. For more details, see Source-Side Deduplication and Cache Optimization for Physical Server. **Note:** • It is recommended to use this only for new jobs. Cohesity recommends not to switch to Source-side Dedup or normal incremental once you create a job with **Cache Optimization** functionality enabled. You can either select source-side dedup or CacheOptimization for a job. • To use the Cache Optimization functionality, both the Cohesity agent and cluster should have version 7.0 and later.
Indexing	Indexing is enabled by default and required for file recovery. The Cohesity cluster will scan all the files in the Protection Group and create an internal index that can be used later by a recovery task to locate files by name. For information about customizing indexing, see Customize Indexing.

<table>
<tr><th>Setting</th><th>Description</th></tr>
<tr><td>Global Exclude Paths</td><td>
Cohesity version 6.6 and higher versions support global excludes at the protection group level, a standard entry for all servers. This feature applies to all types of Supported operating systems for physical agents.

For a file-based Protection Group, specify the exclusion paths for all the servers that are part of the protection group. By default, all files in the / root or c:\ directory are backed up.

Click +Add to exclude a particular path or a particular file for all the specified sources. An exclusion will be a combination of global exclude and object-level exclude paths specified on each server. For more information on object-level exclusions, see Add Exclusions.

Example

When a user configures a protection group on the Cohesity cluster, they can set up global exclude and include paths to specify which data should be backed up and which should be excluded. For instance,
• If /temp is provided as global exclude for a protection group and /temp/data as include path for a source, then /temp/data will be skipped by the Cohesity cluster.
• If /temp is an include path for a source and /temp/data is provided as a global exclude path for the protection group, then all the data under /temp will be backed up, but the /temp/data folder will be excluded from the backup.

The following table lists the support file systems and default exclusions for the physical server file-based backups.

<table>
<tr><th>OS</th><th>Supported File Systems</th><th>Default Exclusions</th></tr>
<tr><td>Linux</td><td>ext3, ext4, xfs, vxfs, ReiserFS, autofs, cvfs, zfs, fuse.mfs, nfs, nfs3, cifs, gpfs, mmfs</td><td rowspan="3">Virtual filesystems are excluded from backups. For example - tmpfs, devtmpfs, CacheFS, procfs, sysfs, etc.</td></tr>
<tr><td>AIX</td><td>jfs2, cdrfs, nfs, nfs3, jfs, vxfs, mmfs, gpfs, autofs</td></tr>
<tr><td>Solaris</td><td>zfs, ufs, nfs, cifs, vxfs</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Setting</th><th>Description</th></tr>
<tr><td></td><td>
<table>
<tr><th>OS</th><th>Supported File Systems</th><th>Default Exclusions</th></tr>
<tr><td>Windows</td><td>NTFS</td><td>Directories excluded from each physical drive.
For example - C:/, D:/, etc
$Recycle.Bin, Cohesity_Bitmap.cty, System Volume Information, System State</td></tr>
</table>

Note: Windows System State backups are supported as part of Bare Machine Recovery (BMR) backups and not Physical Server File-based backups. For more details, please refer to About Bare Machine Recovery.
</td></tr>
<tr><td>Allow Parallel Runs</td><td>Toggle this option to allow parallel backup runs for the Protection Group.
If the Protection Group is currently executing a protection run and a new run is started (can be manual or scheduled), then the current run continues to back up all the unfinished sources. In parallel, the new runs of the Protection Group will start backups for all the objects or entities that are processed completely in the current protection run.</td></tr>
<tr><td>Alerts</td><td>Optional. Select one or more of the following settings if you want alerts to be created for the following triggers:
• Success: Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created.
• Failure: Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created.
• SLA Violation: Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created.
For more information, see Alerts.</td></tr>
<tr><td>Priority</td><td>Select a priority for the Protection Group execution. Cohesity supports concurrent backups, but if the number of Protection Groups exceeds the ability to process them, those with High priority are given the highest priority to execute, Medium the second-highest priority, and Low the lowest priority.</td></tr>
</table>

Setting	Description
SLA	The service-level agreement (SLA) defines the expected time to complete either a full backup or incremental backup. The backup completion time depends on the Windows volume size on AD, objects changed between incremental backups, network speed, and other Protection Groups running on the Cohesity cluster. • Incremental: Enter the number of minutes you expect an incremental protection run to complete. An incremental backup captures only the differences (changed blocks) since the last protection run. • Full: Enter the number of minutes you expect a full backup protection run to complete. A full backup captures the entire object (all blocks).
Description	Optional. Click the plus sign and enter a description for the Protection Group.
Ignorable Errors	Select this option to ignore the following errors during a file-based protection group run for physical servers. You can select one or both options as per your requirements. **End of File** - If this option is selected, the Cohesity cluster ignores the End of File errors during a file-based protection group run and the file will be backed up successfully. **Non-Existent** - If this option is selected, the Cohesity cluster ignores the Non-Existent errors during a file-based protection group run.
Continue on Error	Enable this option to continue physical backups even if errors are encountered during the backup of any included file in the backup runs. This option is enabled by default. Disabling this option would cause the physical backup job runs to fail if any errors are encountered.

8. Click **Protect**.

   The Protection page is displayed and includes the new Protection Group.

> **Note:**
> - If a server is being backed up and files will also be recovered to that same server, the file recover task starts after the backup completes. The converse is also true; if files are being recovered to a server and that same server will be backed up, the backup starts after file recovery completes.
> - For a File-Based backup, the "Protected" and "Protected Size" fields on the source page for physical sources are updated after the source refresh.

Protect a Physical Server (Block-based)

To add or edit a Protection Group for Physical Server:

1. Select **Data Protection > Protection** and do one of the following:
   a. To create a Protection Group— Click **Protect** on the top-right of the page and select **Physical Server** > **Block-based**.
   b. To edit a Protection Group—Click the action icon (⋮) next to the Protection Group and select **Edit**.
2. In the **New Protection** pop-up, do one of the following:
   a. Click **Add Objects** and select the Servers to protect.

      You can also register a new source with the Cohesity cluster so you can protect it.

      A block-based protection group can protect Windows and non-Windows Servers but not both at once. You have to create separate protection jobs to protect Windows and non-Windows Servers.

      > **Note:** A physical server (block-based) can be protected by only one Protection Group at a time. If you want to protect a Server that is already protected by a protection group, you must remove it from its current Group. If the Server being removed is the protection group's only Server, you can delete the Group and its Snapshots or the protection group only. If you delete a snapshot, it may impact the recovery workflows.

   b. Select the physical servers to protect. By default, all Servers are excluded as indicated by the unselected check box. A selected check box (☑) indicates the Server is selected to be protected.

      You can optionally filter the Servers table.

      - In the search field, enter part of the Server name.
      - Select an option from the **Filter** drop-down:
        - **Unprotected**—Displays Servers that are not protected by any Protection Groups in the Cohesity cluster—not protected by Cohesity.
        - **Protected by Cohesity**—Displays Servers that are protected by any Protection Groups in the Cohesity cluster.
        - **Protected by this Job**—Displays Servers that are currently selected to be backed up by this Protection Group. (This option is available only when editing an existing Job.)

Selecting the check box adjacent to Servers selects all of the filtered servers.

The graphical representations are described below.

- An unchecked box indicates the Object is excluded from any Protection Group.

  A shield indicates the Object is already protected by another Protection Group. A Windows physical Server cannot be protected by a new protection group unless you remove it from the current protection group.

- A checked box indicates the Object will be protected by the current Protection Group.

- Click the icon to see details about the object.
- If the object name is in red, it is inaccessible, invalid, or orphaned. If the object is in one of the specified states when the Protection Group runs, no snapshot is created. If the object becomes accessible, a snapshot is created the next time the Protection Group runs.

c. You can select either Windows or a non-Windows physical object and click the edit icon next to the selected server and perform the following actions:

   i. **Take BMR backup**: Toggle on for bare machine recovery (CBMR) backups of the Server. For more information, see About Bare Machine Recovery.

   ii. **Automatically protect all volumes on this Server**: Toggle off and deselect the volumes you do not want to protect. Even if all volumes are selected for protection, new volumes will not be protected until they are added to the protected list.

   iii. Click **Continue**.

3. **Protection Group**: To enter a new name for the protection group, select **New Group** and enter the group name in the **Group Name** field. To use an existing protection group name, select **Existing Group** and select an existing group name from the **Group** drop-down list.
4. **Policy**: Select an existing protection policy or create a new one by selecting **New Policy**.
5. **Storage Domain**: Select an existing storage domain or create a new one by selecting **New Storage Domain**.

> **Note:** Once you create a Protection Group, you cannot change the Storage Domain you selected for that job.

6. Click More options if you want to change or configure any of the additional settings.
   a. **Start Time**: Available only if the selected policy is set to Backup Daily. Indicates when the Protection Group should run. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting.
   b. **SLA**: The service-level agreement (SLA) defines the expected time to complete either a full backup or incremental backup. The backup completion time depends on the Windows volume size on AD, objects changed between incremental backups, network speed, and other Protection Groups running on the Cohesity cluster.
   c. **Incremental**: Enter the number of minutes you expect an incremental protection run to complete. An incremental backup captures only the differences (changed blocks) since the last protection run.
   d. **Full**: Enter the number of minutes you expect a full backup protection run to complete. A full backup captures the entire object (all blocks).
   e. Click **Additional Settings** if you want to change or configure any of the additional settings.

Setting	Description
Pause Future Runs	Toggle this option to stop the protection runs of the Protection Group from executing. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.
End Date	Optional. Toggle on and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.

Setting	Description
QoS Policy	Select an appropriate quality of service (QoS) policy. **Note:** Cohesity recommends specifying a Backup HDD, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy.
Pre and Post Scripts	Edit this option to run scripts on the protected server before and/or after a Protection Group runs. If configured, the scripts are run every time an object is backed up by a Protection Group run. For configuration details, see Configure Pre & Post Scripts.

Setting	Description
Crash Consistent Backups (applies only to **Windows file-based** backup)	Toggle on this option to read files from the snapshots of volumes on which the files (that need backup) are residing before the Protection Group is executed. Optionally, you can enable **Continue with non-consistent backup in case of failure** option to resume the backup in case the crash consistent backups fail. **Exclude Writers**: All the VSS writers associated with the source are included in the backup job by default. However, you can exclude a VSS Writer from the backup job by toggling on the Exclude Writers option. To exclude a VSS Writer at the job level, You can either enter the name of the Writer you want to exclude or select it from the Exclude drop-down list. Additionally, if you have multiple Windows servers in a backup job, you can set the Exclude Writers option at the server level. To do this, click on the edit icon next to the selected server and toggle on the Exclude Writers option to specify the writers to be excluded from the backup job at the server level. Note that excludes defined at the server level will take precedence over the excludes defined at the job level. > **Note:** This is applicable only for Windows block-based backup jobs.
Incremental After Restart	For Windows physical servers, toggle on if you prefer incremental backup for the first scheduled backup job, which runs after an intentional server restart. If an incremental backup is not possible, a full backup is performed. For example, if the server restarts after a power failure, a full backup is performed. > **Note:** Incremental backup consistency across reboots is not guaranteed if I/O operations are performed on the volume outside of the fully functional state of the server. This includes I/O operations that are performed by booting into the recovery mode. For example, if a server is shut down and its volume is attached to another server that does not have the Cohesity agent, ensure that the next backup is a full backup operation. This option is not available for file-based backups.

Setting	Description
Source-Side Deduplication	Toggle on to enable source-side deduplication for all the servers that are part of the Protection Group. Source-side deduplication is not supported on Windows 2008 R2 servers. For more information, see Source-Side Deduplication for Physical Server. Toggle on Source Side Deduplication, click Add Exclusions and select the hostname (IP address) to be excluded from the deduplication protection group. **Note:** The dedupe parameter must be enabled on the storage domains associated with the Linux and Windows servers.
Indexing	Indexing is enabled by default and required for file recovery. The Cohesity cluster will scan all the files in the Protection Group and create an internal index that can be used later by a recovery task to locate files by name. For information about customizing indexing, see Customize Indexing.
Cancel Runs at Quiet Time Start	Available only if the selected policy has at least one quiet time period. Toggle it on to specify that all currently executing protection runs should abort if a quiet time period specified for the Protection Group starts. By default this toggle is off, which means after a protection run starts, it continues to execute even when a quiet time period specified for this protection run starts. However, a new protection run will not start during a quiet time period.
Alerts	Optional. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts.
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups, but if the number of Protection Groups exceeds the ability to process them, those with High priority are given the highest priority to execute, Medium the second-highest priority, and Low the lowest priority.

Setting	Description
Description	Optional. Click the plus sign and enter a description for the Protection Group.

7. Click **Protect**.

   The Protection page is displayed and includes the new Protection Group.

Download Physical Server File List for a Protection Group

System-generated file lists are used to provide more details about the backup process. You can now download CSV files for inclusion-exclusion reports and files backed up successfully or with warnings on the Cohesity cluster.

To download the file lists for a protection run:

1. Select **Data Protection** > **Protection**.
2. On the **Protection** page, select the protection group for which you want to download the file lists.
3. On the **Group Details** page, select the backup run and then select the server instance for which you want to download the file list.
4. Click one of the following options:
   - **Download Inclusion-Exclusion Reports**
   - **Download Success Logs**

Download Error Report for a Physical Protection Group

You can now download the list of all the errors encountered during the protection run for a physical server backup. Once the protection run is complete, you can download the details of the files that are skipped or have encountered errors in a CSV format.

Follow the steps below to download the error report for a Protection Group:

1. On the Cohesity Dashboard, select **Data Protection** > **Protection**.
2. On the **Protection** page, select a protection group that has the warning icon (ICON) in the **Status** column.
3. On the **Group Details** page, click the **Warning** icon .
4. On the **Run Details** page, click **View More** in the **Message** column to view the number of files that were skipped due to errors.

This will download all the error logs in a CSV file format.

Manage the Physical Server Backup Configuration

In Cohesity Data Cloud, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

> **Note:** You cannot update the assigned Storage Domain in the Protection Group settings.

Add a Physical Server to the Protection Group

You can add a new Physical Server to the existing Protection Group for backup. The newly added Physical Server is backed up from the next protection run and it will be a full backup.

Perform the following steps to add Physical Server to the Protection Group:

1. Select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you created for Physical Server.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** field, click the edit icon.
5. Select the Physical Server you want to add to the Protection Group.
6. Click **Save Selection** > **Save**.

The newly added Physical Servers are backed in the next scheduled protection run.

Remove the Physical Server from the Protection Group

From the Edit Protection page, you can remove the Physical Server from the Protection Group that you do not want to back up in the next protection run.

Perform the following steps to remove the Physical Server from the Protection Group:

1. Select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you created for Physical Server.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** field, click the edit icon.
5. Unselect the Physical Server you want to remove from the Protection Group.
6. Click **Save Selection** > **Save**.

Edit Existing Protection Policy

You can edit the existing Protection Policy that is attached to the Protection Group based on your requirements.

Perform the following steps to edit the policy settings:

1. Select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you created for Physical Server.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Policy** field, click the **Edit Policy** icon .

   The **Edit Policy** page appears
5. Edit the settings and then click **Save**.
6. Click **Save**.

Attach New Protection Policy to the Protection Group

You can attach a new Protection Policy to the Protection Group. The new policy is applied to the Protection Group in the next scheduled protection run.

Perform the following steps to attach a new protection policy to the Protection Group:

1. Select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you created for Physical Server.
3. Click the actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, from the **Policy** drop-down, select a new Protection Policy for the Protection Group.
5. Click **Save**.

Start an On-demand Protection Run

You can instantly start a protection run of the Protection Group that you have created to back up Physical Servers. It provides you options to back up all the objects or only selected objects in the Protection Group. If the policy associated with the Protection Group:

- Supports multiple backup types, you can select an incremental or full backup.
- Is configured with replication targets, you can select those targets.
- Is configured with archival targets, you can select those targets.

Perform the following steps to start an on-demand protection run:

1. Select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you created for Physical Server.
3. Click the actions menu (⋮) next to the Protection Group and select **Run Now**.
4. In the pop-up window, perform the following:
   a. From the **Backup** drop-down list, select any one of the following:
      - **All objects in the Protection Group**.
      - **Selected objects in the protection run**.
   b. In the **Backup Type** drop-down list, select the backup type.
   c. Optional. In the **Replicate** section, select the replication target and the retention duration, or click **Add** to add the replication target and the retention duration.
   d. Optional. In the **Archive** section, click **Add** to add the external target to which you want to archive the data and the retention duration. Also, select the **Archive only fully successful runs** checkbox to archive the data only from the completed protection runs.
5. Click **Backup Now**.

Pause Future Protection Runs

You can pause future protection runs for the Protection Group. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

Perform the following steps to pause the future protection runs:

1. Select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you created for Physical Server.
3. Click the actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired then a full backup is triggered

Perform the following steps to resume paused protection runs:

1. Select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you paused.

3. Click the actions menu (⋮) next to the Protection Group and select **Resume**.

Delete the Protection Group

You can delete a Protection Group if you:

You do not want to retain the backups and the local and archived snapshots generated by the Protection Group.

If you want to reclaim the storage space utilized by the Protection Group.

Cohesity Data Cloud provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Delete only the Protection Group. Any local snapshots and or archived snapshots stored on the external targets that this Protection Group captured are not deleted.
- **Delete Protection Group and Snapshots**: Delete the Protection Group and all snapshots, any local snapshots captured by this Protection Group and stored on this cluster are deleted. In addition, any archived snapshots stored on external targets that this Protection Group captured are also deleted.

After deleting the Protection Group, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

Perform the following steps to delete the Protection Group:

1. Select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you created for Physical Server.
3. Click the actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
   - Delete Group - done by typing 'yes' and clicking on 'Delete Group'
   - Delete Group and Snapshots - done by typing 'yes', selecting the toggle to 'Delete Snapshots', and clicking on 'Delete Group'

   Suppose the current Protection Group is replicating snapshots to a remote cluster or archiving snapshots to an external target. In that case, you should cancel these replication or archive tasks before deleting the Protection Group. For instructions, see Cancel Replication and Archive Copy Tasks of a Protection Run.

   If the Protection Group replicates to a remote cluster, the failover job created on the remote cluster is not deleted. In addition, the snapshots that were replicated (copied) to the remote cluster by this job have not been deleted. You can log in to the remote cluster to delete the snapshots and the failover job.

Start On-demand Multiple Protection Runs for Physical Server

After creating a directive file-based Protection Group for a physical server, Cohesity supports to simultaneously trigger more than one protection run of the Protection Group to backup only a specific set of files and folders in each run. This functionality can be achieved using the Cohesity REST API, `/public/protectionJobs/run/{id}`.

To trigger a protection run, add the `metadata file path` parameter in the JSON body of the API and provide the directive file path having the file or folder you plan to backup as the value.

Example to trigger a protection run from using the REST API:

URI

```
https://<cluster_name>/iris-
services/api/v1/public/protectionJobs/run/<protectionGroupID>
```

Method

POST

JSON body

```
{
 "copyRunTargets": [
 ],
 "runNowParameters": [
   {
     "physicalParams": {
       "metadataFilePath": "/home/cohesity/dirfile2"
     },
     "sourceId": 5
   }
 ],
 "runType": "kFull"
}
```

Where **/home/cohesity/dirfile2** is the directive file path that contains a list of files and folders folder that will be backed up using this API.

Similarly, you can simultaneously trigger multiple protection runs of a Protection Group.

Limitation

You cannot simultaneously trigger multiple protection runs to back up the same file or folder.

For example, you cannot start a protection run with the directive file path as **/home/cohesity/dirfile2** if there is already another active protection run of the same Protection Group, which is using the same directive file path.

Source-Side Deduplication and Cache Optimization for Physical Server

Source-side deduplication is a Cohesity feature designed to optimize backup efficiency by eliminating redundant data at the source (physical server) before transferring it to the Cohesity cluster. This process reduces network usage and speeds up backup operations, ensuring efficient data protection for your physical servers.

With source-side deduplication enabled for a physical server during Protection Group creation, unique data blocks that have not been previously transferred are sent to the Cohesity cluster. This significantly minimizes network bandwidth utilization and reduces data transfer times.

Additionally, source-side deduplication integrates seamlessly with Cohesity's built-in deduplication, further optimizing storage by processing only new data blocks.

Advantages of Source-Side Deduplication

- **Reduced Network Traffic**: This feature minimizes the amount of data transferred between physical servers and the Cohesity cluster, conserving network bandwidth.
- **Faster Backups**: Speeds up backup processes, particularly over slower networks such as WANs, enabling quicker recovery point objectives (RPOs).
- **Efficient Resource Utilization**: Offloads deduplication processing from the Cohesity cluster, allowing the system to handle a higher volume of backup workload sessions.
- **Lower Storage Costs**: Reduces overall storage consumption by transmitting only new or changed data blocks.

Cache Optimization

Cache Optimization is a specialized feature that enhances the performance of backups for large files (over 64 GiB) by further refining source-side deduplication functionality. When enabled, only the changed blocks of target files are backed up during subsequent incremental backup runs, rather than the entire file. This ensures efficient storage utilization and reduced backup times.

Requirements

To use Cache Optimization, ensure that both the Cohesity agent and the Cohesity cluster are running version 7.0 or later.

Advantages of Cache Optimization

- **Reduced Network Traffic**: Optimizes data transfers between physical servers and the Cohesity cluster.
- **Lower CPU Usage**: Reduces CPU load on the source server compared to standard source-side deduplication.
- **Improved Performance**: Provides enhanced backup efficiency, particularly for large files, by transferring only changed blocks.

Protect Windows Failover Cluster

With the Failover Clustering feature, users using the Cohesity clusters experience minimum disruptions in service. If one or more nodes of the cluster fail, the backup nodes begin to provide service by a process known as failover.

Currently, Cohesity does not have out-of-box support for backing up Clustered disk resources managed by Windows Failover Cluster (WFC). However, it is still possible to protect Cluster data leveraging existing Physical Protection Jobs using one of the following methods:

Protecting Shared and Local Drives using Block-based Physical Backup

Protecting Shared and local Drives using a File-based Backup (Volume backup)

Protecting Shared and Local Drives using Block-based Physical Backup

To create a block-based protection group for WFC, follow the steps listed below:

1. Install Cohesity Agent on each node of the Windows Failover Cluster and register each Node of WFC as a separate Physical Server. For more information, see Register or Edit a Physical Server.
2. Create a Protection Group (physical server block-based). For more information, see Add or Edit a Protection Group for Physical Servers.
3. Enable **Automatically protect all volumes on this Server** option on every node when creating a protection group.

   If you enable this option, disk changes are automatically detected when a resource failover occurs and required volumes are backed up without requiring any changes to the Protection jobs created.

   > **Note:** If there is no failover, all the backups are incremental (Leveraging CBT) for the Shared disks. If there is a failover/failback on a shared disk over to the other node, the next backup will be a full backup.

Protecting Shared and local Drives using a File-based Backup (Volume backup)

To create a file-based protection group for WFC, follow the steps listed below:

1. Install Cohesity Agent on each node of the Windows Failover Cluster and register each Node of WFC as a separate Physical Server. For more information, see Register or Edit a Physical Server.
2. Create a Protection Group (physical server file-based). For more information, see Add or Edit a Protection Group for Physical Servers.
3. Enable **Protect all local volumes** option on every node when creating a protection group.
4. Provide the volume path in **Exclusions** to exclude any volumes (local drives).

Recovery

The shared drive could be on any of the WFC nodes at the time of backup, You have to search the volume on the backed-up physical servers. Once Volume is found it can be restored to either the original node or any other Physical Server registered with Cohesity. For more information, see Recover Physical Servers.

Protect File Server Role deployed on Windows Server Fail-over Cluster

A failover cluster is a group of independent computers that work together to increase the availability and scalability of clustered roles (formerly called clustered applications and services). Windows Server Failover Cluster (WSFC) supports multiple roles, this feature supports the protection of a WSFC File Server role.

Prerequisites

- Make sure the following prerequisites are met before registering a File Server role as a source in the Cohesity cluster:
- You should create shares for the volumes to be discovered as WSFC File Server role volume on the Cohesity cluster.
- The minimum supported version for WSFC Role is the Cohesity version 6.7 and onwards (both Cohesity Windows Agent and Cohesity cluster).
- WSFC is not supported in multi-tenancy and DMaaS installations.
- Only file servers for general use are supported, scale-out file servers also known as active-active are not supported.

Considerations

Review the following considerations before protecting a WSFC File server role using Cohesity:

- Cohesity supports WSFC running on Windows Server 2012, Windows Server 2012 R2, 2016, and 2019 versions.
- WSFC File Server role protection is supported only on on-prem deployments. Data Management as a Service (Backup as a Service) and Multi-tenancy are not supported.
- This feature supports backup and recovery of data associated with the File server role in general use.
- For a crash-consistent backup, the first backup after failover will be full.
- For a crash-consistent backup, the backup will fail if there is a failover during backup.
- If there is no failover, all the backups are incremental (Leveraging CBT) for shared disks. If there is a failover/failback on a shared disk over to the other node, the next backup will be a full backup.
- A standalone physical server protection Group can also protect all volumes associated with the File Server role. However, Cohesity does not recommend protecting volumes associated with the File Server roles through a standalone physical source.
- Bare Metal Restore (BMR) is not supported for WSFC roles. However, BMR can be done on the Windows Servers which are part of the Failover Cluster.
- Upgrading the Cohesity agent on the File Server role registered as a source will also upgrade the agents on all the nodes within the cluster.
- The backups will run through the owner node of the File Server role cluster as the cluster disks are offline and in a reserve state on other nodes.

Protecting File Server role volumes using Block-based Physical Backup

To create a block-based protection group for File Server Roles, follow the steps listed below:

1. Install Cohesity Agent on each node of the Windows Failover Cluster.
2. To protect a share or a volume attached to a File Server role, register **File Server Role VIP/FQDN**. For more information, see Register or Edit a Physical Server.
3. Create a Protection Group (physical server block-based). For more information, see Add or Edit a Protection Group for Physical Servers.

> **Note:**
> - If there is no failover, all the backups are incremental (Leveraging CBT) for the Shared disks. If there is a failover/failback on a shared disk over to the other node, the next backup will be a full backup.
> - You should create shares for the volumes to be discovered as WSFC File Server role volume on the Cohesity cluster.

Protecting FileServer role volumes using a File-based Backup

To create a file-based protection group for File Server Role, follow the steps listed below:

1. Install Cohesity Agent on each node of the Windows Server Failover Cluster and register File Server VIP as a Physical Server. For more information, see Register or Edit a Physical Server.
2. Create a Protection Group (physical server file-based). For more information, see Add or Edit a Protection Group for Physical Servers.
3. Enable **Protect all local volumes** option while creating a protection group if you want to protect all volumes associated with the File Server role.

   > **Note:**
   > - You should create shares for the volumes to be discovered as WSFC File Server role volume on the Cohesity cluster.
   > - For protection with **Crash Consistency** enabled. If there is no failover, all the backups are incremental for the Shared disks. If there is a failover/failback on a shared disk over to the other node, the next backup will be a full backup.
   > - For protection with **Crash Consistency** disabled. All backups are incremental even if there is a failover/failback of shared disks

4. Provide the file path in Exclusions to exclude any files/folders/drives from backup.

Recovery

Once we have backed up the WSFC resources as file-based or block-based, recovery options like "Files or Folders", and "Instance Volume Mount" can be used to restore data.

For more information, see Recover Physical Servers and Recover Physical Server Files or Folders.

Physical Server Recovery

The physical servers that are backed up on to the Cohesity cluster can be recovered as physical servers, and files and folders. You can also perform bare machine recovery and instant volume mount of the physical server.

Instant Volume Mount for Physical Server

Instant volume mounting is supported for virtual and physical environments. This feature allows the selected backup volumes to be made available at the target location where you can then complete the desired operations. Instant Volume Mount is available for backed-up volumes, whether they are stored locally on the Cohesity cluster or archived to a registered external target.Use cases include granular recovery of Microsoft Exchange, SQL and SharePoint data.

You can mount the volume to its original location or to a new location. For more information, see:

- Instant Volume Mount to the Original Location for Physical Server
- Instant Volume Mount to a New Location for Physical Server

The following table lists the sources and the guest operating systems on which instant volume mounting is supported.

Source	Support for IVM on guest OS	
	Windows	Linux
AHV	No	No
VMware	Yes	Yes
HyperV	Yes	No
Physical*	Yes	Yes

*Supported only for block-based backups.

Prerequisite:

The default path of the recovered file or instantly mounted volume is *<Cluster_IP_address>/<Cloned view name>\<PATH>*.

To access this location, both the target and the Cohesity cluster must be in the same AD domain.

Considerations:

- When recovering a file or instantly mounting a volume from a Windows VM or Physical Server Backup Source that has Windows deduplication installed and enabled for one or more volumes, you must choose a target machine that also has Windows deduplication installed (it does not have to be enabled for any volume). (However, this rule does not apply to Nutanix AHV VMs. If AHV VMs are enabled with Windows deduplication, the only supported recovery option is full VM recovery.)

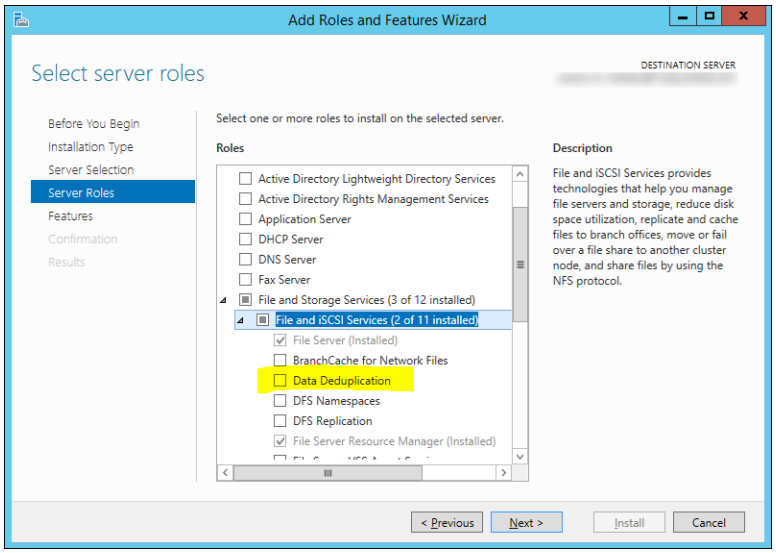
  If the target does not have Windows deduplication installed:

  - File level recovery will fail with the error message: "Windows Data Deduplication role is not installed on the target machine. Retry recovery after installing the Windows Data Deduplication role on the target machine."

- Instant volume mounting will fail with the error message: "Windows Data Deduplication role is not installed on the target machine. Retry recovery after installing the Windows Data Deduplication role on the target machine."

To determine if Windows deduplication is installed on the Source or target machine, follow the steps given below:

1. Open **Server Manager**.
2. Select **Roles and Features > File and Storage Services > File and iSCSI Services**.
3. Select the **Data Deduplication** check box, if necessary.
4. Click **Next** until the **Install** button is enabled and then click **Install**.



- Instant Volume Mount (IVM) restore of ReFS volumes backed up using Windows physical block-based jobs cannot be restored to an alternate Windows server running a lower version of ReFS.
- When mounting volumes on a Linux physical Server, the loop devices present on the Server are used for mounting. Therefore, the number of volumes that can be mounted depends on free loop device availability. By default, the number of available loop devices is 8, but this number can be customized. If the number of configured loop devices is the default of 8, up to eight volumes can be mounted. In this example, if an attempt to mount more than 8 volumes occurs, the mounting of all the volumes after the 8th volume fails and errors are reported.
- Tearing down a cloned database or instant volume mount deletes the mounted volumes. Any new or modified data on these volumes will be deleted along with the volumes, so ensure you back up any important data before teardown.
- You cannot instantly mount a volume from a VM to a physical server, and vice-versa.

Before you can instantly mount a volume, a Snapshot of the Object you want to recover must exist.

Troubleshooting

This section provides troubleshooting information for issues that might occur during IVM recovery.

Authentication Failures

Issue

The IVM recovery fails due to an authentication failure and displays the following error:

"The specified network password is not correct".

Possible Root Cause

The cluster joined the AD but the Windows host has not joined the AD.

Troubleshooting steps

- Create a local user on the Cohesity cluster and use the local user to access the SMB share. To create a local user on the Cohesity cluster, contact Cohesity Support.

or

- Disable SMB Authentication on the Cohesity Data Cloud. Perform the following steps to disable SMB Authentication:
  1. Log in to the Cohesity Data Cloud.
  2. Select **File Services** > **Views** and click the **Global Settings** tab.
  3. Toggle off the **SMB Authentication** setting.

Instant Volume Mount to the Original Location for Physical Server

To perform instant volume mounting to the original server:

1. Select **Data Protection > Recoveries**.
2. Click on **Recover** located at the top right of the page and then select **Physical Server> Instant Volume Mount**.

   The Instant Volume Mount page appears.
3. Search for the server that contains the data you want to mount by entering characters of the server name or by specifying the wildcard character *.

   A list of servers displays.

   You can optionally filter the search results by source, Protection Group, Storage Domain, server type, or date.
4. From the list of search results, select the server that contains the data you want to mount.

   By default, the latest snapshot is selected for recovery.

5. To recover from a different snapshot, mouse over the snapshot from the selected list, and then click the **edit** icon.

   The Edit recovery point for <server_name> page appears.

   > **Note:** In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

   By default, the option to select the snapshot is displayed in the **Timeline** mode. You can also choose to view the option in List mode by clicking the **List** tab in the top-right corner of the page.

   - To select a snapshot from the **Timeline** mode:
     a. From the **Choose a date** drop-down, select a date.

        The snapshots available on the selected date are displayed in blue dots on the timeline bar.

     b. Select the snapshot to be recovered by clicking the corresponding blue dot.

     c. By default, the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.

     d. Click **Select Recovery Point** and then go to step 6.
   - To select a snapshot from the **List** mode:
     a. Select the **List** tab from the top-right corner of the Edit recovery point for <server_name> page.

        By default, the page displays the snapshots available in the last one month.

     b. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.

     c. Select the snapshots to be recovered.

     d. By default, the snapshot is recovered from the local Cohesity cluster. You can also select snapshots archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.

     e. Click **Select Recovery Point** and then go to step 6.
6. Click **Next: Recover Options**.

7. From the **Select Volume(s)** option, perform one of the following actions:
   - Enable **Select all Volumes** to recover all the volumes of the selected server
   - From the **Select one or more options** drop-down list, select the individual volumes you want to recover.

   After volumes are mounted, they may be displayed as different volumes than their source volume. For example, D: volume may be mounted as X: volume.
8. From the **Recover To** options, select **Original Location** to recover the volume to the original location.
9. (Applies only for VMs) With the **Ensure Disks are Online** option enabled, select one of the following options to deploy Cohesity Agent on the target VM.

   > **Note:** For Linux target VMs, you cannot disable this option. For Window target VMs, you can disable this option.

   - **Auto Deploy Cohesity Agent:** Select this option and provide the username and password of the target VM to automatically deploy the Cohesity Agent on the target VM.
   - **Use Existing Cohesity Agent**: Select this option to use the existing Cohesity Agent deployed on the target VM

     The following table provides information on how the volume is mounted when the **Ensure Disks are Online** option is enabled and disabled.

Environment	Ensure Disks are Online option is Turned On	Ensure Disks are Online option is Turned Off
VMware	After the VMDKs are attached to the VM, Cohesity cluster explicitly mounts the volume. To mount the volume to the VM, Cohesity cluster requires the built-in administrator credentials, such as the local system administrator of the VM. It uses the credentials provided in the **Mount Target Credentials** fields for mounting the volume. If the UAC property "Admin Approval mode" is disabled, then you can specify any user who is part of the system's Local Administrator group. • **Note:** VMware Tools are required to bring the disks online, but mounting is still supported without VMware Tools.	The VMDKs are just attached to the VM and the VM may bring the disks online. Cohesity cluster does not explicitly bring the volumes online within the VM. In this case, the Target Volume displays as "n/a" after mounting the volume succeeds.
Standalone Hyper-V host or cluster	You must add the guest VM to the reverse lookup zone in the DNS server to complete the recovery successfully.	Not Applicable

10. Optional. Edit the default settings of the following **Recovery Options**:
    - **Cluster Interface**: By default, the **Auto Select** option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the **Interface Group** drop-down.
    - **Task Name**: Change the default name of the recover task.
11. Click **Recover**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

> **Note:** If a drive letter was provided as the file path for a file-based backup of NTFS volumes, the default attributes for drive letters were preserved, so hidden drives remain hidden. They are still recovered and can be accessed by providing the full path in the search bar.

Instant Volume Mount to a New Location for Physical Server

To perform instant volume mounting to the original server:

1. Select **Data Protection > Recoveries**.
2. Click on **Recover** located at the top right of the page and then select **Physical Server> Instant Volume Mount**.

   The Instant Volume Mount page appears.
3. Search for the server that contains the data you want to mount by entering characters of the server name or by specifying the wildcard character *.

   A list of servers displays.

   You can optionally filter the search results by source, Protection Group, Storage Domain, server type, or date.
4. From the list of search results, select the server that contains the data you want to mount.

   By default, the latest snapshot is selected for recovery.
5. To recover from a different snapshot, mouse over the snapshot from the selected list, and then click the **edit** icon.

   The Edit recovery point for <server_name> page appears.

   > **Note:** In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

   By default, the option to select the snapshot is displayed in the **Timeline** mode. You can also choose to view the option in List mode by clicking the **List** tab in the top-right corner of the page.

   - To select a snapshot from the **Timeline** mode:
     a. From the **Choose a date** drop-down, select a date.

        The snapshots available on the selected date are displayed in blue dots on the timeline bar.

     b. Select the snapshot to be recovered by clicking the corresponding blue dot.

     c. By default, the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.

     d. Click **Select Recovery Point** and then go to step 6.
   - To select a snapshot from the **List** mode:

a. Select the **List** tab from the top-right corner of the Edit recovery point for <server_name> page.

   By default, the page displays the snapshots available in the last one month.

b. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.

c. Select the snapshots to be recovered.

d. By default, the snapshot is recovered from the local Cohesity cluster. You can also select snapshots archived in the cloud by clicking the cloud ( ) icon if available in the **Location** option.

e. Click **Select Recovery Point** and then go to step 6.

6. Click **Next: Recover Options**.
7. From the **Select Volume(s)** option, perform one of the following actions:
   - Enable **Select all Volumes** to recover all the volumes of the selected server
   - From the **Select one or more options** drop-down list, select the individual volumes you want to recover.

   After volumes are mounted, they may be displayed as different volumes than their source volume. For example, D: volume may be mounted as X: volume.
8. From the **Recover To** options, select **New Location** to recover the volume to the original location.
9. From the **Source** drop-down menu, select a registered source having the server to which you want to recover the volume. You can also register a new source by clicking **Register Source** from the **Registered Source** drop-down menu.
10. From the **Target** drop-down menu, select a physical server to which the volume will be mounted.

    > **Note:** To mount to a physical server, the server must already have the Cohesity agent installed and registered with the Cohesity cluster. If not, the server will not be available as a mount target.

11. (Applies only for VMs) With the **Ensure Disks are Online** option enabled, select one of the following options to deploy Cohesity Agent on the target VM.

> **Note:** For Linux target VMs, you cannot disable this option. For Window target VMs, you can disable this option.

- **Auto Deploy Cohesity Agent:** Select this option and provide the username and password of the target VM to automatically deploy the Cohesity Agent on the target VM.
- **Use Existing Cohesity Agent**: Select this option to use the existing Cohesity Agent deployed on the target VM

  The following table provides information on how the volume is mounted when the **Ensure Disks are Online** option is enabled and disabled.

Environment	Ensure Disks are Online option is Turned On	Ensure Disks are Online option is Turned Off
VMware	After the VMDKs are attached to the VM, Cohesity cluster explicitly mounts the volume. To mount the volume to the VM, Cohesity cluster requires the built-in administrator credentials, such as the local system administrator of the VM. It uses the credentials provided in the **Mount Target Credentials** fields for mounting the volume. If the UAC property "Admin Approval mode" is disabled, then you can specify any user who is part of the system's Local Administrator group. • **Note:** VMware Tools are required to bring the disks online, but mounting is still supported without VMware Tools.	The VMDKs are just attached to the VM and the VM may bring the disks online. Cohesity cluster does not explicitly bring the volumes online within the VM. In this case, the Target Volume displays as "n/a" after mounting the volume succeeds.
Standalone Hyper-V host or cluster	You must add the guest VM to the reverse lookup zone in the DNS server to complete the recovery successfully.	Not Applicable

12. Optional. Edit the default settings of the following **Recovery Options**:

- **Cluster Interface**: By default, the **Auto Select** option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the **Interface Group** drop-down.
- **Task Name**: Change the default name of the recover task.

13. Click **Recover**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

> **Note:** If a drive letter was provided as the file path for a file-based backup of NTFS volumes, the default attributes for drive letters were preserved, so hidden drives remain hidden. They are still recovered and can be accessed by providing the full path in the search bar.

Recover Physical Server Files or Folders

Cohesity provides the ability to recover files and folders from a Snapshot created earlier by a Protection Group. Files and folders can be recovered to their original location (limitations apply to physical Servers and specific operating systems) or to a newly specified location, which can be within the original Source or a different one. You can choose to retain the recovered files' and folders' original (at the time of the backup) permissions and attributes. You can also download files and folders from selected Snapshots that were created by a CohesityProtection Group. However, only items that were indexed when the Snapshot was created can be downloaded. Recovering and searching for files and folders in Snapshots created by other backup software is not supported. For information on managing these Protection Groups, Add or Edit a Protection Group for Physical Servers.

To learn more, see About File Recovery.

For more information about the recovery options:

- Recover Files or Folders to the Original Location
- Recover Physical Server Files or Folders to a New Location
- The Cohesity cluster attempts to index all files and folders to a drive on both Windows and Linux systems. If the Cohesity cluster is unable to find mount point information about files or directories, it indexes and displays these files and directories in the `lvol_N` directory, where `N` is a unique number such as `1`.

  On Windows systems, if the Cohesity cluster finds the mount point information about files and directories, it indexes and displays these files and directories with a drive letter such as `C:`.

  Linux LVM indexing supports the following LVM types only: Linear, Striped, Mirrored, Mirrored + Striped, Thin. On Linux systems, how files and directories are indexed and displayed is dependent on the conditions specified in the following table.

Server Type	Volume Type	

Linux Virtual Machine	Simple Volume	The Cohesity cluster detects mount points for entries in the `/etc/fstab` file with the following formats:
		`UUID=ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc /mnt ext4 auto 0`
		`UUID="ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc" /mnt ext4 auto 0`
		If the Cohesity cluster can detect a mount point, it indexes and displays files and directories in the volume with the mount point that was specified in the `/etc/fstab` file. For these example entries, files and directories are indexed with the `/mnt` mount path, such as `/mnt/example/test.txt`.
		If the Cohesity cluster cannot detect a mount point, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

Linux Virtual Machine	LVM Volume	The Cohesity cluster detects mount points for entries in the `/etc/fstab` file with the following formats:
		`UUID=ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc /mnt ext4 auto 0`
		`/dev/mapper/VG1-root /mnt ext4 defaults 1 1`
		`/dev/VG1/root /mnt ext4 defaults 1 1`
		If the Cohesity cluster can detect a mount point, it indexes and displays files and directories in the volume with the mount point specified in the `/etc/fstab` file. For these example entries, files and directories are indexed with the `/mnt` mount path, such as `/mnt/example/test.txt`.
		If the Cohesity cluster cannot detect a mount point, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

Linux Physical	LVM Volume	The Cohesity agent can only return mount data when the volume is mounted on the Linux physical Server. If the volume is mounted, the Cohesity cluster indexes and displays files and directories in the volume with the mount point such as `/mnt/example/test.txt`. If the volume is not mounted, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

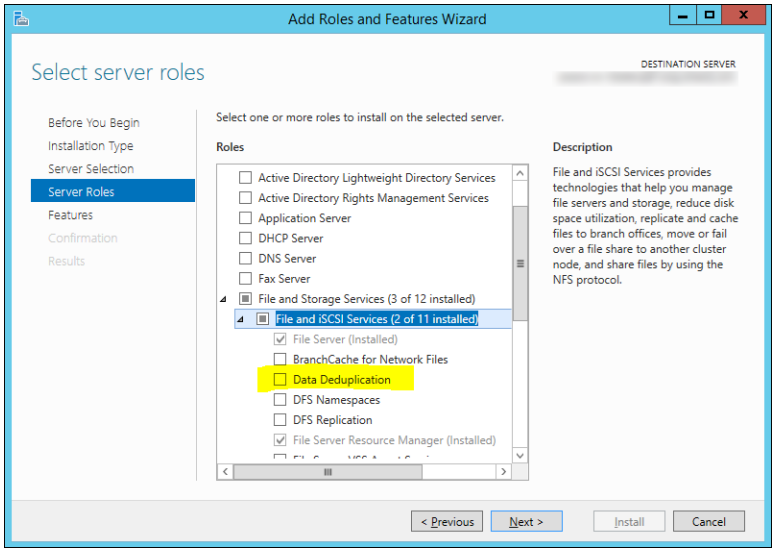
- When recovering a file or instantly mounting a volume from a Windows VM or Physical Server Backup Source that has Windows deduplication installed and enabled for one or more volumes, you must choose a target machine that also has Windows deduplication installed (it does not have to be enabled for any volume). (However, this rule does not apply to Nutanix AHV VMs. If AHV VMs are enabled with Windows deduplication, the only supported recovery option is full VM recovery.)

  If the target does not have Windows deduplication installed:

  - File level recovery will fail with the error message: "Windows Data Deduplication role is not installed on the target machine. Retry recovery after installing the Windows Data Deduplication role on the target machine."
  - Instant volume mounting will fail with the error message: "Windows Data Deduplication role is not installed on the target machine. Retry recovery after installing the Windows Data Deduplication role on the target machine."

  To determine if Windows deduplication is installed on the Source or target machine, follow the steps given below:

  1. Open **Server Manager**.
  2. Select **Roles and Features > File and Storage Services > File and iSCSI Services**.
  3. Select the **Data Deduplication** check box, if necessary.
  4. Click **Next** until the **Install** button is enabled and then click **Install**.



- When unzipping a zip file that was created by downloading files and folders from an archived Snapshot, if the file or folder name has encoded characters, unzip the zip file using the corresponding encoding. For example if a file name in the zip file has a UTF-8 character, unzip the file using the following command:

```
unzip -O UTF-8 Download-Files_Sep_20_2018_3-17pm_3090.zip
```

- When recovering a Linux file, the Cohesity Linux Agent runs the following commands in sudo:
  - mount
  - umount
  - findmnt
  - timeout
  - blkid
  - lsof
  - ls
  - rsync
  - losetup
  - dmsetup
  - lvs
  - vgs
  - lvcreate
  - lvremove
  - lvchange
- Windows behavior (giving each user its own set of mapped networked drives) prevents recovering to an SMB share that was mounted by a different user.

Considerations:

- For Linux Logical Volume Manager (LVM), if all the disks for a volume group are not found by the Cohesity cluster, the Cohesity cluster will not process that volume group. As a result of that, no volumes of this volume group will be recognized or indexed by the Cohesity cluster.
- File recovery is not supported for ReFS volumes in these environments: physical, VMware, Hyper-V and AHV.
- Encrypted folders that have been renamed or deleted cannot be recovered.
- Recovering files/folders with names longer than 200 characters may return an error. This limitation is due to Windows behavior when handling files/folders with long names.
- Downloading files and folders from tape archive locations is not supported.
- Recovering files and folders from VMs to physical servers and from physical servers to VMs is not supported.
- The downloadable zip file can contain regular files and folders only; symlinks are not supported. When unzipping the downloaded files/folders, use a zip utility that supports the ZIP64 format.

- For RHEL5, if LVM is not configured, running a protection job fails with the "No LVM volume found in idbmantasdev" error. For more information, see the Registering or running a Linux protection job fails when no LVM volumes are detected KB article.

Before you can recover a file from a Snapshot, the Snapshot must exist. To recover files from a Snapshot, the files must be indexed during the backup process. To learn more, Add or Edit a Protection Group for Physical Servers.

Recover Physical Server Files or Folders to the Original Location

To recover files and folders of a physical server to the original location:

1. Select **Data Protection > Recoveries**.
2. Click **Recover** located at the top right of the page and then select **Physical Server > Files or Folders**.
3. Select any one of the following options to search for the file or folder:
    - **Files and Folders**: Allows you to search and recover files using file or folder names from any backup available on the Cohesity cluster.
    - **Browse or Specify Path for Search**: Allows you to search and recover files using the name of the server or Protection Group from any backup available on the Cohesity cluster.

If you select..	Then..
Files and Folders	1. Enter characters of the file name, path, or by specifying the wildcard character *. A list of items displays. You can optionally filter the search results by object type, source, object, Protection Group, Storage Domain, files only, or folders only. 2. From the list of search results, select the required files or folders to recover. 3. By default, the latest snapshot is selected for recovery. To recover from a different snapshot: > **Note:** The option to change the recover point is not available if multiple items were selected for recovery. 1. From the selected list, mouse over the snapshot, and then click the **edit** icon. The Edit recovery point page appears. 2. By default, only the snapshots that are indexed are displayed. To display all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. 3. Select a date range and the snapshot point for recovery. 4. By default, the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud (icon) by clicking this icon if available in the **Location** option. 5. When recovering from an archive, consider the following points: • The archive (external target) must be currently registered for the task to succeed. • (*Applies only for cloud archive incremental with periodic full*) Provisioned Capacity Units (PCU) are required for all file-level recoveries. Provisioned capacity ensures that your retrieval capacity for expedited retrievals is available when needed. Each unit of capacity guarantees that at least three expedited retrievals can be performed every five minutes and provides up to 150 MB/s of retrieval throughput. 4. Click **Select Recovery Point** and go to step 4.

If you select..	Then..
Browse	1. Enter the full or partial server or Protection Group name. You can by specify the wildcard character *. You can also optionally filter the search results by object type, source, object, Protection Group, Storage Domain. 2. From the list of search results, select the object whose files or folders are to be recovered. 3. By default, the latest snapshot is selected for recovery. To recover from a different snapshot, click the snapshots drop-down in the top-left corner and select the snapshot you need. 4. **Browse on Indexed Data**: Toggle on this setting to browse the indexed data. It helps to speed up browsing of recovery data. By default, it only displays the files and folders that are indexed. Hidden files, folders, paths such as /usr, /var, /sys , /Windows, /ProgramData etc. are excluded from indexing. To display all the available files and folders, including hidden files and folders toggle off the **Browse on Indexed Data** setting. **Note:** • Changing the snapshot after selecting the items (files or folder) removes the selected items from the cart. • Enabling or disabling the **Browse on Indexed Data** option after selecting the items (files or folder) removes the selected items from the cart. • Deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process. 5. Browse to the file or folder that you want to recover by clicking a folder and subfolders. 6. Click **Save**. 7. After saving the selection, if you want to recover from a different snapshot or change the location from where the snapshot is recovered, perform the following steps: 1. From the selected list, mouse over the snapshot, and click the edit icon. 2. The Edit recovery point page appears. 3. By default, only the snapshots that are indexed are displayed. To display

If you select..	Then..
	all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. 4. Select a date range and the snapshot point for recovery. 5. By default, the snapshot is recovered from the local Cohesity cluster. You can also select a snapshot archived to the cloud (icon) by clicking this icon if available in the **Location** option. When recovering from an archive, consider the following points: • The archive (external target) must be currently registered for the task to succeed. • (*Applies only for cloud archive incremental with periodic full*) Provisioned Capacity Units (PCU) are required for all file-level recoveries. Provisioned capacity ensures that your retrieval capacity for expedited retrievals is available when needed. Each unit of capacity guarantees that at least three expedited retrievals can be performed every five minutes and provides up to 150 MB/s of retrieval throughput. 8. Click **Select Recovery Point** and go to step 4.

The Cohesity cluster attempts to index all files and folders to a drive on both Windows and Linux systems. If the Cohesity cluster is unable to find mount point information about files or directories, it indexes and displays these files and directories in the `lvol_N` directory, where `N` is a unique number such as `1`.

On Windows systems, if the Cohesity cluster finds the mount point information about files and directories, it indexes and displays these files and directories with a drive letter such as `C:`.

Linux LVM indexing supports the following LVM types only: Linear, Striped, Mirrored, Mirrored + Striped, Thin. On Linux systems, how files and directories are indexed and displayed is dependent on the conditions specified in the following table.

Server Type	Volume Type	

Linux Virtual Machine	Simple Volume	The Cohesity cluster detects mount points for entries in the `/etc/fstab` file with the following formats:
		`UUID=ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc /mnt ext4 auto 0`
		`UUID="ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc" /mnt ext4 auto 0`
		If the Cohesity cluster can detect a mount point, it indexes and displays files and directories in the volume with the mount point that was specified in the `/etc/fstab` file. For these example entries, files and directories are indexed with the `/mnt` mount path, such as `/mnt/example/test.txt`.
		If the Cohesity cluster cannot detect a mount point, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

Linux Virtual Machine	LVM Volume	The Cohesity cluster detects mount points for entries in the `/etc/fstab` file with the following formats:
		`UUID=ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc /mnt ext4 auto 0`
		`/dev/mapper/VG1-root /mnt ext4 defaults 1 1`
		`/dev/VG1/root /mnt ext4 defaults 1 1`
		If the Cohesity cluster can detect a mount point, it indexes and displays files and directories in the volume with the mount point specified in the `/etc/fstab` file. For these example entries, files and directories are indexed with the `/mnt` mount path, such as `/mnt/example/test.txt`.
		If the Cohesity cluster cannot detect a mount point, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

Linux Physical	LVM Volume	The Cohesity agent can only return mount data when the volume is mounted on the Linux physical Server. If the volume is mounted, the Cohesity cluster indexes and displays files and directories in the volume with the mount point such as `/mnt/example/test.txt`. If the volume is not mounted, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

4. Once you select the files and folder to recover, select one of the following options:

- **Next Recover Option**: If you select this option, then continue with the step 5 to configure the file recovery options.
- **Download Files**: If you are recovering a single file, this option downloads the file to your browser's download folder. For all other selections, this creates a recover task. When the task is completed, from the Recoveries page, click the task name and then click **Download Files** to download the generated zip file.

  Character replacement explanation for : and \ in file and directory names in zip files

  If the original file or directory name contains a ':' , it is replaced with '_COLON_' in the archive.
  Example:
  - The original name is "a:b" then the archived name is "a_COLON_b"
  - The original name is "a:b:c" then the archived name is "a_COLON_b_COLON_c"

  If the original file or directory name contains a '\', it is replaced with '_BACK_SLASH_' in the archive.
  Example:
  - The original name is "x\y" then the archived name is "x_BACK_SLASH_y"
  - The original name is "x\y\z" then the archived name is "x_BACK_SLASH_y_BACK_SLASH_z"

5. From the **Recover To**, select **Original Server** to recover the files or folders to a Original server.
6. To recover to a different location in the original server, disable the **Recover to Original Path** option, and then provide the location to which the files or folders are to be recovered in the **Recover To** field. By default, the files and folders will be recovered to the original location.
7. Optional. Edit the default settings of the following **Recovery options**:
   - **Overwrite Existing File/Folder**: By default, this option is disabled to create the files and folders in the specified location. Enable this option to overwrite the existing files and folders. Any duplicate files are skipped.

     Example for a Windows alternate location with **Overwrite Existing File/Folder** enabled and the target already exists:

     Files to be recovered: "C:\foo\1.txt", "C:\foo\test\1.txt", "C:\bar", "C:\foo\bar". Specified alternate location: "C:\restore". At the end of the copy, the target folder looks like this:
     - C:\restore\1.txt
     - C:\restore\cohesity<taskid>_0\1.txt

- C:\restore\bar
- C:\restore\cohesity<taskid>_1\bar

If **Overwrite Existing File/Folder** is enabled, this will overwrite the existing files and folders. Whether overwriting occurs depends on the application using the file.

- **Preserve File/Folder Attributes**: By default, this option is enabled and the ACLs, permissions, and timestamps are preserved for all files and folders. If you disable this option, then ACLs and permissions are not preserved. If recovering both folders and files, then folders will receive the new timestamps, but files retain their original timestamps. If recovering only, files, then files will receive the new timestamps.
- **Continue on Error**: Enable this option if you want to continue the recovery even if one of the objects encounters an error. By default, this option is disabled and the recovery operation will fail if one of the objects encounters an error.
- **Cluster Interface**: By default, the **Auto Select** option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the Interface Group drop-down.
- **Task Name**: Change the default name of the recovery task.
- **Save Success Files**: Enable this option to download the success logs for a recovery run.

8. Click **Start Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Download List Information for a Recovery Run

System-generated lists are used to verify success or errors during recovery. You can now download the list information as a CSV file for both successes and failed recovery job runs on the Cohesity cluster.

To download the logs for a recovery run:

1. Select **Data Protection** > **Recoveries** > **Recover**.
2. On the **Recoveries** page, select the recovery run for which you want to download the debug logs.
    1. If you select a successful recovery run, on the Recovery Details page, select the **Show Subtask** button and then click **Download Success** Logs*.
    2. If you select a failed recovery run, on the Recovery Details page, select the **Show Subtask** button and then click **Download Errors**.
    3. If the recovery run is partially successful, select the **Show Subtask** button and then click either the **Download Errors or Download Success Logs***.

> **Note:** * You must enable the **Save Success Files** option under **Recovery** Options while creating a recovery job to be able to download the success logs for a recovery run.

Recover Physical Server Files or Folders to a New Location

To recover files and folders to a new server:

1. Select **Data Protection > Recoveries**.
2. Click **Recover** located at the top right of the page and then select **Physical Server > Files or Folders**.
3. Select any one of the following options to search for the file or folder:
   - **Files and Folders**: Allows you to search and recover files using file or folder names from any backup available on the Cohesity cluster.
   - **Browse or Specify Path for Search**: Allows you to search and recover files using the name of the server or Protection Group from any backup available on the Cohesity cluster.

If you select..	Then..
Files and Folders	1. Enter characters of the file name, path, or by specifying the wildcard character *. A list of items displays. You can optionally filter the search results by object type, source, object, Protection Group, Storage Domain, files only, or folders only. 2. From the list of search results, select the required files or folders to recover. 3. By default, the latest snapshot is selected for recovery. To recover from a different snapshot: > **Note:** The option to change the recover point is not available if multiple items were selected for recovery. 1. From the selected list, mouse over the snapshot, and then click the **edit** icon. The Edit recovery point page appears. 2. By default, only the snapshots that are indexed are displayed. To display all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. 3. Select a date range and the snapshot point for recovery. 4. By default, the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud (icon) by clicking this icon if available in the **Location** option. When recovering from an archive, consider the following points: • The archive (external target) must be currently registered for the task to succeed. • (*Applies only for cloud archive incremental with periodic full*) Provisioned Capacity Units (PCU) are required for all file-level recoveries. Provisioned capacity ensures that your retrieval capacity for expedited retrievals is available when needed. Each unit of capacity guarantees that at least three expedited retrievals can be performed every five minutes and provides up to 150 MB/s of retrieval throughput. 4. Click **Select Recovery Point** and go to step 4.

If you select..	Then..
Browse	1. Enter the full or partial server or Protection Group name. You can by specify the wildcard character *. You can also optionally filter the search results by object type, source, object, Protection Group, Storage Domain. 2. From the list of search results, select the object whose files or folders are to be recovered. 3. By default, the latest snapshot is selected for recovery. To recover from a different snapshot, click the snapshots drop-down in the top-left corner and select the snapshot you need. 4. **Browse on Indexed Data**: Toggle on this setting to browse the indexed data. It helps to speed up the browsing of recovery data. By default, it only displays the files and folders that are indexed. Hidden files, folders, paths such as /usr, /var, /sys , /Windows, /ProgramData etc. are excluded from indexing. To display all the available files and folders, including hidden files and folders toggle off the **Browse on Indexed Data** setting. **Note:** • Changing the snapshot after selecting the items (files or folder) removes the selected items from the cart. • Enabling or disabling the **Browse on Indexed Data** option after selecting the items (files or folder) removes the selected items from the cart. • Deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process. 5. Browse to the file or folder that you want to recover by clicking a folder and subfolders. 6. Click **Save**. 7. After saving the selection, if you want to recover from a different snapshot or change the location from where the snapshot is recovered, perform the following steps: 1. From the selected list, mouse over the snapshot, and click the edit icon. 2. The Edit recovery point page appears. 3. By default, only the snapshots that are indexed are displayed. To display

If you select..	Then..
	all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. 4. Select a date range and the snapshot point for recovery. 5. By default, the snapshot is recovered from the local Cohesity cluster. You can also select a snapshot archived to the cloud (icon) by clicking this icon if available in the **Location** option. When recovering from an archive, consider the following points: • The archive (external target) must be currently registered for the task to succeed. • (*Applies only for cloud archive incremental with periodic full*) Provisioned Capacity Units (PCU) are required for all file-level recoveries. Provisioned capacity ensures that your retrieval capacity for expedited retrievals is available when needed. Each unit of capacity guarantees that at least three expedited retrievals can be performed every five minutes and provides up to 150 MB/s of retrieval throughput. 8. Click **Select Recovery Point** and go to step 4.

The Cohesity cluster attempts to index all files and folders to a drive on both Windows and Linux systems. If the Cohesity cluster is unable to find mount point information about files or directories, it indexes and displays these files and directories in the `lvol_N` directory, where `N` is a unique number such as `1`.

On Windows systems, if the Cohesity cluster finds the mount point information about files and directories, it indexes and displays these files and directories with a drive letter such as `C:`.

Linux LVM indexing supports the following LVM types only: Linear, Striped, Mirrored, Mirrored + Striped, Thin. On Linux systems, how files and directories are indexed and displayed is dependent on the conditions specified in the following table.

Server Type	Volume Type	

Linux Virtual Machine	Simple Volume	The Cohesity cluster detects mount points for entries in the `/etc/fstab` file with the following formats:
		`UUID=ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc /mnt ext4 auto 0`
		`UUID="ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc" /mnt ext4 auto 0`
		If the Cohesity cluster can detect a mount point, it indexes and displays files and directories in the volume with the mount point that was specified in the `/etc/fstab` file. For these example entries, files and directories are indexed with the `/mnt` mount path, such as `/mnt/example/test.txt`.
		If the Cohesity cluster cannot detect a mount point, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

Linux Virtual Machine	LVM Volume	The Cohesity cluster detects mount points for entries in the `/etc/fstab` file with the following formats:
		`UUID=ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc /mnt ext4 auto 0`
		`/dev/mapper/VG1-root /mnt ext4 defaults 1 1`
		`/dev/VG1/root /mnt ext4 defaults 1 1`
		If the Cohesity cluster can detect a mount point, it indexes and displays files and directories in the volume with the mount point specified in the `/etc/fstab` file. For these example entries, files and directories are indexed with the `/mnt` mount path, such as `/mnt/example/test.txt`.
		If the Cohesity cluster cannot detect a mount point, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

Linux Physical	LVM Volume	The Cohesity agent can only return mount data when the volume is mounted on the Linux physical Server. If the volume is mounted, the Cohesity cluster indexes and displays files and directories in the volume with the mount point such as `/mnt/example/test.txt`. If the volume is not mounted, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

4. Once you select the files and folder to recover, select one of the following options:

- **Next Recover Option**: If you select this option, then continue with the step 5 to configure the file recovery options.
- **Download Files**: If you are recovering a single file, this option downloads the file to your browser's download folder. For all other selections, this creates a recover task. When the task is completed, from the Recoveries page, click the task name and then click **Download Files** to download the generated zip file.

  Character replacement explanation for : and \ in file and directory names in zip files

  If the original file or directory name contains a ':' , it is replaced with '_COLON_' in the archive.
  Example:
  - The original name is "a:b" then the archived name is "a_COLON_b"
  - The original name is "a:b:c" then the archived name is "a_COLON_b_COLON_c"

  If the original file or directory name contains a '\', it is replaced with '_BACK_SLASH_' in the archive.
  Example:
  - The original name is "x\y" then the archived name is "x_BACK_SLASH_y"
  - The original name is "x\y\z" then the archived name is "x_BACK_SLASH_y_BACK_SLASH_z"

5. From the **Recover To**, select **New Server** to recover the files or folders to a new server.
6. From the **Registered Source** drop-down menu, select a registered server to which you want to recover the files and folders. You can also register a new source by clicking **Register Source** from the **Source** drop-down menu.
7. From the **Target** drop-down menu, select a server to which the files and files are to be recovered.
8. Change the default location to which the files or folders are recovered. By default, the files and folders are recovered to the **/tmp/** directory.
9. Optional. Edit the default settings of the following **Recovery options**:
   - **Overwrite Existing File/Folder**: By default, this option is disabled to create the files and folders in the specified location. Enable this option to overwrite the existing files and folders. Any duplicate files are skipped.

     Example for a Windows alternate location with **Overwrite Existing File/Folder** enabled and the target already exists:

     Files to be recovered: "C:\foo\1.txt", "C:\foo\test\1.txt", "C:\bar", "C:\foo\bar". Specified alternate location: "C:\restore". At the end of the copy, the target folder looks like this:

- C:\restore\1.txt
- C:\restore\cohesity<taskid>_0\1.txt
- C:\restore\bar
- C:\restore\cohesity<taskid>_1\bar

If **Overwrite Existing File/Folder** is enabled, recovering a file to source when the file is in Fuse may cause the open file to be overwritten. Whether overwriting occurs depends on the application using the file.

- **Preserve File/Folder Attributes**: By default, this option is enabled and the ACLs, permissions, and timestamps are preserved for all files and folders. If you disable this option, then ACLs and permissions are not preserved. If recovering both folders and files, then folders will receive the new timestamps, but files retain their original timestamps. If recovering only, files, then files will receive the new timestamps.
- **Continue on Error**: Enable this option if you want to continue the recovery even if one of the objects encounters an error. By default, this option is disabled and the recovery operation will fail if one of the objects encounters an error.
- **Cluster Interface**: By default, the **Auto Select** option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the Interface Group drop-down.
- **Task Name**: Change the default name of the recovery task.
- **Save Success Files**: Enable this option to download the success logs for a recovery run.

10. Click **Start Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Download List Information for a Recovery Run

System-generated lists are used to verify success or errors during recovery. You can now download the list information as a CSV file for both successes and failed recovery job runs on the Cohesity cluster.

To download the logs for a recovery run:

1. Select **Data Protection** > **Recoveries** > **Recover**.
2. On the **Recoveries** page, select the recovery run for which you want to download the debug logs.
    1. If you select a successful recovery run, on the Recovery Details page, select the **Show Subtask** button and then click **Download Success** Logs*.
    2. If you select a failed recovery run, on the Recovery Details page, select the **Show Subtask** button and then click **Download Errors**.

3. If the recovery run is partially successful, select the **Show Subtask** button and then click either the **Download Errors or Download Success Logs***.

> **Note:** * You must enable the **Save Success Files** option under **Recovery** Options while creating a recovery job to be able to download the success logs for a recovery run.

Recover Physical Servers

Cohesity enables you to perform:

- Bare machine recovery (BMR): To learn more about Cohesity's Cristie BMR integration, see About Bare Machine Recovery. For Cristie product documentation, see CBMR Documentation.
- Physical volumes recovery: For the Windows and Linux servers, you can perform block-level recovery of physical volumes to another volume in the same or different target.

Before you can recover a volume or perform BMR, a snapshot or BMR data must exist. To include CBMR data in physical server protection, the policy must include a BMR backup schedule (Create or Edit a Standard Policy) and the Protection Group must have BMR backup enabled (Add or Edit a Protection Group for Physical Servers).

The options to recover a physical server are as follows:

- Recover Physical Server to the Original Location
- Recover Physical Server to a New Location

Recover Physical Server to the Original Location

Before you can recover volume or bare machine recovery (BMR) data, a snapshot must exist. To create Snapshots, create and run a Protection Group.

You can recover the volumes of a physical server or perform bare machine recovery (CBMR) data, to its original location.

> **Note:** Cohesity's Cristie bare machine recovery (CBMR) is supported for Windows and Linux physical servers. For more information, see About Bare Machine Recovery.

To recover a volume or BMR:

1. Select **Data Protection > Recoveries**.
2. Click on **Recover** located at the top right of the page and then select **Physical Server > Physical Server**.

   The Physical Server page appears.
3. Search for the physical server that contains the snapshots to recover from by entering characters of the server name, or by specifying the wildcard character *.

   A list of servers displays.

   You can optionally filter the search results by source, Protection Group, Storage Domain, and date.
4. From the list of search results, select the server whose volume you want to recover.

   By default, the latest snapshot is selected for recovery.
5. To recover from a different snapshot, mouse over the snapshot from the selected list, and then click the **edit** icon.

   The Edit recovery point for <VM_name> page appears.

   > **Note:** In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

   By default, the option to select the snapshot is displayed in the **Timeline** mode. You can also choose to view the option in List mode by clicking the **List** tab in the top-right corner of the page.

   - To select a snapshot from the **Timeline** mode:
     a. From the **Choose a date** drop-down, select a date.

        The snapshots available on the selected date are displayed in blue dots on the timeline bar.
     b. For recovering CBMR snapshots, select the **Show BMR snapshots** check box.

        The BMR snapshots are also displayed.
     c. Select the snapshot to be recovered by clicking the corresponding blue dot.
     d. By default, the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.
     e. Click **Select Recovery Point** and then go to step 6.

- To select a snapshot from the **List** mode:
  a. Select the List tab from the top-right corner of the Edit recovery point for <VM_name> page.

     By default, the page displays the snapshots available in the last one month.

  b. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.

  c. For recovering CBMR snapshots, select the **Show BMR snapshots** checkbox.

     The BMR snapshots are also displayed.

  d. Select the snapshots to be recovered.

  e. By default, the snapshot is recovered from the local Cohesity cluster. You can also select snapshots archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.

  f. Click **Select Recovery Point** and then go to step 6.

6. Click **Next: Recover Options**.
7. From the **Recover To** options, select **Original Location** to recover the volume to the original location.
8. From the **Select Volume(s)** option perform the following actions:
   a. Select the **Force unmount volume** check box to forcefully unmount the target volume if it is already being used by other processes.
   b. From the list of volumes, select the volumes you want to recover, and from the corresponding **Select** drop-down list, select the volumes onto which the volume should be recovered.
9. **Cluster Interface**: By default, the **Auto Select** option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the **Interface Group** drop-down.
10. **Task Name**: Change the default name of the recovery task.
11. Click **Start Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Cohesity also provides the ability to tear down (delete) BMR jobs for Windows and Linux servers. If you tear down a recovery job, all the views created as part of the recovery task will be inaccessible from the Cohesity cluster.

To tear down a BMR job:

1. Select **Data Protection** > **Recoveries**.
2. Click the BMR job you want to tear down.
3. Click **Tear Down** located at the top-right of the page.
4. Click **Yes, Teardown** to confirm.

Recover Physical Server to a New Location

Before you can recover volume or bare machine recovery (BMR) data, a Snapshot must exist. To create Snapshots, create and run a Protection Group.

You can recover the volumes of a physical server or perform bare machine recovery (CBMR) data, to a new location.

> **Note:** Cohesity's Cristie bare machine recovery (CBMR) is supported for Windows and Linux physical servers. For more information, see About Bare Machine Recovery.

To recover a volume or BMR:

1. Select **Data Protection > Recoveries**.
2. Click on **Recover** located at the top right of the page and then select **Physical Server > Physical Server**.

   The Physical Server page appears.
3. Search for the physical server that contains the snapshots to recover from by entering characters of the server name, or by specifying the wildcard character *.

   A list of servers displays.

   You can optionally filter the search results by source, Protection Group, Storage Domain, and date.
4. From the list of search results, select the server whose volume you want to recover.

   By default, the latest snapshot is selected for recovery.
5. To recover from a different snapshot, mouse over the snapshot from the selected list, and then click the **edit** icon.

   The Edit recovery point for <VM_name> page appears.

   > **Note:** In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

By default, the option to select the snapshot is displayed in the **Timeline** mode. You can also choose to view the option in List mode by clicking the **List** tab in the top-right corner of the page.

- To select a snapshot from the **Timeline** mode:
  a. From the **Choose a date** drop-down, select a date.

     The snapshots available on the selected date are displayed in blue dots on the timeline bar.

  b. For recovering CBMR snapshots, select the **Show BMR snapshots** check box.

     The BMR snapshots are also displayed.

  c. Select the snapshot to be recovered by clicking the corresponding blue dot.

  d. By default, the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option.

  e. Click **Select Recovery Point** and then go to step 6.

- To select a snapshot from the **List** mode:
  a. Select the List tab from the top-right corner of the Edit recovery point for <VM_name> page.

     By default, the page displays the snapshots available in the last one month.

  b. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range.

  c. For recovering CBMR snapshots, select the **Show BMR snapshots** check box.

     The BMR snapshots are also displayed.

  d. Select the snapshots to be recovered.

  e. By default, the snapshot is recovered from the local Cohesity cluster. You can also select snapshots archived in the cloud by clicking the cloud ( ) icon if available in the **Location** option.

  f. Click **Select Recovery Point** and then go to step 6.

6. Click **Next: Recover Options**.

7. From the **Recover To** options, select **New Location** to recover the volume to a new location.
8. From the **Registered Source** drop-down menu, select a registered source having the server to which you want to recover the volume. You can also register a new source by clicking Register Source from the **Registered Source** drop-down menu.
9. From the **Physical Server** drop-down menu, select a server to which the volume will be mounted.

   > **Note:** The target server must already have the Cohesity agent installed and registered with the Cohesity cluster. If not, the server will not be available as a mount target.

10. From the **Select Volume(s)** option perform the following actions:
    a. Select the **Force unmount volume** check box to forcefully unmount the target volume if it is already being used by other processes.
    b. From the list of volumes, select the volumes you want to recover, and from the corresponding **Select** drop-down list, select the volumes onto which the volume should be recovered.
11. **Cluster Interface**: By default, the **Auto Select** option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the **Interface Group** drop-down.
12. **Task Name**: Change the default name of the recovery task.
13. Click **Start Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Cohesity also provides the ability to tear down (delete) BMR jobs for Windows and Linux servers. If you tear down a recovery job, all the views created as part of the recovery task will be inaccessible from the Cohesity cluster.

To tear down a BMR job:

1. Select **Data Protection** > **Recoveries**.
2. Click the BMR job you want to tear down.
3. Click **Tear Down** located at the top-right of the page.
4. Click **Yes, Teardown** to confirm.

Chapter 16: MS Applications

Cohesity supports the backup and recovery of the following applications:

Active Directory 3607

MS Exchange Server 3624

Active Directory

This chapter includes the following topics:

Active Directory Key Concepts

The following topics introduce you to key concepts about Active Directory protection and object recovery.

About Active Directory Data Protection

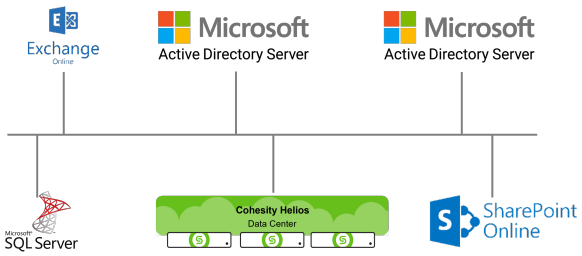
A Cohesity Active Directory (AD) backup captures an app-consistent VSS snapshot of all volumes on the Active Directory domain controller (DC). For instructions on how to use the Cohesity UI to back up AD, review Protect Active Directory.

Cohesity's AD backup implementation is intended to protect sufficient AD data to enable granular object recovery and object attribute compare and recovery.

If the objective is to recover an entire AD DC virtual server, protect the VM as described in Add or Edit a Protection Group for Virtual Servers. For AD DC bare metal server recovery, protect the process described in Add or Edit a Protection Group for Physical Servers. App-consistent VM/bare metal snapshots and crash-consistent snapshots are available.

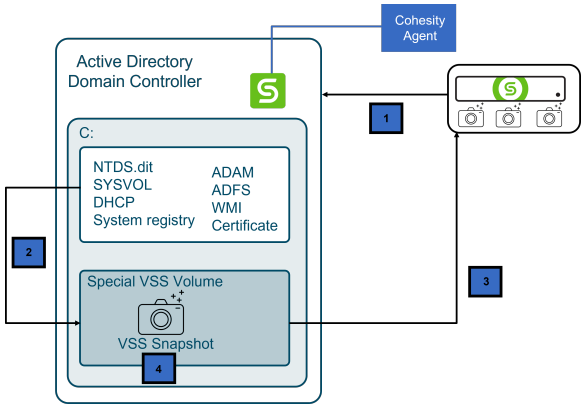
All configurations are for illustrative purposes only. Cohesity recommends following Active Directory best practices.

The following diagram displays an example Microsoft application environment that contains Active Directory.



The AD backup task consists of the following actions:

1. When a Protection Group starts, the Cohesity cluster requests an AD snapshot be taken.



2. A Volume Shadow Copy Service (VSS) snapshot of AD is captured using VSS.

   The snapshot is a full VSS backup and uses Cohesity change block tracking (volume CBT).

3. The snapshot data is copied to the Cohesity cluster.
4. The VSS snapshot is deleted.

About Active Directory Object Recovery

A Cohesity Active Directory (AD) recovery mounts the volume that contains NTDS.dit. For instructions on how to use the Cohesity UI to recover AD, review Recover Active Directory Objects.

You can use Cohesity for these Active Directory recovery types:

- Granular object recovery

  For example, Users, Computers and Groups

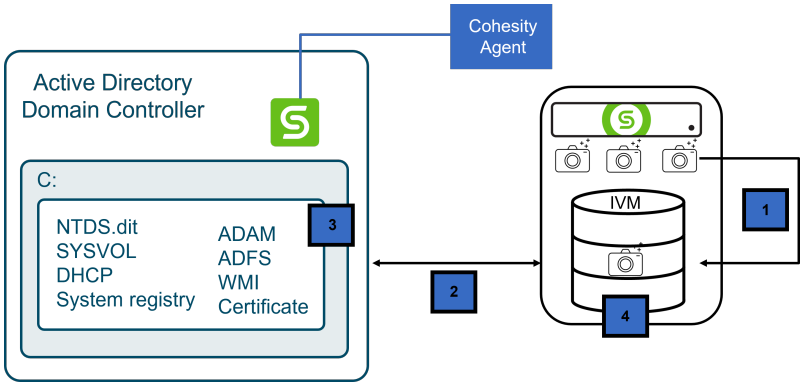
- Granular object attribute compare and recovery

  For example, description, email address, group membership, custom attributes

- Group Policy Object (GPO)

The AD recover task consists of the following actions:

1. When an AD recovery starts, the Cohesity cluster creates an instant volume mount (IVM) on the cluster that contains the requested snapshot of AD data (NTDS.dit).



2. The Cohesity agent mounts the IVM and accesses it through SMB. If the Cohesity cluster has joined an AD domain, then the cluster must join that AD domain (Join an AD Domain) to access the SMB volume.
3. The agent accesses the snapshot on a custom LDAP port, such as 53389, and the three subsequent ports.

   LiveAD is accessed to execute LDAP queries based on user input to compare objects, accept object or attribute and update LiveAD.
4. Optionally unmount the IVM.

   You can tear down the IVM when you finish using it.

Group Policy Object Recovery

You can recover the GPO if you have accidentally deleted it or if the GPO was updated and you do not want the updates.

GPO recovery involves recovering the following two components of the GPO and also the GPO links:

- **Group Policy Container** - It represents the attributes relevant to the GPO content. Each GPO contains two containers Machine and User and the respective containers contain specific information related to the machine and user nodes of the GPO. For more information, see Group-Policy-Container class.
- **Group Policy Template** - Contains the content of the GPO. It resides in a share known as SYSVOL. The share is replicated to every DC in the domain and the share contains separate directories named with GPO GUID for each GPO.
- **GPO links** - A GPO can be linked to different AD objects such as Domain, Site, and OrganizationalUnit. The links are maintained as the attribute (gPLink) of the corresponding AD objects.

Cohesity enables you to recover the following using the Cohesity UI:

- the Group Policy Container in AD.
- the SYSVOL folder for the GPO
- GPO links for all the objects that are linked to the GPO in cases where the GPO was deleted.

Active Directory Protection Requirements

Supported Versions

For more information on the supported versions, see Microsoft Applications.

Prerequisites

- Verify anti-virus exclusions are added for Cohesity Windows agent binaries under `C:\Program Files\Cohesity` and the log folder, `C:\ProgramData\Cohesity`.
- For the protection and granular recovery, the minimum required Cohesity version and agent is 6.4.
- Group Policy Object (GPO) on PowerShell execution. On all AD DCs where the Cohesity agent is running, Windows PowerShell script execution must be enabled.

Protection

- On all DCs where the agent is installed, open Cohesity port 50051 (For more information, see Manage Firewall Ports.)

Recovery

- On the recovery target DC, open the custom LDAP ports specified in the recover task. See Recover Active Directory Objects for more information.
- The AD Adapter has the same port requirements as filesystem backup. For recovery, it is the same as filesystem via an SMB (445), plus the addition of any 4 free consecutive ports of your choice.
- If the Cohesity cluster has joined an AD domain, then the cluster must join the target recovery AD domain to access the SMB volume. If the cluster has joined a forest (root/parent domain) and Trusted Domain Discovery is enabled from the cluster, the cluster does not need to join the child domains to perform recovery.

  The SMB volume is accessed using the Cohesity cluster computer object credentials registered in the AD. Ensure that there is a DNS server entry for the cluster computer object FQDN and that clocks are synchronized between AD and the Cohesity cluster (Kerberos allows no more than 5 minute skew).
- To perform object recovery to a Windows 2019 AD DC, you must join the Cohesity cluster to the Windows 2019 domain due to SMB security requirements.
- The recovering administrator user must have View privileges (the minimum permissions) on the production AD object. Otherwise, object recovery is prevented and the object is displayed as 'missing' and its properties are not shown.
- When recovering a deleted object from an earlier forest/domain functional backup (such as Windows 2000 functional level) to a later AD DC (such as Windows 2012 R2),

you may see differences in attributes (such as ntSecurityDescriptor) on the recovered object due to AD schema upgrades and prebuilt group memberships.

- Get-SystemAttributesInternal attributes (such as objectGuid, objectSid, usnChanged) are considered system properties, which are not compared and cannot be recovered due to AD restrictions. They are, however, displayed when browsing a snapshot. The Cohesity REST API has the ability to include system properties in attribute comparison.
- Manually teardown and rerun the domain recovery search and attempt object recovery if the connection to the mounted AD snapshot is lost. This happens if your Windows machine reboots in the middle of a granular restore or if the single-node cluster gets upgraded/rebooted.

Multitenancy

- The Cohesity cluster is part of both domains.
- A DNS server is set with conditional forwarding that forwards requests to the right Domain DCs.
- AD replicas are in the same DC as the Cohesity cluster.

Supported Workflows

The AD adapter supports the following workflows:

- Backup of Domain Controllers.
- Granular Recovery of AD objects.
- Granular Recovery of GPOs (Group Policy Objects).
- Granular Recovery of AD object attributes.

Minimum Permissions

- Agent installation - Install the agent on all AD DCs with FSMO roles that you want to protect.

  Use an AD Domain Admin account to install the Cohesity agent with the Volume CBT driver.

  The service can run as the LocalSystem account.
- Recovery - The AD account that performs recovery must be one of the following:
  - Domain Admin or Enterprise Admin
  - Domain user with delegated permissions to the OU where objects will be recovered, and reanimate permission on the AD Recycle Bin, if enabled (Delegation of Active Directory Recycle Bin).

Limitation

- Mounting a snapshot that was captured as a lower version domain/forest functional level/AD schema than the target DC FFL/Schema version, requires setting this gflag to true: magneto_active_directory_mount_ntds_allow_upgrade. Otherwise, the mount may fail after a 1 hour timeout.

  Obtain the AD schema version from:

  ```
  Get-ADObject (Get-ADRootDSE).schemaNamingContext -Property
  objectVersion
  ```

- If a Cluster or Windows machine is not part of Active Directory, workflows involving mounting Cohesity View on the Windows machine over SMB, including IVM restore, file folder restore from block-based backup, CBMR backup, and other Hyper-V workflows, will fail on the Cohesity cluster from Cohesity version 6.8 onwards.

Active Directory Best Practices

Cohesity recommends the following best practices when protecting Active Directory:

- Protect all domain controllers that have FSMO roles.

  For example, in the case of role failover this practice helps to ensure a backup (snapshot) is present even if a backup DC becomes primary at some point.

Active Directory Non-Cohesity-Specific Information

This section discusses Active Directory requirements, limitations and behavior that are not specific to Cohesity.

Target AD Server Reboot During Recovery

If a target AD server is rebooted or a single-node Cohesity cluster is upgraded/rebooted during a recovery, the recovery will fail. The Cohesity admin must perform a tear down operation of the recovery task and then re-attempt object recovery.

Objects Recovered with New SIDs when AD Recycle Bin is not Enabled

Any recovered user, group and computer objects will have a new security descriptor (SID) if the Recycle Bin is not enabled on the AD forest, or if you recover after the tombstone lifetime has expired.

This is due to an AD limitation that prevents APIs setting object SIDs. The SID is permanent within a domain during an object's lifetime. This is a general limitation for all backup vendors and Microsoft API users. If these SIDs were inherent to any groups or ACLs, they would need to be adjusted manually. Cohesity always attempts to recover a missing object from the Recycle Bin and creates a new object (thus, a different SID) only when it is not found in the Recycle Bin. An object comparison reveals the SID difference.

NTDS VSS Limitation

Microsoft NTDS VSS writer does not support Ntds.dit files on a mount point (such as C:\mount).

ntSecurityDescriptor ACL Attribute Recovery

The ntSecurityDescriptor security ACL attribute of an object within an OU may be delegated and inherited. In this case, the ACL cannot be recovered for the object because AD prevents it, showing the attribute as different. Recover the ntSecurityDescriptor of the OU.

Object Recovery by a Non-Domain Admin/Enterprise Admin

If a non-domain administrator/enterprise administrator account (such as HelpDesk) is delegated to perform object recovery and the Recycle Bin feature is enabled on the AD forest, the account must have Reanimate Tombstone object permissions to look up and recover objects from the AD Recycle Bin. For more information, see MSDN.

Delegated Permissions for a Non-Admin for Recovery

When giving delegated permissions to a non-admin user, choosing everything under "Delegate the following common tasks" gives delegate permissions for create/delete/manage user accounts, groups and inetOrgPerson accounts. You should specify permissions for other object types (such as computers and organizational units) separately. For object recovery to succeed, you must grant permissions to read and write all attributes in addition to create and delete object permissions.

Set Up Active Directory for Data Protection

This topic describes how to set up an Active Directory (AD) domain controller (DC) to be protected by a Cohesity cluster.

If the AD DC is already registered as a physical server with the Cohesity cluster, skip to the Register Active Directory steps. If the server is not registered with the Cohesity cluster at all, start with Set Up the Cohesity Agent on an AD DC.

Set Up the Cohesity Agent on an AD DC

Install the Cohesity agent on each AD DC that you want Cohesity to protect.

1. Select **Data Protection > Sources**.
2. Click **Download Cohesity Agent**. Ensure the agent has been downloaded to the appropriate server.
3. As an AD Domain Admin, run the executable and complete the installation wizard.
4. **Volume CBT (Changed Block Tracker):** Install this component for the best incremental backup performance. Installing this component requires a one-time reboot to load the Cohesity Volume CBT driver.

   File System CBT (Changed Block Tracker): This component is not required.

5. **Service Account Credentials:** The service can run as the LocalSystem account.
6. Wait for the installation to finish. The agent starts automatically.
7. Reboot the machine.
8. Repeat the agent installation process on each AD domain controller you want to protect.

Register Active Directory

Register each AD DC that you want Cohesity to protect.

1. Select **Data Protection > Sources**.
2. Click **Register** on the top-right of the page and then select **Applications > Active Directory**.
3. Specify the hostname (FQDN) or IP address (IPv4 or IPv6) of the server to register.
4. Click **Register**.

   When registration finishes, a new entry appears in two sections on the Sources page, Active Directory and Physical. If the DC was already registered as a physical server, a new entry appears in the Active Directory section.

   The Sources page displays the following information for AD sources:

   - Total Size shows the Windows physical volume size.
   - Protected Size shows the AD database size.

Related Topic

Active Directory Protection Requirements.

Protect Active Directory

This topic describes how to protect Active Directory (AD).

Protect Active Directory Overview

1. Register an AD source with the Cohesity cluster if one is not already registered. See Set Up Active Directory for Data Protection
2. Select **Data Protection > Sources**.
3. Locate the AD source you want to protect and click **Protect Active Directory** from the actions menu.

Create an AD Protection Group

> **Note:** This page displays registered AD servers only, so only AD servers are selected regardless of the other servers within the source object hierarchy.

1. In the Cohesity Dashboard, select **Data Protection > Protection**
2. Click **Protect** on the top-right of the page and then select **Applications > Active Directory**. You can select multiple objects to protect.
3. In the **New Protection** pop-up, do one of the following:
   - Protect the Active Directory by specifying a subset of options such as objects, protection group and policy by clicking the edit icon corresponding to the following options:
     i. **Add Objects**: Select the registered Active Directory source or click **Register Source** to register an Active Directory. From the **Objects** list, select the objects to protect.
     ii. **Protection Group**: Specify a name for the Protection Group.
     iii. **Policy**: Select an existing policy or click **Create Policy** to create a new protection policy.
     iv. **Storage Domain**: Select the appropriate storage domain.

     > **Note:** This option is visible on the **New Protection** pop-up only if there is more than one storage domain.

     v. Click **Protect**.
   - To protect an Active Directory by specifying all the options, click **More Options**.
4. **Source:** Select the servers to protect.
5. **Policy:** Select an existing protection policy or create a new one by selecting **New Policy**.

   Storage Domain: Select an existing storage domain or create a new one by selecting **New Storage Domain**.

   > **Note:** Once you create a Protection Group, you cannot change the Storage Domain you selected for that job.

   The selected storage domain stores the snapshots by this Protection Group.
6. Click **Protect**.

   The Protection page is displayed and includes the new Protection Group.

Name: Enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.

Advanced Settings

- **Start Time:** Indicates when the Protection Group should run. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting.

  The default time zone is the browser's time zone. You can change the time zone by selecting a different time zone.
- **End Date:** Optional. Toggle on and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
- **QoS Policy:** Select an appropriate quality of service (QoS) policy.

  > **Note:** Cohesity recommends specifying **Backup HDD**, which is the default.

  - **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group.
  - **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups.
  - **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy.
  - **TestAndDev High:** The Cohesity cluster writes the data to an SSD drive for this Protection Group. The I/Os with this QoS policy are given higher priority compared to other QoS policies. Use this policy for workloads that require lower I/O latency.
- **Pre & Post Scripts:** Edit this option to run scripts on the protected server before and/or after a Protection Group runs. If configured, the scripts are run every time an object is backed up by a Protection Group run.

  For configuration details, see Configure Pre & Post Scripts.
- **Cancel Runs at Quiet Time Start:** Available only if the selected policy has at least one quiet time period. Toggle it on to specify that all currently executing protection runs should abort if a quiet time period specified for the Protection Group starts. By default this toggle is off, which means after a protection run starts, it continues to execute even when a quiet time period specified for this protection run starts. However, a new protection run will not start during a quiet time period.
- **Alerts:** Optional. Select one or more of the following settings if you want alerts to be created for the following triggers:

  - **Success:** Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created.
  - **Failure:** Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created.
  - **SLA Violation:** Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created.

  For more information, see Alerts.
- **Priority:** Select a priority for the Protection Group execution. Cohesity supports concurrent backups, but if the number of Protection Groups exceeds the ability to process them, those with **High** priority are given the highest priority to execute, **Medium** the second-highest priority, and **Low** the lowest priority.
- **Email Recipients**: You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the Protection Group.

  > **Note:**
  > The connection to the SMTP Server must be enabled to send email notification. You can enable the SMTP Server connection in the configuration settings page (Cohesity UI > **Settings** > **Summary** > **Configure** > **Enable SMTP Server**).

- **SLA:** The service-level agreement (SLA) defines the expected time to complete either a full backup or incremental backup. The backup completion time depends on the Windows volume size on AD, objects changed between incremental backups, network speed, and other Protection Groups running on the Cohesity cluster.
  - **Incremental:** Enter the number of minutes you expect an incremental protection run to complete. An incremental backup captures only the differences (changed blocks) since the last protection run.
  - **Full:** Enter the number of minutes you expect a full backup protection run to complete. A full backup captures the entire object (all blocks).

Recover Active Directory Objects

This topic describes how to recover Active Directory (AD) objects. Before you can recover an AD object, a successful snapshot must exist.

Cohesity cluster must join the AD domain for AD source backup and to perform AD granular object recovery. If the cluster has joined a forest (root/parent domain) and Trusted Domain Discovery is enabled from the cluster, the cluster does not need to join the child domains. For information about joining a domain, see Join Active Directory. Kerberos authentication handles recovery credentials. AD users can be defined as Cohesity cluster users and

assigned different roles for cluster operations (for more information, see Users and Groups).

Recover AD Object Overview

1. Select **Data Protection > Recoveries**.
2. Click **Recover > Applications > Active Directory**.
3. Select the AD DC and snapshot you want to recover.

   For Sources that are protected as Virtual machines or as Physical Hosts, choose the Active Directory Snapshot instead of the VM Snapshot or Physical host Snapshot.
4. Set recovery options.

Set Recovery Options

1. **Domain Controller:** Select a domain controller.
2. **AD Administrative Username:** Enter the username to use for the recovery. It must be one of the following:
   - Domain Admin or Enterprise Admin
   - Domain user with delegated permissions to the OU where objects will be recovered and reanimate permission on the AD Recycle Bin, if enabled.
3. **Password:** Enter the account password.
4. **Port:** Enter the port number to use for the recovery.

   This port and the 3 consecutive port numbers after it must be currently unused and opened for inbound traffic in the Windows Firewall.

   Windows Server 2008 and newer versions of Windows Server have increased the dynamic client port range for outgoing connections. The new default start port is 49152, and the default end port is 65535.

   For more information on Dynamic Port Range, see Active Directory and Active Directory Domain Services Port Requirements.

   > **Note:** These LDAP ports do not need to be opened for hosts outside the AD DC. Only the Cohesity agent must use these ports.

   Example:

   ```
   C:\Users\Administrator>netsh advfirewall firewall add rule
   name="Cohesity_Agent_In" dir=in action=allow protocol=TCP
   localport=1033-1036
   ```
5. **Recover from:** Select a snapshot to recover from.
6. Click **Continue**.

Browse Snapshots

After successfully mounting a snapshot, you can browse the snapshot to review the differences between the backup and live data.

1. Select **Data Protection > Recoveries**.
2. Click the task name.
3. Click **Browse Snapshot**.

Entity Hierarchy Navigation

The protected source and where the snapshot is mounted are displayed at the top left. The AD domain's entire entity hierarchy is displayed on the left of the page. Navigate the hierarchy to display desired objects.

Search

You can use the search bar for text searches or run your own customized AD LDAP queries. Search queries are executed against the currently selected entity hierarchy level. To search the entire hierarchy, ensure the top level is selected.

An example LDAP query to search for a user named AutomationUser02:

```
(&(objectcategory=person)(sAMAccountName=AutomationUser02))
```

Differences

If a difference exists between the backup and live data, an object's difference column displays one of the following:

- Yes - The backup and live data differ
- Missing - The object is missing from the source

Recover

You can recover only objects that have differences.

Select an object's check box and click **Recover**. Drilling down to an object's lowest level allows you to view its individual properties and whether to view only recoverable changes.

When recovering multi-value objects, select one of the following:

- Merge Values - Merge the values from the backup and live data
- Overwrite Values - Overwrite the live values with the backup values

When recovering a missing user, you must provide a password that meets your enterprise password requirements or the recovery will fail. The following options are also available:

- User must change the password at the next login. This is on by default.
- Recover in a disabled state. This is off by default.

After Recovering Objects or Attributes

After a successful recovery, Recovered is displayed next to any recovered objects.

When you finish recovery, click **Done** in the top right corner and select an option:

- Stay - Continue browsing the snapshot
- Keep mount and Leave - Keep the snapshot mounted but leave the Browse Snapshot page
- Unmount and Leave - Unmount the snapshot and leave the Browse Snapshot page. This destroys the snapshot. To use the snapshot later, you must start another Recover task.

Audit Recover Tasks

Use the following methods to audit AD recoveries:

- View recoveries on the Cohesity cluster.
  1. Select **Data Protection > Recoveries**.
  2. Click the task name.
  3. The Details tab lists objects recovered from that AD snapshot. Mouse over the object name for additional details.
- View the Windows application event log in the event viewer. The source for Cohesity recoveries will be CohesityAgent.

Tear Down

If you left a snapshot mounted, tear it down using these steps:

1. Select **Data Protection > Recoveries**.
2. Click the snapshot's task name.

   Its status should be Success.
3. Click **Tear Down** and confirm.

   After teardown finishes, the status should be Destroyed.

Recover Active Directory Domain Controller

Cohesity provides the ability to recover the Active Directory (AD) Domain Controllers that are backed up on the Cohesity cluster. The procedural steps below align with Microsoft best practices.

Prerequisites and Considerations

For recovering AD:

- Snapshots of the AD domain controller must be available on the Cohesity cluster.

- You must have the local administrator username and password.
- Windows Firewall should permit TCP Port 50051 inbound traffic from the Cluster for the instant mount
- Permission should be given to the instant volume mount to access the temporary SMB mount used during the recovery.
- The steps listed here are specific to the recovery of the AD Domain Controller.

Recover AD Domain Controller

Perform the following steps to recover AD Domain Controller:

1. On the Domain Controller, configure the Domain Controller host to boot in Directory Services Repair Mode (DSRM):
    1. Press **WIN+R** on the keyboard.
    2. Type **msconfig** and click **OK**.
    3. Select the **Boot** tab.
    4. Under **Boot Options**, select the **Safe Boot** check box.

        > **Note:** Once the **Safe Boot** is enabled, the AD services are disabled. DNS and all other AD services are not available.

    5. Select **Active Directory repair** and click **OK**.
    6. Restart the Domain Controller host.
2. Log in to the Domain Controller host as the local administrator.
3. In the Cohesity UI, select the snapshot for restore, then download the folders containing the AD data (NTDS and SYSVOL). For more information, see Instant Volume Mount.
4. On the Domain Controller host:
    1. Rename the old NTDS and SYSVOL folders.
    2. Copy over the same folders (NTDS and SYSVOL) from the Instant Volume Mount to the Domain Controller host.
5. From the Cohesity UI, tear down the Instant Volume Mount. For more information, see Teardown a Mounted Volume.
6. On the Domain Controller, configure the Domain Controller host to boot in normal mode:
    1. Press **WIN+R** on the keyboard.
    2. Type **msconfig** and click **OK**.
    3. Select the **Boot** tab.

4. Under **Boot Options**, clear the **Safe boot** check box.
5. Restart the Domain Controller host.

7. Log in to the Domain Controller host as the domain administrator.

Active Directory Data Protection FAQs

This topic answers frequently asked questions about protecting and recovering Active Directory (AD) objects.

Sources

Where do I need to install the Cohesity agent?

Install the agent on all DCs with FSMO roles that you want Cohesity to protect.

How do I upgrade the agent?

You can upgrade agents to the latest version from the Cohesity cluster.

Permissions

What permissions are required?

- Agent installation - Install the agent on all AD DCs with FSMO roles that you want to protect.

  Use an AD Domain Admin account to install the Cohesity agent with the Volume CBT driver.

  The service can run as the LocalSystem account.
- Recovery - The AD account that performs recovery must be one of the following:
  - Domain Admin or Enterprise Admin
  - Domain user with delegated permissions to the OU where objects will be recovered and reanimate permission on the AD Recycle Bin, if enabled (Delegation of Active Directory Recycle Bin).

Protection

If I protect the DCs, will the servers they run on be protected?

AD protection is intended to protect sufficient AD data to enable granular object and attribute recovery. The implementation does not protect the entire VM or physical server. To accomplish that, define separate VM/physical server protection.

If I protect a forest DC, are all DCs in the forest protected?

No. Protecting forest a DC does not protect all DCs in the forest. You must protect individual DCs.

Recovery

Do I need to open firewall ports when recovering?

Yes. Recovery requires opening firewall ports to mount a snapshot on AD. For example, port 33389 and the 3 subsequent ports must be opened.

A snapshot is missing a user that was added to production AD. What is wrong?

If a new user was added to production AD after the snapshot was captured, the user will not be present in the snapshot on the cluster.

How do I recover an entire OU?

First recover the OU container and then recover all objects inside it.

Can I recover multi-value attributes?

Yes. Merge/overwrite options are provided for multi-value attributes such as url, telephone, etc.

Can I recover a deleted OrganizationalUnit object?

Yes. If the OrganizationalUnit (OU) is accidentally deleted, you can recover the OU from the snapshot. When you recover an OU object, all the attributes of the OU object including the `gPLink` attribute are recovered.

Can I recover GPO links for Domain, Site or OrganizationalUnit?

Yes. You can recover GPO links by initiating the recovery at an attribute level for an object. For example, recovery of attribute `gPLink` for OrganizationalUnit.

Can I recover Active Directory Domain Controller?

Yes. For more information, see Recover Active Directory Domain Controller.

Can I recover all AD objects?

Yes. You can recover all AD objects including GPOs except system attributes.

Can I recover system attributes?

No. You cannot recover system attributes. For example, system IDs or object IDs. Cohesity cannot restore system attributes if the object is deleted or not available in the AD recycle bin.

Can I recover attributes from the AD recycle bin if the AD recycle bin is enabled?

If the AD recycle bin is enabled, Cohesity will attempt to restore from the AD recycle bin and attempt to preserve everything of that object from the AD recycle bin restore.

If the AD recycle bin is not enabled or the object is past TTL, the system attributes of that object are not restored.

MS Exchange Server

This chapter includes the following topics:

MS Exchange Server Requirements

This topic provides information about the supported platform, permission, requirements, and limitation for protecting the Exchange Server by Cohesity cluster.

Supported Versions

For more information, see Microsoft Applications.

Minimum Permissions

- The Cohesity agent service logon should be running as a specific AD account (not LocalSystem or local computer account such as local administrator) that has privileges to run Exchange Management PowerShell and query AD for Exchange objects. Exchange Management PowerShell is required for executing the following sets of cmdlets to get the Exchange server, DAG, and database topologies:
  - Get-ExchangeServer
  - Get-Mailboxdatabase
  - Get-Mailbox
  - Get-MailboxDatabaseCopyStatus
  - Get-DatabaseAvailabilityGroup

  The following permissions are required to register and backup Exchange Servers:
  - **Backup Operators group** on AD Domain.
  - **Exchange Servers and Organization Management groups** under the **Microsoft Exchange Security Groups** Organizational Unit.
  - **Local Administrators group** on the Exchange Server.
- For recovering mailbox or databases:
  - You need special privileges for the Ontrack user. Refer the Ontrack documentation for the permission requirements.
  - The Exchange server must have joined the same AD domain as the Cohesity cluster for SMB authentication.

Prerequisites

- Verify anti-virus exclusions are added for Cohesity Windows Agent binaries under `C:\Program Files\Cohesity including RunE2E.exe` and the log folder, `C:\ProgramData\Cohesity`.
- Install the Cohesity agent on the Microsoft Exchange Servers.
- Install Kroll Ontrack® PowerControls™ 9.2 or later on a Windows server that has joined the same active directory as the Microsoft Exchange Servers. Kroll Ontrack is required for:

    - Exchange mailbox recovery.
    - A Windows server with 32-bit Microsoft Outlook installed.
- Verify MS Exchange Server services are running.
- On the Server's Windows system, set the Power Plan to High performance.
- On physical servers with an installed agent, open the following ports:
    - TCP port 50051 for backup operations (incoming)
    - Standard AD and SMB port (445) for restore operations (outgoing)

Setup MS Exchange Server

To back up Exchange Servers (standalone and DAG) on the Cohesity cluster, you must first register them as a source on the Cohesity cluster. This topic describes how to set up standalone Exchange Servers and Exchange servers on DAG to be protected by a Cohesity cluster. This involves the following steps:

1. Download and Install the Agent.
2. Register Exchange Server

Download and Install the Agent

Install the Cohesity agent for Windows on each Exchange server that you want Cohesity to protect.

1. Select **Data Protection > Sources**.
2. Click **Download Cohesity Agent** and download the agent for Windows. Ensure the agent has been downloaded to the appropriate server.
3. Run the agent executable as an AD account admin having privileges to run the Exchange Management PowerShell and query AD for Exchange objects. For more information see, minimum permissions.

   The welcome page of the Cohesity agent setup wizard appears.
4. Click **Next**.
5. **File System CBT (Changed Block Tracker)**: Install this component to perform MS Exchange Server file-based protection.
6. **Service Account Credentials**: Enable **The following user account** and enter the specific AD account that has privileges to run the Exchange Management PowerShell and query AD for Exchange objects. For more information see, minimum permissions.
7. Wait for the installation to finish.

   The agent starts automatically.
8. Repeat the agent installation process on each Exchange server you want to protect.

This includes any standalone MS Exchange servers and MS Exchange Server nodes on DAG.

Register Exchange Server

Once you install the Cohesity agent on the server, you must register the Exchange Server with the Cohesity cluster.

- Register Standalone Exchange Server
- Register Exchange Server on DAG

Ensure one of the following:

- Cohesity cluster has joined the DNS server of the Exchange Server.
- Exchange servers are specified in the host mapping on the Cohesity cluster.

Prerequisite

You must install the Cohesity agent on the server before you register the standalone Exchange server or Exchange server on DAG. Click the **Download Cohesity Protection Service** link and then download and install the Windows agent on the server. For more information, see Download and install agent.

Register Standalone Exchange Server

1. Navigate to **Data Protection > Sources**.
2. Click **Register** > **Applications** > **Exchange Server**.
3. Specify the hostname or FQDN of the Exchange server.

   > **Note:** Ensure you have installed the Cohesity agent on the server.

4. Click **Register**.

The standalone Exchange Server is registered as a source.

Register Exchange Servers on DAG

1. Navigate to **Data Protection > Sources**.
2. Click **Register** > **Applications** > **Exchange Server**.
3. Specify the hostname, FQDN of the DAG endpoint, or the FQDN of a node in the DAG.

   > **Note:** Ensure you have installed the Cohesity agent on the server.

4. Click **Register**.

   The Register MS Exchange Server screen appears. Provide the additional information to complete the registration.

5. **DAG Preference**: Select one of the following options from the drop-down list to set the backup preference:
    - **Passive and Active Copy**: Takes backup from healthy passive copy. However, if all the passive database copies on DAG are unhealthy, then Cohesity will take the backup from the active database copy.
    - **Passive Copy Only**: Takes backup only from the passive database copy.
6. **Backup Preference Order**: Select one of the following options to set the backup preference order of the Exchange Servers (nodes) of a DAG :
    - **Reverse of the databases' Activation Preference Order**: Backup passive copies with the highest activation preference order and least lag time specified in Exchange Server Management.
    - **Specify backup preference order**: Allows you to set your preferred backup order of the servers of a DAG. This option is recommended if the network distance between the Cohesity cluster and the DAG node is large.
7. Select the nodes you want to register. In the above step, if you have selected to specify the backup preference order, then the order of backup will be as per the order you select the discovered nodes/server.

    > **Note:** All the DAG nodes must be registered with one cluster. The backup will fail if you select nodes registered with different clusters.

8. If you have not installed the Cohesity agent on the server, click the **Download Cohesity Protection Service** link and then download and install the Windows agent on the server.
9. Click **Complete Registration**.

The Exchange Servers on DAG are registered as a source. However, the nodes and databases of the DAG that are in maintenance mode will not be registered. Cohesity recommends you to register all the nodes of a DAG if you have selected **Passive and Active Copy** as the backup preference option. Otherwise, if a passive copy is not found in the registered nodes, it may back up from the active copy of the database, which is undesirable.

Protect MS Exchange Server

Cohesity provides support for backup and recovery of Microsoft Exchange Servers (Standalone and DAG) running on a physical server or VM. This topic describes how to protect MS Exchange Server.

Protect Exchange Server Overview

1. Register an Exchange Server source with the Cohesity cluster if one is not already registered. See Setup MS Exchange Server.
2. Select **Data Protection > Sources**.
3. Locate the Exchange Server source you want to protect and click the action menu (⋮) and select **Protect**.

You can also protect MS Exchange Server by performing the following steps:

1. Navigate to **Data Protection > Protection**.
2. Click **Protect** > **Application** > **Exchange Server**.
3. Select the source to protect.

Create an Exchange Server Protection Group

> **Note:** This page displays registered MS Exchange Server only, so only MS Exchange servers are selected regardless of the other servers within the source object hierarchy.

1. Navigate to **Data Protection > Protection**.
2. Click **Protect** > **Application** > **Exchange Server**.
3. In the **New Protection** pop-up, do one of the following:
   - Protect the Exchange Server by specifying a subset of options such as objects, protection group and policy by clicking the edit icon corresponding to the following options:
     i. **Add Objects**: Select the registered Exchange Server source or click **Register Source** to register an Exchange Server. From the **Objects** list, select the mailbox databases in the Exchange Server to protect.
     ii. **Protection Group**: Specify a name for the Protection Group.
     iii. **Policy**: Select an existing policy or click **Create Policy** to create a new protection policy.
     iv. **Storage Domain**: Select the appropriate storage domain.

     > **Note:** This option is visible on the **New Protection** pop-up only if there is more than one storage domain.

     v. Click **Protect**.

- To protect an Exchange Server by specifying all the options, click **More Options**.

4. **Source**: Select the source to protect.
5. **Objects**: Select the mailbox databases in the Exchange Server to protect and then click **Save Selection**. By default, all objects in the source are excluded as indicated by the unselected check box. Expand the source objects and select the objects you want to include in the Protection Group. A selected check box ( ) indicates the object is selected to be backed up.

   If appropriate for your organization, enable Auto Protect.

   Click to turn on Auto Protect. By enabling this option, any new mailbox database added to the Exchange Server will automatically be protected by this Protection Group and become protected on the next run.

   For example, you create a Protection Group that backs up an Exchange Server. The Protection Group runs for two weeks and then a new database is added to the Exchange Server. The next time the Protection Group runs, if the object hierarchy has been refreshed on the Cohesity cluster, the new database is also backed up even though the new database has not been explicitly selected to be included in the Protection Group. The object hierarchy is automatically refreshed every four hours. To manually refresh the object hierarchy, select **Data Protection > Sources**, find the source in the list and click . To exclude an object from Auto Protect, click .

   - Indicates an Auto Protected object.
   - Excluded objects are not protected. The icon indicates that an ancestor of the object is Auto Protected but this object is explicitly excluded.

   Protection of dismounted databases, recovery database types, and deleted databases are automatically skipped by the Protection Group.

   You can optionally use the filter icon to filter users or groups based on.

   - **Show All**—Displays all the Objects in the Cohesity cluster.
   - **Selected Objects**—Displays the selected Objects in the Cohesity cluster.
   - **Unprotected**—Displays Objects that are not protected by any Protection Groups in the Cohesity cluster—not protected by Cohesity.
   - **Protected by Cohesity**—Displays Objects that are protected by any Protection Groups in the Cohesity cluster.

   The graphical representations are described below.

- An unchecked box indicates the Object is excluded from any Protection Group.

  A shield indicates the Object is already protected by another Protection Group. A Windows physical Server cannot be protected by a new Job unless you remove it from the current job.

- A checked box indicates the Object will be protected by the current Protection Group.
- Click the icon to see details about the object.
- An outlined shield indicates that not all Objects are protected.
- If the object name is in red, it is inaccessible, invalid, or orphaned. If the object is in one of the specified states when the Protection Group runs, no snapshot is created. If the object becomes accessible, a snapshot is created the next time the Protection Group runs.

6. **Protection Group**: To enter a new name for the Protection Group, select **New Group** and enter the Group Name in the **Group Name** field. To use an existing Protection Group name, select the **Existing Group** and select an existing group name from the **Group** drop-down list.
7. **Policy**: Set the policy for your Protection Group. Under **Policy**, select the appropriate Protection Policy, choose one of the defaults (Bronze, Silver, or Gold), or create a New Policy if the available policies do not meet your schedule and retention needs.

   Cohesity recommends you to create a policy with the

   - **Log Backup (Databases)** option if your incremental backup window exceeds the desired time window. The backup will automatically skip the circular logging enabled databases during the log backup window.
   - **Retry Options** set to 3 and the time between retries as five minutes.

     For more information see, Create or Edit a Standard Policy.

   Storage Domain: Select an existing storage domain or create a new one by selecting **New Storage Domain**.

   > **Note:** Once you create a Protection Group, you cannot change the Storage Domain you selected for that job.

   A Storage Domain defines the level of storage efficiency, security, and resilience for the data being protected in Cohesity. In a Storage Domain, you can enable or disable deduplication, compression, and/or encryption for the domain, and select the necessary level of resilience (that is, the number of faults tolerated).

If a Storage Domain with the right settings exists, select that one. Otherwise, create a new one with Add Storage Domain. See Create or Edit Storage Domains.

If you need to create a new Storage Domain:

- You can enable or disable deduplication and compression at any time.
- You can enable or disable encryption only when you create the Storage Domain for the first time.
- There are no benefits if you perform deduplication and compression on the encrypted data.

8. **Start Time**: Available only if the selected policy is set to Backup Daily. Indicates when the job should run. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting
9. After selecting a Storage Domain, if you need to change any of the Advanced settings, scroll down and click **Edit** on the right.

Advance Settings	Description
End Time	Optional. Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts prior to this date runs until completion even if it completes after this date.

Advance Settings	Description
QoS Policy	Select an appropriate quality of service (QoS) policy. **Note:** Cohesity recommends specifying **Backup HDD**, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. but it doesn't change or take effect on the currently running task.
Indexing	This option is enabled by default and is required for file recovery. By enabling this option, Cohesity cluster will scan all the files in the Protection Group and create an internal index that can be used later by a recover task to locate files by name.
Exchange Log Truncation	This option is enabled by default and truncates the Exchange server transaction logs. If this option is disabled, then "copy only" backup is taken and transaction logs are not truncated.
Cancel Runs at Quiet Time Start	Available only if the selected policy has at least one quiet time period. Toggle it on to specify that all currently executing job runs should abort if a quiet time period specified for the Protection Group starts. By default this toggle is off, which means after a job run starts, it continues to execute even when a quiet time period specified for this job starts. However, a new job run will not start during a quiet time period.

Advance Settings	Description
Alerts	Optional. Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts.
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of jobs exceeds the ability to process jobs, this will be the priority of implementation of the jobs: 1. High-priority jobs 2. Medium-priority jobs 3. Low-priority jobs.
Email Recipients	You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the job.
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).
Description	Optional. Click the plus sign and enter a description for the Protection Group.

10. Click **Protect**.

Your Protection Group runs appear in the list on the Protection Groups page.

Once your Protection Group completes its first run, the Exchange Server will be ready for recovery, replication, and archival.

Recover MS Exchange Server

This topic describes how to recover the Exchange Server objects (Exchange Databases) that you have successfully backed up on the Cohesity cluster. Cohesity supports two types of recovery options for Exchange Server objects.

View-Based Recovery

Cohesity mounts the view over SMB on the target server. The mounted views contain the database files and transaction logs. You can use Ontrack to perform recovery of mailbox databases including granular recoveries such as individual mailboxes, emails, files, and folders.

> **Note:** Microsoft Exchange (on-premises) requires Ontrack® software and a license for the granular recovery of mailbox databases such as individual mailbox, emails, files and folders.
> Cohesity recommends you to install Ontrack® on a separate Windows machine (than Exchange server) with an AD account that has appropriate mailbox permissions. The Windows machine must be registered as a physical source on Cohesity. On recovery, Cohesity will expose an SMB share with Exchange database files that can be opened using Ontrack®. You can also use Exchange tools such as **ESEUTIL.EXE** to perform manual inspection and recovery.

The Exchange database files will be recovered to the following SMB path of the Cohesity View:

```
\\<cluster_Ip>\<storage _domain>.<view_name>.fs\exchange
```

For example:

```
\\10.10.10.10\DefaultStorageDomain.ExchView_1585178933.fs\exchange
```

Database recovery

MS Exchange database recovery allows you to restore Exchange Server databases to a healthy state during a failure or data loss event. These databases store email messages, calendar items, contacts, and other vital information, making their recovery crucial for business continuity. When recovering an MS Exchange database, you can either overwrite the original database or restore to an alternate database.

> **Important:**
> If you want to **Overwrite the Original Database**, you must enable the **This database can be overwritten by a restore** parameter from the **Exchange Admin Center**.
>
> To enable the parameter:
>
> 1. Log in to the **Exchange Admin Center**.
> 2. Select **Servers** from the left-nav and then navigate to **databases**.
>
>   This will list all the databases on the Exchange Server.
> 3. Select the database you want to overwrite and then click the **Edit** icon at the top-right corner to open the database properties window.
> 4. In the database properties window, navigate to the **Maintenance Tab** and select the **This database can be overwritten by a restore** check-box.
> 5. Click **Save**.

To recover Exchange Server Objects:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** > **Applications** > **Exchange Server**.
3. On the Recover page, On the Recover page, select Database or View.
4. Search for the mailbox database you want to recover by entering any of the following options:
   a. Mailbox Database name
   b. User name of the mailbox
   c. E-mail address of the mailbox
   d. IP address or hostname of Exchange Server.
5. You can optionally specify the wildcard character *. You can also optionally narrow the search results by specifying filter criteria, for example, you can filter the search results by a specific Protection Group, source or date.

   > **Note:** If you choose multiple databases, recovery to the original location is the only option available.

6. Select the object(s) you want to recover.

7. From the **Selected** object list, click the edit icon and select the exact snapshot you want to recover, and then click **Select Recovery Point**. By default, the latest Snapshot is recovered.
8. When performing a **View-Based** recovery, provide the following details:
    a. In the **Cohesity View** field, change the default name of the View where you want to recover the data to. This cannot be an existing view name. Cohesity will perform a mount to the target server and you can use this SMB path to access the view from the target server.
    b. In the **Server Running Recovery Tool** drop-down list, select the target server to which the SMB view should be mounted.

    > **Note:** For granular recovery, access the view from the target server running the recovery tool using the SMB path and then perform the desired Granular Level Recovery (GLR) operations to recover data to the server.

9. When recovering a **Database**, provide the following details:
    a. **Targets**: Select **Overwrite Original Database** or **Alternate Database**.

    If you want to **Overwrite the Original Database**, the original DB files on the Exchange Server will be deleted. To perform this operation, you must enable the **This database can be overwritten by a restore** parameter from the Exchange Admin Center. For more information, see Database Recovery.

    In addition, the **Overwriting Original Database** has an additional **Roll-Forward recovery** option. If this is enabled, the latest transaction logs available on the Exchange Server will be used when replying logs on the EDB.

    If you select an alternate database, provide the following details:

    a. **Exchange Server**: Select the target server from the drop-down where you want to recover.

    > **Note:** The target server should be registered as an Exchange Server on the Cohesity cluster.

    b. **Database Name**: Provide a database name for the restored database.
    c. **Database File Path**: Specify the database file path for the restored database.
    d. **Log Directory**: Specify the database transaction logs directory path for the restored database.

10. Click **Recover Options**.
    a. **Restore as Recovery Database**: Enable this option to restore the database as a recovery database. A recovery database (RDB) is a special kind of mailbox database that allows you to mount and extract data from a restored mailbox database as part of a recovery operation. RDBs allow you to recover data from a backup or copy of a database without disrupting user access to current data.
    b. **Mount Database**: Enable this option to restart the Information Store service and mount the new Database.

    > **Note:** When a new Database is created Microsoft recommends restarting the Information Store service. However, restarting the Information Store service will bring down all the other databases hosted on that Exchange server. This may take a long time and cause client connection failures.

    c. **Task Name**: Optionally, change the default name for the recover task in the Task Name field.
11. Click **Recover**.

The restore process is initiated. You can monitor the recovery task from the Recoveries page.

> **Note:** After a successful recovery of the Exchange Database, the user must run a full backup of the recovered database.

Unregister MS Exchange Server

You can unregister an Exchange Server from the Cohesity cluster. Before you unregister it, you must delete the Protection Groups associated with the Exchange Server.

1. Delete a Protection Group
2. Unregister Exchange Server
3. Uninstall the Cohesity Agent

Delete a Protection Group

Perform the following steps to delete a Protection Group:
If the Protection Group is deleted, then overwrite restores cannot be performed on the job.

1. Select **Data Protection > Protection**.
2. Find the Job in the list and in the **Actions** column select **Delete**.

Alternatively, drill-down on a Job name in the **Job** column of the list. In the Job Details page, click the (**Delete Job**) icon.

3. Choose one of the following:
   - **Delete Protection Group Only:** Select this option to delete only the Protection Group. Any local snapshots and or archived snapshots stored on the external targets that were captured by this Job are not deleted.
   - **Delete Protection Group and Snapshots:** If you select the option to delete the Job and all Snapshots, any local Snapshots captured by this Job and stored on this Cluster are deleted. In addition, any archived Snapshots stored on external targets that were captured by this Job are also deleted. (To selectively delete the Snapshots for specific protection runs without deleting the Job, see Deleting Snapshots or Objects.)

   If the current job is replicating snapshots to a remote cluster or archiving snapshots to an external target, you should probably cancel these replication or archive tasks before deleting the job. For instructions, see Cancel Replication and Archive Copy Tasks of a Protection Group Run.

   If the Job is replicating to a remote cluster, the inactive job created on the remote cluster is not deleted. In addition, the snapshots that were replicated (copied) to the remote cluster by this job are not deleted. You can log in to the remote cluster to delete the snapshots and the inactive job.

Unregister Exchange Server

Follow the steps listed below to unregister the Exchange Server:

1. Navigate to **Data Protection > Sources**.
2. Navigate the source hierarchy to the Exchange Server, mouse over its actions menu, and click **Unregister**.
3. Click **Unregister**.

The Exchange Server will be unregistered from the Cohesity cluster. However, the physical server on which the Exchange Server is running will not be unregistered from the Cohesity cluster.

Uninstall the Cohesity Agent

For information about uninstalling the Cohesity agent from an Exchange server, see Install and Manage the Agent on Windows Servers.

MS Exchange Server Limitation

- **Microsoft Exchange limitation**: Exchange Management Powershell does not work with **Group Managed Service Account (gMSA)**. Therefore, the Cohesity agent

service account cannot be a gMSA. If gMSA is specified (even if the account is part of Backup Operators, Exchange Servers, Organization Management), the Powershell remote session fails.

- Only full/incremental backup runs are archived. LOG backups are not archived.

Truncate Logs in Microsoft Exchange Servers on Physical Windows Servers

Microsoft Exchange Email Server truncates transaction logs dynamically after a successful backup of a physical Windows Server that hosts the Exchange Email Server.

Cohesity has qualified truncating logs for the following Microsoft Exchange Servers hosted on physical Servers:

- Microsoft Exchange 2019 running on supported Windows Servers (Standalone and DAG)
- Microsoft Exchange 2016 running on supported Windows Servers (Standalone and DAG)
- Microsoft Exchange 2013 running on supported Windows Servers (Standalone and DAG)
- Microsoft Exchange 2010 SP3 running on supported Windows Servers (Standalone and DAG)

When a protection run protecting physical servers occurs, an app-consistent backup is always triggered so if the physical server is a Windows server with Microsoft Exchange, the Exchange logs are dynamically truncated by Microsoft Exchange. To disable log truncation for Microsoft Exchange with VMware VADP backups, see Enable or Disable Log Truncation.

If the Windows Server has an Exchange server but the log truncation fails, an error is reported. However, the backup can successfully complete.

> **Note:** The physical Server adapter includes Exchange Log Truncation functionality. You can also backup the Exchange Server using the Exchange Server adapter.

For more information on how to leverage Cohesity for Exchange Server backups using the physical adapter, see the How to protect and truncate logs for Exchange VMs (Standalone or DAG) on Hyper-V KB article.

Cohesity provides support for backup and recovery of Microsoft Exchange Servers (Standalone and DAG) running on a physical server or VM. For more information, see Protect MS Exchange Server.

Enable or Disable Exchange Log Truncation

To enable or disable Exchange Log Truncation, perform the steps below:

1. Navigate to **Data Protection** > **Protection**.
2. Click the protection job (VM that is running Exchange).
3. Click the **Settings** tab.
4. Click **Edit**.
5. Click **Edit** on the exchange object.
6. Toggle on or off **Exchange Log Truncation**.
7. Click **Save**.
8. Click **Protect**.

MS Exchange Server Troubleshooting

Category	Issue	Workaround
Source Registration	IP address-based DAG Exchange registration may fail due to Cohesity Cluster not able to resolve FQDN of the DAG nodes.	Add the Exchange node DNS server to Cohesity cluster DNS server or to Cohesity host mapping.
Recovery	Repeatedly mounting SMB share of the Exchange database recovery with the same view name and tearing down may cause issues in accessing the view in Windows Explorer.	Provide a unique view name for each database recovery.
Backup	Incremental backup schedule after a Windows reboot or DAG node switchover pulls the entire Exchange database EDB file.	None. File- based change block tracking (CBT) information is not preserved across Windows reboots. Log backup is not affected by this and only new log files are pulled for a DAG database copy.
Snapshot delete	Deletion of snapshots from protection runs in the middle or expiration of the log backup may subsequent snapshots until incremental/full to be not recoverable .	None. Delete only the oldest snapshots of backup runs.

Chapter 17: SAN Volume

Cohesity supports the backup and recovery of the following SAN devices:

- IBM Storage FlashSystem
- Pure Storage
- HPE Alletra Storage MP

IBM Storage FlashSystem

The Cohesity cluster supports backing up IBM Storage FlashSystem volumes and volume groups in a Protection Group. Protection Groups can run repetitively on a schedule.

To learn more about the relationship between Protection Groups and Policies, see About Policies and Protection Groups. For instructions on how to use the Cohesity UI to back up IBM Storage FlashSystem volumes, see Protect an IBM Storage FlashSystem Volume or a Volume Group.

Plan and Prepare for IBM Storage FlashSystem

This topic provides information on minimum permissions, prerequisites and considerations to protect IBM Storage FlashSystem with Cohesity cluster.

Minimum Permissions

Ensure that the IBM Storage FlashSystem user account you use to register, manage, and protect the FlashSystem resources has an **Administrator** role. For security reasons, Cohesity recommends not to use the **IBM superuser** account or any account configured within the **SecurityAdmin** group.

Support Matrix

Before you register your IBM Storage FlashSystem with the Cohesity cluster, ensure that Cohesity supports the IBM Storage FlashSystem versions. For more information, see Supported Software.

Ports Used for Communication

Ensure all necessary ports are open in the firewall between the Cohesity cluster and IBM Storage FlashSystem. For more information, see Manage Firewall Ports.

Prerequisite

- IBM Storage FlashSystem API and data traffic ports should be accessible from all the Cohesity nodes. For more information, see Ports Used for Communication.
- It is important to note that the Cohesity cluster's node(s) should not be added manually as a host or host cluster on the IBM Storage FlashSystem as this will be done automatically when registering the array as a source on the Cohesity cluster.

Considerations

- Due to the IBM Storage FlashSystem volume name character limit, Cohesity does not support backing up volumes with names greater than 45 characters.
- IBM Storage FlashSystem supports block-based backups of volumes and volume groups.
- With IBM Storage FlashSystem, you have the flexibility to create volumes while utilizing various capacity-saving methods such as thin-provisioning, compression, deduplication, or a combination of these methods. However, it's important to note that if there is a predefined provisioning policy set for the storage pool, the volume-level settings will not be applicable. In case of a restore, the system will restore the capacity-saving options based on the target storage pool's properties and the existence of any predefined provisioning policies.
- IBM Storage FlashSystem supports Safeguarded Snapshot creation for basic volumes, but it is not supported for mirrored volumes.
- The IBM Storage FlashSystem can manage a combination of internal and external storage. Currently, Cohesity provides Data Protection for volumes and volume groups that are part of the internal storage of IBM Storage FlashSystem.

Register or Edit an IBM Storage FlashSystem

You can register IBM Storage FlashSystem on the Cohesity cluster to protect the IBM Flash volumes.

Before you Begin

Meet Prerequisites

Ensure that the requirements for the IBM FlashSystem, such as software version, user account role privileges, and firewall ports, are met.

Check iSCSI connectivity

By registering an IBM FlashSystem as a storage array, you can ensure that its Logical Unit Number (LUN) becomes eligible for protection on the Cohesity cluster. The LUN of both the Internet Small Computer Systems Interfaces (iSCSI) or Fiber Channels (FC) is needed to access the storage device.

After completing the iSCSI configuration and enabling the iSCSI discovery on the IBM FlashSystem, verify the iSCSI connectivity between the Cohesity cluster and the IBM FlashSystem. To check if the connection is working, log into any of the Cohesity cluster nodes and run the following command:

```
iscsiadm -m discovery -t sendtargets -p <ipaddress>
```

For additional iSCSI commands, see Additional iSCSI Commands.

Register IBM Storage FlashSystem

1. Navigate to **Data Protection** > **Sources**.
2. Click **Register** > **SAN**.
3. Select the source type as **IBM Storage FlashSystem**.
4. Enter the information described below:

Field	Description
Management Host or IP Address	Specify the Management Host or IP Address of the IBM Storage FlashSystem to register.
Username	Specify a user with a Storage Admin role.
Password	Enter the password for the specified user.

5. Click **Register**.

Protect an IBM Storage FlashSystem Volume or a Volume Group

A Protection Group that protects IBM Storage FlashSystem volumes captures Snapshots and these Snapshots are required for the following tasks:

- Recover volumes
- Replicate Snapshots
- Archive Snapshots

Before you begin

When you create a Protection Group, you can select an existing source, policy, or storage domain. You can also create them while creating the Protection Group. However, you might find it easier to create them prior to creating the Protection Group, as described in the following topics.

- Register or Edit an IBM Storage FlashSystem
- Create or Edit a Standard Policy
- Create or Edit Storage Domains

To Protect an IBM FlashSytem Volume or a Volume Group:

You can now protect IBM Storage FlashSystem volumes or volume groups using a Protection Group on the Cohesity cluster.

1. Navigate to **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then select **SAN**.
3. In the **New Protection** pop-up, you can select either a single volume and volume group, or multiple volumes or volume groups, but not a combination of both.

   To Protect a Volume:

   Select the **Volume List** View ( ) on the top-right to list the volumes. From the **Volume** list, select the volumes you want to back up.

   To Protect a Volume Group:

   Select the **Volume Group** View ( ) on the top-right to list the volume groups. Select the volume groups and then click the **Auto-Protect Volume Group** option to protect the selected volume groups. If you select this option, any new volumes added to the volume group will be automatically protected from the next protection group run.

   > **Note:** Selecting an item in Volume View and changing the view to Volume Group causes the selection to be lost.

   After selecting one of the above options, click the edit icon and provide the following information:

   1. **Add Objects**: From the **Objects** list, select the **Volume Groups** you want to backup or click **Register Source** to register a new Volume Group.
   2. **Protection Group**: Specify a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.

3. **Policy**: Select an existing policy or click **Create Policy** to create a new protection policy. For **Storage Array Snapshot creation**, you have to define the storage array snapshot parameters during the policy creation. For more information, see Create or Edit a Standard Policy.

   > **Note:** If you define a storage array snapshot in the protection policy, the Protection Group will trigger a Storage Array Snapshot as per the frequency defined in the protection policy.

4. **Storage Domain**: Select the appropriate storage domain. For more information, see Manage Storage Domains.
5. To protect Volume Group by specifying all the options, click **More Options**.

Advance Settings	Description
Start Time	Available only if the selected policy is set to Backup Daily. Indicates when the Protection Group should run. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting.
End Time	Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts prior to this date runs until completion even if it completes after this date.
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks). • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. **Note:** Users with similar SLAs can be grouped together and a custom policy and Protection Group can be created to achieve different SLAs.

Advance Settings	Description
Pause Future Runs	Toggle on this option to stop protection runs of the Protection Group from executing. Once you enable this option, no protection runs will be scheduled for this Protection Group.
End Date	Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts before this date runs until completion even if it completes after this date.
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of jobs exceeds the ability to process jobs, this will be the priority of implementation of the jobs: a. High b. Medium c. Low
QoS Policy	Select an appropriate quality of service (QoS) policy. **Note:** Cohesity recommends specifying **Backup HDD**, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy.
Safe Guarded Copy Snapshot	Select this option to enable safeguarded snapshots for the protection group run.

Advance Settings	Description
Pre & Post Scripts	Toggle Enable to run scripts on the Unix server. When creating a Protection Group, you can configure: • **Pre Scripts**: Scripts that will be executed before the protection run. • **Post Backup Scripts**: Scripts that will be executed after the protection run. • **Post Snapshot Scripts**: Scripts that will be executed after the snapshot has been created on the source. If enabled, the scripts are executed during the protection run as configured. You can distinguish between the scripts that are run on the different objects (entities) using the COHESITY_BACKUP_ENTITY environment variable. The Cohesity cluster populates this environment variable with the name of the backed object (or entity). For more information, see Configure Pre & Post Scripts. For more information, see Configure Pre & Post Scripts.
Quiet Times	Available only if the selected policy has at least one quiet time period. Toggle it on to specify that all currently executing protection runs should abort if a quiet time period specified for the Protection Group starts. If the option is toggled off, then after a protection run starts, it continues to execute even when a quiet time period specified for this Protection Group starts. However, a new protection run will not start during a quiet time period.
Alerts	Select one or more of the following **Alerts On** settings if you want alerts to be created for the following triggers: • SLA Violation: Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts. • Failure: Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • Success: Create an informational alert when the Protection Group completes successfully. Emails are not sent when informational alerts are created. To send emails when alerts are triggered for the Protection Group, in the **Email Recipients** field, add the email addresses of the recipients.
Description	Enter a brief description about the Protection Group.

6. Click **Protect**.

Recover an IBM Storage FlashSystem Volume or Volume Group

You can recover the volume and volume groups backups from the Cohesity cluster to an IBM Storage FlashSystem.

To recover an IBM Storage FlashSystem Volumes or a Volume Group follow the steps listed below:

1. Select **Data Protection** > **Recoveries**.
2. Click on **Recover** located at the top-right of the page and then select **SAN**.
3. Search for the Volume or Volume Group in the backup run by entering the Volume Group name, a volume name, a name sub-string, or by specifying the wildcard character *.

   You can optionally filter the search results by source, Protection Group, Storage Domain, and date.
4. From the search results list, select the volume or volume group you want to recover.

   By default, the latest snapshot is selected for recovery.
5. To recover from a different snapshot, mouse over the snapshot from the selected list, and then click the **Edit** icon.

   By default, the latest snapshot is selected for recovery. You can also view and select the older snapshots by clicking the **Protection Run** drop-down. When you select a snapshot, the volumes associated with that snapshot are displayed.
6. From the **Recover To** options, select **Original Location** to recover to the same storage pool of the IBM Storage FlashSystem or select **New Location**. If a new location is selected, then select the **Storage Pool** for the new location.
7. In the **Rename** field, you can specify the name of the recovered volume group by adding prefixes and/or suffix strings to the name of the original volume group.
8. **Task Name**: Change the default name of the recovery task.
9. Click Start **Recovery**.

The recovery task is initiated. You can monitor the recovery task from the **Recoveries** page.

Recover a Storage Array Snapshot for IBM Storage FlashSystem Volume or Volume Group

You can recover a Storage Array Snapshot for IBM Storage FlashSystem Volumes or a Volume Group by following the steps listed below:

To recover a Storage Array Snapshot for IBM Storage FlashSystem Volumes or a Volume Group follow the steps listed below:

1. Select **Data Protection** > **Recoveries**.
2. Click on **Recover** located at the top-right of the page and then select **SAN**.
3. Search for the Volume or Volume Group in the backup run by entering the Volume Group name, a volume name, a name sub-string, or by specifying the wildcard character *.

   You can optionally filter the search results by source, Protection Group, Storage Domain, and date.
4. From the search results list, select the volume or volume group you want to recover.

   By default, the latest snapshot is selected for recovery.
5. To recover a Storage Array Snapshot, mouse over the snapshot from the selected list, and then click the **Edit** icon.
6. In the **Edit Recovery Point** window, select **Storage Array Snapshot** as the backup type.
7. From the **Recover To** option, **Original Location** is selected by default. You can recover the storage array snapshot to the original location only.
8. Select the **Storage Pool** to recover the storage array snapshot.
9. In the **Rename** field, you can modify the name of the recovered Volume Group by adding prefixes and/or suffix strings to the name of the original Volume Group.
10. **Use Thin Clone**: Enable this option to create a thin clone of the selected snapshot instead of a complete copy.
11. **Task Name**: Change the default name of the recovery task.
12. Click Start **Recovery**.

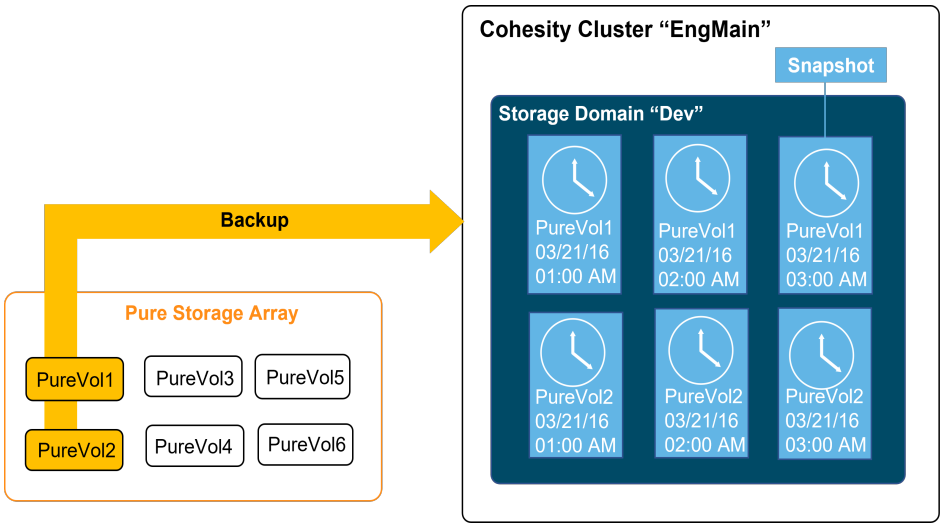
The recovery task is initiated. You can monitor the recovery task from the **Recoveries** page.

Pure Storage

The Cohesity cluster supports backing up multiple Pure Storage volumes in a single Protection Group. Protection Groups can run repetitively on a schedule.

To learn more about the relationship between Protection Groups and Policies, see Manage Protection Policy. For instructions on how to use the Cohesity UI to back up Pure Storage volumes, see Manage Protection Groups.

For example, you could create a Protection Group with a schedule that backs up specific Pure Storage volumes every hour as illustrated in the following figure.



During a Protection Group Run, Cohesity Snapshots of the Pure Storage volumes are saved on the Cohesity cluster with a date and time stamp. For incremental backups, Cohesity uses Pure Storage's ability to track changed blocks so that only those blocks are backed up to the Cluster.

For instructions on how to use the Cohesity UI to back up Pure Storage volumes, see Protect a Pure Volume or a Protection Group.

Plan and Prepare for Pure FlashArray

This topic provides information on minimum permissions, prerequisites and considerations to protect Pure FlashArray with Cohesity cluster.

> **Note:** The Pure Protection Group is an Early Access feature. Contact your Cohesity account team to enable the feature.

Minimum Permissions

Ensure you have the required minimum permissions to register Pure FlashArray as a source with the Cohesity. For more information, see Ensure Adequate Privileges for Cohesity on the Source.

Support Matrix

Before you register your Pure FlashArray with the Cohesity cluster, ensure that Cohesity supports the Pure FlashArray versions. For more information, see Supported Software.

Ports Used for Communication

Ensure all necessary ports are open in the firewall between the Cohesity cluster and Pure FlashArray. For more information, see Manage Firewall Ports.

Prerequisite

The Pure Flash array needs to have a Network Interface Card (NIC) and iSCSI discovery IP configured on the array.

Considerations

- iSCSI needs to be configured on the Pure FlashArray for volume backup.
- Recovering a Pure Storage volume with the same name as a volume that is pending eradication is not supported.

  Workaround - Recover the volume with a different name or log in to the Pure FlashArray and eradicate the deleted volume.
- If a Pure FlashArray reaches its maximum number of volumes or snapshots, Pure Storage backup jobs and recovery tasks for that array will fail. A Pure Storage volume also has a maximum number of allowed snapshots. If it reaches this limit, backing up the volume fails.

  Workaround - Delete and eradicate some volumes or snapshots and then trigger the backup or recovery.
- Due to a Pure Storage volume name character limit, Cohesity does not support backing up volumes with names greater than 45 characters.
- Cohesity does not currently support backing up Pure FlashArrays with Challenge-Handshake Authentication Protocol (CHAP) authentication enabled.
- If a Cohesity cluster has been destroyed and then recreated, its Cohesity host entry from the original Pure FlashArray registration is retained on the array. This causes IQN collision when registering the same Pure FlashArray with the recreated Cluster. IQN collision causes Cohesity backups of the array to fail.

  Workaround - Follow the below steps:

  - Run the following command on any Node in the Cluster to obtain the Cluster's IQN: `allssh cat /etc/iscsi/initiatorname.iscsi`
  - On the Pure FlashArray, remove the host entry that matches the obtained IQN.
  - Unregister and re-register the Pure FlashArray with the Cohesity cluster.
- If a Cluster upgrade is running during a Pure Storage backup job, the job may fail. The job will succeed on the next retry attempt.
- Cohesity does not currently support Pure Storage PODS or Active Cluster but you can register the individual arrays within the Active Cluster separately as standalone arrays.
- There is a limitation on the number of hosts that can be accommodated in the Pure FlashArray. When this limit is reached, it may lead to iSCSI communication failures during the backup processes.

  Error Message:

```
Encountered HTTP error kBadRequest with GET request for /host/cohesity-
1732787028580538/volume [Host does not exist.]
```

Workaround

Follow the below steps:

- Create a free slot for a new host entry in the Pure FlashArray.
- Choose one of the following options:
  - Restart the Backup Manager service using the following CLI commands:

    ```
    iris_cli cluster stop service-names=magneto
    ```

    ```
    iris_cli cluster start service-names=magneto
    ```

  - Alternatively, you can wait for an hour for the host creation process to complete.

- The following lists the considerations for a Pure Protection Group during the backup and recovery process:
  - Cohesity does not support the protection of empty Pure Protection Groups.
  - The name of the Pure Protection Group and Pure volumes created during recovery will be based on the specified suffix and prefix.
  - If the newly created PPG or a volume has the same name as that of the PPGs or volumes belonging to an existing PPG, then the recovery jobs will fail.
  - Volume Group will not be created. It should pre-exist. The recovery volumes will be created in the same volume group in which the original volume was present. If the volume group is not present at the time of recovery then the recovery job will fail.

Register or Edit a Pure FlashArray

You can register Pure FlashArray on the Cohesity cluster to protect the Pure Storage volumes. You can also register Pure FlashArray to leverage storage array-based snapshots for VMDKs.

Prerequisite

The Pure FlashArray needs to have a Network Interface Card (NIC) and iSCSI discovery IP configured on the array.

Register Pure Storage

Before registering or editing a Pure FlashArray, ensure it meets prerequisites, minimum permissions, and firewall port requirements in the Plan and Prepare for Pure FlashArray.

Registering a Pure FlashArray as a Storage array makes its LUN (both iSCSI and FC) content eligible to be protected on the Cohesity cluster.

After you complete the iSCSI configuration and have an iSCSI discovery set/enabled on the Pure Flash array, verify the iSCSI connectivity between the Cohesity cluster and the Pure Flash array. To verify the connectivity, you can manually log in to one of the configured iSCSI targets on the Pure Flash array from any one of the Cohesity cluster nodes.

Run the following command to check the iSCSI connectivity:

```
iscsiadm -m discovery -t sendtargets -p <ipaddress>
```

For additional iSCSI commands, see Additional iSCSI commands.

1. Navigate to **Data Protection > Sources**.
2. Click **Register > SAN**.
3. Select the source type as **Pure**.
4. Enter the information described below:

> **Note:** To leverage storage array-based snapshot for VMDKs, you must also register the corresponding VMware vCenter where FlashArray Datastore is mounted with the Cohesity cluster.

Field	Description
Management Host or IP Address	Specify the Management Host or IP Address of the Pure FlashArray to register.
Username	Specify a user with a Storage Admin role.
Password	Enter the password for the specified user.

5. Click **Register**

Additional iSCSI Commands

The table below lists the additional iSCSI commands:

Command	Description
iscsiadm -m node -T <targetname> -p <ipaddress> -l	Use this command to log in to a specific target.
iscsiadm -m node -T <targetname> -p <ipaddress> -u	Use this command to log out from a specific target.
iscsiadm -m node -T< targetname> -p <ipaddress>	Use this command to display the target information.

Command	Description
iscsiadm -m node -s -T <targetname> -p <ipaddress>	Use this command to display the statistics of a target.
iscsiadm -m session	Use this command to display all the current logged-in sessions.
iscsiadm -m discovery -o show	Use this command to display the iSCSI database regarding discovery.
iscsiadm -m node -o show	Use this command to display the targets to log into.
iscsiadm -m session -o show	Use this command to display the sessions logged into.

Related Topic

Ensure Adequate Privileges for Cohesity on the Source

Protect a Pure Volume or a Protection Group

A Protection Group that protects Pure Storage volumes captures Snapshots and these Snapshots are required for the following tasks:

- Recover volumes
- Replicate Snapshots
- Archive Snapshots

Before you begin

When you create a Protection Group, you can select an existing source, policy, or storage domain. You can also create them while creating the Protection Group. However, you might find it easier to create them prior to creating the Protection Group, as described in the following topics.

- Register or Edit a Pure FlashArray
- Create or Edit a Standard Policy
- Create or Edit Storage Domains

To Protect a Pure Volume or a Protection Group :

You can now protect Pure volumes or multiple volumes using a Pure Protection Group on the Cohesity cluster.

1. Navigate to **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then select **SAN**.

3. In the **New Protection** pop-up, you can either select a Volume or a Pure Protection Group:

   To Protect a Volume:

   Select the **Volume List** View ( ) on the top right to list the volumes. From the **Volume** list, select the volumes you want to back up.

   To Protect a Pure Protection Group:

   Select the **Pure Protection Group** View ( ) on the top-right to list the **Pure Protection Groups**. From the Pure Protection Group list, select the Pure Protection Group you want to back up.

   After selecting one of the above options, click the edit icon and provide the following information:

   1. **Add Objects**: From the **Objects** list, select the **Pure Protection Groups** you want to backup or click **Register Source** to register a new Pure Protection Group.
   2. **Protection Group**: Specify a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.
   3. **Policy**: Select an existing policy or click **Create Policy** to create a new protection policy. For more information, see Create or Edit a Standard Policy.
   4. **Storage Domain**: Select the appropriate storage domain. The default time zone in the Start Time field is the browser's time zone. You can change the time zone of the job by selecting a different time zone. For more information, see Manage Storage Domains.
   5. To protect Pure Protection Group by specifying all the options, click **More Options**.

Advance Settings	Description
End Time	Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts prior to this date runs until completion even if it completes after this date.

Advance Settings	Description
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of jobs exceeds the ability to process jobs, this will be the priority of implementation of the jobs: a. High b. Medium c. Low
QoS Policy	Select an appropriate quality of service (QoS) policy. > **Note:** Cohesity recommends specifying **Backup HDD**, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy.
Retain on Pure Storage Array	Enter the number of the most recent snapshots to retain on the Pure FlashArray. Retaining the last 5 snapshots is the default. You can change this number or choose to retain All Snapshots. To take incremental snapshots, this value must be at least 1.

Advance Settings	Description
Pre & Post Scripts	Toggle Enable to run scripts on the Unix server. When creating a Protection Group, you can configure: • **Pre Scripts**: Scripts that will be executed before the protection run. • **Post Backup Scripts**: Scripts that will be executed after the protection run. • **Post Snapshot Scripts**: Scripts that will be executed after the snapshot has been created on the source. If enabled, the scripts are executed during the protection run as configured. You can distinguish between the scripts that are run on the different objects (entities) using the COHESITY_BACKUP_ENTITY environment variable. The Cohesity cluster populates this environment variable with the name of the backed object (or entity). For more information, see Configure Pre & Post Scripts. For more information, see Configure Pre & Post Scripts.
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks). • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. > **Note:** Users with similar SLAs can be grouped together and a custom policy and Protection Group can be created to achieve different SLAs.
Quiet Times	Available only if the selected policy has at least one quiet time period. Toggle it on to specify that all currently executing protection runs should abort if a quiet time period specified for the Protection Group starts. If the option is toggled off, then after a protection run starts, it continues to execute even when a quiet time period specified for this Protection Group starts. However, a new protection run will not start during a quiet time period.

Advance Settings	Description
Alerts	Select one or more of the following **Alerts On** settings if you want alerts to be created for the following triggers: • SLA Violation: Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts. • Failure: Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • Success: Create an informational alert when the Protection Group completes successfully. Emails are not sent when informational alerts are created. To send emails when alerts are triggered for the Protection Group, in the **Email Recipients** field, add the email addresses of the recipients.
Pause Future Runs	Toggle on this option to stop protection runs of the Protection Group from executing. Once you enable this option, no protection runs will be scheduled for this Protection Group.
Description	Enter a brief description about the Protection Group.

6. Click **Protect**.

Recover a Pure Volume or a Protection Group

You can recover the Pure Protection Groups backed up onto the Cohesity cluster.

To recover Pure Volumes or a Protection Group follow the steps listed below:

1. Select **Data Protection** > **Recoveries**.
2. Click on **Recover** located at the top-right of the page and then select **SAN**.
3. Search for the Pure Protection Group that contains the snapshots to recover from by entering characters of the Pure Protection Group name, a volume name, or any constituent volume (which is part of a PPG) by specifying the wildcard character *.

   You can optionally filter the search results by source, Protection Group, Storage Domain, and date.
4. From the search results list, select the Pure Protection Group you want to recover.

   By default, the latest snapshot is selected for recovery.

5. To recover from a different snapshot, mouse over the snapshot from the selected list, and then click the **Edit** icon.

   By default, the latest snapshot is selected for recovery. You can also view and select the older snapshots by clicking the **Protection Run** drop-down. When you select a snapshot, the volumes associated with that snapshot are displayed.
6. After you select the snapshot to be recovered then click **Select Recovery Point**.
7. From the **Recover To** options, select **Original Location** to recover the volume to the same Pure FlashArray or select **New Location** to recover the volume to a new Pure FlashArray.
8. In the **Rename** field, you can specify the name of the recovered Pure Protection Group by adding prefixes and/or suffix strings to the name of the original Pure Protection Group.
9. **Task Name**: Change the default name of the recovery task.
10. Click Start **Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

HPE Alletra Storage MP

Cohesity now supports using storage array snapshots for VMware backups on the HPE Alletra MP storage array. This integration allows Cohesity to leverage the native snapshot capabilities of the storage array, resulting in more efficient and reliable backups of VMware VMs.

Register or Edit HPE Alletra Storage MP

You can register the HPE Alletra Storage MP array to leverage storage array snapshot- for VMware VM based backups.

Registering a Nimble Storage as a Storage array makes its LUN (both iSCSI and FC) content eligible to be protected on the Cohesity cluster.

After you complete the iSCSI configuration and have an iSCSI discovery set/enabled on the Nimble array, verify the iSCSI connectivity between the Cohesity cluster and the PE Alletra Storage MP array. To verify the connectivity, log into any of the Cohesity cluster nodes and run the following command:

```
iscsiadm -m discovery -t sendtargets -p <ipaddress>
```

For additional iSCSI commands, see Additional iSCSI commands.

Perform the following steps to register the HPE Alletra Storage MP Array:

1. Navigate to **Data Protection > Sources**.
2. Click **Register > SAN**.

3. Select the source type as **HPE Alletra Storage MP**.

> **Note:** You can register the HPE Alletra Storage MP by selecting the source type as HPE Alletra Storage MP.

4. Enter the following information:

> **Note:** You must also register the corresponding VMware vCenter where Storage Array Datastore is mounted with the Cohesity cluster.

Field	Description
Management Host or IP Address	Specify the Management Host or IP Address of the HPE Alletra Storage MP to register.
Username	Specify the user name used for accessing the HPE Alletra Storage MP. Ensure that the user being used has the Edit role.
Password	Enter the password for the specified user.

5. Click **Register**.

   When registration finishes, a new entry appears in the Sources table.

Additional iSCSI Commands

The table below lists the additional iSCSI commands:

Command	Description
iscsiadm -m node -T <targetname> -p <ipaddress> -l	Use this command to log in to a specific target.
iscsiadm -m node -T <targetname> -p <ipaddress> -u	Use this command to log out from a specific target.
iscsiadm -m node -T< targetname> -p <ipaddress>	Use this command to display the target information.
iscsiadm -m node -s -T <targetname> -p <ipaddress>	Use this command to display the statistics of a target.
iscsiadm -m session	Use this command to display all the current logged-in sessions.

Command	Description
iscsiadm -m discovery -o show	Use this command to display the iSCSI database regarding discovery.
iscsiadm -m node -o show	Use this command to display the targets to log into.
iscsiadm -m session -o show	Use this command to display the sessions logged into.

After registering the snapshot provider, to leverage the VMware snapshots from HPE Alletra Storage MP, you must enable the **Leverage Storage Snapshots for Data Protection** field and select **Storage Array/NAS** when creating the protection group for VMware VMs. For more information, see create a Protection Group for VMware.

Using the **Leverage Storage Snapshots for Data Protection** option with the **Leverage SAN Transport for Data Protection** option is not recommended.

Chapter 18: Hadoop

The Cohesity Hadoop DataProtect solution natively integrates with Cloudera distributions to provide consistent backup and recovery for Hadoop deployments. The Cohesity solution supports Hive, HBase, and HDFS data sources.

Based on the policy settings, the Cohesity NoSQL and Hadoop Service initiates a backup of the HDFS, Hive, or Hbase. The first backup is a full backup and everything after that is an incremental backup only. The service scales horizontally based on the available compute and memory resources on Cohesity. Multiple backup and recovery streams run in parallel to reduce the backup and recovery window. The necessary Cohesity Views are automatically generated where the backups are going to be written. Communication between Cohesity and Hadoop is managed by the NoSQL and Hadoop Service as described in the section below. See the following topics for details:

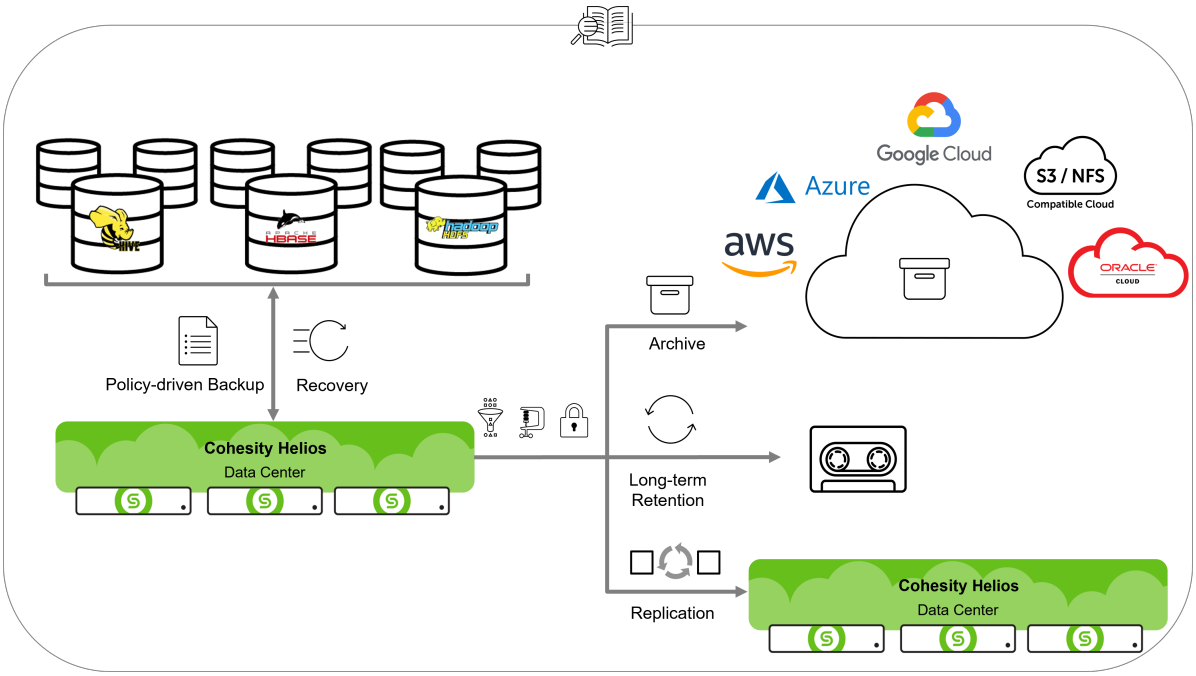
Core components 3665
Hadoop Features 3666
Plan and Prepare for Hadoop Protection 3666
Register a Hadoop Source 3672
Backup Hadoop 3674
Recover Hadoop 3683

Core components

The following lists the core components of the Cohesity Hadoop solution:

- Physical or virtual Hadoop clusters.
- Cohesity Data Cloud.
- Cohesity Compute Nodes.
- Cohesity NoSQL and Hadoop Service running on Cohesity Compute Nodes.
- Optional. Archive or tiering target at your data center or cloud provider of choice.

As illustrated in the below figure, you can integrate Cohesity with an existing Hadoop infrastructure by installing the Cohesity NoSQL and Hadoop Service on Compute Nodes. Once the service is installed and running, you can create protection policies, Protection Groups, and replication schedules for the Hadoop file system and databases. Once the data is protected, it can be archived, sent to tape, and or replicated to another instance running in the cloud or on-premises as shown in the below image.



Hadoop Features

Following are the key Hadoop-specific features of the solution:

- Support Cloudera distributions of Hadoop.
- Support Hive, Hbase, and HDFS.
- Incremental-forever backups - after the first full backup, all subsequent backups are incremental only forever.
- Granular backup and recovery - backup and recover individual tables, databases, or files.
- Automatically handle topology changes seamlessly (node addition, removal, IP changes, etc.)
- Support Kerberos enabled clusters.
- Support SSL-enabled clusters.

Plan and Prepare for Hadoop Protection

The following topics provide guidance that helps you get ready to implement the Hadoop DataProtect Solution:

Supported Versions

For more information, see NoSQL and Hadoop Platforms.

> **Note:** Users have to create new workflows when upgrading their Hadoop cluster to Cloudera Data Platform 7.x versions. For more information, see Cloudera Data Platform Upgrade and Migration.

Prerequisites

Make sure the following prerequisites are met before using Hadoop DataProtect Solution.

- The NoSQL and Hadoop Service is in Running status. See NoSQL and Hadoop Service for details.
- The hostname to IP address and reverse resolution of all the hadoop primary nodes and Kerberos server (KDC) is working from all the NoSQL and Hadoop Service PODs.
- Refer to the NoSQL and Hadoop Service - Post Installation Procedures to get a general idea about the following operations:
  - Manage SSL enabled NoSQL primary clusters
  - Work with Kerberos Security enabled primaries for data protection
- Kerberos-Enabled Hadoop
- SSL-Enabled Hadoop
- Kerberos + SSL-Enabled Hadoop

Kerberos-Enabled Hadoop

The following section describes the steps you need to perform for adding a Kerberized Hadoop data repository.

Adding Kerberized Hadoop data repository:

This section describes the steps that must be performed on the primary source cluster prior to successfully add new Kerberized HDFS, HBase, or Hive data repositories. These steps are also needed when you are adding a new data repository with a new set of Kerberos principals.

> **Note:** At the end of these steps, service restart is required on both Primary and NoSQL Hadoop clusters. Protection runs will be killed. Please plan this activity when no protection runs are in progress.

1. Add the new realm to NoSQL and Hadoop Services as mentioned in the section Work with Kerberos Security enabled primaries for data protection.
2. Make changes to the Primary cluster's HDFS, Hive and HBase configuration.

   Let us assume that you plan to use the following as backup/recovery user principals on your primary Hadoop cluster:

   ```
   imanis_hdfs@PRIMARY.REALM - Kerberos principal used for HDFS workflows
   imanis_hbase@PRIMARY.REALM - Kerberos principal used for HBase workflows
   imanis_hive@PRIMARY.REALM - Kerberos principal used for Hive workflows
   ```

   These Kerberos principals map to corresponding Unix users. For example, imanis_hdfs@PRIMARY.REALM maps to Unix user imanis_hdfs on your primary cluster nodes.

   Similarly, imanis_hbase@PRIMARY.REALM maps to imanis_hbase and imanis_hive@PRIMARY.REALM maps to imanis_hive Unix user. All these three users should be added to a group, for example, imanis_supergroup in all cluster Nodes of your primary hadoop cluster.

   The steps for performing the changes on the primary cluster differ from vendor to vendor. The below example is applicable for Cloudera 6.0. For other vendors and versions please refer to the vendor-specific documentation.

   - Grant superuser privileges in the primary Hadoop cluster to the Kerberos principals used for backup/recovery.
     a. In **Cloudera Manager Admin Console**, click **HDFS** service > **Configuration** tab.
     b. Search for the dfs.permissions.superusergroup property and add imanis_supergroup to this property.
     c. Save the changes and restart HDFS service.
   - Set hbase.superuser to imanis_hbase
     a. In **Cloudera Manager Web UI**, click **HBase** > **Configuration** tab.
     b. Search for hbase.superuser and set it to imanis_hbase.
     c. Deploy the changed configuration and restart HBase service.
   - On the primary Hadoop cluster, add hbase.superuser property to the hbase-site.xml if not already present.

```
<property>
<name>hbase.superuser</name>
<value>imanis_hbase</value>
</property>
```

- On the primary Hadoop cluster, add dfs.webhdfs.enabled property in the hdfs-site.xml file:

```
<property>
<name>dfs.webhdfs.enabled</name>
<value>true</value>
</property>
```

SSL-Enabled Hadoop

The following section describes the tasks you need to perform before adding SSL-enabled Hadoop as a source data repository in the Cohesity cluster.

Before adding SSL-enabled Hadoop, do the following:

1. Consult your Hadoop system admin to get the SSL certificates of all nodes in your production Hadoop system.
2. Import SSL certificates from your primary cluster into Cohesity by following the steps documented in Manage SSL enabled NoSQL primary clusters .
3. After importing the SSL certificates(step #2), run the following command from any one node of the Cohesity cluster to verify if your Hadoop primary is accessible from the NoSQL and Hadoop Service node.

   Log in to one of the Cohesity cluster nodes and run the following:

   ```
   $ kubectl.sh get pods --all-namespaces   | grep  imanis-nodemanager-0
   athena-104    imanis-nodemanager-0                   1/1        Running
           3       41h
   ```

   Log in to imanis container using the following command:

   ```
   $ kubectl.sh exec -it imanis-nodemanager-0   -n athena-104 /bin/bash
   ```

   Check if you can reach the primary namenode host from Imanis container using the following command:

   ```
   $ ping <primary_namenode_hostname>
   hdfs dfs -ls swebhdfs://<primary_namenode_hostname>:50470/
   ```

4. Go ahead and add this SSL-enabled Hadoop as a data repository in Cohesity.

Kerberos + SSL-Enabled Hadoop

The following section describes the tasks you need to perform before adding Kerberos + SSL-enabled Hadoop as a source data repository in Cohesity.

Before adding Kerberos + SSL-enabled Hadoop, do the following:

1. First, follow the steps mentioned in the Kerberos-Enabled Hadoop section for Kerberos-related configuration required for adding Kerberized Hadoop primary.
2. Then, consult your Hadoop system admin to get the SSL certificates of all nodes in your production Hadoop system.
3. Refer to SSL-Enabled Hadoop.
4. Log in to one of the Cohesity cluster nodes and run the following:

```
$ kubectl.sh get pods --all-namespaces   | grep  imanis-nodemanager-0

athena-104    imanis-nodemanager-0                   1/1        Running
        3       41h

$ kubectl.sh exec -it imanis-nodemanager-0   -n athena-104 /bin/bash
```

5. Run the following command to log in with user hdfs on the Cohesity container:

```

$ kinit -kVt $INSTALL_DIR/conf/talena.keytab imanis_hdfs@PRIMARY.REALM
```

> **Note:** If the Kerberos configuration steps are correctly performed, this command should succeed. Use klist command to verify that imanis_ hdfs@PRIMARY_REALM is the active kerberos principal.

6. Run the List command (ls) as the following:

```
$ hdfs dfs -ls swebhdfs://<namenode>:50470/
```

7. Execute the kdestroy command for imanis_hdfs@PRIMARY.REALM principal.

```
$ kdestroy
```

8. Go ahead and add this Kerberos + SSL-enabled Hadoop as a data repository in Cohesity.

Considerations

Hadoop HDFS

- Unicode characters in hdfs file and directory names are not supported.
- Special characters % ; + (percent semicolon plus) in hdfs file and directory names are not supported.
- Access Control Lists (ACLs) are not supported.

Hive

- Backup and Recovery across versions/vendors is not supported. For example, performing a data backup from CDH 5.8.2 and then recovering it to CDH 5.12.2 might cause data loss.
- Special characters, except underscore(_), are not supported for database and table names.
- Access Control Lists (ACLs) is not supported.
- For Cloudera Data Platform 7.x, backup and Recovery of hive databases: sys and information_schema is not supported.

HBase

- Backup and Recovery across versions/vendors is not supported. For example, performing a data backup from CDH 5.8.2 and then recovering it to CDH 5.12.2 might cause data loss.
- Access Control Lists (ACLs) is not supported.

Firewall Ports

For more information on the required firewall ports that are to be open to enable communication between Cohesity and Hadoop DataProtect Solution, see Open-Source Software Platform.

Minimum Permissions

This section describes the minimum set of permissions needed for the Hadoop DataProtect Solution to communicate with the source.

For kerberized setup:

User principal provided in UI must have super user privileges of production hadoop cluster and must have full access to the production HDFS/HIVE/Hbase system.

For non-kerberized setups:

NoSQL and Hadoop Service user (hdfs) must have full access to the production HDFS/HIVE/Hbase setups.

Register a Hadoop Source

Register Hadoop Applications as Sources

To configure Hadoop applications for data protection in Cohesity, you need to register them as sources. All three applications - HDFS, Hbase and Hive - can be registered together.

Before you register Hadoop as a source, ensure that you have reviewed and completed the instructions provided in the Plan and Prepare for Hadoop Protection topic.

To register Hadoop as a source:

1. Navigate to **Data Protection > Sources**.
2. Click **Register** on the top-right of the page and then select **Hadoop**. The **Discover Hadoop** dialog is displayed.
3. Under the **Discovery** tab, enter the required details. Refer the table below for the field descriptions.
    - Choose either **Password** or **Private Key** as the authentication type. If you choose **Password**, enter the SSH Username and Password in the respective fields. Else if you choose **Private Key**, enter the Login(SSH username), SSH private key and passphrase in the respective fields.

Field	Description
Host	IP or hostname of any host from which the configuration file can be read.
Hadoop Configuration Directories	Directory path for the Hadoop configuration file.
Distribution	Select the Hadoop distribution for this cluster.
Hadoop Version	Enter the Hadoop version for this cluster.
HDFS Connection Protocol	Select the protocol for connecting to HDFS. The available options are: • Web HDFS • DFS **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

4. Click **Register**. The **Register Sources** tab is displayed.
5. If the primary source is kerberized, enter the Kerberos principal and edit the application details that are identified by the system. Below table contains the fields and their descriptions.

Field Descriptions

Field	Description
HDFS	
namenode Address	HDFS Namenode IP or hostname.
webhdfsPort	HDFS WebHDFS port.
HBase	
Zookeeper Quorum	Zookeeper Quorum for this HBase.
HBase Data Root Directory	Data Root Directory for this HBase
Kerberos Principal	The kerberos principal to be used to connect to this Hbase source.
Hive	
Metastore Address	MetastoreAddress for this Hive.
Metastore Port	MetastorePort for this Hive.
Kerberos Principal	The kerberos principal to be used to connect to this Hive source

6. Click **Register**.

If the registration is successful, the registered cluster appears in the list on the **Sources** page. After registration, each application - HDFS, Hive and HBase - functions as an independent source.

Reconfigure HDFS, Hive and HBase Sources

You can individually reconfigure the registered HDFS, Hive and Hbase sources and update the configuration details that you had provided during the registration process with the latest configuration.

To reconfigure HDFS/ Hive/ HBase:

1. Navigate to **Data Protection > Sources**.
2. Browse to the required HDFS/ Hive/ HBase source you want to edit and click ⋮ > **Reconfigure**. The respective **Reconfigure** dialog is displayed.
3. Edit the authentication details and other configurations as required. Refer Field Descriptions for more details.

   > **Note:** Performing step 4 leads to rediscovering the source. The source ID, protection runs and Protection Groups that are already created are retained.

4. To update the details, click **Update**.

Refresh HDFS, Hive and HBase Source

You can manually refresh the HDFS, Hive and HBase source configuration and fetch the latest changes on the source.

To refresh the Source Configuration:

1. Navigate to **Data Protection > Sources**.
2. Click ⋮ next to the required HDFS/ Hive/ HBase source and select **Refresh**.

Unregister HDFS, Hive and HBase Source

If you want to stop taking backups of the HDFS/ Hive/ HBase source, you can unregister the source from Cohesity.

> **Note:** Make sure that you delete all the Protection Groups and backup snapshots associated with the source.

To unregister the HDFS/ Hive/ HBase Source:

1. Navigate to **Data Protection > Sources**.
2. Click ⋮ next to the HDFS/ Hive/ HBase source and select **Unregister**.

Backup Hadoop

Cohesity provides a simple sequence of tasks that constitute the procedure for backing up your HDFS/ Hive/ HBase source. Once HDFS/ Hive/ HBase is registered as a source on Cohesity, you can start configuring your backups.

HDFS/ Hive/ HBase objects are protected using a Protection Group and a Protection Policy. A Protection Group enables you to select the objects that you want to back up. It uses the

schedules and settings defined in the Protection Policy to determine when and how backups are captured and replicated.

A Protection Policy is a reusable list of settings that define the type of backup, backup schedule and backup snapshot retention. Also, for Disaster Recovery, you can add replication for the Protection Group using the Protection Policy. For detailed instructions on how to create a Protection Policy, refer Create or Edit a Standard Policy.

Protect HDFS Objects

To protect a HDFS object:

1. Navigate to **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then select **Hadoop > HDFS**. The **New Protection** page is displayed.
3. Select the required **Source** from the dropdown.
4. To protect all the objects in the selected data source, select **Protect Entire Data source**.
5. To protect specific paths in the selected data source, select **Protect Specific Paths**.

   Enter the paths to include and exclude and click + Add to add the paths.

   > **Note:** Specific path fields accept absolute paths and regular expressions.
6. Click **Save Selection**.
7. Under **Protection Group**, enter a protection group name. Existing protection groups cannot be used while creating a new HDFS protection.
8. Under **Protection Policies**, select an existing protection policy or create a New Policy if the available policies do not meet your schedule and retention needs.
9. Select the appropriate **Storage Domain**. For more information, refer Manage Storage Domains.
10. After selecting a Storage Domain, if you need to change any of the additional settings on the HDFS Protection page, scroll down and click **Edit** on the right. For more information, see Additional Settings.
11. Click **Protect**.

Your new Protection Group is now active and running.

Protect Hive Objects

To protect a Hive object:

1. Navigate to **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then select **Hadoop > Hive**. The **New Protection** page is displayed.
3. Select the required **Source** from the dropdown.
4. Select the required objects to protect such as hive databases, tables, or views.

   > **Note:** If the number of objects exceeds the threshold (10000 objects), the UI will display only the hive database objects and it will not show the tables or views.

5. To auto protect an object, click adjacent to it. For more details, see Enable or Disable Auto Protect.
6. Click **Save Selection**.
7. Under **Protection Group**, enter a protection group name. Existing protection groups cannot be used while creating a new Hive protection.
8. Under **Protection Policies**, select an existing protection policy or create a New Policy if the available policies do not meet your schedule and retention needs.
9. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains.
10. After selecting a Storage Domain, if you need to change any of the additional settings on the HDFS Protection page, scroll down and click **Edit** on the right. For more information, see Additional Settings.
11. Click **Protect**.

Your new Protection Group is now active and running.

Protect HBase Objects

To protect a HBase object:

1. Navigate to **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then select **Hadoop > HBase**. The **New Protection** page is displayed.
3. Select the required **Source** from the dropdown.
4. Select the required objects to protect.
5. To auto protect an object, click adjacent to it. For more details, see Enable or Disable Auto Protect.

6. Click **Save Selection**.
7. Under **Protection Group**, enter a protection group name. Existing protection groups cannot be used while creating a new HBase protection.
8. Under **Protection Policies**, select an existing protection policy or create a New Policy if the available policies do not meet your schedule and retention needs.
9. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains.
10. After selecting a Storage Domain, if you need to change any of the additional settings on the HBase Protection page, scroll down and click **Edit** on the right. For more information, see Additional Settings.
11. Click **Protect**.

Your new Protection Group is now active and running.

Additional Settings

Field	Description
End Date	Optional. Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts prior to this date runs until completion even if it completes after this date.
QoS Policy	Select an appropriate quality of service (QoS) policy. **Note:** Cohesity recommends specifying **Backup HDD**, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Concurrency	Maximum number of backup streams that will be created to exchange data with the cluster. By default, maximum scaling is capped at 16.

Field	Description
Bandwidth Throttling	Maximum network bandwidth that each backup stream can use for exchanging data with the cluster.
Indexing	• HDFS - Files/directories are indexed. • Hive, HBase - Databases/tables are indexed. **Note:** The indexing option for HDFS is not mandatory since the default indexing policy is sufficient. For Hive and Hbase, the indexing options are not displayed since the default indexing policy is selected automatically.
Alerts	Optional. Select one or more of the following settings if you want alerts to be created for the following triggers: • Success: Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • Failure: Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • SLA Violation: Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts. You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection group.
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection groups exceeds the ability to process protection groups, this will be the priority of implementation of the protection groups: • High-priority protection groups • Medium-priority protection groups • Low-priority protection groups.

Field	Description
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • Incremental: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. • Full: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks).
Pause Future Runs	Once enabled, no protection runs will be scheduled.
Include & Exclude	You have the option to include or exclude objects for protection in addition to the currently selected objects. To enable the Include and Exclude options: • Click icon. • Toggle on Enable Partial Protection. • Select the include or exclude option. • Click Select File. **Note:** You can upload a file with a maximum size of 30 MB. This file should contain fully qualified names of hive databases, tables, or views, with each name separated by a new line. For example: • mydb.table1 • empdb.table1 • empdb.table2 • empdb.view1
Description	Optional. Enter a brief description about the Protection Policy.

Manage Backup Configuration

A backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

Add Objects to an existing Protection Group

You can add new objects to the Protection Group created for HDFS/ Hive/ HBase protection. The newly added objects are backed up from the next protection run.

To add objects to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for HDFS/ Hive/ HBase.
3. Click ⋮ next to the Protection Group and select **Edit**. The **Edit Protection** page is displayed.
4. For HDFS, click + and enter the paths.
5. For Hive and HBase, click ✎ next to **Objects**.
6. Make the required changes. For more information, see Protect HDFS Objects, Protect Hive Objects and Protect HBase Objects.
7. Click **Protect**.

Enable or Disable Auto Protect

The Auto Protect option enables you to automatically protect the objects that are added to the Hive/ HBase source. You can auto protect either the entire cluster or a Keyspace.

When the Auto Protect option is enabled:

- All the objects that are added to the Hive/ HBase source in the future are automatically added to the Protection Group and are protected from the next protection run.
- All the objects that are removed from the Hive/ HBase source in the future are automatically removed from the Protection Group and are not protected from the next protection run. The existing backups are preserved until the snapshot expires.

When the Auto Protect option is disabled, you need to manually:

- Add newly added objects, in the Hive/ HBase source, to the Protection Group.
- Remove existing objects, that are removed from the Hive/ HBase source, from the Protection Group. The existing backups are preserved until the snapshot expires.

To enable or disable Auto Protect:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Hive/ HBase. For more information, see Protect Hive Objects and Protect HBase Objects.
3. Click ⋮ next to the Protection Group and select **Edit**.
4. On the **Edit Protection** page, in the **Object** area, click **Edit**.

5. In the pop-up window , toggle the to enable or disable Auto Protect.
6. Click **Protect**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group in the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Hive/HBase. For more information, see Protect Hive Objects and Protect HBase Objects.
3. Click ⋮ next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Protect**.

Start an On-demand Protection run

You can manually start a run for the Protection Group that you have created to backup Hive/HBase objects. It provides you with options to:

- Back up all the objects in the Protection Group.
- Select an incremental or full backup.
- Add replication and archive.

To start a protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Hive/HBase.
3. Click ⋮ next to the Protection Group and select **Run Now**.
4. In the pop-up window, perform the following:
    1. The **Backup** drop-down list is defaulted to **Backup all Objects in the Protection Group**
    2. In the **Backup Type** drop-down list, select the backup type.
    3. If required add details for Replication and Archival.
5. Click **Backup Now**.

Pause Future Protection Runs

You can pause future protection runs of the Protection Group. However, if a protection run is in progress, it continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Hive/HBase.
3. Click ⋮ next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired then a full backup is triggered.

To resume future protection run:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had paused.
3. Click ⋮ next to the Protection Group and select **Resume**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the snapshots(local, archived, and replicated) that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete the Protection Group

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived snapshots generated by the Protection Group and reclaim the space utilized by the Protection Group.

> **Note:** The storage space reclaimed by deleting the Protection Group takes some time to reflect.

To delete the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for Hive/ HBase.
3. Click the ⋮ next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
    - Delete Protection Group Only
    - Delete Protection Group and Snapshots

Recover Hadoop

You can recover the protected HDFS/ Hive/ HBase Objects using Cohesity. You can recover to the same location or an alternate location.

> **Important:**
> - Recovering at the protection group level is supported for HDFS/ Hive/ HBase.
> - Recovering multiple protection groups in a single recovery task is not supported.
> - Recovering of items in the same protection group but from different recovery points is not supported in the same recovery task. You need to create different recovery tasks for different recovery points.
> - Recovering objects from more than one protection group in a single recovery task is not supported.

Recover HDFS Objects

To recover HDFS objects you can search through the backups using the protection group, keyspaces or table names for the objects you plan to recover, and then start the recovery.

To recover HDFS objects:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** on the top-right of the page and then select **Hadoop > HDFS**. The **New Recovery** dialog is displayed.
3. Search for the HDFS protection groups or objects that need to be recovered.

    > **Note:** Wildcards are supported in the search.

4. Accept the latest Recovery Point or click ✎ and select a different recovery point.
    - Snapshots: Select a different recovery point. You can change the time zone before or after selecting a new restore time.
5. Click **Next: Recover Options**. The recovery details are displayed.
6. Under **Recover As** select **Replace Original** or **New Object**.
    - **Replace Original** - Replace the object(s) back to the source from where it was backed up.
    - **New Object** - Specify the target for the recovered object. Use the toggle to **Overwrite existing objects with the same name**. A warning is displayed, enter **YES** to proceed.
7. Under **Recovery Options**, select the required options for the recovery. For more information, see Recovery Options.
8. Click **Start Recovery** to start the recovery operation.

Recover Hive Objects

To recover Hive objects you can search through the backups using the protection group, keyspaces or table names for the objects you plan to recover, and then start the recovery.

To recover Hive objects:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** on the top-right of the page and then select **Hadoop> Hive**. The **New Recovery** dialog is displayed.
3. Search for the Hive protection groups or objects such as hive databases, tables, or views. that need to be recovered.

    > **Note:** Wildcards are supported in the search.

4. Accept the latest Recovery Point or click ✎ and select a different recovery point.
    - Snapshots: Select a different recovery point. You can change the time zone before or after selecting a new restore time.
5. Click **Next: Recover Options**. The recovery details are displayed.
6. Under **Recover As** select **Replace Original** or **New Object**.
    - **Replace Original** - Replace the object(s) back to the source from where it was backed up.

- **New Object** - Specify the target for the recovered object. Use the toggle to **Overwrite existing objects with the same name**. A warning is displayed, enter **YES** to proceed.

7. If you select **New Object**, enter a suffix to append to all the selected objects.
8. Under **Recovery Options**, select the required options for the recovery. For more information, see Recovery Options.
9. Click **Start Recovery** to start the recovery operation.

Recover HBase Objects

To recover HBase objects you can search through the backups using the protection group, keyspaces or table names for the objects you plan to recover, and then start the recovery.

To recover HBase objects:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** on the top-right of the page and then select **Hadoop > HBase**. The **New Recovery** dialog is displayed.
3. Search for the HBase protection groups or objects that need to be recovered.

   > **Note:** Wildcards are supported in the search.

4. Accept the latest Recovery Point or click ✎ and select a different recovery point.
   - Snapshots: Select a different recovery point. You can change the time zone before or after selecting a new restore time.
5. Click **Next: Recover Options**. The recovery details are displayed.
6. Under **Recover As** select **Replace Original** or **New Object**.
   - **Replace Original** - Replace the object(s) back to the source from where it was backed up.
   - **New Object** - Specify the target for the recovered object. Use the toggle to **Overwrite existing objects with the same name**. A warning is displayed, enter **YES** to proceed.
7. If you select **New Object**, under **Recovery Options** in the **Rename** field, choose Bulk Rename to append a suffix to all the selected objects, or choose Rename Individual Objects.
8. Under **Recovery Options**, select the required options for the recovery. For more information, see Recovery Options.
9. Click **Start Recovery** to start the recovery operation.

Recovery Options

Field	Description
Concurrency	Maximum number of recovery streams that will be created to exchange data with the cluster. By default, maximum scaling is capped at 16.
Bandwidth Throttling	Maximum network bandwidth that each recovery stream can use for exchanging data with the cluster.
Task Name	Recovery task name.

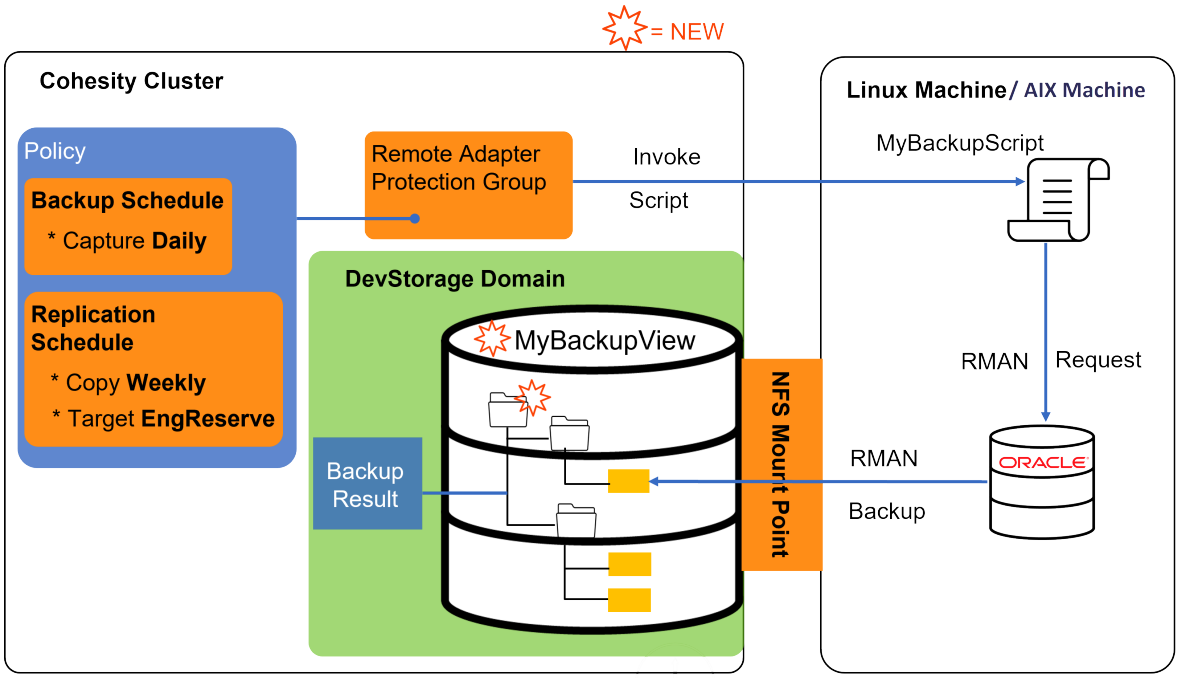
Chapter 19: About the Remote Adapter

> **Note:** Cohesity Remote Adapter functionality is not supported if SmartFiles is not licensed on your Cohesity cluster.

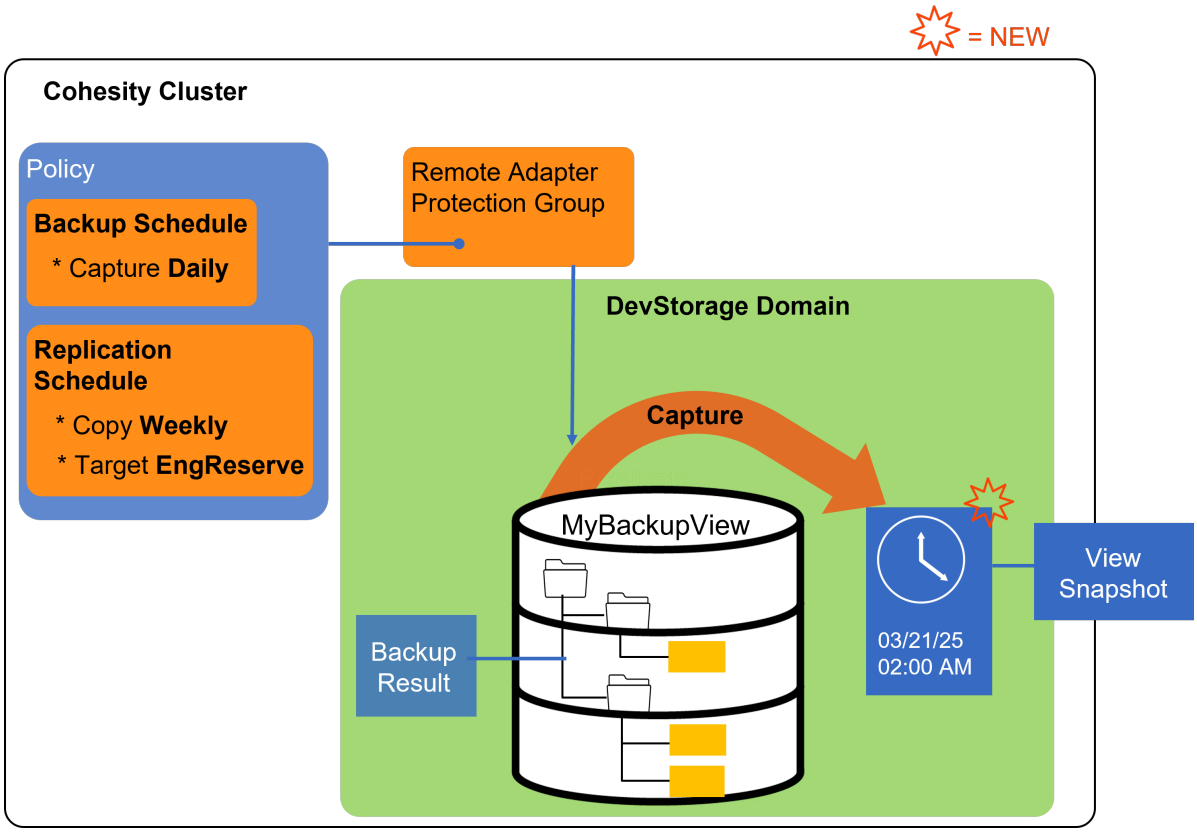
Remote Adapter Protection Groups provide the ability to run scripts or executables on a remote AIX or Linux machine using protection schedules defined by a Cohesity Policy. Typically Remote Adapter Protection Groups invoke scripts that back up using third party tools such as Oracle's RMAN.

During the configuration of the Remote Adapter Job, a new View is created to store the results of the backup. After a script run, the Job captures a Snapshot of the View with the backup results. If the Policy associated with the Remote Adapter Job has a replication schedule and an archive schedule, the View Snapshot is copied to a remote Cluster and to an archive External Target.

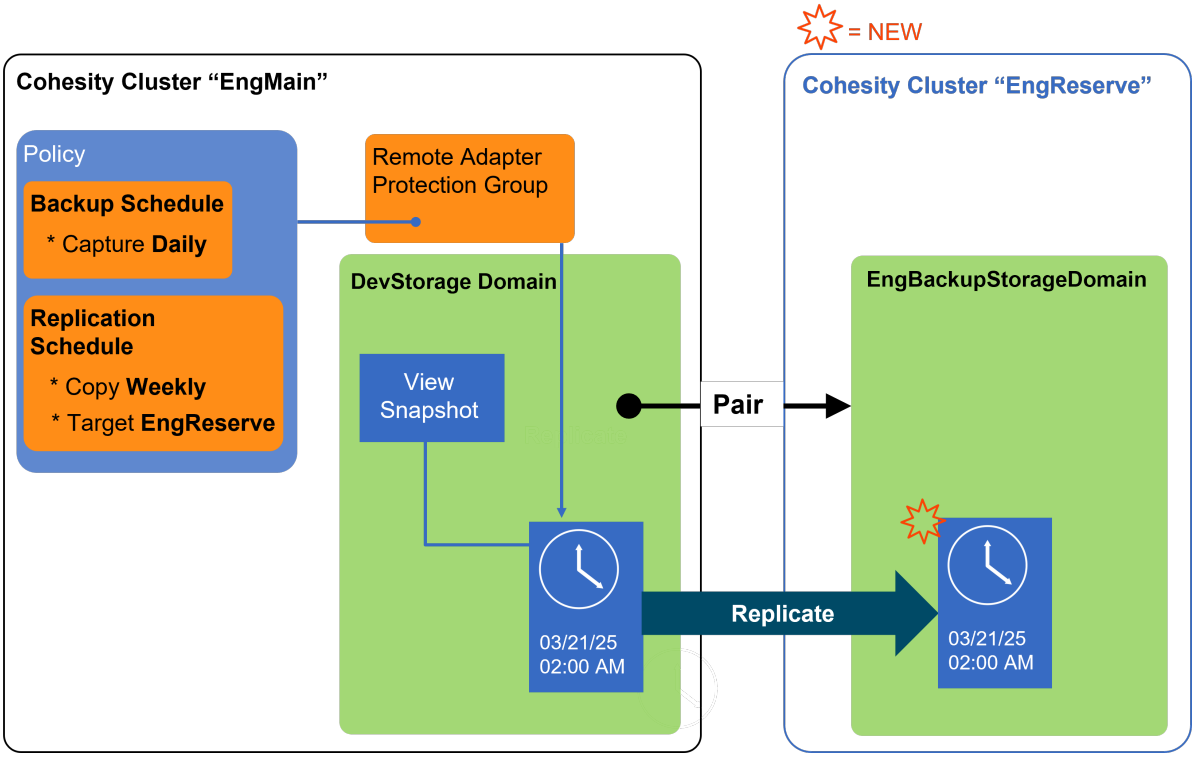
For example, a Remote Adapter Job could invoke a script that backs up Oracle databases using Oracle's Recovery Manager (RMAN). The results of the backup are stored in a new View created during the configuration of the Remote Adapter Job. Cohesity provides an example Bash shell script that invokes an Oracle's RMAN to back up a database.



The Job captures a Snapshot of the View with the backup results.



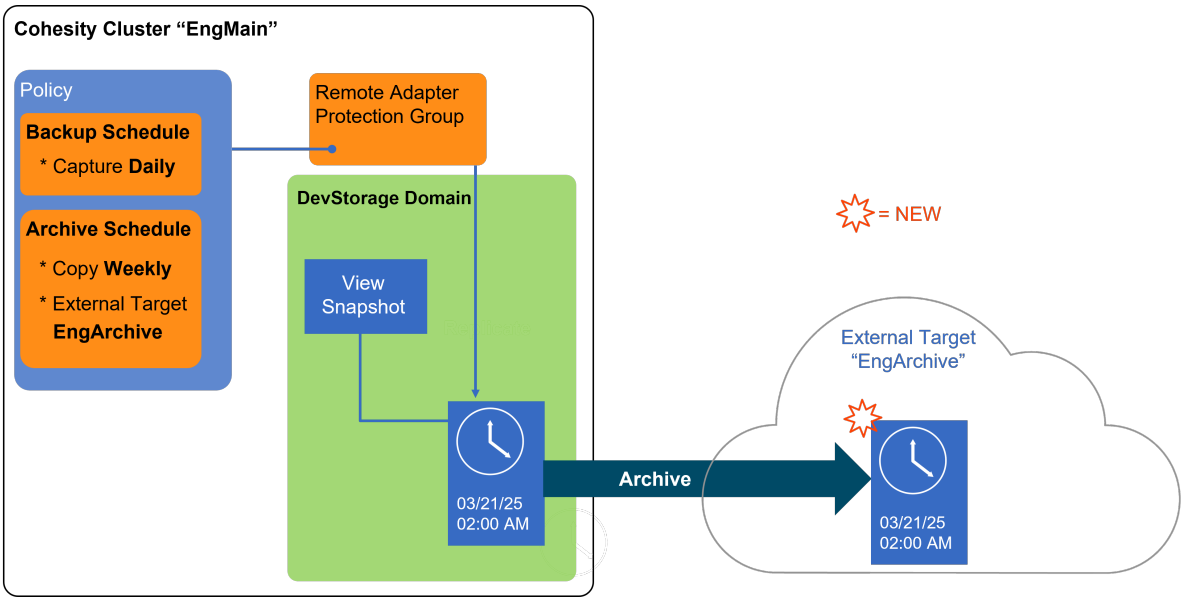
If the Policy associated with the Remote Adapter Job has a replication schedule, the Snapshot is copied to a remote Cluster ("EngReserve", below).



Replication occurs if the following conditions are met:

- The Policy associated with the Remote Adapter Protection Group has a replication schedule. In this example, the Policy defines a Weekly replication schedule.
- The Policy associated with the Remote Adapter Protection Group specifies a remote Cluster as the replication Target and there is a Storage Domain pairing between the capturing Cluster and this remote Cluster. In the example above, the Policy specifies the `EngReserve` Cluster as a Replication Target and there is Storage Domain pairing between `DevStorageDomain` on the `EngMain` Cluster and `EngBackupStorageDomain` on the `EngRerserve` Cluster.

If the Policy associated with the Remote Adapter Job has an archive schedule, the Snapshot is copied to an archive External Target.



Archival occurs if the following conditions are met:

- The Policy associated with the Remote Adapter Protection Group has an archive schedule. In this example, the Policy defines a Monthly archive schedule.
- The Policy associated with the Remote Adapter Protection Group specifies an External Target as the archive Target. In this example, the Policy specifies the `EngArchive` External Target as an archive Target.

For more information about creating and configuring a Remote Adapter Protection Group, see Add or Edit a Remote Adapter Protection Group.

Recommendations for Dedupe-focused Backups with RMAN

For higher storage-side dedupe with RMAN backups, Cohesity recommends the following settings:

RMAN Parameter	Recommendation
FILESPERSET	1
Number of channels	Number of Cohesity nodes or greater
Compression	None
Encryption	None

Example of a full RMAN backup script

In the example below, four Oracle channels are created and each channel is directed to a separate Cohesity node leveraging the Cohesity dedupe:

```
DATABASE = “Name of DB” ORACLE_HOME=/u01/OracleHomes/db/product/dbhome_1
COHESITY_DIR_PATH =/mnt/oracle01 COHESITY_DIR_PATH2=/mnt/oracle02 COHESITY_
DIR_PATH3=/mnt/oracle03  COHESITY_DIR_PATH4=/mnt/oracle04

set ORACLE_SID=${DATABASE}
$ORACLE_HOME/bin/rman target=/ << EOF
RUN {
allocate channel C1 type disk FORMAT '$COHESITY_DIR_PATH/%U' MAXOPENFILES 1;
allocate channel C2 type disk FORMAT '$COHESITY_DIR_PATH2/%U' MAXOPENFILES
1;
allocate channel C3 type disk FORMAT '$COHESITY_DIR_PATH3/%U' MAXOPENFILES
1;
allocate channel C4 type disk FORMAT '$COHESITY_DIR_PATH4/%U' MAXOPENFILES
1;

BACKUP FULL DATABASE PLUS ARCHIVELOG FILESPERSET 1 TAG 'dedupe_focused';
RELEASE CHANNEL C1;
RELEASE CHANNEL C2;
RELEASE CHANNEL C3;
RELEASE CHANNEL C4;
}

EOF
```

Add or Edit a Remote Adapter Protection Group

Remote Adapter Protection Groups provide the ability to run scripts or executables on a remote AIX or Linux machine using protection schedules defined by a Cohesity Policy. Typically Remote Adapter Protection Groups invoke scripts that back up using third party tools such as Oracle's RMAN.

During the configuration of the Remote Adapter Job, a new View is created to store the results of the backup. After a script run, the Job captures a Snapshot of the View with the backup results. If the Policy associated with the Remote Adapter Job has a replication schedule and an archive schedule, the View Snapshot is copied to a remote Cluster and to an archive External Target.

The Protection Group captures snapshots of views and snapshots of views are required for the following tasks:

- creating a new view from a view snapshot
- replicating snapshots

- archiving snapshots

The Cohesity cluster supports backing up the following entities stored in the view:

- ordinary files
- directories
- symbolic links
- hard links

These entities can be captured in a view snapshot and restored to a new view. The backup and recovery of the following special files is supported: pipes, block devices, sockets and character devices.

Limitation:

If Remote Adapter jobs are running on a Cohesity cluster and the cluster is upgraded, the nodes are restarted and any scripts still running on the remote system are killed and restarted. This may happen repeatedly.

When you create a Remote Adapter Protection Group, you will create a View or use an existing View to store the result of the scripts. You must then mount the View on your system and configure your script to write the results to a directory in the mounted View. At the end of the Remote Adapter protection run, the Cohesity cluster captures a Snapshot of the View.

When you create a Remote Adapter Protection Group, you can select an existing Policy, Storage Domain and View. You can also create them while creating the Protection Group. However, you might find it easier to create them prior to creating the Protection Group, as described in the following topics.

- Create or Edit a Standard Policy
- Create or Edit Storage Domains
- Create Views Using a Predefined Template

To create a Remote Adapter Protection Group:

1. Navigate to **Data Protection > Protection** and do one of the following:
   - To create a Protection Group—Click **Protect** on the top-right of the page and then select the type of Protection Group.
   - To edit a Protection Group—Click the action icon (⋮) next to the Protection Group and select **Edit**.

   Here the Protection Group type is **Remote Adapter**.
2. **Name:** Enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.
3. **Linux Hostname or IP:** Specify the Hostname or the IP Address of the Linux system where the scripts are located and will be run.

4. **Username:** Specify the username on the Linux system that will be running the scripts.
5. **Cluster SSH Public Key:** Set up permissions on the Linux system to allow the Cohesity cluster to run the scripts remotely on the system.
   a. Click **Copy Key to Clipboard** to copy the SSH public key into the clipboard.
   b. Log in to the Linux system with the username specified earlier.
   c. In the home directory of the user, determine if there is a `.ssh` directory that contains a file called `authorized_keys`:

      ```
      ls -lr ~/.ssh
      ```

   d. Add the SSH key to the `authorized_keys` file located in the `~/.ssh` directory of the specified User:
      - If the directory and file do not exist, create the `.ssh` directory in the home directory.

        ```
        [oracle@localhost ~]$ cd ~
        [oracle@localhost ~]$ mkdir .ssh
        ```

      - Change directories into the `.ssh` directory, create the `authorized_keys` file and paste the SSH key into a new line of the file.

        ```
        [oracle@localhost ~]$ touch ~/.ssh/authorized_keys
        ```

      - If the `.ssh` directory exists but the file does not, change directories into the `.ssh` directory, create the `authorized_keys` file and paste the SSH key into a new line of the file.
      - If the `authorized_keys` file exists in the `.ssh` directory, edit the `authorized_keys` file and paste the SSH key into a new line of the file.
   e. Set the `.ssh` directory and `authorized_keys` file permissions:

      ```
      chmod 700 .ssh
      ```

      ```
      chmod 640 .ssh/authorized_keys
      ```

6. **Policy:** Select an existing protection policy or create a new one by selecting **New Policy**.
7. **Script (with Full Path):** Enter the full path to the script, for example `/home/joe/scripts/myscript.sh`.
8. **Parameters:** If the script requires parameters, enter them in this field.

   Storage Domain: Select an existing storage domain or create a new one by selecting **New Storage Domain**.

> **Note:** Once you create a Protection Group, you cannot change the Storage Domain you selected for that job.

The selected Storage Domain will contain the new View where the script results are stored.

9. **NFS View:** Select an existing View create a new one by selecting **Add View**. For more information, see Create Views Using a Predefined Template. The View will contain the script results.
10. **NFS Mount Path:** Click **Copy NFS Path to Clipboard** for use later when you mount the View on the Linux system.
11. **Start Time:** Indicates when the Protection Group should run. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting.

    The default time zone is the browser's time zone. You can change the time zone by selecting a different time zone.
12. **End Date:** Optional. Toggle on and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
13. **QoS Policy:** Select an appropriate quality of service (QoS) policy.

    > **Note:** Cohesity recommends specifying **Backup HDD**, which is the default.

    - **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group.
    - **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups.
    - **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy.
    - **TestAndDev High:** The Cohesity cluster writes the data to an SSD drive for this Protection Group. The I/Os with this QoS policy are given higher priority compared to other QoS policies. Use this policy for workloads that require lower I/O latency.
14. **Alerts:** Optional. Select one or more of the following settings if you want alerts to be created for the following triggers:

- **Success:** Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created.
- **Failure:** Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created.
- **SLA Violation:** Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created.

For more information, see Alerts.

15. **Priority:** Select a priority for the Protection Group execution. Cohesity supports concurrent backups, but if the number of Protection Groups exceeds the ability to process them, those with **High** priority are given the highest priority to execute, **Medium** the second-highest priority, and **Low** the lowest priority.
16. **Email Recipients**: You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the Protection Group.

> **Note:**
> The connection to the SMTP Server must be enabled to send email notification. You can enable the SMTP Server connection in the configuration settings page (Cohesity UI > **Settings** > **Summary** > **Configure** > **Enable SMTP Server**).

17. **SLA:** The service-level agreement (SLA) defines the expected time to complete either a full backup or incremental backup. The backup completion time depends on the Windows volume size on AD, objects changed between incremental backups, network speed, and other Protection Groups running on the Cohesity cluster.
    - **Incremental:** Enter the number of minutes you expect an incremental protection run to complete. An incremental backup captures only the differences (changed blocks) since the last protection run.
    - **Full:** Enter the number of minutes you expect a full backup protection run to complete. A full backup captures the entire object (all blocks).
18. **Description:** Optional. Click the plus sign and enter a description for the Protection Group.
19. Click **Protect**.

    The Protection page is displayed and includes the new Protection Group.

About SAP HANA Database Backups

Cohesity's software-defined platform provides a simple, fast, and cost-effective backup, recovery, and data management solution for growing SAP HANA database environments. It provides an SAP HANA-BRINT 1.1 certified Cohesity BACKINT plugin for backups.

> **Tip:** To protect the SAP HANA database using the Cohesity Connector Agent, see SAP HANA.

When the Cohesity BACKINT plugin is installed and configured on the SAP HANA system, it manages the communication between SAP HANA and the Cohesity cluster.

The Cohesity BACKINT plugin is available for both x86-64 and IBM PowerPC systems. For data transfer between the SAP HANA node and the Cohesity cluster, the Cohesity BACKINT plugin leverages NFS or RPC for IBM PowerPC and RPC for x86-64 systems respectively.

> **Note:** Cohesity supports the recovery of SAP HANA 2.0 backups across both Intel x86-64 and Power PC platforms, allowing you to restore your critical SAP HANA data regardless of the underlying hardware architecture.

You can perform the following operations for data and logs using one of the following SAP HANA interfaces:

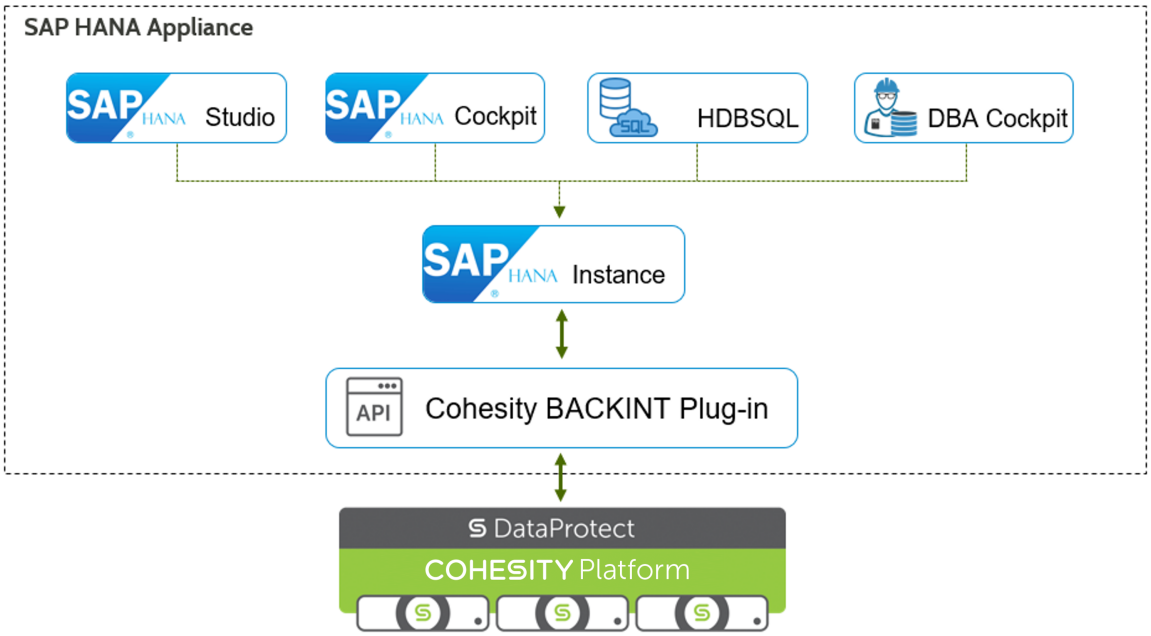
Interface	Operations
SAP HANA Studio	Backup Recovery Inquire Deletion
SAP HANA Cockpit	
HDBSQL	
DBA Cockpit	

Core Components

The following are the core components for protecting SAP HANA databases:

- SAP HANA appliance
- Cohesity BACKINT plugin
- Cohesity Data Cloud (Self-Managed)

As illustrated, you can integrate the Cohesity Cohesity Data Cloud (Self-Managed) with a new or existing SAP HANA infrastructure by installing the Cohesity BACKINT plugin on SAP HANA.



The Cohesity BACKINT plugin on SAP HANA enables you to perform the following functions:

Category	Supported Functions
Operations	Backup Restore Inquire Deletion
Supported Backup Types	Data Logs
Database Type	System Database Tenant Database
Configuration	Single Node SAP HANA Setup Multi-node SAP HANA Setup (Scale-out and Scale-up architecture)
Deployment	SAP HANA instance as a multi-tenant setup

Supported SAP HANA Releases and Environments

For more information on supported SAP on Oracle versions, see Supported Software versions.

Create a Cohesity View with IP Allowlist for SAP HANA node

Create a Cohesity view to provide a storage location in a storage domain on the Cohesity cluster for the SAP HANA database nodes. For more information on views, see Cohesity Views.

To provide effective authorization and prevent rogue access to the Cohesity cluster, the SAP HANA node IP address must be added in the Cohesity view configuration. For detailed instructions to create a view, see Create Views Using a Predefined Template.

Adding Custom Allowlist for the Cohesity View

While creating a Cohesity View, you have an option to add an allowlist for the View. Ensure that you add the SAP HANA node IP address in the Allowlist for the Cohesity View.

To add subnets to the allowlist of the Cohesity view:

1. In the **Create View** page, under the **Advanced** section, expand **Security**.
2. In the **Allowlist** section, perform the following:
    1. Select **Override Global Allowlist** and click **Add Allowlist**.
    2. In the **Subnet IP** and **Subnet Mask** fields respectively, enter the Subnet IP address and Subnet Mask to specify a range of systems that should have permissions to access and mount the Cohesity View.
    3. In the **NFS Permissions**, **SMB Permissions**, and **S3 Permissions** drop-down lists, select the NFS, SMB, and S3 permissions respectively.
    4. In the **NFS Root Squash** and **NFS All Squash** drop-down lists, specify whether to turn on NFS Root or NFS All squash respectively.
    5. In the **Description** field, enter a brief description.
    6. Click **Add**.
    7. Repeat these steps to add additional subnets to the allowlist of the Cohesity view.

> **Note:**
> - To use the IP allowlist feature the Cohesity cluster should be upgraded to 6.3 release or later.
> - If the Override Global Allowlist toggle is off, this View can only be accessed and mounted by systems specified by the Global Cohesity cluster Allowlist.
> - In case of a multinode HANA setup, specify all nodes individually in the global IP allowlist.

Install the Cohesity BACKINT plugin

The Cohesity BACKINT plugin is available for both Intel-based x86 and IBM PowerPC systems. Cohesity supports IPv6 for SAP HANA.

This topic covers instructions on how to:

- Install the Cohesity BACKINT plugin on x86-64 Platform
- Install the Cohesity BACKINT plugin on IBM PowerPC Platform

Install the Cohesity BACKINT plugin on x86-64 Platform

The Cohesity BACKINT plugin is an SAP HANA-BRINT 1.1 certified service that enables you to establish communication between the Cohesity cluster and the SAP HANA nodes.

The BACKINT plugin is available as a script installer and also as an RPM-based installer for the x86-64 system. Based on your requirements, download the appropriate installer.

Prerequisites

Before you install the BACKINT plugin, make sure that you:

- Create a Cohesity view with the **DefaultStorageDomain** options:
  - In an SAP HANA single-node setup, install the BACKINT plugin in the appropriate SAP HANA directory.
  - For a multi-node setup, install the BACKINT plugin on a shared NFS path that all the nodes can access in the SAP HANA deployment.

  For more information, see Create a Cohesity View with IP Allowlist for SAP HANA node.
- Download and copy the appropriate BACKINT plugin installer for x86-64 systems. For more information, see Download the BACKINT plugin Installer.
- Check if the SAP HANA node has an `<SID>adm` user account, if not, then create an Operating System (OS) user account to own the backup files on the Cohesity view. The format of the user account must be `<SID>adm`.
- "bash" shell is required for BACKINT plugin installation, backup, and restore workflows.
- Run the following command on the SAP HANA node to synchronize time between the SAP HANA server and the Cohesity NTP server:

  ```
  timedatectl set-ntp true
  ```

- If you are using the RPM-based installer, ensure that you configure the following environment variables on the SAP HANA node(s):

Environment Variable	Description	Mandatory?	Command
SID	The <SID>adm user account that must own the backup files on the Cohesity view. If you have not created the user account, then create an Operating System (OS) user account in the following format: <SID>adm. Where <SID> is a unique three-character code called SAP System Identification (SID). It is available for every R/3 installation (SAP system) that consists of a database server and several application servers.	Yes	export SID=<VALUE>
SYSTEMDB_KEY	The SAP HANA HDBUSERSTORE key to connect to the SYSTEM DB.	No	export SYSTEMDB_KEY=<HDBUSERSTORE key>
CLUSTER_PORT	The ports in the firewall to allow the Cohesity cluster to transmit and receive data. The supported values are 11111 or 11113. By default the port is set as 11117.	No	export CLUSTER_PORT=<Port_number>
WORKFLOW	The type of workflow you intend to install the BACKINT plugin. The supported values are uda or ra. The uda value is for Universal Data Adapter workflow and ra is for Remote Adapter workflow. Default is uda.	No	export WORKFLOW=ra
MULTI_TENANCY	The type of deployment. The supported values are vlan or hyx. Specify vlan for 'VLAN' and hyx for 'Single Homed NAT' deployments.	No	export MULTI_TENANCY=<VALUE>
STANDBY	Specify if you are installing the BACKINT plugin on a standby node. Supported values are 1 or 0.	No	export STANDBY=<VALUE>

Environment Variable	Description	Mandatory?	Command
HANA_ VERSION	The SAP HANA version. Supported values are 1 or 2.	No	`export HANA_ VERSION=<VALUE>`
DEBUG	Option to enable installer debug. Supported values are 1 or 0.	No	`export DEBUG =<VALUE>`

Download the BACKINT plugin Installer

Cohesity provides a BACKINT plugin installer to backup and restore SAP HANA databases. The BACKINT plugin is available as script-based and RPM-based installers on the Cohesity Download portal. Log on to the Cohesity Download portal, download the respective BACKINT plugin installer, and copy the installer to the SAP HANA host.

Install the BACKINT plugin using the Script Installer

The Cohesity BACKINT plugin is an SAP HANA-BRINT 1.1 certified service that enables you to establish communication between the Cohesity cluster and the SAP HANA nodes.

> **Note:** For multi-node SAP HANA deployments, ensure that you install the Cohesity BACKINT plugin on the shared NFS path where all the SAP HANA nodes have access or install the plugin on all the nodes of the SAP HANA deployment as an SAP HANA admin user.

On the SAP HANA node, perform the following to install the plugin:

1. Log on to the SAP HANA node's bash CLI.
2. Make the plugin installer (`cohesity_secure_connector_service_<version>_sap_hana_installer`) executable using the following command:

   ```
   SAP_HANA_SERVER:/home/adminse # chmod +x cohesity_secure_connector_service_<version>_sap_hana_installer
   ```

3. Ensure that the `opt` folder in the `/usr/sap/<SID>/SYS/global/hdb/` directory, if not create the `opt` folder as follows:

   ```
   SAP_HANA_SERVER:/usr/sap/COH/SYS/global/hdb # mkdir opt
   ```

> **Note:** During the BACKINT plugin installation, by default, the script installer extracts the files to the `/tmp` directory. If you plan to extract the files to a different directory, you can define the directory path in the `TMPDIR` environment variable as follows: `export TMPDIR=<directory_path>`.

4. Install the plugin using the following command:

```
./cohesity_secure_connector_service_<version>_sap_hana_installer -- --install --install-dir=<backint install directory> --sid=<SID> --systemdb-key=<systemdb_key> --workflow=<workflow>
```

Where:

Options	Mandatory?	Description
`--install-dir`	No	The directory on the SAP HANA node on which you want to install the BACKINT plugin. **Note:** If `--install-dir` is not specified, the BACKINT plugin is installed in the `/usr/sap/${SAPSYSTEMNAME}/home` directory.
`--systemdb-key`	NO	The SAP HANA HDBUSERSTORE key to connect to the SYSTEM DB. • Use the option `--systemdb-key-k <user_store_key>` only if you want to edit the global.ini file and create a symbolic link from `HDBBACKINT` to the BACKINT plugin. • If you plan to back up your SAP HANA databases using the BACKINT plugin, ensure that you use the option `--systemdb-key <user_store_key>`. • If you have not used the option `--systemdb-key <user_store_key>` while installing the BACKINT plugin, specify the option `--systemdb-key <user_store_key>` while upgrading the BACKINT plugin.

Options	Mandatory?	Description
`--cluster-port`	No	The ports in the firewall to allow the Cohesity cluster to transmit and receive data. The supported values are 11111 or 11113. By default the port is set as `11117`.
`--workflow`	No	The type of workflow you intend to install the BACKINT plugin. The supported values are `uda` or `ra`. The `uda` value is for Universal Data Adapter workflow and `ra` is for Remote Adapter workflow.
`--multi-tenancy`	No	The type of deployment. The supported values are `vlan` or `hyx`. Specify `vlan` for 'VLAN' and `hyx` for 'Single Homed NAT' deployments.
`--standby`	No	Specify if you are installing the BACKINT plugin on a standby node.
`--hana-version`	No	The SAP HANA version. Supported values are 1 or 2. By default, the value is set to 1.
`--debug`	No	Option to enable installer debug.

Install the BACKINT plugin using the RPM-based Installer

On the SAP HANA node, perform the following to install the BACKINT plugin using an RPM-based installer, `cohesity-hana-backint-<version>.1-1.x86_64.rpm`. You can install the BACKINT plugin using a `root` user account or a user account with `sudo` privileges.

To install the BACKINT plugin using a user account with sudo privileges:

1. Log in to the SAP HANA node's bash CLI.
2. Navigate to the directory where you have copied the RPM-based installer.
3. Run the following command to install the BACKINT plugin:

```
sudo -E rpm -ivh  cohesity-hana-backint-<version>.x86_64.rpm
```

To install the BACKINT plugin using the `root` user account:

1. Log on to the SAP HANA node's bash CLI as a root user.
2. Navigate to the directory where you have copied the RPM-based installer.
3. Run the following command to install the BACKINT plugin:

```
rpm -ivh cohesity-hana-backint-<version>.x86_64.rpm
```

Verify the BACKINT plugin Installation

To verify if the RPM-based BACKINT plugin installation is successful, run the following command:

```
rpm -qa|grep  cohesity-hana-backint
```

The following is a sample output of the command:

```
sap-hana-1.eng:qqqadm> rpm -qa|grep  cohesity-hana-backint
cohesity-hana-backint-<version>.1-1.x86_64
```

Update the Cohesity Parameter File

As part of the Cohesity BACKINT plugin installation, Cohesity provides a parameter file (`cohesity_param_file`) that enables SAP HANA to use the Cohesity BACKINT plugin for a backup job.

The parameter file is available in the <`backint_install_directory`>. Edit the parameter file and enter the values for the following parameters:

Parameter	Description
`cluster_ips`	List of IP addresses of the Cohesity Cluster. **Note:** Ensure that you provide only the virtual IP addresses.
`cluster_port`	The port number of the Cohesity cluster nodes that the plugin uses to establish communication between SAP HANA and the Cohesity cluster. The default port number is 11113 (gRPC). **Note:** You can also use the 11111 (SunRPC) port to establish communication between SAP HANA and the Cohesity cluster. Ensure that you open the 11111 (SunRPC) port on the Cohesity cluster.
`view_name`	The name of the Cohesity view used to store the backup data. **Note:** Ensure that the Cohesity view name does not contain the path of the Cohesity view or Cluster Name or IP address.
`io_thread_count`	The number of IO threads for reading or writing data on the Cohesity view.

max_outstanding_io	The number of pending IO threads. The range is 1-128 and the recommended value is 32.
max_io_size_bytes	Maximum size of each IO in bytes. The range is 1048576-4194304 bytes and the recommended value is 4194304 bytes.
max_cached_io	The maximum number of IO cached/prefetched. The range is 1-128 and the recommended value is 64.
rpc_timeout_msecs	Timeout in milliseconds for RPC requests.
inquire_period_days	The number of days for which the inquire information is returned. The default value is 180 days.
log_dir	Location on the SAP nodes where the Cohesity BACKINT plugin creates the debug logs.
metafiles_read_concurrency	Tune the metadata read performance for inquiry and restoration. The default value is 100.
max_backup_streams	The number of pipes that are backed up in parallel at any time by Cohesity BACKINT plugin during the backup process. It is recommended that you provide the number of IP addresses of the Cohesity Cluster that you define in the `cluster_ips` parameter.
enable_dedup_write	To enable source-side deduplication during backup, set this parameter value to true. **Note:** By default, source-side deduplication is disabled during the backup process.
use_tcp_proxy	To use anycast IP address and stream data through multiple TCP connections. Set this parameter value to `true`, if you want to use anycast IP load balancing in your deployment.
proxy_port_range	Use the `proxy_port_range` parameter only if you have set the `use_tcp_proxy` parameter to true. Enabling the `use_tcp_proxy` parameter opens certain ports on the localhost interface on the SAP HANA source. However, if you have a firewall enabled that blocks these ports, then you need to allowlist a range of ports and specify that range of ports using the `proxy_port_range` parameter. For example, `'proxy_port_range : "32001-35000"'`

Schedule and Run an SAP HANA Backup Job

Using external applications like SAP HANA Cockpit, SAP HANA Studio or using native SQL, schedule and run the backup job.

Uninstall the Cohesity BACKINT plugin

To uninstall the Cohesity BACKINT plugin, run the following command on the SAP HANA node's bash CLI:

```
cohesity_secure_connector_service_<version>_sap_hana_installer -- -u -d
<backint_install_directory> -s <SID>
```

If you have installed BACKINT plugin using the RPM-based installer, you can uninstall the service using the following steps.

To uninstall the BACKINT plugin using the `<SID>adm` user account, use the following command:

```
sudo -E rpm -evh cohesity-hana-backint-<version>.1-1.x86_64
```

To uninstall the BACKINT plugin using the `root` user account, use the following command:

```
rpm -evh cohesity-hana-backint-<version>.1-1.x86_64
```

The following is a sample output of the command:

```
[root@sap-hana-1 home]# rpm -evh cohesity-hana-backint-<version>.1-1.x86_64
```

Upgrade the Cohesity BACKINT plugin

To upgrade the BACKINT plugin, run the following command on all SAP HANA nodes:

```
cohesity_secure_connector_service_<version>_sap_hana_installer -- -n -d
<backint_install_directory> -s <SID> -k <systemdb_key>
```

Install the Cohesity BACKINT plugin on IBM PowerPC Platform

This topic covers instructions on how to install the BACKINT plugin for SAP HANA on IBM PowerPC Platform.

Prerequisites

Before you install the BACKINT plugin, make sure that you:

- Create a Cohesity view with the **DefaultStorageDomain** options:
  - In an SAP HANA single-node setup, install the BACKINT plugin in the appropriate SAP HANA directory.
  - For a multi-node setup, install the BACKINT plugin on each node of the SAP HANA deployment.
    For more information, see Create a Cohesity View with IP Allowlist for SAP HANA node.
- SAP HANA node(s) must be using JDK version 1.8 or higher.
- Install NFS common utility packages on the SAP HANA node(s) if you want to use NFS for data transfer between the SAP HANA node and the Cohesity cluster.

- Download and copy the appropriate BACKINT plugin installer for IBM PowerPC systems to the node or nodes of your SAP HANA deployment. For more information, see Download the BACKINT Plugin Installer.
- Check if the SAP HANA node has a `<SAP_HANA_system_ID>adm` user account, if not, then create an Operating System (OS) user account to own the backup files on the Cohesity view. The format of the user account must be `<SAP_HANA_system_ID>adm`.
- Use "bash" shell to install the BACKINT plugin and to run backups and restore workflows of SAP HANA databases.
- Create SAP HANA HDBUSERSTORE key to connect to the SYSTEM DB. You can create the key using the `hdbuserstore` command. For detailed instructions, see hdbuserstore Commands in SAP HANA documentation.
- By default, SAP HANA uses BACKINT protocol version 1.5 on the IBM PowerPC Platform, starting from SAP HANA 2.0 SPS 05. However, if you have an earlier version of SAP HANA databases, you can enable it to use BACKINT protocol version 1.5 by configuring the `global.ini` file with the following command:

```
hdbsql -AU <USER_STORE_KEY> "alter system alter configuration
('global.ini', 'SYSTEM') set ('backup', 'backint_protocol_version') =
'1.5' with reconfigure"
```

> **Note:** Ensure that the Cohesity BACKINT plugin and SAP HANA use the same BACKINT protocol version in your deployment. You can specify the BACKINT protocol version that the Cohesity BACKINT plugin uses using the Cohesity Parameter File.

Download the BACKINT Plugin Installer

Cohesity provides a BACKINT plugin installer to backup and restore SAP HANA databases. The BACKINT plugin is available as script-based and RPM-based installers on the Cohesity Download portal. Log on to the Cohesity Download portal, download the respective BACKINT plugin installer, and copy the installer to the SAP HANA host.

Install the BACKINT Plugin Using Script Based Installer

Cohesity BACKINT plugin is an SAP HANA-BRINT 1.1 certified service that enables you to establish communication between the Cohesity cluster and the SAP HANA nodes.

The BACKINT plugin can be installed only using `<sid>adm` user.

> **Note:** For multi-node SAP HANA deployments, ensure that you install the Cohesity BACKINT plugin on the shared NFS path where all the SAP HANA nodes have access or install the plugin on all the nodes of the SAP HANA deployment as an SAP HANA admin user.

On the SAP HANA node, perform the following to install the BACKINT plugin:

1. Log on to the SAP HANA node's bash CLI.
2. Make the BACKINT plugin installer (`cohesity_secure_connector_service_hana_<version>_sap_hana_java_installer`) executable using the following command:

   ```
   SAP_HANA_SERVER:/home/adminse # chmod +x cohesity_secure_connector_service_hana_<version>_sap_hana_java_installer
   ```

3. Ensure that the `/opt` folder in the `/usr/sap/<SID>/SYS/global/hdb/` directory, if not create the `/opt` folder as follows:

   ```
   SAP_HANA_SERVER:/usr/sap/COH/SYS/global/hdb # mkdir opt
   ```

   > **Note:** During the BACKINT plugin installation, by default, the script installer extracts the files to the `/tmp` directory. If you plan to extract the files to a different directory, you can define the directory path in the `TMPDIR` environment variable as follows: `export TMPDIR=<directory_path>`.

4. Run the following command to install the BACKINT plugin:

   ```
   ./cohesity_secure_connector_service_<version>_sap_hana_java_installer -- --install=<backint install directory> --sid=<SID> --systemdb-key=<systemdb_key> --workflow=<workflow>
   ```

   > **Note:** You can view the details of BACKINT plugin installer options using the `--help` option. For example: `./cohesity_secure_connector_service_sap_hana_installer --help`After the BACKINT plugin is installed, the BACKINT plugin agent is available at: `<backint_install_directory>/cohesity_backint_plugin/uda_scripts`

   Where:

Options	Mandatory?	Description
`--install-dir`	No	The directory on the SAP HANA node on which you want to install the BACKINT plugin. **Note:** If `--install-dir` is not specified, the BACKINT plugin is installed in the `/usr/sap/${SAPSYSTEMNAME}/home` directory.
`--systemdb-key`	NO	The SAP HANA HDBUSERSTORE key to connect to the SYSTEM DB. • Use the option `--systemdb-key-k <user_store_key>` only if you want to edit the global.ini file and create a symbolic link from `HDBBACKINT` to the BACKINT plugin. • If you plan to backup your SAP HANA databases using the BACKINT plugin, ensure that you use the option `--systemdb-key <user_store_key>`. • If you have not used the option `--systemdb-key <user_store_key>` while installing the BACKINT plugin, specify the option `--systemdb-key <user_store_key>` while upgrading the BACKINT plugin.
`--cluster-port`	No	The ports in the firewall to allow the Cohesity cluster to transmit and receive data. The supported values are 11111 or 11113. By default the port is set as `11117`.
`--workflow`	No	The type of workflow you intend to install the BACKINT plugin. The supported values are `uda` or `ra`. The `uda` value is for Universal Data Adapter workflow and `ra` is for Remote Adapter workflow.
`--multi-tenancy`	No	The type of deployment. The supported values are `vlan` or `hyx`. Specify `vlan` for 'VLAN' and `hyx` for 'Single Homed NAT' deployments.

Options	Mandatory?	Description
`--standby`	No	Specify if you are installing the BACKINT plugin on a standby node.
`--hana-version`	No	The SAP HANA version. Supported values are 1 or 2. By default, the value is set to 1.
`--debug`	No	Option to enable installer debug.
`--catalog-view`	No	The name of the catalog view where the backup metadata resides. **Note:** The catalog view name should not include the view path or cluster name or IP address.

Install the BACKINT Plugin Using RPM Based Installer

Before you install the BACKINT plugin Using RPM-based installer, ensure that you configure the following environment variables on the SAP HANA machine:

Environment Variable	Description	Mandatory?	Command
`SID`	The <SID>adm user account that must own the backup files on the Cohesity view. If you have not created the user account, then create an Operating System (OS) user account in the following format: <SID>adm. Where <SID> is a unique three-character code called SAP System Identification (SID). It is available for every R/3 installation (SAP system) that consists of a database server and several application servers.	Yes	`export SID=<VALUE>`
`SYSTEMDB_KEY`	The SAP HANA HDBUSERSTORE key to connect to the SYSTEM DB.	No	`export SYSTEMDB_KEY=<HDBUSERSTORE key>`

Environment Variable	Description	Mandatory?	Command
CLUSTER_PORT	The ports in the firewall to allow the Cohesity cluster to transmit and receive data. The supported values are 11111 or 11113. By default the port is set as 11117.	No	export CLUSTER_PORT=<Port_number>
WORKFLOW	The type of workflow you intend to install the BACKINT plugin. The supported values are uda or ra. The uda value is for Universal Data Adapter workflow and ra is for Remote Adapter workflow. Default is uda.	No	export WORKFLOW=ra
MULTI_TENANCY	The type of deployment. The supported values are vlan or hyx. Specify vlan for 'VLAN' and hyx for 'Single Homed NAT' deployments.	No	export MULTI_TENANCY=<VALUE>
STANDBY	Specify if you are installing the BACKINT plugin on a standby node. Supported values are 1 or 0.	No	export STANDBY=<VALUE>
HANA_VERSION	The SAP HANA version. Supported values are 1 or 2.	No	export HANA_VERSION=<VALUE>
DEBUG	Option to enable installer debug. Supported values are 1 or 0.	No	export DEBUG=<VALUE>
CATALOG_VIEW	The name of the catalog view where the backup metadata resides. **Note:** The catalog view name should not include the view path or cluster name or IP address.	No	export CATALOG_VIEW=<VALUE>

To install the BACKINT plugin using rpm-based installer:

1. Log on to the SAP HANA node's bash CLI using <SID>adm user.
2. Make the BACKINT plugin installer (`cohesity-hana-java-backint-<version>.noarch.rpm`) executable using the following command:

```
> chmod +x cohesity-hana-java-backint-<version>.noarch.rpm
```

3. Install the BACKINT plugin using the following command:

```
> sudo -E rpm -ivh cohesity-hana-java-backint-<version>.noarch.rpm
```

Update the Cohesity Parameter File

As part of the Cohesity BACKINT plugin installation, Cohesity provides a parameter file (`cohesity_param_file`) that enables SAP HANA to use BACKINT plugin for a backup job.

The parameter file is available in the <`backint_install_directory`>. Edit the parameter file and enter the values for the following parameters:

Parameter	Description
`cluster_ips`	List of IP addresses of the Cohesity Cluster. **Note:** Ensure that you provide only the virtual IP addresses.
`cluster_port`	The port number of the Cohesity cluster nodes that the plugin uses to establish communication between SAP HANA and the Cohesity cluster. The default port number is 11113 (gRPC). **Note:** You can also use the 11111 (SunRPC) port to establish communication between SAP HANA and the Cohesity cluster. Ensure that you open the 11111 (SunRPC) port on the Cohesity cluster.
`view_name`	The name of the Cohesity view used to store the backup data. **Note:** Ensure that the Cohesity view name does not contain the path of the Cohesity view or Cluster Name or IP address.
`sap_nfs_mount_path`	The NFS mount path.
`sap_nfs_mount_options`	The NFS mount options.
`sap_max_read_write_retries`	The Maximum number of retries during reads or writes.
`sap_max_io_size_in_bytes`	Maximum size of each IO in bytes. The range is 1048576-4194304 bytes and the recommended value is 4194304 bytes.

`sap_max_data_queue_size`	Maximum number of IO cached or prefetched. The range is 1-128 and the recommended value is 64.
`sap_max_num_inflight_io`	Maximum number of inflight reads or writes at a given time. The range is 1-128.
`sap_max_io_asynchronous_callback_concurrency`	Maximum number of asynchronous callback threads for NFS read-write.
`sap_max_backup_streams`	The number of pipes that are backed up in parallel at any given time by BACKINT plugin during the backup process. It is recommended that you provide the number of IP addresses of the Cohesity Cluster that you define in the `cluster_ips` parameter.
`sap_max_restore_streams`	The number of pipes that are restored in parallel at any given time by BACKINT plugin during the restore process. It is recommended that you provide the number of IP addresses of the Cohesity Cluster that you define in the `cluster_ips` parameter.
`sap_max_metafiles_read_concurrency`	Tune the metadata read performance for inquiry and restore. The default value is 4.
`sap_max_inquire_period_days`	The number of days for which the inquire information is returned. The default value is 180 days.
`backint_log_dir`	Location on the SAP nodes where the BACKINT plugin creates the debug logs.
`java_log_level`	The java log level. The supported values are: • all • trace • debug • info • warn • error • fatal
`service_type`	The type of service. The supported values are NFS and RPC.

`backint_ protocol_ version`	The BACKINT protocol version that you want the BACKINT plugin to use. The BACKINT protocol version 1.5 is supported by default from SAP HANA 2.0 SPS 05 or later versions on the IBM PowerPC Platform. By default, the BACKINT plugin supports BACKINT protocol version 1.0. The supported values are 1.0 and 1.5.

Schedule and Run an SAP HANA Backup Job

Using external applications like, SAP HANA Cockpit, SAP HANA Studio or using native SQL, schedule and run the backup job.

Uninstall the BACKINT Plugin

To uninstall the BACKINT plugin using the root user account, use the following command:

Using the Script installer:

```
./cohesity_secure_connector_service_<version>_sap_hana_java_installer -- --
uninstall --install-dir=<backint_install_directory> --workflow=<workflow>
```

Using the RPM installer:

```
> sudo -E rpm -evh cohesity-hana-java-backint-<version>.noarch.rpm
```

Upgrade the BACKINT Plugin

To upgrade the BACKINT plugin, run the following command on all SAP HANA nodes.

Using the Script installer:

```
./cohesity_secure_connector_service_<version>_sap_hana_java_installer -- --
upgrade --install-dir=<backint_install_directory> --workflow=<workflow>
```

Using the RPM installer:

```
sudo -E rpm -Uvh cohesity-hana-java-backint-<version>.noarch.rpm
```

Create a Remote Adapter Job for SAP HANA Database

You can create backup jobs and purge jobs for SAP HANA databases using the Remote Adapters on Cohesity cluster.

To Create a Protection Group for SAP HANA Database

1. Run the following command on the SAP HANA node's bash CLI as an SAP HANA admin user.

   For example, if the SID is `DEV` and the secure connector service installation location is `/usr/sap/DEV/home/install`.

   ```
   /usr/sap/DEV/home/install/backup_job.sh
   ```

2. Navigate to **Data Protection > Protection** and do one of the following:

- To create a Protection Group—Click **Protect** on the top-right of the page and then select the type of Protection Group.
- To edit a Protection Group—Click the action icon (⋮) next to the Protection Group and select **Edit**.

Here the *Job Type* is **Remote Adapter**.

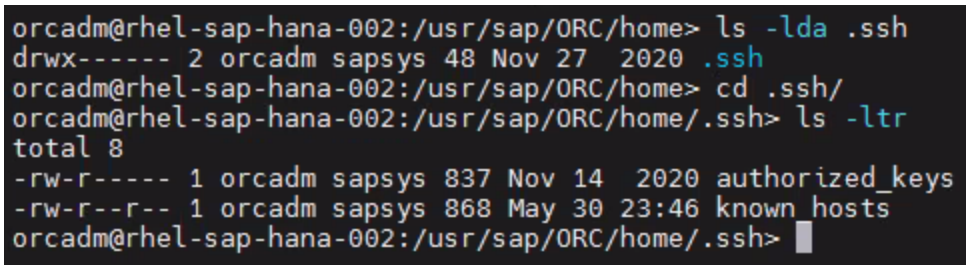
3. **Name:** Enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.
4. **Linux Hostname or IP:** Specify the Hostname or the IP Address of the Linux system where the scripts are located and will be run.
5. **Username:** Specify the username on the Linux system that will be running the scripts.
6. **Cluster SSH Public Key:** Set up permissions on the Linux system to allow the Cohesity cluster to run the scripts remotely on the system.
   a. Click **Copy Key to Clipboard** to copy the SSH public key into the clipboard.
   b. Log in to the Linux system with the username specified earlier.
   c. In the home directory of the user, determine if there is a `.ssh` directory that contains a file called `authorized_keys`:

      ```
      ls -lr ~/.ssh
      ```

   d. Add the SSH key to the `authorized_keys` file located in the `~/.ssh` directory of the specified User:
      - If the directory and file do not exist, create the `.ssh` directory in the home directory, change directories into the `.ssh` directory, create the `authorized_keys` file and paste the SSH key into a new line of the file.
      - If the `.ssh` directory exists but the file does not, change directories into the `.ssh` directory, create the `authorized_keys` file and paste the SSH key into a new line of the file.
      - If the `authorized_keys` file exists in the `.ssh` directory, edit the `authorized_keys` file and paste the SSH key into a new line of the file.
   e. Set the `.ssh` directory and `authorized_keys` file permissions:

      ```
      chmod 700 .ssh
      chmod 640 .ssh/authorized_keys
      ```

      For example:



7. **Policy:** Select an existing protection policy or create a new one by selecting **New Policy**.
8. **Script (with Full Path):** Enter the full path to the script, for example: `/usr/sap/DEV/home/install/backup_job.sh`.
9. **Parameters:** If the script requires parameters, enter them in this field.

   For example: `--backup-delta=INCREMENTAL --user-store-key=SYSTEMDB --tenant-database-names=BHE,BWE --mode=1`

   > **Note:**
   > You can define the values for the **backup_job.sh** script parameters either using the long or short options. Ensure that:
   >
   > - If you are using the long options, you need to define the value for the parameter using the "=" character. For example, `--tenant-database-names=BHE`.
   > - If you are using the short options, you need to define the value for the parameter using a single whitespace. For example, `-t BHE`.

Parameter	Mandatory?	Description
`-t, --tenant-database-names`	Yes	Specify a comma-separated list of tenant database names that need to be backed up. The default value is `SYSTEM DB`. **Note:** Do not include space between the tenant database names. For example: `--tenant-database-names=ORC,PRD,QTY` or `-t ORC,PRD,QTY`.

Parameter	Mandatory?	Description
`-b, --backup-delta`	No	Specify the backup type. Allowed values are `INCREMENTAL` or `DIFFERENTIAL`. The default value is `COMPLETE`. **Note:** If you have not specified the backup type in the parameter, then a full backup (`COMPLETE`) is performed.
`-k, --user-store-key`	Yes	The user store key to connect to the `SYSTEM DB`.

Parameter	Mandatory?	Description
`-m, --mode [0|1]`	No	The backup order of the databases: • If `--mode=1`, then the backup is performed in the order of `SYSTEM DB`, all tenant databases, and `SYSTEM DB` as per SAP standard backup. • If `--mode=0`, then the backup is performed only for the provided tenant databases. Allowed values are 0 or 1. The default value is 0.

Parameter	Mandatory?	Description
`-l, --backup-log-file [file]`	No	Define the path and filename of the log file to store the backup script logs. By default, the log filename is set as: `/tmp/cohesity_hana_backup_logs/cohesity_hana_backup_<time_in_seconds>_<pid>.log`
`-d, --debug`	No	Allows you to enable shell script debugging. By default, shell script debugging is disabled.
`-e, --enable-safepurge`	No	Enable to delete the failed backups or the backups not present in the catalog from the View. By default, the option is disabled

Parameter	Mandatory?	Description
`-r, --retention-days`	No	You can use the same Protection Group to run both the backup Remote Adapter job (`backup_job.sh`) and the purge Remote Adapter job (`purge_job.sh`). To run the purge job, you need to specify the number of days for the data to be purged from the catalog. This means that any data that is older than the specified number of days will be removed from the catalog. **Note:** It is recommended to use separate Protection Groups to run the backup Remote Adapter job (`backup_job.sh`) and the purge Remote Adapter job (`purge_job.sh`)

Storage Domain: Select an existing storage domain or create a new one by selecting **New Storage Domain**.

> **Note:** Once you create a Protection Group, you cannot change the Storage Domain you selected for that job.

The selected Storage Domain will contain the new View where the script results are stored.

10. **NFS View:** Select an existing View create a new one by selecting **Add View**. For more information, see Create Views Using a Predefined Template. The View will contain the script results.
11. **NFS Mount Path:** Click **Copy NFS Path to Clipboard** for use later when you mount the View on the Linux system.
12. **Start Time:** Indicates when the Protection Group should run. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting.

    The default time zone is the browser's time zone. You can change the time zone by selecting a different time zone.
13. **End Date:** Optional. Toggle on and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
14. **QoS Policy:** Select an appropriate quality of service (QoS) policy.

    > **Note:** Cohesity recommends specifying **Backup HDD**, which is the default.

    - **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group.
    - **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups.
    - **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy.
    - **TestAndDev High:** The Cohesity cluster writes the data to an SSD drive for this Protection Group. The I/Os with this QoS policy are given higher priority compared to other QoS policies. Use this policy for workloads that require lower I/O latency.
15. **Alerts:** Optional. Select one or more of the following settings if you want alerts to be created for the following triggers:

- **Success:** Create an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created.
- **Failure:** Create a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created.
- **SLA Violation:** Create a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created.

For more information, see Alerts.

16. **Priority:** Select a priority for the Protection Group execution. Cohesity supports concurrent backups, but if the number of Protection Groups exceeds the ability to process them, those with **High** priority are given the highest priority to execute, **Medium** the second-highest priority, and **Low** the lowest priority.
17. **Email Recipients**: You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the Protection Group.

> **Note:**
> The connection to the SMTP Server must be enabled to send email notification. You can enable the SMTP Server connection in the configuration settings page (Cohesity UI > **Settings** > **Summary** > **Configure** > **Enable SMTP Server**).

18. **SLA:** The service-level agreement (SLA) defines the expected time to complete either a full backup or incremental backup. The backup completion time depends on the Windows volume size on AD, objects changed between incremental backups, network speed, and other Protection Groups running on the Cohesity cluster.
    - **Incremental:** Enter the number of minutes you expect an incremental protection run to complete. An incremental backup captures only the differences (changed blocks) since the last protection run.
    - **Full:** Enter the number of minutes you expect a full backup protection run to complete. A full backup captures the entire object (all blocks).
19. Click **Protect**.

    The Protection page is displayed and includes the new Protection Group.

To Create a Purge Job for SAP HANA Database

The purge Remote Adapter job removes the expired backups (decided by the retention period) from the Cohesity view. The full backup is independent, and the incremental, log, and differential backups depend on the full backup. Hence, we retain the last successful full backup on or before the retention period.

For example, suppose the purge Remote Adapter job is triggered on November 26th, and the retention period is configured as 14 days. In that case, the last successful full backup on

or before November 12th is retained, and any backups older than the last successful full backups are deleted.

1. Run the following command on the SAP HANA node's bash CLI as an SAP HANA admin user.

   ID is `DEV` and secure connector service installation location is `/usr/sap/DEV/home/install`.

   ```
   /usr/sap/DEV/home/install/purge_job.sh
   ```

2. The steps for creating a purge job is similar to creating a backup job for the SAP HANA database. Follow the same steps listed in the Create a Remote Adapter Job for SAP HANA Database section.

However, you must note the following:

- For **Script (with Full Path):** Enter the full path to the script.

  ```
  /usr/sap/DEV/home/install/purge_job.sh
  ```

- For **Parameters:**, enter the following parameters.

  > **Note:**
  > You can define the values for the **purge_job.sh** script parameters either using the long or short options. Ensure that:
  >
  > - If you are using the long options, you need to define the value for the parameter using the `"="` character. For example, `--tenant-database-names=BHE`.
  > - If you are using the short options, you need to define the value for the parameter using a single whitespace. For example, `-t BHE`.

Parameter	Mandatory?	Description
`-t, --tenant-database-names`	Yes	The names of the tenant database for which backups are purged. **Note:** Ensure that you add all the tenant DBs for the SID in a comma separated list, for example, `./purge_job.sh -r 7 -t AOV,H0V,S0V,COCKPITDB -k COHESITY -e`
`-k, --user-store-key`	Yes	The user store key to connect to the `SYSTEM DB`.

Parameter	Mandatory?	Description
`-l, --purge-log-file [file]`	No	Define the log file's path and filename to store the purge script logs. By default, the log filename is set as: `/tmp/cohesity_hana_purge_logs/cohesity_hana_purge_<time_in_seconds>_<pid>.log`
`-d, --debug`	No	Allows you to enable shell script debugging. The default value is `off`.
`-y, --yes-all`	No	Enables you to answer '`yes`' to all the questions in the purge script. The default value is `off`.
`-r, --retention-days`	No	Define to purge any data from the catalog older than the number (#) of days passed.
`-e, --enable-safe-purge`	No	Enable to delete the failed backups or the backups not present in the catalog from the Cohesity View. By default, the option is disabled.

SAP HANA Certificate Authentication

The SAP HANA Certification provides the necessary authentication and also verifies whether the SAP HANA database, which performs backups to the Cohesity cluster, is a trusted entity. This certification provides the capability to set verification which allows only trusted sources to write to the Cohesity cluster through the SpanFS.

Create an SAP HANA Authentication Certificate

This section lists the steps for creating an SAP HANA authentication certificate.

1. Start the Cohesity CLI locally and log in to the Cohesity cluster using the ssh command with the `support` user account and specify the IP address. For more information, see Using the Cohesity CLI and List of Cohesity CLI Commands.

   ```
   ssh support@198.51.100.12
   ```

2. If prompted, enter the password.

   ```
   [support@198.51.100.12's password:
   ```

   The cohesity_shell prompt is displayed.

3. Log in to the CLI:

   ```
   cohesity shell# iris_cli
   ```

   The admin prompt is displayed.

4. Optionally, run the help command for a list of CLI commands.

```
admin@198.51.100.12> help
```

5. Run the cluster gen-src-cert command to generate a new SAP HANA certificate.

```
admin@198.51.100.12 cluster gen-src-cert cert-name="newdemocert" cert-
validity=100 host-name="10.2.146.175" host-target="/tmp"
Success: Certificate "newdemocert" generation and deployment
successful.
```

Parameter Name	Description
cert-name	Name of the certificate file. Its naming format is ${cert-name}_<random_number>.cfg.
cert-validity	The validity of the source certificate generated. The time is displayed in days.
host-name	The IP address/host name of the target system where you want to move the certificate. This is a mandatory parameter because the certificate generation process needs details of the host machine to generate public and private keys.
host-target	The file directory path on the Cohesity cluster where the certificate is generated.

> **Note:** After the SAP HANA certificate is generated on the Cohesity cluster, manually copy the certificate to your SAP HANA machine.

6. Update the following parameters in the parameter file.

Parameter Name	Description
cluster_port	Port number on Cohesity cluster nodes to which the BACKINT executable connects. Use the port 11117 for secure connection (certificate config path should be a valid path). Use the port 11111 for an insecure connection (certificate config path should be an empty string). Contact Cohesity Support to enable these ports.
certificate_ config_path	The path to which the certificate is generated and deployed from the Cohesity Dashboard to the SAP HANA Node. You can use this path as the default config path: `/usr/sap/ORC/home/install/newdemocert.cfg`

7. Run the `list-source-certificates` command to check all the global certificates deployed from the cluster.

Deploy an SAP HANA Certificate in a Multi-node Setup

This section lists the steps to deploy an SAP HANA authentication certificate in a multi-node SAP HANA setup.

1. Generate and deploy the SAP HANA authentication certificate to any one of the nodes in a multi-node SAP HANA system using the instructions provided in the previous section.
2. Use SCP to securely transfer the certificate to a target location on all the remaining (N-1) nodes.

   ```
   scp <certificate_config_path> ip_address:<certificate_config_path>
   ```

   Example

   ```
   scp /usr/sap/ORC/home/install/cert.cfg 10.2.146.72:
   /usr/sap/ORC/home/install/cert.cfg
   ```

3. Change the `cluster_port parameter` value to 11117 and update the `certificate_config_path` parameter value to the correct path of the certificate in the respective paramfile of each of the N nodes.

Source-Side Deduplication for SAP HANA

The Cohesity source-side deduplication provides storage efficient deduplication that enhances your SAP HANA environment with faster backups and reduced network traffic between SAP HANA and Cohesity cluster.

Enabling this functionality shifts the deduplication processes to the SAP HANA node and reduces the CPU consumption on the Cohesity cluster thus allowing further scaling to support more workloads. Additionally, source-side deduplication plugin integrates with Cohesity's built-in deduplication and minimizes data traffic by moving only the new data blocks.

Advantages of the source-side deduplication plugin:

- Faster backups.
- Reduces network traffic between SAP HANA nodes and Cohesity cluster.
- Enables more frequent backups resulting in higher RPOs.
- Offloading deduplication reduces the CPU consumption and enables the Cohesity cluster to run more backup workload sessions.

You can enable source-side deduplication during a backup or recovery process.

To enable source-side deduplication during backup:

Edit the `cohesity_param_file` located at `<backint_install_directory>`. Set the `enable_dedup_write` parameter to `true`.

> **Note:** By default, source-side deduplication is disabled during the backup process.

Alternate Restore of SAP HANA Database

Using the SAP HANA Studio, you can perform an alternate restore of the SAP HANA database backed up on the Cohesity cluster using the Cohesity BACKINT Secure Connector Service. For example, you can restore the SAP HANA database to a new or active database on the same or different SAP HANA system.

Restore to a New or Active Database on the Same SAP HANA System

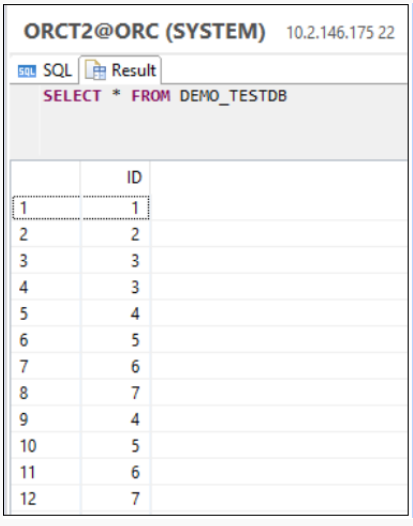
You can restore the SAP HANA database backed up on the Cohesity cluster to a new or active database on the same SAP HANA system.

Prerequisites

Before you restore the SAP HANA database, ensure that:

- You back up the database using either the SAP HANA Studio, hdbsql, or the Cohesity Remote Adapter. For instructions to back up the database using the Cohesity Remote Adapter, see Create a Remote Adapter Job for SAP HANA Database.

> **Note:** In this topic, for ease of understanding, the database and the table backed up in the Cohesity cluster are referred to as `ORCT2` and `DEMO_TEXTDB`, respectively.



- If you plan to restore the database to a new database, create a new database, for example, `ORCT3`.

  Sample Command:

```
hdbsql SYSTEMDB=> create database ORCT3 system user password
Fr8shst8rt;
0 rows affected (overall time 80.351254 sec; server time 80.347960 sec)
```

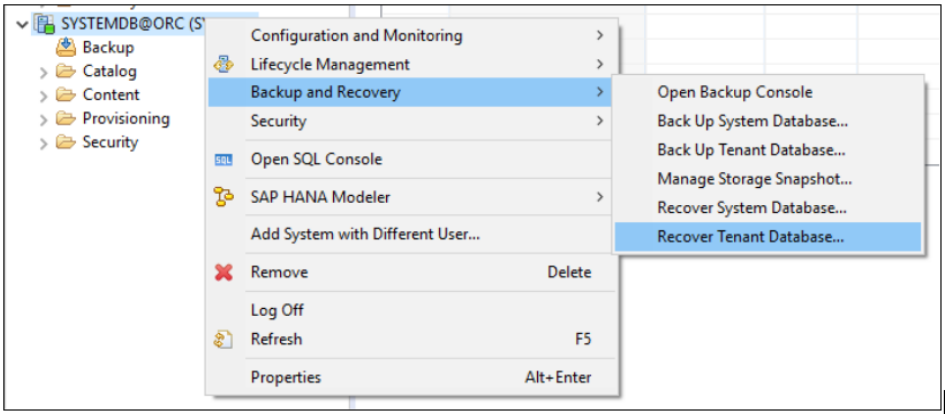
To restore the database to a new or active database on the same SAP HANA system:

1. Log on to the SAP HANA system..
2. Verify the status of the source and target databases (for example, `ORCT3`) using the following command:

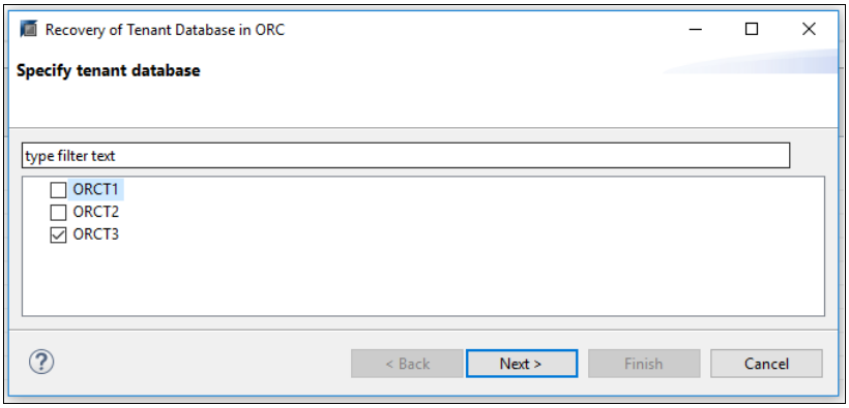
   > **Note:** The target database can be a new or active database based on your requirement.

```
hdbsql SYSTEMDB=> select * from "SYS"."M_DATABASES";
| DATABASE | DESCRIPTION     | ACT | ACTIVE_S | OS_USER  | OS_GROUP |
RESTART | F |
| -------- | --------------- | --- | -------- | -------- | -------- | -
------ | - |
| SYSTEMDB | SystemDB-ORC-22 | YES |          |          |          |
DEFAULT | ? |
| ORCT1    | ORC-22          | YES |          |          |          |
DEFAULT | ? |
| ORCT2    |                 | YES |          |          |          |
DEFAULT | ? |
| ORCT3    |                 | YES |          |          |          |
DEFAULT | ? |
```

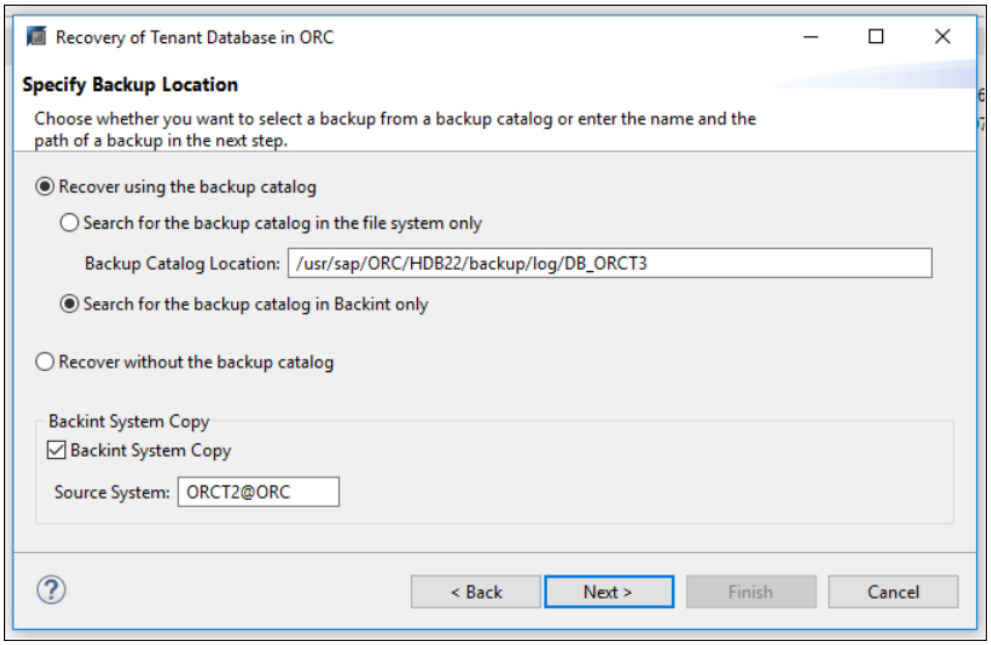
   Ensure that the target database shows the **ACTIVE** status as **Yes**.
3. Log on to the SAP HANA Studio.
4. Right-click on the source database (`SYSTEMDB@ORC (SYSTEM)`), select **Backup and Recovery** > **Recover Tenant Database**.



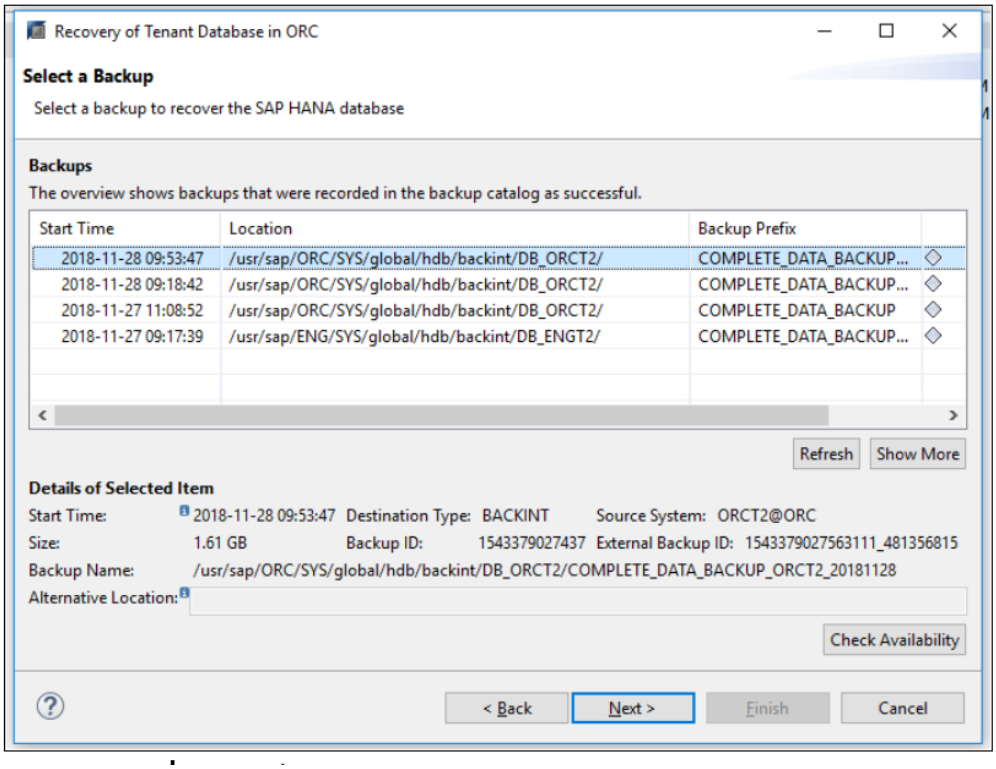
5. Select the target database (for example, `ORCT3`) on the **Specify tenant database** window and click **Next**.



6. Select **Recover the database to a specific data backup** and click **Next** on the **Specify Recovery Type** window.
7. On the **Specify Backup Location** window, select the **Backint System Copy** checkbox, and in the **Source System** field, enter the source database name and the SAP HANA SID in the `DBNAME@SID` format (for example, `ORCT2@ORC`). Then, click **Next**.

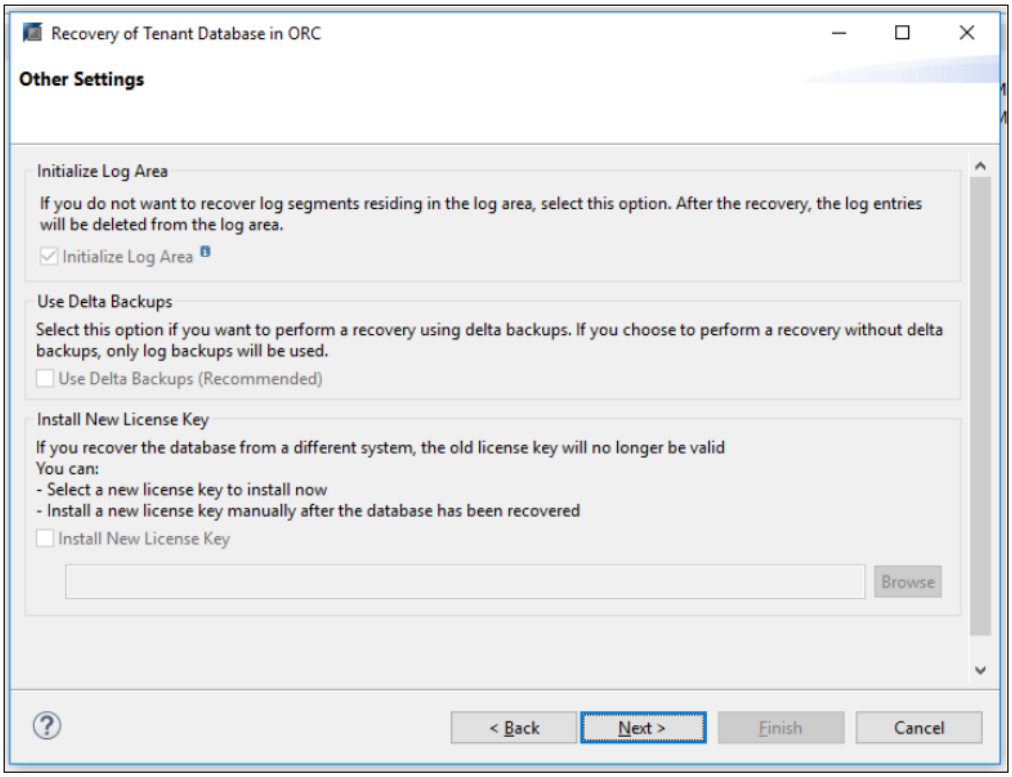


8. On the **Select a Backup** window, select a backup from the backup catalog list that you want to recover to the SAP HANA database and click **Check Availablity**.

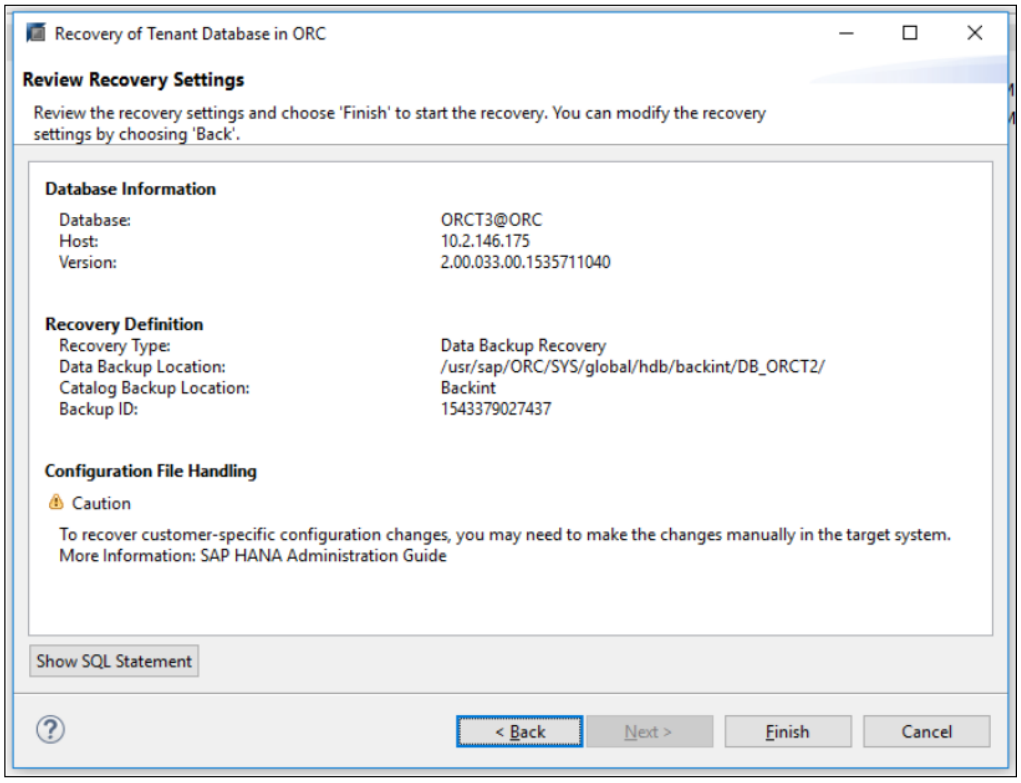


Once the selected backup is **Available**, click **Next**.

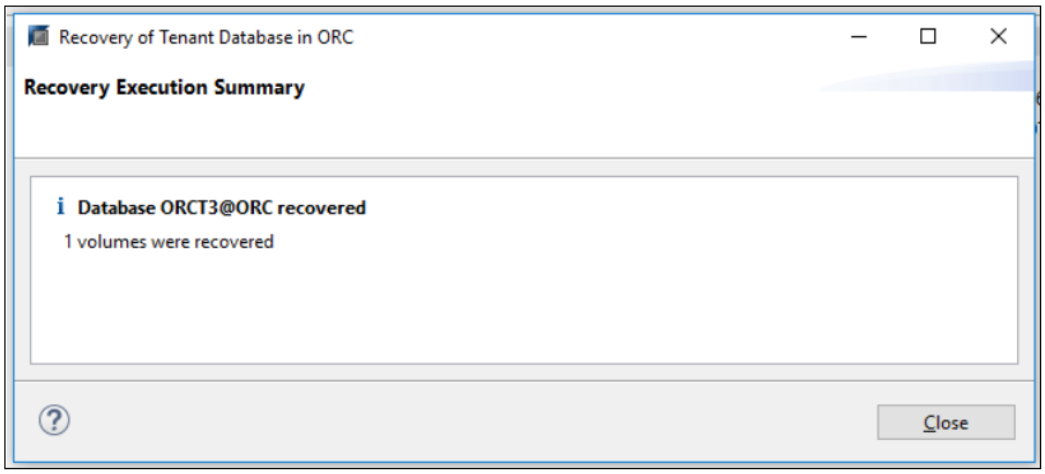
9. On the **Other Settings** window, select the required options based on your requirements and click **Next**.



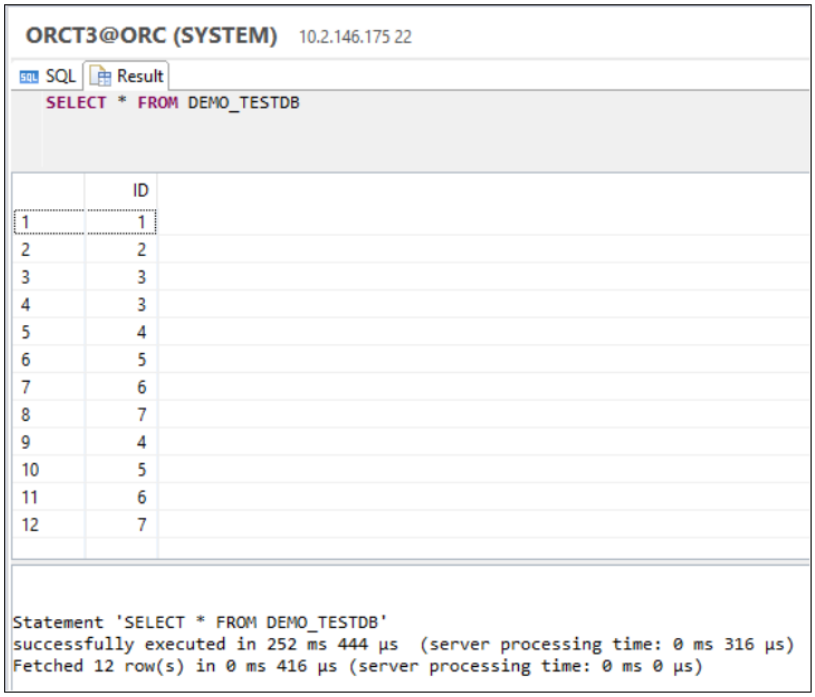
10. On the **Review Recovery Settings** window, review the recovery settings and click **Finish** to start the recovery.



11. On the **Recovery Progress Information** window, verify the recovery progress and click **close** the recovery is completed.



The data is recovered on the target database as shown below:



Restore to a New or Active Database on a Different SAP HANA System

You can restore the SAP HANA database backed up on the Cohesity cluster to a new or active database on a different SAP HANA system.

Prerequisites

Before you restore the SAP HANA database, ensure that:

- Install the Cohesity BACKINT Secure Connector service on the target SAP HANA server. For more information, see Install the Cohesity BACKINT plugin.
- From the Cohesity UI, add the IP address of the target SAP HANA node to the custom allowlist of your Cohesity view configuration. For more information, see Create a Cohesity View with IP Allowlist for SAP HANA node.
- If you regularly perform scheduled SAP HANA backups using Cohesity Remote Adapter then perform a backup now or use a recent backup for restore. For more information, see Create a Remote Adapter Job for SAP HANA Database. Otherwise you can use SAP HANA Studio, SAP HANA Cockpit or hdbsql to perform a backup.
- From the SAP HANA Cockpit, take a backup of the source database to the Cohesity cluster to ensure you have correctly installed the Cohesity BACKINT Secure Connector service. In this topic, for ease of understanding, the database and the table backed up on the Cohesity cluster are referred to as ENGT2 and DEMO_TESTDB, respectively.

	ID
1	11
2	12
3	13
4	14
5	15
6	1
7	2
8	3
9	4
10	5
11	21
12	22
13	23
14	24
15	25

- If you plan to restore the database to a new database, create a new database, for example, `ORCT3`.

  Sample Command:

```
hdbsql SYSTEMDB=> create database ORCT3 system user password
Fr8shst8rt;
0 rows affected (overall time 80.351254 sec; server time 80.347960 sec)
```

To restore the database to a new or active database on a different SAP HANA system:

1. Log on to the SAP HANA system.
2. Verify the status of the source and target databases (for example, `ORCT3`) using the following command:

   > **Note:** The target database can be a new or active database based on your requirement.

```
hdbsql SYSTEMDB=> select * from "SYS"."M_DATABASES";
| DATABASE | DESCRIPTION     | ACT | ACTIVE_S | OS_USER  | OS_GROUP |
RESTART | F |
| -------- | --------------- | --- | -------- | -------- | -------- | -
------ | - |
| SYSTEMDB | SystemDB-ORC-22 | YES |          |          |          |
DEFAULT | ? |
| ORCT1    | ORC-22          | YES |          |          |          |
DEFAULT | ? |
```

```
| ORCT2    |                  | YES |           |           |           |
DEFAULT | ? |
| ORCT3    |                  | YES |           |           |           |
DEFAULT | ? |
```

Ensure that the target database shows the **ACTIVE** status as **Yes**.

3. Configure the source database's parameter file in the target database (`ORCT3`). Perform the following:
   a. Copy the parameter file (`cohesity_param_file`) from the source SAP HANA system to the target SAP HANA system.
   b. Update the **global.ini** file in the target SAP HANA system. You must update the following parameter files using the mentioned commands:
      - Update the **catalog_backup_parameter_file** file. Run the following command:

        ```
        hdbsql ORCT3=> ALTER SYSTEM ALTER CONFIGURATION
        ('global.ini','SYSTEM') SET ('backup','catalog_backup_
        parameter_file') = '/usr/sap/ORC/home/install/cohesity_param_
        file_$(SAPSYSTEMNAME)' WITH RECONFIGURE;
        ```

      - Update the **data_backup_parameter_file** file. Run the following command:

        ```
        hdbsql ORCT3=> ALTER SYSTEM ALTER CONFIGURATION
        ('global.ini','SYSTEM') SET ('backup','data_backup_parameter_
        file') = '/usr/sap/ORC/home/install/cohesity_param_file_
        $(SAPSYSTEMNAME)' WITH RECONFIGURE;
        ```

      - Update the **log_backup_parameter_file** file. Run the following command:

        ```
        hdbsql ORCT3=> ALTER SYSTEM ALTER CONFIGURATION
        ('global.ini','SYSTEM') SET ('backup','log_backup_parameter_
        file') = '/usr/sap/ORC/home/install/cohesity_param_file_
        $(SAPSYSTEMNAME)' WITH RECONFIGURE;
        ```

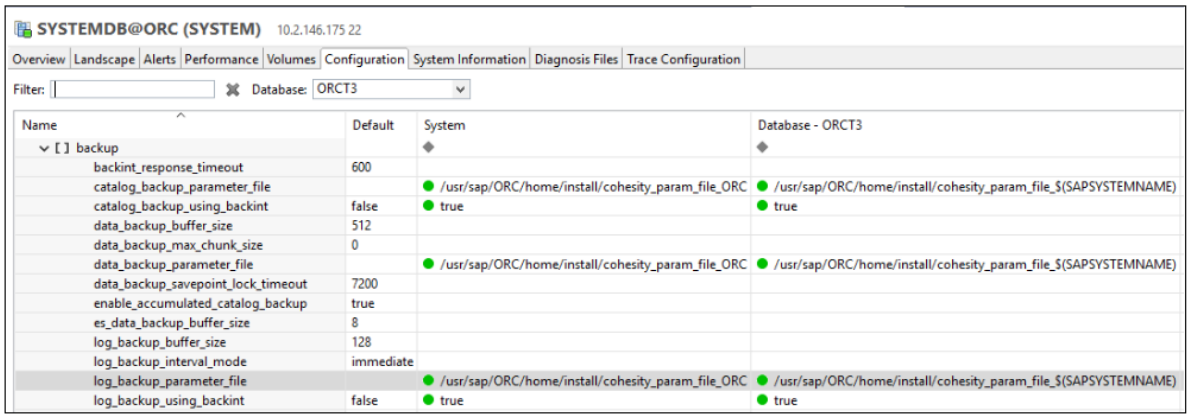
      - Update the **catalog_backup_using_backint** file. Run the following command:

        ```
        hdbsql ORCT3=> ALTER SYSTEM ALTER CONFIGURATION
        ('global.ini','SYSTEM') SET ('backup',''catalog_backup_using_
        backint') = '/usr/sap/ORC/home/install/cohesity_param_file_
        $(SAPSYSTEMNAME)' WITH RECONFIGURE;
        ```

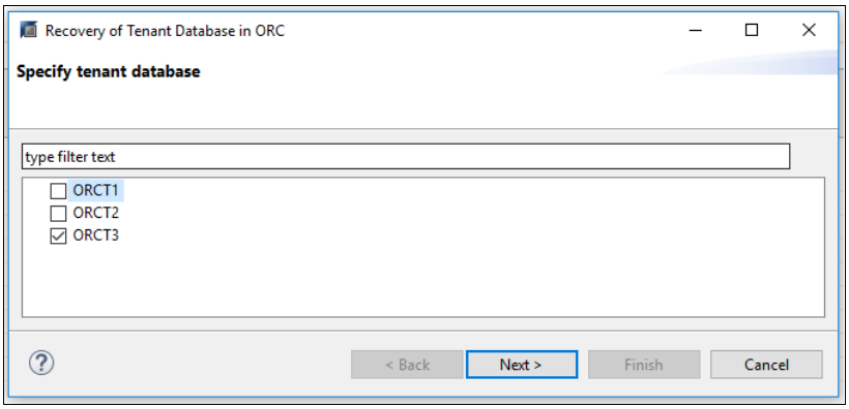
- Update the **log_backup_using_backint** file. Run the following command:

```
hdbsql ORCT3=> ALTER SYSTEM ALTER CONFIGURATION
('global.ini','SYSTEM') SET ('backup',''log_backup_using_
backint') = '/usr/sap/ORC/home/install/cohesity_param_file_
$(SAPSYSTEMNAME)' WITH RECONFIGURE;
```

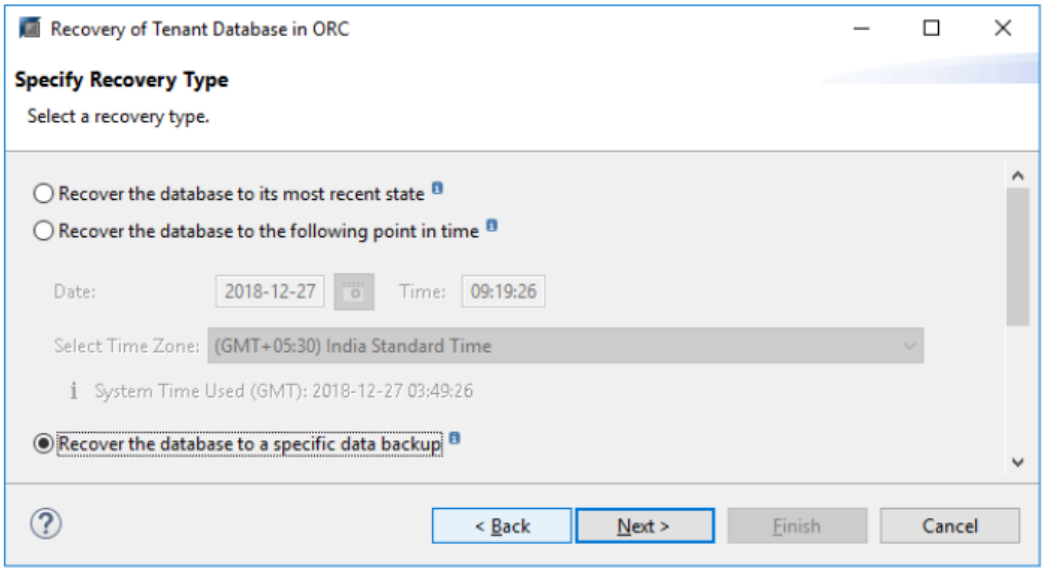
Using the SAP HANA Cockpit, verify if the default value is replaced with `usr/sap/ORC/home/install/cohesity_param_file_$(SAPSYSTEMNAME).`



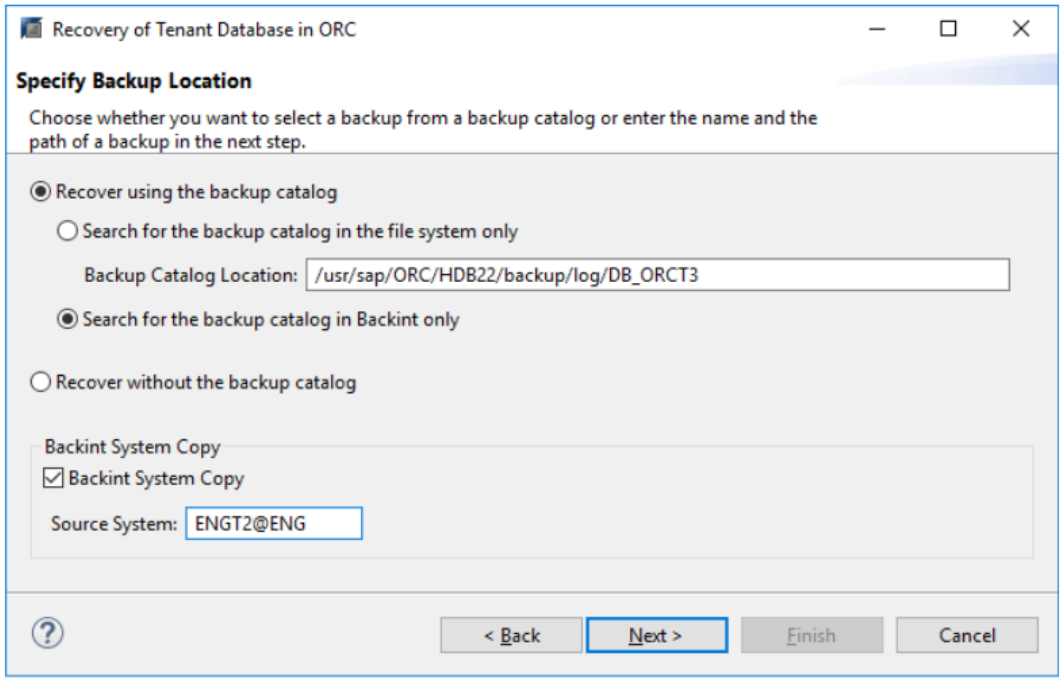
4. In SAP HANA Studio, right-click on the source database and click **Backup and Recovery** > **Recover Tenant Database**.
5. Select the target database (for example, `ORCT3`) on the **Specify tenant database** window and click **Next**.



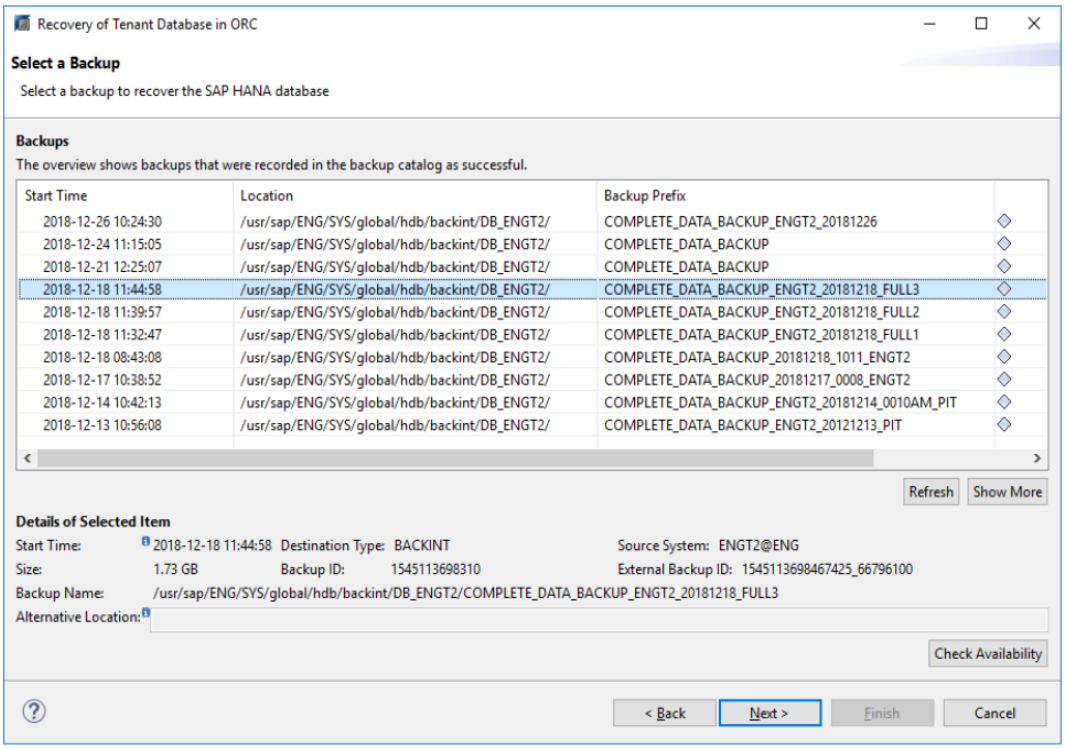
6. Select **Recover the database to a specific data backup** and click **Next** on the **Specify Recovery Type** window.



7. On the **Specify Backup Location** window, select the **Backint System Copy** checkbox and in the **Source System** field, enter the source database name and the SAP HANA SID in the `DBNAME@SID` format (for example, `ENGt2@ENG`). Then, click **Next**.

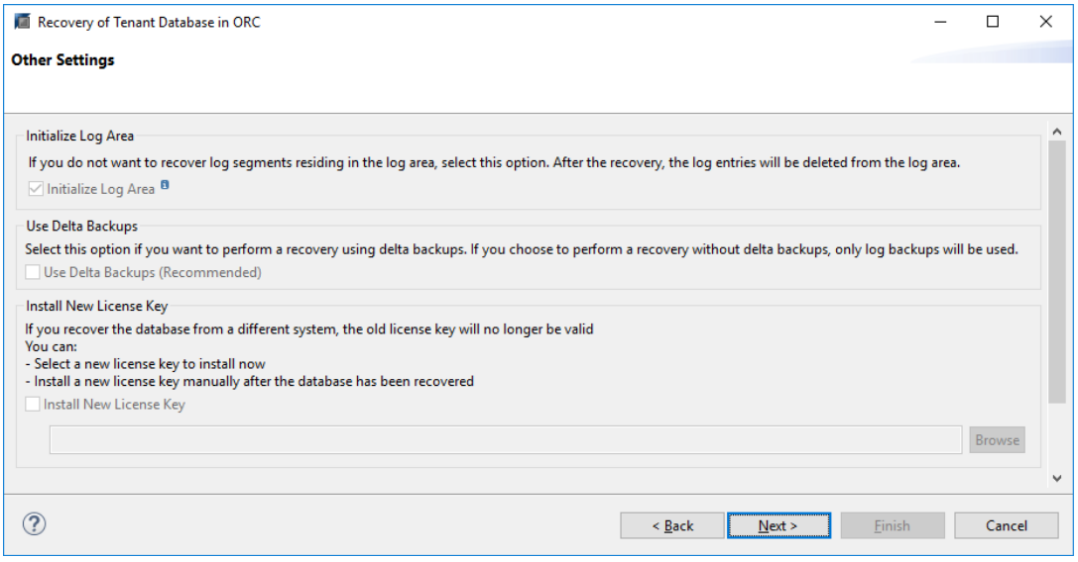


8. On the **Select a Backup** window, select a backup from the backup catalog list that you want to recover to the SAP HANA database and click **Check Availablity**.

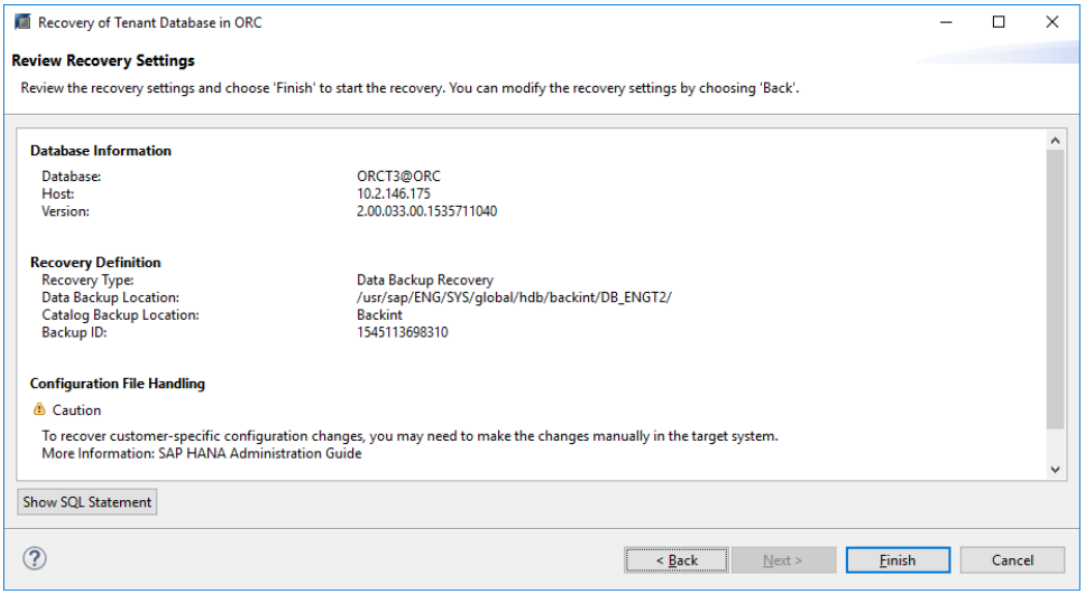


Once the selected backup is **Available**, click **Next**.

9. On the **Other Settings** window, select the required options based on your requirements and click **Next**.



10. On the **Review Recovery Settings** window, review the recovery settings and click **Finish** to start the recovery.



11. On the **Recovery Progress Information** window, verify the recovery progress and click **close** when the recovery is completed.

The data is recovered on the target database as shown below:

	ID

Replicate View and Restore SAP HANA Database

You can replicate the SAP HANA database data captured on a Cohesity cluster to a remote Cluster by performing the following tasks:

> **Note:** To restore from archival or replication, one needs to disable auto log backups.

1. From the Cohesity cluster (source) where the SAP HANA data is captured, create a connection to the receiving (target) cluster where the view will be replicated.

   For information about registering a connection to the target cluster, see Create a Connection to the Remote Cohesity Cluster.
2. From the target cluster, create a connection back to the source cluster.
3. From the source cluster, create a Remote Adapter Protection Group with replication enabled in the policy.

   For information about creating Remote Adapter job with replication enabled, see Add or Edit a Remote Adapter Protection Group.

Restore SAP HANA DB from the Replicated View

To restore the replicated data back to a SAP HANA Database, perform the following steps:

1. On the target cluster, create a clone of the replicated View. For information about cloning a View, see Clone a View.
2. Log in to the HANA database where you want to restore the replicated data. In the parameter file, replace the existing cluster IP address (source cluster IP address) with the target cluster IP address
3. Perform the restore operation. For more information about SAP HANA restore, see Alternate Restore of SAP HANA Database.

Archive View and Restore SAP HANA Database

You can archive the Snapshots of SAP HANA databases captured on a Cohesity cluster to an external target by performing the following tasks:

> **Note:** To restore from archival or replication, one needs to disable auto-log backups.

1. From the Cohesity cluster where the SAP HANA data is captured, register an external target. For more information, see Register an External Target.
2. Create a remote Adapter protection with archival enabled in the policy. For information about creating Remote Adapter job with archival enabled, see Add or Edit a Remote Adapter Protection Group.

Retrieve Archived Data to an Alternate Cohesity cluster

CloudRetrieve provides the ability to download data that was archived from a Cohesity cluster to an alternate Cohesity cluster. For more information see, About CloudRetrieve.

To retrieve the SAP HANA data from the external target to another Cohesity cluster, perform the following steps:

1. Register the external target that contains the data you want to download to the alternate Cohesity cluster.
2. Submit a search for Protection Groups that contain the data you want to download from the cloud external target. The search may take a few hours to complete. If the job to be downloaded is from a particular Cohesity cluster, specify the job name and cluster name to narrow the results.
2. If the external target's encryption key file is managed manually, upload the key file to the alternate Cohesity cluster before triggering the search. See Create a CloudRetrieve Search Task for more details.
3. Download a snapshot from any of the Protection Groups in the search results. You can also build a local index of Protection Groups that ran during a specified date range. Downloading can take a few hours to complete. See Create a CloudRetrieve Download Task for more details.
4. Recover or clone any downloaded objects using the Cohesity recovery or clone workflows. See CloudRetrieve Downloaded Protection Groups for more details.

Restore HANA DB from the Archived View

You can restore the retrieved data from the remote Cohesity cluster to the SAP HANA database by performing the following steps:

To restore the replicated data back to a SAP HANA Database, perform the following steps:

1. On the remote Cohesity cluster, create a clone of the retrieved View. For information about cloning a View, see Clone a View.
2. Login to the SAP HANA database where you want to restore the retrieved data. In the parameter file, replace the existing Cohesity cluster IP address (primary clusterCohesity cluster IP address) with the remote Cohesity cluster IP address.
3. Perform the restore operation. For more information about SAP HANA restore, see Alternate Restore of SAP HANA Database.

SAP HANA Database FAQ

1. Which SAP HANA versions are supported by Cohesity SAP HANA BACKINT plugin on 6.2 DataProtect?
   SAP HANA Platform Edition 2.0.
2. Is Cohesity SAP HANA Certified?
   Yes, Cohesity is certified on SAP HANA Platform Edition 2.0.

3. Which SAP HANA Environments are supported by the Cohesity SAP HANA BACKINT plugin on 6.2 DataProtect onwards?
   Single Tenancy and Multitenancy environments are supported.
4. Which OS version is supported with the Cohesity SAP HANA BACKINT plugin on 6.2 DataProtect onwards?
   All versions that are supported by SAP HANA Platform Edition (Intel platforms).
5. What is Cohesity SAP HANA BACKINT plugin?
   It is an SAP HANA agent installed on the SAP HANA appliance.
6. Does the Cohesity SAP HANA BACKINT plugin leverages BACKINT?
   Yes, the Cohesity SAP HANA BACKINT plugin leverages SAP HANA BACKINT to protect the SAP HANA appliance.
7. Does the Cohesity SAP HANA BACKINT plugin install requires a reboot of the SAP HANA nodes?
   No, the Cohesity SAP HANA BACKINT plugin (Cohesity SAP HANA agent) does not require a reboot of the SAP HANA nodes or restart of the SAP HANA instances.
8. Does the Cohesity SAP HANA BACKINT plugin support client-side dedupe?
   Yes, it is supported from the 6.4.1x release onwards.
9. Is the Cohesity SAP HANA BACKINT plugin leverages NFS?
   Yes. The Cohesity SAP HANA BACKINT plugin for IBM PowerPC systems leverages NFS. But, the Cohesity SAP HANA BACKINT plugin for Intel x86 based systems does not leverage the NFS protocol. It uses remote snapFS.
10. If I have a Multi-node SAP HANA system, do I need to install the Cohesity SAP HANA BACKINT plugin in all the nodes?
    Yes, this would allow the Cohesity SAP HANA BACKINT plugin to take advantage of the high availability functionality when any of the SAP HANA nodes are down to service the Cohesity SAP HANA BACKINT plugin.
11. Does the SAP HANA Studio require a restart if the `global.ini` was modified via the CLI?
    Yes. If you have modified `global.ini` for the Cohesity SAP HANA BACKINT plugin for Intel x86 based systems then the SAP HANA Studio requires a restart to apply the changes.
12. Does SAP HANA have any dependencies with Cohesity Linux or Oracle adapters?

    No, Cohesity SAP HANA BACKINT plugin is independent of the Linux file/block or Oracle adapters. SAP HANA BACKINT plugin does not need the Cohesity Linux agent service to be installed for SAP HANA protection. However, both the SAP HANA BACKINT plugin and the Linux agent can coexist together for their respective functionalities.
13. Do we need to create a folder, or use the SAP HANA View created for the Remote adaptor job?

No. Do not manually create any folders inside the View dedicated to the Remote adaptor job, as the Purge script will fail if any folders or files are created manually within the SAP HANA View.

SAP on Oracle

Cohesity provides a simple, fast, and cost-effective backup, recovery, and data management solution for Oracle databases running on the large-scale SAP ERP on Linux operating systems.

SAP uses backup BR*TOOLS to back up Oracle databases. Cohesity provides the following methods to backup Oracle database leveraging the BR*TOOLS:

- **Backup using BACKINT Secure Connector Service for Oracle** - Cohesity provides an SAP-certified BACKINT Secure Connector Service for Oracle that leverages BR*TOOLs for protecting Oracle databases.
- **Backup using custom Oracle SBT (Secure Backup to Tapes) and BACKINT Secure Connector Service for Oracle** - Cohesity provides a custom SBT extension that you can use along with BACKINT Secure Connector Service to backup Oracle databases.

Using the backup methods you can back up and restore the following for Oracle databases running in an SAP system:

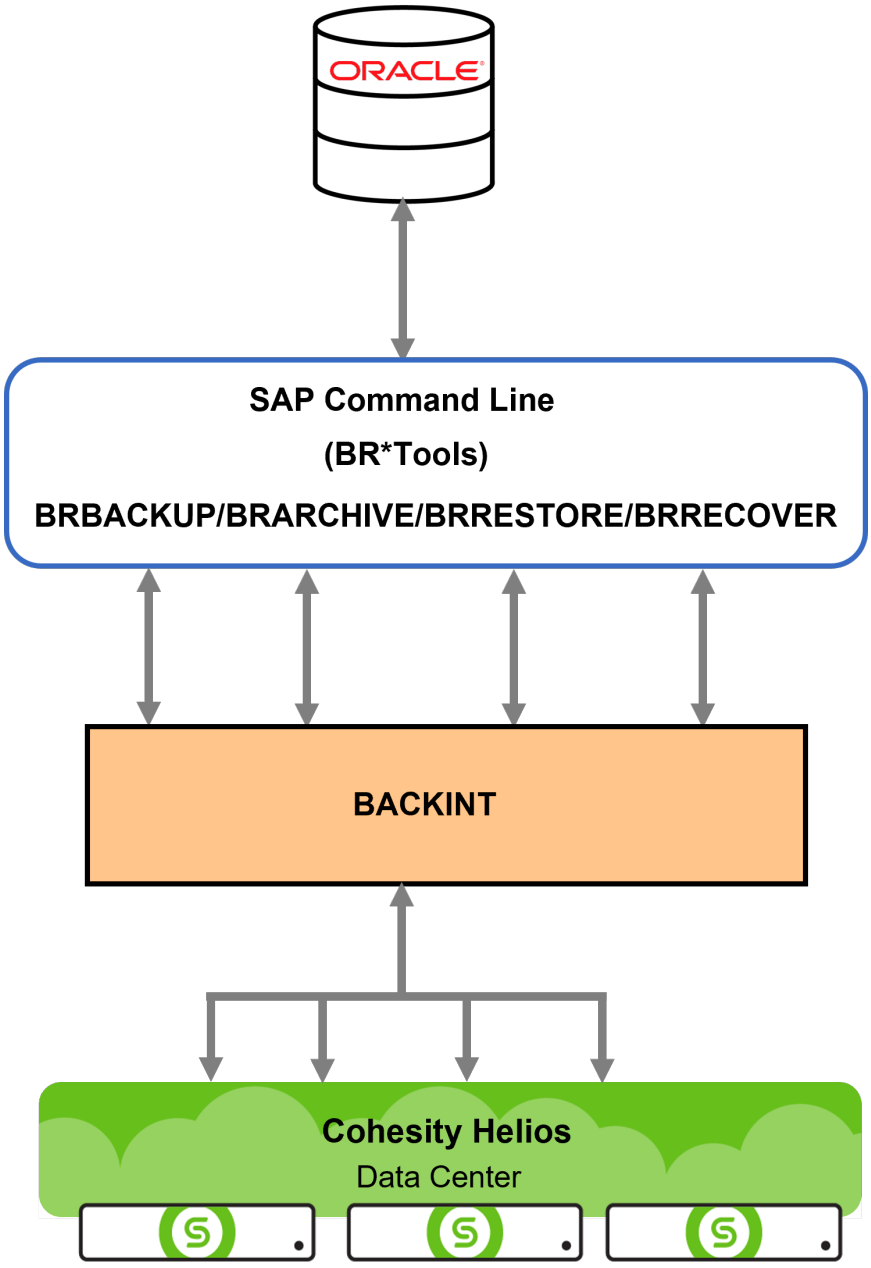
- Oracle database files such as data files (***.dbf**) and control files (***.ctl**)
- Archived redo logs
- Parameter files such as PFILE or SPFILE
- SAP BR*TOOLS files
- SAP files

Core Components

The following are the core components for protecting Oracle databases running on an SAP system:

- Oracle Database
- SAP BR*TOOLS
- Cohesity BACKINT Secure Connector Service for Oracle
- Cohesity Data Cloud (Self-Managed)

As illustrated, you can integrate the Cohesity Data Cloud (Self-Managed) with new or existing Oracle database deployments in SAP by installing the Cohesity BACKINT Secure Connector Service for Oracle.



Plan and Prepare

This topic provides information on supported Oracle databases on SAP, and prerequisites for installing the Cohesity BACKINT Secure Connector Service for Oracle.

Supported Versions

For more information on supported SAP on Oracle versions, see Supported Software versions.

> **Note:** Backing up SAP on Oracle databases using custom Oracle SBT and BACKINT Secure Connector Service is supported only on SAP on Oracle databases running on Linux (x86-64) system.

Prerequisites

Make sure that you:

- Install OpenJDK JRE 1.8 or later, on the SAP system.
- Create a Cohesity view with the **DefaultStorageDomain** options. For more information, see Create a Cohesity View with IP Allowlist for the SAP Node.
- Download and copy the Cohesity BACKINT Secure Connector Service for Oracle to the SAP system. For more information, see Download the BACKINT Secure Connector Service for Oracle Installer
- Check if the SAP node has an `<SID>adm` user account; if not, create an Operating System (OS) user account to own the backup files on the Cohesity view. The format of the user account must be `<SID>adm`, where `SID` represents the SAP System Identification. It is a unique three-character code available for every R/3 installation (SAP system) that consists of a database server and several application servers.
- Use "bash" shell to install the Cohesity BACKINT Secure Connector Service for Oracle and to run backups and restore workflows of SAP on Oracle databases.
- Ensure that the NTP time is in sync between the client and the Cohesity cluster. Perform the following on the client:
  - Verify if NTP is enabled and synchronized in the client using the following command:

    ```
    timedatectl
    ```

  - If the NTP time is not synchronized, use the following command to synchronize the NTP time

    ```
    timedatectl set-ntp true
    ```

- The BACKINT Secure Connector Service for Oracle can be installed using a `root` user account or using a user account with `sudo` user privileges. If you are installing the BACKINT Secure Connector Service for Oracle using a `sudo` user account, for example, `oracle`. Ensure that you add the following entries in the **sudoers** file of the `oracle` account:

  ```
  Defaults:oracle !requiretty

  oracle ALL=(ALL) NOPASSWD:ALL
  ```

- If you are using the RPM-based installer, ensure that you configure the following environment variables on the SAP on Oracle node(s):

Environment Variable	Description	Command
ORACLE_HOME	The path to the Oracle database installation directory.	export ORACLE_HOME=<Oracle-home-Directory-Path>
SAPDATA_HOME	The directory of the database files.	export SAPDATA_HOME=<SAP-Home-Directory-Path>
SERVICE_USER	The <SID>adm user account that must own the backup files on the Cohesity view. If you have not created the user account, then create an Operating System (OS) user account in the following format: <SID>adm. Where <SID> is a unique three-character code called SAP System Identification (SID). It is available for every R/3 installation (SAP system) that consists of a database server and several application servers.	export SERVICE_USER=qqqadm Where qqqadm is the <SID>adm user account and qqq is the SAP System Identification (SID).
ORACLE_SID	The System ID (SID) of the Oracle database instance.	export ORACLE_SID=<Oracle_SID>
CLUSTER_IPS	A comma-separated list of virtual IP addresses of the servers in the Cohesity cluster. **Note:** Ensure that you use virtual IP addresses (VIPs) instead of physical IP addresses (node IP addresses). The physical IP address is bound to a node, and if the node goes down, then the IP address is no longer accessible and causes the backup to fail. Hence, Cohesity recommends using VIP because of the resilience; if the node fails, it won't cause backup failures.	export CLUSTER_IPS=<IP1>,<IP2>,<IP3>,...
VIEW_NAME	The name of the Cohesity view that you have created for SAP on Oracle. For more information, see Create a Cohesity View with IP Allowlist for the SAP Node. **Note:** Ensure that the Cohesity view name does not contain the path of the Cohesity view or Cluster name or IP address.	export VIEW_NAME=<view name>

Environment Variable	Description	Command
SERVICE_TYPE	The type of service. By default set to REMOTESNAPFS. Allowed values are: REMOTESNAPFS or NFS.	

Create a Cohesity View with IP Allowlist for the SAP Node

Create a CohesityView to provide a storage location in a storage domain on the Cohesity cluster for the SAP on Oracle nodes. For more information on views, see Cohesity Views.

To provide effective authorization and prevent rogue access to the Cohesity cluster, the SAP node IP address must be added to the allowlist in the Cohesity view configuration.

Adding Custom Allowlist for the Cohesity View

While creating a Cohesity View, you have an option to add an allowlist for the View. Ensure that you add the SAP HANA node IP address to the allowlist for the Cohesity View.

To add subnets to the allowlist of the Cohesity view:

1. In the **Create View** page, under the **More Options**, expand **Security**.
2. In the **IP Allowlist** section, perform the following:
    1. Select **Override Global Allowlist** and click **Add Allowlist**.
    2. In the **Subnet IP** and **Subnet Mask** fields respectively, enter the Subnet IP address and Subnet Mask to specify a range of systems that should have permissions to access and mount the Cohesity View.
    3. In the **NFS Permissions**, **SMB Permissions**, and **S3 Permissions** drop-down lists, select the NFS, SMB, and S3 permissions respectively.
    4. In the **NFS Root Squash** and **NFS All Squash** drop-down lists, specify whether to turn on NFS Root or NFS All squash respectively.
    5. In the **Description** field, enter a brief description.
    6. Click **Add**.
    7. Repeat these steps to add additional subnets to the allowlist of the Cohesity view.

Note:

- To use the IP allowlist feature, you need to upgrade the Cohesity cluster to 6.3 release or later.
- If the Override Global Allowlist toggle is off, this View can only be accessed and mounted by systems specified by the Global Cohesity cluster Allowlist.
- In case of a multinode HANA setup, specify all nodes individually in the global IP allowlist.

Download the BACKINT Secure Connector Service for Oracle Installer

The BACKINT Secure Connector Service for Oracle is available as a script installer for x86-64 systems.

To download the installer:

1. Navigate to **Data Protection > Sources**, and click **Download Cohesity Agent**.
2. In the **Download Agents** window, click **SAP on Oracle** and then select **Script installer** or **RPM** based on your requirement.
   The installer of BACKINT Secure Connector Service for Oracle is downloaded to your local machine.
3. Copy the installer to the node or nodes of the SAP deployment.

Install the BACKINT Secure Connector Service for Oracle

Cohesity BACKINT Secure Connector Service for Oracle is an SAP-certified service that enables you to establish communication between the Cohesity cluster and the SAP on Oracle nodes.

The BACKINT Secure Connector Service for Oracle can be installed using a `root` user account or using a user account with `sudo` user privileges. Cohesity supports IPv6 for SAP Oracle in x86_64 architectures with gRPC data transfer. If you are installing the BACKINT Secure Connector Service using a `sudo` user account, for example, `oracle`. Ensure that you add the following entries in the `sudoers` file of the `oracle` user account:

```
Defaults:oracle !requiretty
oracle ALL=(ALL) NOPASSWD:ALL
```

Prerequisites

- Before installing the BACKINT Secure Connector service for Oracle you must set the `ORACLE_HOME` and `SAPDATA_HOME` exports on the SAP Oracle host.

  Syntax:

- `export ORACLE_HOME=<oracle database>`

  Example:

  ```
  export ORACLE_HOME=/oracle/SAL/121
  ```

- `export SAPDATA_HOME=<oracle database>`

  Example:

  ```
  export SAPDATA_HOME=/oracle/SAL
  ```

- Run the following command on the SAP Oracle node to synchronize time between the SAP Oracle server and the Cohesity NTP server:

  ```
  timedatectl set-ntp true
  ```

Install the BACKINT Secure Connector Service using the Script Installer

On the SAP node, perform the following to install the BACKINT Secure Connector Service using the script installer, `cohesity_secure_connector_service_sap_oracle_installer_sap_oracle_java_installer`.

To install the BACKINT Secure Connector Service for Oracle:

1. Log on to the SAP node's bash CLI.
2. Navigate to the directory where you have downloaded the script installer.
3. Make the Secure Connector Service installer (`cohesity_secure_connector_service_sap_oracle_installer_sap_oracle_java_installer`) executable using the following command:

   ```
   [oracle@sapnet ~]$ chmod +x cohesity_secure_connector_service_sap_oracle_installer_sap_oracle_java_installer
   ```

4. Install the Secure Connector Service for Oracle using the following command:

   ```
   cohesity_secure_connector_service_sap_oracle_installer_sap_oracle_java_installer -- --install -s <SID> -a <comma_separated_cohesity server_ip_addresses> -v <view_name> -S ora<SID>
   ```

   Where:

   - `-s <SID>` - SAP System Identification (SID) is a unique three-character code that is available for every R/3 installation (SAP system) that consists of a database server and several application servers.
   - `-a <comma_separated_cohesity server_ip_addresses>` - The comma-separated list of virtual IP addresses of the servers in the Cohesity Cluster.

> **Note:** You can also specify the hostname instead of the IP addresses to perform the mount. For successful mount operation, you must specify the proper mapping between the IP addresses and the hostname in the `/etc/hosts` file.

For example:

```
[oracle@sapnet ~]$ nslookup cluster.cohesity.com
Server:         xxx.xx.xx.50
Address:        xxx.xx.xx.50#3
Name:   cluster.cohesity.com
Address: xxx.xx.xx.244
Name:   cluster.cohesity.com
Address: xxx.xx.xx.246
Name:   cluster.cohesity.com
Address: xxx.xx.xx.247
Name:   cluster.cohesity.com
Address: xxx.xx.xx.248
```

- `-v <view_name>` - The Cohesity View that you have created for SAP on Oracle.

The following is a sample output of the successful installation:

```
[oracle@saptest ~]$ ./cohesity_secure_connector_service_6.5.1_sap_oracle_
java_installer -- --install -s SAL -a
10.2.196.217,10.2.196.219,10.2.196.221,10.2.196.223 -v view-oracle
Verifying archive integrity... All good.

Install the BACKINT Secure Connector Service using the RPM-based Installer

On the SAP HANA node, perform the following to install the BACKINT Secure Connector Service using an RPM-based installer, `cohesity-oracle-backint-6.6-1.x86_64.rpm`. You can install the BACKINT Secure Connector Service using a `root` user account or a user account with `sudo` privileges.

To install the BACKINT secure connector service using a user account with `sudo` privileges:

1. Log in to the SAP node's bash CLI.
2. Navigate to the directory where you have copied the RPM-based installer.
3. Run the following command to install the BACKINT secure connector service:

```
sudo -E rpm -ivh  cohesity-oracle-backint-6.6-1.x86_64.rpm [--
prefix=<install_dir>]
```

Where, `prefix` is an optional parameter. It enables you to define a directory on the SAP node on which you want to install the BACKINT secure connector service. The default installation directory is **/opt**.

The following is a sample output of the successful installation, where `SERVICE_USER` is `saladm` and `SID` is `SAL`:

```
[oracle@saptest ~]$ sudo -E rpm -ivh cohesity-oracle-backint-6.6-1.x86_
64.rpm

Cohesity DataProtect 6.5 for SAP Oracle Linux
backint.jar, Build Version: qa-ENG_172760-125cbd48
Successful Installation of Cohesity secure connector service
```

To install the BACKINT secure connector service using the `root` user account:

1. Log in to the SAP node's bash CLI as a root user.
2. Navigate to the directory where you have copied the RPM-based installer.
3. Run the following command to install the BACKINT secure connector service:

```
rpm -ivh cohesity-oracle-backint-6.6-1.x86_64.rpm [--prefix=<install_
dir>]
```

Where, `prefix` is an optional parameter. It enables you to define a directory on the SAP node on which you want to install the BACKINT secure connector service. The default installation directory is **/opt**.

The following is a sample output of the successful installation, where `SERVICE_USER` is `saladm` and `SID` is `SAL`:

```
[root@saptest ~]$ rpm -ivh cohesity-oracle-backint-6.6-1.x86_64.rpm

Update the Cohesity Parameter File

As part of the BACKINT Secure Connector Service for Oracle installation, Cohesity provides a parameter file (`initSID.utl`) that enables the SAP on Oracle node to use the BACKINT Secure Connector Service for a backup job. The parameter file is available at: `<SAPDATA_HOME>/sapprof/initSID.utl`.

The following is a sample `initSID.utl` file:

```
##-------------------------------------------------------------------------
----
## List of IPs' of Cohesity cluster. Only VIPs can be used and not physical
IPs.
##-------------------------------------------------------------------------
----
cluster_ips : "${IP_ADDRESS}"

##-------------------------------------------------------------------------
----
## If service_type is 'REMOTESNAPFS' then port number on Cohesity cluster
nodes
## to which BACKINT executable connects.
## Port 11117 for secure connection (certificate config path should be a
valid
## path) otherwise port 11111 for insecure connection (certificate config
path
## should be an empty string).
## If service_type is 'NFS' then this field is not applicable.
##-------------------------------------------------------------------------
----
cluster_port : 11113

##-------------------------------------------------------------------------
----
## Name of the view on which backup data resides (Note: View Name should not
## contain the View Path or Cluster Name/IP).
##-------------------------------------------------------------------------
----
view_name : "${VIEW_NAME}"

##-------------------------------------------------------------------------
----
## Mount path for nfs approach.
##-------------------------------------------------------------------------
```

```
----
sap_nfs_mount_path : "/tmp/cohesity_nfs"

##------------------------------------------------------------------------
----
## Mount options for nfs approach.
##------------------------------------------------------------------------
----
# rsize, wsize: The  maximum  number of bytes in each network READ/WRITE
request that the NFS client
# can receive/send when reading/writing data from/to a file on an NFS
server.  The actual data
# payload size of each NFS READ/NFS WRITE request is equal to or smaller
than the rsize/wsize
# setting. The largest read/wsize payload supported by the Linux NFS client
is
# 1,048,576 bytes (one megabyte).
# The rsize/wsize mount option as specified on the mount(8) command line
appears
# in the /etc/mtab file. However, the effective rsize/wsize value negotiated
by
# the client and server is reported in the /proc/mounts file.
sap_nfs_mount_options : "rsize=1048576,wsize=1048576"

##------------------------------------------------------------------------
----
## Maximum number of retries during reads/writes.
##------------------------------------------------------------------------
----
sap_max_read_write_retries : 3

##------------------------------------------------------------------------
----
## Maximum size of each IO in bytes. The range is 1048576-4194304 bytes.
##------------------------------------------------------------------------
----
sap_max_io_size_in_bytes : 1048576

##------------------------------------------------------------------------
----
## Maximum number of IO cached/prefetched. The range is 1-128.
##------------------------------------------------------------------------
----
sap_max_data_queue_size : 4
```

```
##-------------------------------------------------------------------------
----
## Maximum number of inflight read-writes at a time.The range is 1-128.
##-------------------------------------------------------------------------
----
sap_max_num_inflight_io : 4

##-------------------------------------------------------------------------
----
## Maximum number of asynchronous callback threads for NFS read-write for
## SAP Hana and for local as well for SAP Oracle.
##-------------------------------------------------------------------------
----
sap_max_io_asynchronous_callback_concurrency : 2

##-------------------------------------------------------------------------
----
## Maximum number of pipes that will be backed up parallelly at any time by
## Cohesity Secure Connector Service during the backup.
##-------------------------------------------------------------------------
----
sap_max_backup_streams : 4

##-------------------------------------------------------------------------
----
## Maximum number of pipes that will be restored parallelly at any time by
## Cohesity Secure Connector Service during the restore.
##-------------------------------------------------------------------------
----
sap_max_restore_streams : 4

##-------------------------------------------------------------------------
----
## To tune, metadata read performance for inquiry and restore.
## The default value is 4.
##-------------------------------------------------------------------------
----
sap_max_metafiles_read_concurrency : 10

##-------------------------------------------------------------------------
----
## Number of days for which inquire information is returned.
##-------------------------------------------------------------------------
```

```
----
sap_max_inquire_period_days : 180

##-------------------------------------------------------------------------
----
## Location on SAP nodes where the Cohesity Secure Connector Service
## will create debug logs.
##-------------------------------------------------------------------------
----
backint_log_dir : "/tmp/cohesity_logs"

##-------------------------------------------------------------------------
----
## Java log level. It can possibly take these values:
## all/trace/debug/info/warn/error/fatal
##-------------------------------------------------------------------------
----
java_log_level : "info"

##-------------------------------------------------------------------------
----
## Service Type
##-------------------------------------------------------------------------
----
service_type : "REMOTESNAPFS"

##-------------------------------------------------------------------------
----
## Database Type
##-------------------------------------------------------------------------
----
database_type : "ORACLE"
```

Edit the parameter file and enter the values for the following parameters:

Parameter	Description
`cluster_ips`	List of IP addresses of the Cohesity Cluster. **Note:** Ensure that you provide only the virtual IP addresses.

Parameter	Description
view_name	The name of the Cohesity view used to store the backup data. **Note:** Ensure that the Cohesity view name does not contain the path of the Cohesity view or Cluster Name or IP address.
sap_nfs_mount_path	The NFS mount path.
sap_nfs_mount_options	The NFS mount options.
sap_max_read_write_retries	The Maximum number of retries during reads or writes.
sap_max_io_size_in_bytes	Maximum size of each IO in bytes. The range is 1048576-4194304 bytes.
sap_max_data_queue_size	Maximum number of IO cached or prefetched. The range is 1-128.
sap_max_num_inflight_io	Maximum number of inflight reads or writes at a given time. The range is 1-128.
sap_max_io_asynchronous_callback_concurrency	Maximum number of asynchronous callback threads for NFS read-write.
sap_max_backup_streams	The number of pipes that are backed up parallelly at any time by Cohesity BACKINT Secure Connector Service for Oracle during the backup process.
sap_max_restore_streams	The number of pipes that are backed up parallelly at any time by Cohesity BACKINT Secure Connector Service for Oracle during the restore process.
sap_max_metafiles_read_concurrency	Tune the metadata read performance for inquiry and restore. The default value is 4.
sap_max_inquire_period_days	The number of days for which the inquire information is returned.
backint_log_dir	Location on the SAP nodes where the BACKINT Secure Connector Service creates the debug logs.

Parameter	Description
java_log_level	The java log level. The supported values are: • all • trace • debug • info • warn • error • fatal
service_type	The type of service. By default, the value is set to REMOTESNAPFS. The supported values are REMOTESNAPFS or NFS.
database_type	The type of database. The supported value is ORACLE.

Uninstall the Cohesity BACKINT Secure Connector Service for Oracle

To uninstall the Cohesity BACKINT Secure Connector Service for Oracle, run the following command with appropriate parameters on SAP bash CLI:

```
cohesity_secure_connector_service_sap_oracle_installer_sap_oracle_java_
installer -- --uninstall -s <SID>
```

The following is a sample of the output:

```
[oracle@saptest ~]$ ./cohesity_secure_connector_service_6.5.1_sap_oracle_
java_installer -- --uninstall -s SAL
Verifying archive integrity... All good.
Uncompressing Cohesity Backint  100%

Backup SAP on Oracle Databases

You can back up the Oracle database running on the SAP system using the SAP BR*TOOLS or using a Remote Adaptor Protection Group provided by Cohesity. See the following topics for details:

Backup Using SAP BR*TOOLS

SAP provides BR*TOOLS to back up Oracle databases. The Cohesity BACKINT Secure Connector Service leverages BR*TOOLs for protecting Oracle databases.

The SAP BR*TOOLS includes a BRBACKUP tool that enables you to back up data files, control files, and online redo log files of the database. When you back up the files on the SAP

system using the BRBACKUP tool, it calls the Cohesity BACKINT Secure Connector Service to transfer the backup files to the Cohesity cluster. For more information on SAP BR*TOOLS, refer to SAP on Oracle Documentation.

Sample

The following is a sample of the BRBACKUP command and the output:

```
[saladm@user@123 ~]$ brbackup -d util_file -t offline -m all -p initSAL.sap
-u system/fr9shst8rt -c
BR0051I BRBACKUP 7.40 (40)

Backup Using BACKINT Secure Connector Service

SAP provides BR*TOOLS to back up Oracle databases. The Cohesity BACKINT Secure Connector Service leverages BR*TOOLs for protecting Oracle databases. When the BACKINT Secure Connector Service for Oracle is installed and configured on the SAP system, it manages the communication between the SAP system and the Cohesity cluster.

The SAP BR*TOOLS includes a BRBACKUP tool that enables you to back up data files, control files, and online redo log files of the database. When you back up the files on the SAP system using the BRBACKUP tool, it calls the Cohesity BACKINT Secure Connector Service to transfer the backup files to the Cohesity cluster. For more information on SAP BR*TOOLS, refer to SAP on Oracle Documentation.

Considerations

Review and understand the following considerations before you protect your SAP on Oracle databases using Cohesity BACKINT Secure Connector Service:

- Incremental backups of the Oracle databases are not supported. For incremental backups, use the custom Oracle SBT along with the BACKINT Secure Connector Service. For more information, see Backup Using Oracle SBT and BACKINT Secure Connector Service.
- Source-side deduplication is not supported if you use only BACKINT Secure Connector to backup SAP on Oracle databases.

Backup Using a Remote Adaptor Protection Group

As part of the BACKINT Secure Connector Service for Oracle installation, Cohesity provides a backup script for the backup of SAP on the Oracle database. The backup script leverages the SAP BR*TOOLS capabilities provided by SAP. You can create a Remote Adaptor Protection Group and define the script parameters that enable you to back up the SAP on the Oracle database.

Backup Script Parameters

In the Remote Adaptor Protection Group, you can define the following script argument for your SAP on Oracle backup configuration:

Backup Script Parameters	Descriptions
`-m, --mode`	The mode of backup. You can specify the following: • **full** for full backup. • **incr** for incremental backup • **arch** to archive offline redo log files
`-t, --type`	The type of backup. You can specify offline or online backups based on your requirements. **Note:** In case of offline backup, the database is shut down before performing the backup.
`-D, --device`	The device type for performing the backup. The following are the device types, you can specify: • **util_file**: To backup all the files using the BACKINT Secure Connector Service for Oracle. • **rman_util**: To backup the data files using the custom SBT extension and other files using the BACKINT Secure Connector Service for Oracle.
`-l, --log-file [file]`	The filename of the log file where you want to log the backup script logs. By default the logs are stored as follows: `/tmp/cohesity_backup_script_logs/cohesity_oracle_backup_script_<time_in_seconds>_<pid>.log`
`-c, --channels`	Specify the number of channels configured for backups using RMAN. By default, the number of channels configured in the `rman_channels` parameter in the **init<SID>.sap** file is used.
`-r, --retention-days`	The retention period in days. The backups older than the specified retention period are deleted from both the catalog and the Cohesity View.
`-d, --debug`	Allows you to enable shell script debugging with set -x. By default, shell script debugging is disabled.

Create a Remote Adapter Protection Group for SAP on Oracle

To create a Remote Adapter Protection Group:

1. Navigate to **Data Protection** > **Protection** and do one of the following:
    a. To create a Protection Group—Click the plus icon on the top-right of the page and then select the type of Protection Group.
    b. To edit a Protection Group—Click the action icon next to the Protection Group and select **Edit**.
2. Here the *Job Type* is **Remote Adapter**. **Name**: Enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes and periods. This field is required.
3. **Linux Hostname or IP**: Specify the Hostname or the IP Address of the Linux system where the scripts are located and will be run.
4. **Username**: Specify the username on the Linux system that will be running the scripts.
5. **Cluster SSH Public Key**: Set up permissions on the Linux system to allow the Cohesity cluster to run the scripts remotely on the system.
    a. Click **Copy Key to Clipboard** to copy the SSH public key into the clipboard.
    b. Log in to the Linux system with the username specified earlier.
    c. In the home directory of the user, determine if there is a .ssh directory that contains a file called authorized_keys:

    ```
    ls -lr ~/.ssh
    ```

    d. Add the SSH key to the `authorized_keys` file located in the **~/.ssh** directory of the specified User:
        1. If the directory and file do not exist, create the .ssh directory in the home directory, change directories into the .ssh directory, create the authorized_keys file and paste the SSH key into a new line of the file.
        2. If the **.ssh** directory exists but the file does not, change directories into the .ssh directory, create the authorized_keys file and paste the SSH key into a new line of the file.
        3. If the authorized_keys file exists in the .ssh directory, edit the authorized_keys file and paste the SSH key into a new line of the file.
    e. Set the **.ssh** directory and authorized_keys file permissions:

    ```
    chmod 700 .ssh
    chmod 640 .ssh/authorized_keys
    ```

6. **Policy**: Select an existing protection policy or create a new one by selecting **New Policy**.
7. **Script (with Full Path)**: Enter the full path to the script, for example:

```
 rhel-sap-oracle-003:devadm> /usr/sap/SAL/cohesity/scripts/backup_
job.sh
```

8. **Parameters**: Enter the parameters for the backup script based on your requirements. For more information, see Backup Script Parameters.

   For example:

Use Cases	Sample Script Arguments
Create a full online backup using the BACKINT Secure Connector Service.	`-m full -t online -D util_file`
Create a full online backup using the BACKINT Secure Connector Service with 30 days retention period.	`-m full -t online -D util_file -r 30`
Archive offline redo log files using BACKINT Secure Connector Service.	`-m arch -D util_file -r 30`

Backup Using Oracle SBT and BACKINT Secure Connector Service

Oracle database provides a custom third-party backup extension called SBT (Secure Backup to Tapes) for Oracle database backups. Cohesity provides a custom SBT extension that provides full backup and restore capabilities for Oracle databases.

SAP BR*TOOL supports extensions to back up the Oracle databases using the custom SBT extension libraries. You can use the custom SBT extension along with the BACKINT Secure Connector Service to perform:

1. Incremental Oracle database backups.
2. Multistream the multi-node backups using Oracle RMAN channels, thus enabling you to split the data between multiple nodes for optimal performance.
3. Source side deduplication.

> **Note:** Backing up SAP on Oracle databases using custom Oracle SBT and BACKINT Secure Connector Service is supported only on SAP on Oracle databases running on Linux (x86-64) system.

Backup Process

The Oracle database is backed up using the custom SBT extension in the following phases:

1. The BRBACKUP or BRARCHIVE commands call RMAN and start the Oracle server process. The Oracle server process reads the Oracle database files to be backed up

from the Oracle database and transfers it to the external backup library. The external backup library acts as a backup client, and it passes the data to the backup server. The server backs up the data to the Cohesity cluster.

2. The BRBACKUP uses the BACKINT Secure Connector Service to transfer the control file, the initialization profile, and the log files to the backup client. The backup client then transfers the data to the backup server, and the backup server backs up the data to the Cohesity cluster.

> **Note:** The control file contains the information related to the files' backup from the first phase.

For more information, see the values `rman_disk` or `rman_stage` for the backup_dev_type parameter.

Backup Using a Remote Adaptor Protection Group

As part of the BACKINT Secure Connector Service for Oracle installation, Cohesity provides a backup script for the backup of SAP on the Oracle database. The backup script leverages the SAP BR*TOOLS capabilities provided by SAP. You can create a Remote Adaptor Protection Group and define the script parameters that enable you to back up the SAP on the Oracle database.

Backup Script Parameters

In the Remote Adaptor Protection Group, you can define the following script argument for your SAP on Oracle backup configuration:

Backup Script Parameters	Descriptions
`-m, --mode`	The mode of backup. You can specify the following: • **full** for full backup. • **incr** for incremental backup • **arch** to archive offline redo log files
`-t, --type`	The type of backup. You can specify offline or online backups based on your requirements. **Note:** In case of offline backup, the database is shut down before performing the backup.

Backup Script Parameters	Descriptions
`-D, --device`	The device type for performing the backup. The following are the device types, you can specify: • **util_file**: To backup all the files using the BACKINT Secure Connector Service for Oracle. • **rman_util**: To backup the data files using the custom SBT extension and other files using the BACKINT Secure Connector Service for Oracle.
`-l, --log-file [file]`	The filename of the log file where you want to log the backup script logs. By default the logs are stored as follows: `/tmp/cohesity_backup_script_logs/cohesity_oracle_backup_script_<time_in_seconds>_<pid>.log`
`-c, --channels`	Specify the number of channels configured for backups using RMAN. By default, the number of channels configured in the `rman_channels` parameter in the **init<SID>.sap** file is used.
`-r, --retention-days`	The retention period in days. The backups older than the specified retention period are deleted from both the catalog and the Cohesity View.
`-d, --debug`	Allows you to enable shell script debugging with set -x. By default, shell script debugging is disabled.

Create a Remote Adapter Protection Group for SAP on Oracle

To create a Remote Adapter Protection Group:

1. Navigate to **Data Protection** > **Protection** and do one of the following:
   a. To create a Protection Group—Click the plus icon on the top-right of the page and then select the type of Protection Group.
   b. To edit a Protection Group—Click the action icon next to the Protection Group and select **Edit**.
2. Here the *Job Type* is **Remote Adapter**. **Name**: Enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes and periods. This field is required.
3. **Linux Hostname or IP**: Specify the Hostname or the IP Address of the Linux system where the scripts are located and will be run.
4. **Username**: Specify the username on the Linux system that will be running the scripts.

5. **Cluster SSH Public Key**: Set up permissions on the Linux system to allow the Cohesity cluster to run the scripts remotely on the system.
   a. Click **Copy Key to Clipboard** to copy the SSH public key into the clipboard.
   b. Log in to the Linux system with the username specified earlier.
   c. In the home directory of the user, determine if there is a .ssh directory that contains a file called authorized_keys:

      ```
      ls -lr ~/.ssh
      ```

   d. Add the SSH key to the `authorized_keys` file located in the **~/.ssh** directory of the specified User:
      1. If the directory and file do not exist, create the .ssh directory in the home directory, change directories into the .ssh directory, create the authorized_keys file and paste the SSH key into a new line of the file.
      2. If the **.ssh** directory exists but the file does not, change directories into the .ssh directory, create the authorized_keys file and paste the SSH key into a new line of the file.
      3. If the authorized_keys file exists in the .ssh directory, edit the authorized_keys file and paste the SSH key into a new line of the file.
   e. Set the **.ssh** directory and authorized_keys file permissions:

      ```
      chmod 700 .ssh
      chmod 640 .ssh/authorized_keys
      ```

6. **Policy**: Select an existing protection policy or create a new one by selecting **New Policy**.
7. **Script (with Full Path)**: Enter the full path to the script, for example:

   ```
    rhel-sap-oracle-003:devadm> /usr/sap/SAL/cohesity/scripts/backup_
   job.sh
   ```

8. **Parameters**: Enter the parameters for the backup script based on your requirements. For more information, see Backup Script Parameters.

   For example:

Use Cases	Sample Script Arguments
Create a full online backup using the custom SBT extension and BACKINT Secure Connector Service.	`-m full -t online -D rman_util`

Use Cases	Sample Script Arguments
Create a full online backup using the custom SBT extension and BACKINT Secure Connector Service with 30 days retention period and the number of channels set to 8.	`-m full -t online -D rman_util -c 8 -r 30`
Create an online incremental backup using the custom SBT extension and BACKINT Secure Connector Service.	`-m incr -t online -D rman_util -c 8 -r 30`
Archive offline redo log files using the custom SBT extension and BACKINT Secure Connector Service.	`-m arch -D rman_util -r 30`

Archive Offline Redo Log Files

The SAP BR*TOOLS includes a BRARCHIVE tool that enables you to archive offline redo log files. When you archive the offline redo log files on the SAP system using the BRARCHIVE tool, it calls the Cohesity BACKINT Secure Connector Service to transfer the archived files to the Cohesity cluster. For more information on SAP BR*TOOL, refer to SAP on Oracle Documentation.

Sample

The following is a sample of the BRARCHIVE command and the output:

```
[saladm@user@123 ~]$ brarchive -d util_file -cds -p initSAL.sap -u sys-
tem/fr8shst8rt -c

Restore SAP on Oracle Databases

The SAP BR*TOOLS includes a BRRESTORE tool that enables you to restore an entire database backup or parts of it when the backup was performed using the BRBACKUP tool. When you restore the file to the SAP system using the BRRESTORE tool, it calls the Cohesity BACKINT Secure Connector Service to restore the files from the Cohesity cluster. For more information on SAP BR*TOOL, refer to SAP on Oracle Documentation.

Sample

The following is a sample of the BRRESTORE command and the output:

```
[saladm@saptest ~]$ brrestore -d util_file -b last -m full -p initSAL.sap -u
system/fr8shst8rt
BR0401I BRRESTORE 7.40 (40)
```

```

Chapter 20: Kubernetes

Kubernetes is an open-source software platform that automates the deployment, management, and scaling of containerized applications. Using Cohesity Data Cloud, you can backup (file-based) and recover the Kubernetes cluster resources, PersistentVolumesClaims (PVCs), and metadata of the Kubernetes namespaces. Cohesity uses the Cohesity's Data Mover pod that will be deployed in the Kubernetes cluster for backing up the PVCs of the Kubernetes namespaces. Cohesity uses the third-party software, Velero, to back up the cluster and namespace scoped Kubernetes resources.

Plan and Prepare for Protecting Kubernetes Clusters

Before you register your Kubernetes cluster with the Cohesity cluster and protect the namespaces of the Kubernetes container, ensure that:

- Cohesity cluster supports the Kubernetes cluster version you plan to protect. For more information, see Supported Versions.
- The firewall ports required for the communication between the Cohesity cluster and Kubernetes cluster are open. For more information, see Network Firewall Considerations.
- You have the minimum permission required to register and manage your Kubernetes cluster. For more information, see Minimum Permission.
- You meet the prerequisites to register and manage your Kubernetes cluster. For more information, see Prerequisites.
- You have read the considerations for the backup and recovery of the Kubernetes cluster. For more information, see Considerations.

Supported Versions

Cohesity cluster supports data protection and recovery of the Kubernetes clusters. For supported versions of the Kubernetes clusters, see Supported Versions.

Network Firewall Considerations

If there is a firewall between the Cohesity cluster and the Kubernetes cluster, the following ports need to be opened.

Cohesity cluster	Type:Port	Direction	Kubernetes cluster	Type:Port	Usage Notes
Cohesity cluster nodes	TCP:	Outgoing	Kubernetes cluster api-address	TCP: <Kubernetes API server port>	Kubernetes cluster and Velero API Access. For more details on Velero support, see the Considerations section.
Cohesity cluster nodes	TCP:	Outgoing	Kubernetes cluster worker nodes	TCP:30000-32767[1] TCP:32000-(32000+#<worker nodes>)[2]	Cohesity cluster to Cohesity Datamover communication
Cohesity cluster VIPs	TCP:3000	Incoming	Kubernetes cluster	TCP	Velero S3 communication for metadata backups and restores

1 TCP:30000-32767 are supported only on releases 6.6.0a to 6.6.0d_u1.

2 TCP:32000-(32000+#<worker nodes>) are supported only on releases 6.6.0d_u2 and later.

Minimum Permission

To register the Kubernetes cluster with the Cohesity cluster, you must provide the Bearer token ID of the Kubernetes service account. Ensure that the service account has the cluster-admin role on the Kubernetes cluster.

> **Note:** This Bearer token ID will be used for all communications with the Kubernetes API server.

Prerequisites

Ensure that you meet the following prerequisites to register and manage your Kubernetes cluster:

- **Valid Certificate with Subject Alternative Name (SAN) field** —On the Cohesity cluster, install a valid certificate with the SAN field. The SAN field is used to specify additional host names (such as sites, IP addresses, and common names) to be protected by a single SSL certificate, such as a Multi-Domain or Extend Validation Multi-Domain Certificate. For more information, see Update SSL Certificates Using Cohesity CA or Customer CA certificate.
- **Create a Cohesity service account on Kubernetes to register Kubernetes on Cohesity cluster**—For registering a Kubernetes cluster with the Cohesity cluster, you can either use a default service account with the cluster-admin role or a dedicated service account with the cluster-admin role account. Cohesity recommends you to create a dedicated account in the default namespace.

  For example, to create a 'cohesity' service account on Kubernetes, use the following command:

  ```
  kubectl create serviceaccount cohesity -n default
  ```

  Assign the cluster-admin role to the 'cohesity' service account using the following command:

  ```
  kubectl create clusterrolebinding cohesity-admin --clusterrole=cluster-admin --serviceaccount=default:cohesity
  ```

  The above example can be run from any client or workstation from which `kubectl` is typically run for a given Kubernetes cluster that is registered and protected by the Cohesity cluster.

  > **Note:** Custom roles can be used as an Early Access feature after contacting Cohesity support.

- If you use a Kubernetes cluster 1.24 or later, run the following command to generate the Bearer Token ID or secret token for your service account.

  ```
  kubectl apply -f - <<EOF
  apiVersion: v1
  kind: Secret
  metadata:
    name: cohesity-token
    annotations:
      kubernetes.io/service-account.name: cohesity
  type: kubernetes.io/service-account-token
  EOF
  ```

  Sample Ouput

  ```
  secret/cohesity-token created
  ```

- **Extract the Bearer token ID**—To register the Kubernetes cluster with Cohesity cluster, you must have the Bearer token ID of the Kubernetes service account. Extract the Bearer token of the service account that has admin privileges on the Kubernetes cluster.

  Extract the Bearer token using the following command:

  ```
  kubectl describe secrets -n default cohesity-token | grep token: | awk
  '{print $2}' | head -1

  eyJhbGciOiJSUzI1NiIsImtpZCI6IjRtZzBkX0VRLXMwV05veFdvcjR3eGw1N2c4MUk0RX

  zyMdAl6Chba6q10ffjC_zjhU_Lm7wp31-BTMelg-1W_5b3uni4pCGD8EPGPw
  ```

- **Obtain the Cohesity Datamover Docker Image**—To back up the PVCs of the Kubernetes namespaces, you must push the Cohesity Datamover image to an image registry accessible by your Kubernetes cluster.

  To install the Cohesity Datamover image:

  1. Obtain the Datamover image that matches closely with your Cohesity cluster version from the Cohesity Download page.
  2. To push the Datamover image to your Docker registry:
     1. Run the following command to log into your Docker image registry:

        ```
        docker login <your image registry server>.fqdn
        ```

        If prompted, enter the credentials that have the permissions to push the Cohesity Datamover image to your image registry. Skip this login command if your image registry does not require authentication to push images.
     2. Load the Datamover image:

```
docker load --input cohesity-datamover-<your Datamover version>.tar
```

Replace <your Datamover version> in the preceding command with the version in your Datamover image name.

Example:

```
docker load --input cohesity-datamover-6.6.0d_u6.tar
```

```
docker load --input cohesity-datamover-6.8.1_u1.tar
```

3. Run the following command, and from the command result, make a note of the Image ID of the Datamover image:

```
docker images
```

4. Tag the Datamover image with the Image ID you made a note of in step c:

```
docker image tag <ID of your image> <your image registry server>.fqdn/path/cohesity-datamover:<your Datamover version>
```

5. Push the Datamover image to your Docker registry:

```
docker push <your image registry server>.fqdn/path/cohesity-datamover:<your Datamover version>
```

> **Note:** The preceding example assumes you use Docker to load, tag, push, and pull the Docker images. If you use Podman, replace `docker` with `podman`.

Considerations

- Cohesity uses the third-party software Velero to facilitate the backup and restore of namespace data.

  If your Kubernetes clusters are of versions earlier than 1.16, use Velero 1.4. If your Kubernetes clusters are of versions 1.16 or later, use Velero 1.12. For more information, see Upgrade Velero and Datamover.
- If Kubernetes is not accessed through the internet, you must provide the path to the registry from which Velero should be pulled.
- Cohesity cluster only supports the backup of the user-created application namespaces of the Kubernetes cluster and does not support the backup of default or infrastructure namespaces such as kube-node-lease, kube-public, kube-system, and so on.
- Cohesity supports restoring namespaces backed up from one Kubernetes cluster to a different Kubernetes cluster if the storage class of the Kubernetes clusters is the same.

- Cohesity does not support Tanzu Kubernetes Grid Integrated Edition (TKGI).
- Cohesity does not support data protection of Kubernetes clusters in private networks behind NAT gateways (Dynamic/Static NAT, Port Address Translation PAT).
- For new protection jobs, S3 embedded credentials are used by default.
- For existing protection jobs, incremental backups continue using the Cohesity S3 account ID. S3 embedded credentials are used only after a full backup is performed.
- For recovery, the credential type depends on the snapshot selected:
  - If the snapshot was created using the Cohesity S3 account, recovery uses the same.
  - If the snapshot was created using S3 embedded credentials, recovery uses embedded credentials.
- For replication, the target cluster must support S3 embedded credentials (version 7.3 or later). Otherwise, the replication job will fail.

> **Note:** Do not delete the Cohesity user if any protection job is still using the old approach (Cohesity S3 account ID). Deleting the user will cause incremental backups to fail, and existing snapshots will become unrecoverable.

- When restoring to an alternate cluster, Cohesity (through Velero) does not automatically restore Custom Resource Definitions (CRDs). This is an intentional design choice meant to avoid potential conflicts or compatibility issues that could occur if the target cluster already has CRDs with different versions or schemas.

Register and Manage Kubernetes Cluster

To protect the namespaces of the Kubernetes cluster, you must first register your Kubernetes cluster as a source on the Cohesity cluster. After registering your source, you can also perform the following actions:

- Update the Kubernetes cluster source configuration.
- Refresh the source details.
- Unregister the Kubernetes cluster from the Cohesity cluster.
- Configure User-defined Priority Class, Labels, and Annotations for Cohesity Deployed Resource

Register Kubernetes Cluster as a Source

Before you register the Kubernetes cluster as a source on the Cohesity cluster, ensure that you:

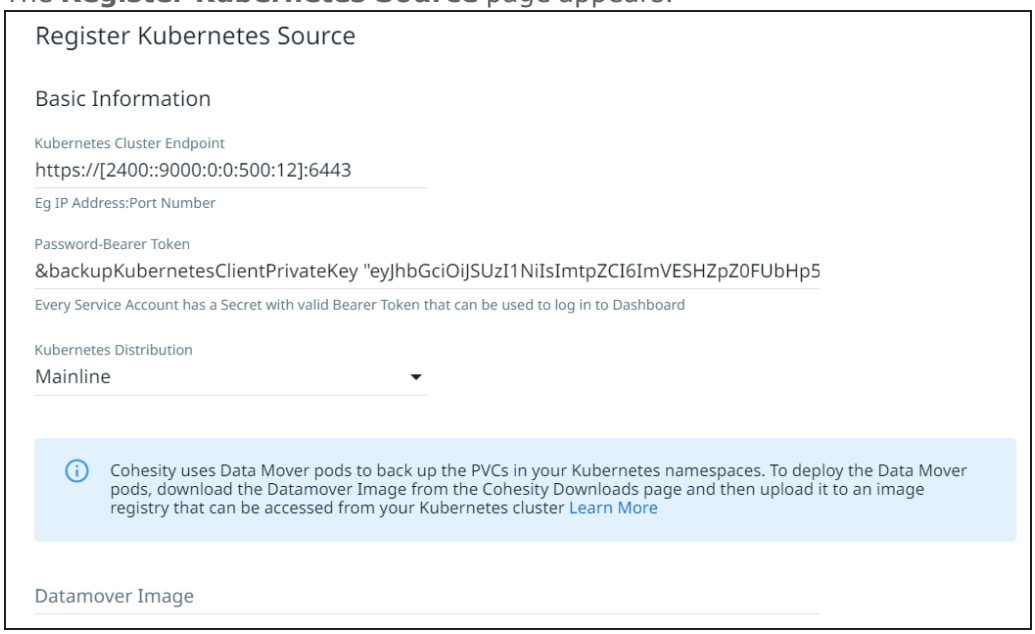
- Review the requirements, considerations, and best practices.
- Perform the prerequisite tasks.

For more information, see Plan and Prepare for Protecting Kubernetes Clusters.

To register the Kubernetes cluster as a source on the Cohesity cluster:

1. Navigate to **Data Protection > Sources**.
2. Click **Register** and then select **Kubernetes Cluster**.

   The **Register Kubernetes Source** page appears.



3. In the **Kubernetes Cluster Endpoint** field, based on your requirements, enter the Kubernetes API Server endpoints in one of the following formats:

   https://<FQDN>:<port_number>

   IPv4

   Format: https://<IPv4 address>:<port_number>

   Example: https://10.14.58.2:6443

   IPv6

   Format: https://[<IPv6 address>]:<port_number>

   Example: https://[2400::9000:0:0:500:12]:6443

4. In the **Password-Bearer Token** field, enter the Bearer token ID of the Kubernetes service account. For information on obtaining the Bearer token ID, see Plan and Prepare for Protecting Kubernetes Clusters.
5. From the **Kubernetes Distribution** drop-down, select one of the following Kubernetes distributions you want to backup and recover:

- Mainline (Vanilla Kubernetes)
- Redhat Openshift
- VMware Tanzu

6. *(Optional)* **Velero OpenShift Plugin Image**: This field is displayed if you have selected Redhat OpenShift as the Kubernetes Distribution.

   Download the latest plugin from the Red Hat website. In the **Velero OpenShift Plugin Image** field, enter the location where the Velero Openshift image is saved in your Docker registry. If you leave this field blank, the Cohesity cluster will automatically attempt to pull the latest image from the Red Hat website.

   You can download the Cohesity Velero OpenShift Plugin Image from the Cohesity Downloads page.

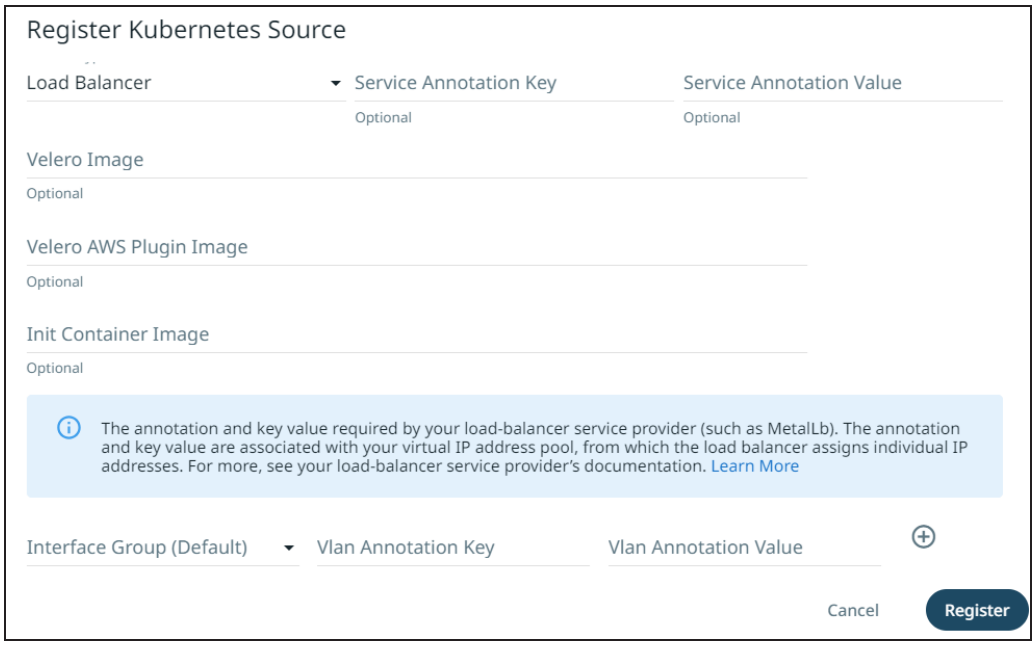
   > **Note:** This option is available only if you have selected Redhat OpenShift as the Kubernetes Distribution.

7. **Datamover Image**: Enter the location where you have the Datamover image saved in your Docker registry. The image must be entered in the format: `<Image_name>:<TAG>`.

   > **Note:** To protect the namespace level data in Vanilla Kubernetes 1.22 clusters, use the DataMover version that matches closely with your Cohesity cluster version. For more information, see Upgrade Velero and Datamover.

8. *(Optional)* **Service Type**: Enable this field to route external traffic to your Kubernetes cluster node via dedicated VLANs.

   From the drop-down, select one of the following service types:



- **NodePort** service type allows you to route external traffic through a fixed port (which you can set within the range of 30000-32767) on every Kubernetes node. In a NodePort setup, external traffic has direct access to the Kubernetes node.
- **Load Balancer** service type allows you to route external traffic via an external Load Balancer functionality. Load Balancers monitor the availability of your Kubernetes pods and route incoming service requests to the relevant pods. In a Load Balancer setup, external traffic has access to the Kubernetes node through the Load Balancer only.

  Service Annotation Key and **Service Annotation Value**

  Enter the Service annotation key-value pairs. These key-value pairs are utilized to store metadata that offers information about the selected Kubernetes service that Cohesity deploys. This metadata does not affect the behavior of the Kubernetes cluster.

  > **Note:** The Service Type field is an Early Access feature. Contact your Cohesity account team to enable it.

9. *(Optional)* **Velero Image**: Enter the location where you have the Velero image saved in your Docker registry. If you leave this field blank, then the Velero image will be pulled from a public image registry on the internet. You can download the Cohesity Velero Image from the Cohesity Downloads page.

> **Note:** You need Velero 1.8.1 to protect the namespace level data in Vanilla Kubernetes 1.22 clusters. For more information, see Upgrade Velero and Datamover.

10. *(Optional)* **Velero AWS Plugin Image**: Enter the location where you have the Velero plugin image for AWS saved in your Docker registry. If you leave this field blank, then the Velero plugin image for AWS will be pulled from a public image registry on the internet. You can download the Cohesity Velero AWS Plugin Image from the Cohesity Downloads page.
11. *(Optional)* **Init Container Image**: Enter the location where you have the Init Container image saved in your Docker registry. If you leave this field blank, then Cohesity will use the Datamover image as the Init Container image.
12. **Interface Group (Default)**: Displays all the Interface Groups set in your cluster. Click the **+** icon to add as many Interface Groups as needed. Once the Interface Groups are created, the traffic of the Service Type (you selected in Step 8) will only flow through the Interface Group(s), creating a separate channel for the traffic.

    Vlan Annotation Key and **Vlan Annotation Value**: Displayed only if the **Load Balancer Service Type** is selected. Enter the key-value pair to specify a VLAN that the Load Balancer service deploys to.

    Load balancer services allow you to configure a specific kind of address pool (in this case VLAN). For example, if you use the MetalLB LoadBalancer service, you need to set the **Vlan Annotation Key** to "metallb.universe.tf/address-pool" and the **Vlan Annotation Value** should be the name of the address pool. For more information, see the documentation of your LoadBalancer service.

    > **Note:** The Interface Group field is an Early Access feature. Contact your Cohesity account team to enable it.

13. Click **Register**.

Post-Registration Task

Once you register the Kubernetes cluster with the Cohesity cluster, perform the following actions:

- Run the following command to view the ports associated with each node of the Kubernetes cluster.

```
kubectl get services -n cohesity-<cluster-id>
```

Ensure the ports associated with the nodes are open to enable communication between the Kubernetes cluster and the Cohesity cluster.

For information on other required ports, see Network Firewall Considerations.

- Verify all of the pods in the Kubernetes cluster are in running state by running the following command:

```
kubectl get pods -n cohesity-<cluster-id>
```

The namespaces are displayed on the **Sources** page of the Cohesity Dashboard only after all the pods are either in the running state or error state.

- Refresh the Kubernetes source if there is an error on the source page. For more information, see Refresh the Kubernetes Source.

Update the Kubernetes Cluster Source Configuration

You can update the Kubernetes cluster details that you had provided during the registration process with the latest Kubernetes cluster configuration.

To edit the Kubernetes cluster source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Kubernetes cluster source and select **Edit**.
3. In the Register Kubernetes Source page, update the respective configurations.
4. Click **Register**.

> **Note:** When a Kubernetes source is edited to update the Velero image, Velero AWS plugin image, OpenShift plugin image, or DataProtect plugin image, the changes are not applied to the source, even though the edit appears to be successful.
> As a workaround, manually delete the Velero deployment from the Cohesity namespace in the source Kubernetes cluster, and then perform the source edit.

Refresh the Kubernetes Source

You can refresh the Kubernetes and fetch the latest changes on the Kubernetes cluster. To refresh the Kubernetes cluster source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Kubernetes cluster source and select **Refresh**.

Unregister Kubernetes Cluster

If you plan to stop taking the backup of your Kubernetes cluster namespace, you can unregister the Kubernetes cluster source from the Cohesity cluster.

Before unregistering, ensure to delete all the Protection Groups associated with the Kubernetes source.

To unregister the Kubernetes cluster:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Kubernetes cluster source and select **Unregister**

Configure User-defined PriorityClass, Labels, and Annotations for Cohesity Deployed Resources

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

You can provide the priority class names for pods deployed by it. You also have the option to select labels and annotations that will be applied to the pods and services deployed by Cohesity.

The Kubernetes source must include a PriorityClass resource with the specified name. The PriorityClass is assigned to each pod in its configuration. Labels track pods, while annotations on pods and services manage external network access rules.

You can specify the priority class for pods and also apply user-defined labels and annotations to the pods and services deployed by Cohesity at the Kubernetes source for data protection.

To provide Priority Class, Labels, and Annotations:

1. Navigate to **Data Protection > Sources**.
2. Click **Register** and then select **Kubernetes Cluster**.

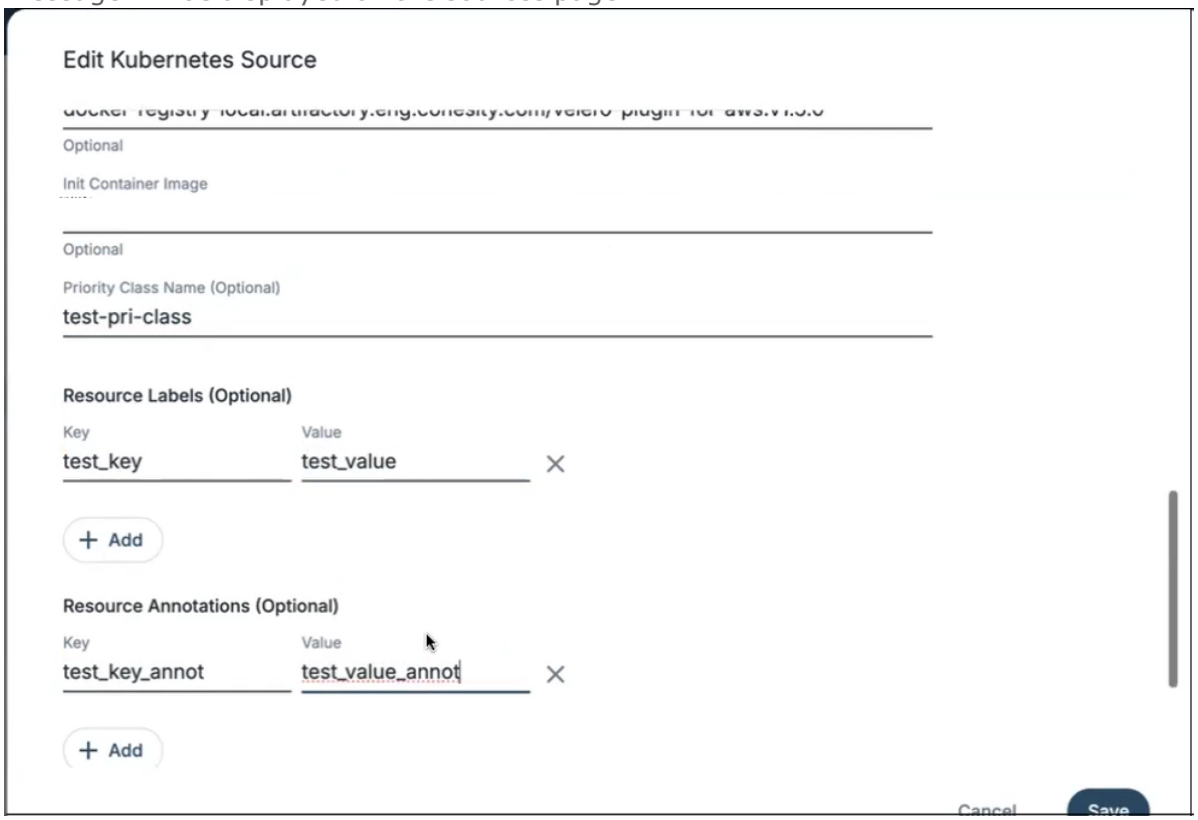
   The **Register Kubernetes Source** page appears.
3. Click the actions menu (⋮) next to the Kubernetes cluster source and select **Edit**.
4. Select the **Optional** field.
5. (*Optional*) **Priority Class Name**: In the Priority Class Name field, enter the name of the PriorityClass object available at the source. Pods deployed by Cohesity will specify this priority class name in their specifications. If a priority class for the pods is specified during the registration or modification of the source, the priority class will

first be validated to ensure it exists at the source. If it does not exist, the registration or editing process will fail.

During registration, the Velero and Datamover pods use the priority class to ensure they receive the appropriate priority assignment.

The Velero and Datamover pods will be updated with the new value during modification. Consequently, the pods will restart automatically.

If a priority class was specified during registration and you later deleted it from the Kubernetes source, the existing pods will remain unchanged. Upon the next refresh, it will be detected that the priority class no longer exists in the source, and an error message will be displayed on the sources page.



> **Note:** Before adding the priority class name, make sure that the priority class is already existing in the Kubernetes source.

6. (*Optional*) **Resource Labels Key** and **Resource Labels Value**: Enter the Resource Labels key-value pairs.

   (*Optional*): **Resource Annotations Key** and **Resource Annotations Value**: Enter the Resource Annotations key-value pairs.

   If labels or annotation maps are provided during source registration, Velero and Datamover pods and services will be labeled and annotated accordingly.

When source modifications occur, such as changes to labels or annotation maps, both the Velero and Datamover pods are updated with the new labels and annotations. This update triggers a restart of the pods, which can disrupt ongoing backup and recovery processes. Any subsequent attempts within the same run will be successful. While the Datamover services will be updated with new labels and annotations, they will not be restarted.

If a label or annotation with a specific key is deleted, the associated pods and services will be updated to reflect an empty string as the value for those keys. Additionally, if the Velero deployment or the data mover DaemonSet and services are deleted, and a manual refresh of the source is initiated, any labels and annotations with empty string values will be removed.

When you perform a search, you can filter the labels or annotations you provide and list the resources accordingly.

This is supported for both Load Balancer and NodePort service types.

Upgrade Velero and Datamover

Cohesity uses third-party software Velero 1.4 to back up and recover data at the namespace level.

If Kubernetes is not accessed through the internet, you must provide the path to the registry from which Velero should be pulled. For Cohesity Cluster version 7.2 and later, if Kubernetes is accessible from the internet, the Cohesity Kubernetes code will pull Velero version 1.15.

Configure Velero while Registering a Kubernetes Cluster

When you are registering the Kubernetes cluster as a source or re-registering a deleted Kubernetes cluster, on the Register Kubernetes Source page:

- In the **Velero Image** field, enter the location of the Velero image saved in your Docker registry.
- In the **DataMover Image** field, enter the location of the supported DataMover image saved in your Docker registry.

Upgrade Velero in Existing Kubernetes Cluster Sources

If you have existing Kubernetes Clusters registered with the Cohesity cluster, verify whether the Cohesity namespace is present or absent in the registered source. The procedure to upgrade Velero is different when the Cohesity namespace is present and when the Cohesity namespace is absent.

Verify if the Cohesity Namespace is Present

Run the following command on the master node of the Kubernetes cluster:

```
- kubectl get ns
```

Sample Output:

NAME	STATUS	AGE
<auto-rec-jenkins-del	Active	23h
cohesity-21234567891234	Active	7d8h
default	Active	24d
Jenkins	Active	21d
kube-node-lease	Active	24d
Kube-public	Active	24d
Kube-system	Active	24d
longhorn-system	Active	20d
mysql	Active	12d
wordpress	Active	21d

Check if there are namespaces with Cohesity cluster IDs in the command output. For example, `cohesity-21234567891234` is the Cohesity namespace in the preceding sample.

Upgrade When Cohesity Namespace is Absent

If the Cohesity namespace is absent, no warnings or alerts are displayed in the Cohesity cluster regarding the requirement to upgrade Velero and Data Mover.

To upgrade Velero:

1. Run the following command on any node of the Kubernetes cluster (or from a node in another Kubernetes cluster that has access to the Kubernetes command-line tool) to delete the Velero Custom Resource Definition (CRD):

   ```
   - kubectl delete crds -l component=velero
   ```

2. To edit the Kubernetes cluster source configuration:
   a. Navigate to **Data Protection** > **Sources**.
   b. Click the Actions menu (⋮) next to the Kubernetes cluster source and select **Edit**.
   c. In the Register Kubernetes Source page, enter the locations of the new Velero and Data Mover images in the **Datamover Image** and **Velero Image** fields, respectively.
   d. Click **Register**.

   When registration is complete, a new entry appears on the Sources page.

Upgrade When the Cohesity Namespace is Present

If the Cohesity namespace is present in a registered Kubernetes cluster, a message is displayed in the Cohesity cluster indicating that you must upgrade the Cohesity data protection resources in the Kubernetes cluster. The message will also help you understand which Velero and Data Mover versions you must upgrade to.

To upgrade Velero:

1. Stop all the Kubernetes protection jobs that are currently running and ensure there are no active protection runs on the Kubernetes source.
2. Run the following command to delete the Cohesity namespace in the Kubernetes cluster:

   ```
   - kubectl delete ns <name of the Cohesity namespace>
   ```

   Example

   ```
   - kubectl delete ns cohesity-21234567891234
   ```
3. Run the following command on any node of that Kubernetes cluster (or from a node in another Kubernetes cluster that has access to the Kubernetes command-line tool) to delete the Velero CRD:

   ```
   - kubectl delete crds -l component=velero
   ```
4. To edit the Kubernetes cluster source configuration:
   a. Navigate to **Data Protection** > **Sources**.
   b. Click the Actions menu (⋮) next to the Kubernetes cluster source and select **Edit**.
   c. In the Register Kubernetes Source page, enter the locations of the new Velero and Data Mover images in the **Datamover Image** and **Velero Image** fields, respectively.
   d. Click **Register**.

   When registration is complete, a new entry appears on the Sources page.

Backup Kubernetes Cluster Resources, PVCs, and Namespaces

Cohesity supports the backup of PVCs, Kubernetes cluster resources and metadata of the Kubernetes namespaces. Cohesity uses the Data Mover pod that will be deployed in the Kubernetes cluster for backing up the PVCs of the Kubernetes namespaces.

Cohesity supports the backup of PVCs with the volumeMode set to Filesystem.

The supported file systems include ext3, ext4, xfs, vxfs, ReiserFS, autofs, cvfs, zfs, fuse.mfs, nfs, nfs3, cifs, gpfs, and mmfs.

Cohesity also supports the backup of PVCs with CSI drivers using CSI volume snapshotting capability.

> **Note:** The backup of PVCs with CSI drivers using CSI volume is an Early Access feature. Contact Cohesity Support support for enabling this feature.

After registering the Kubernetes cluster as a source on the Cohesity cluster, you can start configuring your backups. Cohesity recommends the first full and an incremental forever approach for the backup. However, you can do periodic full backups, based on your requirements.

The temporary pods created during backups by Cohesity will have their priority class set to the specified value for the source. Additionally, the labels and annotations will be applied to the temporary pods.

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

Protect Kubernetes Namespaces

In the Cohesity cluster, Kubernetes namespaces are protected using a Protection Group and a Protection Policy. A Protection Group uses the schedules and settings defined in the policy to determine when and how backups are captured, archived, or replicated.

A Protection Policy is a reusable set of settings that define how and when objects are protected and replicated. You can select which standard or custom policy to use when creating a Protection Group.

To protect the namespaces of the Kubernetes containers:

1. In the Cohesity cluster UI, perform one of the following:
   - Select **Data Protection > Protection**. Click **Protect** displayed on the top-right of the page and then select Kubernetes Cluster.
   - Select **Data Protection > Sources**. Click the Actions menu (⋮) next to the Kubernetes source and then select Protect.
2. From the **Registered Source** drop-down list, select the registered Kubernetes source or click **Register Source** to register an Kubernetes source. For more information, see Register Kubernetes Cluster as a Source.
3. From the **Objects** list, select the namespaces that you plan to backup and click **Save Selection**.

> **Note:** You can use the advanced filters that are available to search and find the namespaces you plan to protect. Also, you can click the shield icon to enable Auto Protect at the Kubernetes cluster level or based on the namespace label(s). For more information, see Enable or Disable Auto Protect.

Exclude or Include PVCs

Cohesity enables you to choose which PVC to back up or exclude in a Kubernetes Namespace or Protection Group. (For details on how to include or exclude a PVC from a Protection Group, see the Advanced Settings section.)

To include or exclude PVCs for Kubernetes namespace:

a. In the **New Protection** dialog, click the **Edit** ( ) icon next to that selected namespace.

> **Note:** To turn ON the **PVC Inclusion/Exclusion** option to an existing Protection Group, click the Actions menu (⋮) for that Protection Group and select **Edit**. In the **Edit Protection** dialog, under **Objects**, select the namespace and click the **Edit** icon.

b. In the **Options** dialog, turn ON the **Enable PVC Inclusion/Exclusion** toggle.

c. You can choose to either include or exclude the PVCs. Select **Include** or **Exclude**, and then select the PVCs from the drop-down.

d. Click **Save**.

Once saved, the **Customized** link appears next to the **Edit** icon. Click the link if you want to modify the **PVC inclusion/exclusion** settings.

> **Note:** PVC Inclusion or Exclusion settings of a Kubernetes namespace take precedence over the settings of its Protection Group.

Exclude or Include Resources

Cohesity enables you to choose which Custom Resources to back up or exclude in a Kubernetes namespace or Protection Group. (For details on how to include or exclude a resource from a Protection Group, see the Advanced Settings section.)

To include or exclude Resource for Kubernetes namespace:

a. In the **New Protection** dialog, click the **Edit** ( ) icon next to that selected namespace.

b. In the **Options** dialog, turn ON the **Enable Resource Inclusion/Exclusion** toggle.

c. You can choose to either include or exclude the resource. Select **Include** or **Exclude**, and then select the resource from the drop-down.

   You can add other custom resources by clicking **Add Custom Resources**.

   - When you select a resource from the drop-down menu, only that specific resource will be backed up.
   - When you select the **Backup only PVC and related resources** option, the **Enable Resource Inclusion/Exclusion** option will be disabled. As a result, you can back up only PVCs and dependent resources, and skip other resources (for example Secrets).
   - To back up a PVC and include or exclude other resources, you have two options:
     - **Specify Inclusion/Exclusion for Individual PVCs**: Navigate to the PVC Inclusion/Exclusion panel to configure the inclusion or exclusion settings for individual PVCs. Instead of selecting the **Backup Only PVC** option, configure resource-level inclusion/exclusion through the **Enable Resource Inclusion/Exclusion** dropdown. In this scenario, the PVC-related resources will be automatically identified, since the individual PVC inclusion/exclusion settings have been specified.
     - **Configure Resource-Level Inclusion/Exclusion Directly**: Instead of setting inclusion/exclusion at the individual PVC level, you can directly configure resource-level inclusion/exclusion through the **Enable Resource Inclusion/Exclusion** dropdown. With this method, you must explicitly select the PVC-related resources you want to include or exclude, along with any other resource categories you wish to manage.

d. Click **Save**.

Once saved, the **Customized** link appears next to the **Edit** icon. Click the link if you want to modify the **Resource inclusion/exclusion** settings.

4. In the Protection Group section, perform one of the following:
   - Select **New Group** to create a new Protection Group. In the **Name** field, enter a name from the Protection Group and go to step 5.
   - Select **Existing Group** to use the settings of an existing Protection Group. From the **Group** list, select an existing Protection Group and click **Protect**.

5. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, Create or Use an Existing Protection Policy .
6. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains.
7. In the **Start Time** field, select the time and time zone to start the protection run. This option is available only if the selected policy is set to Backup Daily. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
8. Cohesity supports protecting PVCs with the snapshot and restore feature of Container Storage Interface (CSI) drivers on CSI volumes. This option is disabled by default in your Cohesity protection job. To enable this feature, turn ON the **Leverage CSI snapshot** toggle. Once enabled, Cohesity clusters will begin utilizing snapshots captured by CSI drivers to protect the PVCs. These snapshots are crash-consistent, meaning that the PVC is in the same state as it was during the crash.
9. If you need to change any of the advanced settings on the Protection Group page, click the down arrow icon next to **Advance Settings** and click **Edit** on the right. For more information, Advanced Settings.
10. Click **Protect**.

    Your new Protection Group is now active and running.

Advanced Settings

Advance Settings	Description
Pause Future Runs	Enable **Pause Future Runs** to stop protection runs of the Protection Group from executing. Once you enable this option, no protection runs will be scheduled for this Protection Group.
End Date	Enable **End Date** and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts prior to this date runs until completion even if it completes after this date.

Advance Settings	Description
QoS Policy	Select an appropriate quality of service (QoS) policy. **Note:** Cohesity recommends specifying **Backup HDD**, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Alerts	Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts.
Email Recipients	You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection run.
Priority	Select a priority for the Protection Group eProtection Groupxecution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs

Advance Settings	Description
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks). • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. > **Note:** Users with similar SLAs can be grouped together and a custom policy and Protection Group can be created to achieve different SLAs.
Description	Enter a brief description about the Protection Group.
Include or Exclude PVC	Cohesity enables you to choose which PVCs to include or exclude in the Protection Group. To select the PVCs: a. Turn ON the **Enable PVC Inclusion/Exclusion** toggle. b. In the **Logical Rule** drop-down, select “Match Any of the following labels” or “All of the following labels”. c. Select **Include** or **Exclude**. d. Click **+ Add**. e. Enter the PVC’s label. The label is the unique identifier assigned to that PVC in the Kubernetes cluster. You can add more PVC until you have all the PVCs you want to be included or excluded for that Protection Group. > **Note:** PVC Inclusion or Exclusion settings of the Namespace take precedence over the settings of its Protection Group.
Include or Exclude Resource	Cohesity enables you to choose which resource types to include or exclude in the Protection Group. To select the Resource: a. Turn ON the **Enable Resource Inclusion/Exclusion** toggle. b. Select **Include** or **Exclude**. c. Click **+ Add**.

Create or Use an Existing Protection Policy

A Protection Policy is a reusable set of settings. It enables you to define how and when Kubernetes namespaces are protected, replicated, and archived. A standard policy provides various settings that you can configure for a Protection Group.

Create a Protection Policy with the settings listed in the Policy Settings for Kubernetes. For detailed instructions on how to create a Protection Policy, see Create or Edit a Standard Policy.

Policy Settings for Kubernetes

The following table lists the applicable policy settings for Kubernetes:

Field	Description
DataLock	If applicable, add a DataLock for compliance and regulatory requirements, to ensure that your protected data, including local backups, archives, and replication, cannot be modified until the DataLock expiration. Once applied, a DataLocked Snapshot will be deleted only after its retention period expires. A DataLock prevents all users, including those who have the Data Security role in Cohesity Data Cloud, from modifying or deleting any Snapshots that were generated by the Protection Groups that use this Policy. Only users with the Data Security role can add, modify, or remove a DataLock from a Policy.
Backup	Defines when backups are captured, how long they are retained and the type of backup to capture.
Periodic Full Backup	Use this option to choose when to run a periodic full backup.
Extended Retention	Add this to retain a subset of snapshots (backups) for longer than defined by the protection schedule.
Quiet Times	Quiet times define time periods when new protection runs are not started. For example, you might want to configure hourly backups that run during weekdays but not on Saturdays or Sundays. Quiet times only prevent new protection runs from starting during the specified time period. The protection runs that started before the quiet times are not affected and will continue to run. For example, if a protection run starts at 12:45 AM on Saturday morning and there is a weekend quiet time that starts at 1 AM on Saturday morning, the protection run will continue to run past 1 AM. No new protection runs are started during the quiet times.
Retry Options	Use this option to customize the retry settings for capturing Snapshots. By default, the Cohesity cluster attempts to capture Snapshots three times before the Protection Group fails. The default time between retries is five minutes. You can customize the number of retries and how long to wait between each attempt.

Field	Description
Replication	To replicate snapshots to another, click the **Replication** icon from the floating menu. The copied snapshots are stored in the storage domain of the remote cluster.
Archival	To add an archive schedule, click the **Archival** icon from the floating menu.

Use an Existing Protection Policy

You can edit an existing Protection Policy and configure it with applicable policy settings for Kubernetes cluster. In this case, all the policy settings apart from the settings applicable to Kubernetes cluster are ignored.

To use and existing Protection Policy:

1. In the Cohesity cluster, navigate to **Data Protection > Policies**.
2. On the **Policies** page, select the policy that you plan to edit.
3. On the **Policy Details** page, click **Edit** and configure the applicable policy settings for Kubernetes cluster. For information on the applicable policy settings, see Policy Settings for Kubernetes.
4. Click **Save**.

The updated policy settings are applied to the Protection Group in the next protection run.

Manage the Kubernetes Backup Configuration

In Cohesity Data Cloud, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

> **Note:** You cannot update the registered Kubernetes cluster and the assigned Storage Domain in the Protection Group settings.

Add Namespaces to the Protection Group

You can add new namespaces to the Protection Group for backup. The newly added namespaces are backed up from the next protection run, and it will be a full backup.

To add namespaces to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had created for the Kubernetes cluster.
3. Click the Actions menu (⋮) next to the Protection Group and select **Edit**.

4. On the Kubernetes page, click the edit icon in the **Objects** section.
5. From the namespaces list, select the namespaces that you plan to add to the backup and click **Save Selection**.
6. Click **Save**.

Remove Namespaces from the Protection Group

You can remove the Kubernetes namespaces from the Protection Group that you do not want to back up in the next protection run. When you remove a namespace from the Protection Group, the incremental backup of this namespace is not performed from the future protection run. The existing backup for the namespace is preserved until the snapshot expires.

To remove namespaces from the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for the Kubernetes cluster.
3. Click the Actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the Kubernetes page, click the edit icon in the **Objects** section.
5. From the namespaces list, unselect the namespaces that you plan to remove to the backup and click **Save Selection**.
6. Click **Save**.

Enable or Disable Auto Protect

You can enable the Auto Protect option at the:

- **Kubernetes cluster level**: Automatically protect the new namespaces that are added to the Kubernetes container.
- **Label level of the namespaces**: Automatically protect the new namespaces that are tagged with the same label you selected while enabling the auto protect.

When the Auto Protect option is enabled:

- All the namespaces that are added to the Kubernetes cluster or tagged with the same label in the future are automatically added to the Protection Group and are protected from the next protection run.
- All the namespaces that are removed from the Kubernetes cluster or untagged from the specified label in the future are automatically removed from the Protection Group and are not protected from the next protection run. The existing backup for the namespace is preserved until the snapshot expires.

When the Auto Protect option is disabled, you need to manually:

- Add newly added namespaces to the Protection Group.

- From the Protection Group, remove existing namespaces that are deleted on Kubernetes. The existing backups of the namespaces are preserved until the snapshot expires.

Enable or Disable Auto Protect at Kubernetes cluster level

To enable or disable Auto Protect at the Kubernetes cluster level:

1. Navigate to **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had created for the Kubernetes cluster.
3. Click the Actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the Kubernetes page, click the edit icon in the **Objects** section.
5. Click the icon in the cluster level to enable or disable Auto Protect and click **Save Selection**.
6. Click **Save**.

Enable or Disable Auto Protect at Label level

To enable or disable Auto Protect at the Kubernetes label level:

1. Navigate to **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had created for the Kubernetes cluster.
3. Click the Actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Kubernetes** page, click the edit icon in the **Objects** section.
5. Select the label icon ( ) available on the top-right of the **Objects** section.
