6. From the **label** drop-down list, select the label(s) for which you want to enable **Auto Protect**.
7. Click the icon in the enable or disable Auto Protect and click **Save Selection**.
8. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had created for Kubernetes.
3. Click the Actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Start an On-demand Protection Run

You can manually start a protection run of the Protection Group that you have created to back up the namespaces of the Kubernetes cluster. It provides you with options to:

- Back up all the objects or only selected objects in the Protection Group.
- Select an incremental or full backup.
- Add replication.
- Add Archival.

To start a protection run:

1. Navigate to **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had created for Kubernetes.
3. Click the Actions menu next (⋮) to the Protection Group and select **Run Now**.
4. In the pop-up window, perform the following:
    a. In the **Backup** drop-down list, select any one of the following:
        - **Backup all Objects in the Protection Group**
        - **Backup only selected Objects in the Protection Group**
    b. In the **Backup Type** drop-down list, select the backup type. By default, an incremental backup will be performed.
    c. Optional. In the **Replicate** section, select the replication target and the retention duration.
    d. Optional. In the **Archive** section, select the Archival target and the retention duration.
5. Click **Run Now**.

Pause Future Protection Runs

You can pause future protection runs for the Protection Group. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had created for Kubernetes.
3. Click the Actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had paused.
3. Click the Actions menu (⋮) next to the Protection Group and select **Resume**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- Delete Protection Group Only: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- Delete Protection Group and Snapshots: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

  After deleting the Protection Group and Snapshots, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had created for Kubernetes.
3. Click the Actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
   - **Delete Protection Group Only**
   - **Delete Protection Group and Snapshots**

Quiesce Kubernetes Workloads during Backups

Quiescing involves pausing an application to achieve a consistent state in preparation for a backup.

Cohesity supports quiescing stateful Kubernetes workloads before capturing Persistent Volume Claims (PVCs) volume snapshots during backup in a namespace. After the snapshots are taken, the Kubernetes workloads are automatically unquiesced. This ensures consistent and reliable snapshots for stateful applications running in Kubernetes.

When running a protection job for a namespace, there are pre-snapshot and post-snapshot hooks. Before taking a snapshot of any PVC attached to a Kubernetes pod within an application, the application should be in a consistent state. After taking the snapshot, a post-snapshot hook is executed called "unquiescing," which allows applications to resume their operations.

You can define actions to be executed before and after taking a snapshot. Hooks allow specific scripts to run within a group of pods identified by key-value pairs known as label selectors (each pod will have its labels). You can select pods constituting an application (which needs to be quiesced) by specifying labels. Velero will execute the designated script within the pod's container and provide the exit status of the script.

Each script has a timeout feature, with a default of 60 seconds. You can extend this duration if necessary. The scripts are executed at the container level, running on each container within a pod. You can specify a container name to execute a script on specific containers within the same pod.

To quiesce Kubernetes workloads during backups:

1. Register Kubernetes source.
2. In the Kubernetes source, select **Namespaces** > **Quiesce Rules** to view the different quiesce modes.
3. Choose any **Quiesce Mode**, for example, "Applying following rules together" to add different rules.
4. Click **Add Rule** to add a rule. You're able to add multiple rules.
5. Add the Key value under the **Pod Selector Labels**.
6. Click **Add Script** under pre-hooks to enter the container name, the command that needs to be run, and the timeout value in seconds. You can add multiple scripts under pre-hooks.
7. You can choose between "True" or "False" to indicate whether the backup should continue or fail when the script fails by selecting **Continue Backup when Script fails**. If the script fails, the protection job will still back up the PVC. However, if the script fails, the protection job will also fail.
8. Click **Add Script** under **Post Snapshot Scripts** to enter the container name, the command that needs to be run, and the timeout value in seconds. You can add multiple scripts under **Post Snapshot Scripts**.

9. Run the scripts. Ensure that the specified script is located at the correct path within the pod before you execute it.

   The pre-snapshot hook is triggered prior to taking snapshots of the PVCs. After the backup of the PVCs is completed, the post-snapshot hook is triggered to finalize the process. The **Backup Task Activity** for quiescing-ins, as shown in the pulse logs, will provide details about the execution of both the pre and post-snapshot hooks.

Recover Kubernetes

PVCs and the metadata of namespaces backed up to the Cohesity cluster can be restored. You can also perform granular recovery of files and folders within the PVCs.

- Recover Kubernetes Cluster
- Granular Recovery of Files and Folders

Recover Kubernetes Cluster

You can restore the PVCs and the metadata of the namespaces that are backed up onto the Cohesity cluster. You can restore the namespaces to the same location or to an alternate location.

> **Note:**
> - Cohesity does not support the granular-level recovery of the namespaces.
> - When recovering a namespace in Kubernetes, you may encounter a "Timed out" error on the Cohesity UI if the namespace is being recovered to an existing namespace where one or more pods are already awaiting a volume/PVC resource being recovered.
>
>   These pods might have been introduced in previous recovery attempts with certain excluded PVCs or through manual deployment.

Recovering Namespaces to the Same Location

When you are recovering the namespaces to the same or original location, then only the resources, PVCs, or the metadata of the Kubernetes namespaces that are missing or deleted from the original location are restored from the namespace snapshot you selected for recovery. Cohesity does not overwrite or restore the resources, PVCs, or the metadata of the Kubernetes namespace that already exists in the original location.

For example, a Kubernetes namespace you want to restore to the same location contains a deployment resource and a service account. When Cohesity initiates the restore to the original location and if the service account is missing from the original location, then Cohesity will restore only the service account. The restore of the deployment resource is skipped.

To restore the namespaces of a Kubernetes cluster to the same location:

1. In the Cohesity cluster UI, navigate to **Data Protection > Recoveries**.
2. Click **Recoveries** on the top-right of the page and then select **Kubernetes Cluster** as the recovery source.

   The Kubernetes Namespaces page appears.
3. Search for a namespace or Protection Group that contains the snapshots to recover from by entering characters of the namespace name, Protection Group name, or by specifying the wildcard character *.

   You can optionally filter the search results by source, Protection Group, Storage Domain, or date.
4. From the list of search results, select one or more objects (namespaces) or Protection Groups that contain the snapshots to recover.

   > **Note:**
   > - If you have selected a Protection Group, then all the namespaces backed up in the latest protection run of this Protection Group will be selected for recovery. The option to select these namespaces individually will be greyed out in the search result list.
   > - You can only select Protection Groups and namespaces with snapshots stored in the same Storage Domain and belonging to the same source. Once you select a namespace or Protection Group, the **Storage Domain** and **Source** filters will automatically get locked.

   By default, the latest snapshot is selected for recovery.
5. To recover from a different snapshot, perform the following steps depending on the object selected:

   > **Note:** In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

To choose a different snapshot for a..	Then..
Protection Group	a. From the selected lists, mouse over the snapshot, and then click the **edit** icon. b. From the **Protection Run** drop-down menu, select the snapshot from which you want to recover the namespaces. By default the snapshot is recovered from the local cluster. c. Optionally, you can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. d. Click **Select Recovery Point** and then go to step 6.
Namespace	a. From the selected lists, mouse over the snapshot, and then click the edit icon. The Edit recovery point for <namespace_name> page appears. By default, the page displays the snapshots available in the last one month. b. Optionally, you can also select a snapshot from a different date range or by selecting the date range from the **Date** drop-down list. Once you select the date range and then click **Apply**, the Edit recovery point page displays the available snapshots in the specified range. c. Select the snapshots to be recovered. By default, the snapshot is recovered from the local cluster. d. Optionally, you can also select snapshots archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. e. Click **Select Recovery Point** and then go to step 6.

6. Click **Next: Recover Options**.
7. From the **Recover To** options, select **Original Location** to recover the namespace to the original location.
8. From the **PVC Selection** option, select the PVCs of the namespace you want to recover.
9. Optional. Edit the default settings of the following **Recovery Options**:
    - **Rename**: Add Prefix and/or Suffix strings to the names of the new namespaces created by this task. For example, you could specify Prefix Test_ and Suffix _QA

to the namespace's name WinOS and when the namespace is recovered, the new namespace that is created is called Test_WinOS_QA.

- **Task Name**: Change the default name of the recovery task.
- **Namespace Resources**: Allows you to select the namespace resources you want to recover. Enable the following options to customize these settings: Click the edit icon on **Namespace Resources**.
  - **Resources**: In the Resources you can select the following options:
    a. **Persistent Volume Claim (PVC) Inclusion/Exclusion**: Enable this option to choose which PVCs to include or exclude in the recovery task.

       You also have an option to recover only PVCs and their dependent resources. The dependent resources include: ConfigMaps and PersistentVolumes.

    b. **Resource Inclusion/Exclusion**: Enable this toggle to include or exclude resource classes, and then select the protected resource from the drop-down.
  - **Storage Class**: Enable the following options to customize these settings:
    a. **Unbind PVCs from original PV mapping**: Before using this recovery option, you must specify the location of the Cohesity DataProtect Plugin image in the **Cohesity DataProtect Plugin Image Path** field during registration of a source.

       When enabled, the DataProtect Plugin Image clears certain fields from all PVCs within the namespace during the recovery process. This action removes references to the original PersistentVolume (PV), allowing the recovered PVCs to dynamically provision a new PV or bind to any available PV.

       This option is useful if the snapshot contains PVCs with a Retain reclaimPolicy.

    b. To map recovered PVCs to a different storage class:
       i. Click **+ Add** to create a new mapping.
       Each mapping includes two drop-down lists:
          - Left drop-down: Select a storage class from the source (backed-up) Kubernetes cluster.
          - Right drop-down: Select a storage class from the target Kubernetes cluster.

This mapping ensures that any PVCs using the selected source storage class are recreated using the selected target storage class during recovery.

ii. To create additional mappings, click **+ Add**.

10. Click **Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Recovering Namespaces to an Alternate Location

You can recover the namespaces of the Kubernetes to an alternate Kubernetes cluster that is registered with the Cohesity cluster. If you are recovering the Kubernetes namespace to an alternate location, then the entire namespace is restored. However, if you are restoring to this location again, then Cohesity will not restore the resources, PVCs, or the metadata of the Kubernetes namespace that already exist in the location.

To restore the namespaces of a Kuberneters cluster to the alternate location:

1. In the Cohesity cluster UI, navigate to **Data Protection > Recoveries**.
2. Click **Recoveries** on the top-right of the page and then select **Kubernetes Cluster** as the recovery source.

   The Kubernetes Namespaces page appears.
3. Search for a namespace or Protection Group that contains the snapshots to recover from by entering characters of the namespace name, Protection Group name, or by specifying the wildcard character *.

   You can optionally filter the search results by source, Protection Group, Storage Domain, or date.
4. From the list of search results, select one or more objects (namespaces) or Protection Groups that contain the snapshots to recover.

   Note:
   - If you have selected a Protection Group, then all the namespaces backed up in the latest protection run of this Protection Group will be selected for recovery. The option to select these namespaces individually will be greyed out in the search result list.
   - You can only select Protection Groups and namespaces with snapshots stored in the same Storage Domain and belonging to the same source. Once you select a namespace or Protection Group, the **Storage Domain** and **Source** filters will automatically get locked.

   By default, the latest snapshot is selected for recovery.

5. To recover from a different snapshot, perform the following steps depending on the object selected:

> **Note:** In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

To choose a different snapshot for a..	Then..
Protection Group	a. From the selected lists, mouse over the snapshot, and then click the **edit** icon. b. From the **Protection Run** drop-down menu, select the snapshot from which you want to recover the namespaces. By default the snapshot is recovered from the local cluster. c. Optionally, you can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. d. Click **Select Recovery Point** and then go to step 6.
Namespace	a. From the selected lists, mouse over the snapshot, and then click the edit icon. The Edit recovery point for <namespace_name> page appears. By default, the page displays the snapshots available in the last one month. b. Optionally, you can also select a snapshot from a different date range or by selecting the date range from the **Date** drop-down list. Once you select the date range and then click **Apply**, the Edit recovery point page displays the available snapshots in the specified range. c. Select the snapshots to be recovered. By default, the snapshot is recovered from the local cluster. d. Optionally, you can also select snapshots archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. e. Click **Select Recovery Point** and then go to step 6.

6. Click **Next: Recover Options**.

7. From the **Recover To** options, select **New Location** to recover the namespace to the new location.
8. From the **PVC Selection** option, select the PVCs of the namespace you want to recover.
9. Optional. Edit the default settings of the following **Recovery Options**:
    - **Rename**: Add Prefix and/or Suffix strings to the names of the new namespaces created by this task. For example, you could specify Prefix Test_ and Suffix _QA to the namespace's name WinOS and when the namespace is recovered, the new namespace that is created is called Test_WinOS_QA.
    - **Task Name**: Change the default name of the recovery task.
    - **Namespace Resources**: Allows you to select the namespace resources you want to recover. Enable the following options to customize these settings: Click the edit icon on **Namespace Resources**.
        - **Resources**: In the Resources you can select the following options:
            a. **Persistent Volume Claim (PVC) Inclusion/Exclusion**: Enable this option to choose which PVCs to include or exclude in the recovery task.

            You also have an option to recover only PVCs and their dependent resources. The dependent resources include: ConfigMaps and PersistentVolumes.

            b. **Resource Inclusion/Exclusion**: Enable this toggle to include or exclude resource classes, and then select the protected resource from the drop-down.
        - **Storage Class**: Enable the following options to customize these settings:
            a. **Unbind PVCs from original PV mapping**: Before using this recovery option, you must specify the location of the Cohesity DataProtect Plugin image in the **Cohesity DataProtect Plugin Image Path** field during registration of a source.

            When enabled, the DataProtect Plugin Image clears certain fields from all PVCs within the namespace during the recovery process. This action removes references to the original PersistentVolume (PV), allowing the recovered PVCs to dynamically provision a new PV or bind to any available PV.

            This option is useful if the snapshot contains PVCs with a Retain reclaimPolicy.

            b. To map recovered PVCs to a different storage class:

i. Click **+ Add** to create a new mapping.
Each mapping includes two drop-down lists:
   - Left drop-down: Select a storage class from the source (backed-up) Kubernetes cluster.
   - Right drop-down: Select a storage class from the target Kubernetes cluster.

   This mapping ensures that any PVCs using the selected source storage class are recreated using the selected target storage class during recovery.

ii. To create additional mappings, click **+ Add**.

10. Click **Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Recover Kubernetes Namespaces

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

The temporary pods created during recovery by Cohesity will have their priority class set to the specified value for the source. Additionally, the labels and annotations will be applied to the temporary pods.

Granular Recovery of Files and Folders

Cohesity supports Kubernetes clusters for granular recovery of files and folders within Persistent Volume Claims (PVCs). It allows for the selective recovery of files and folders from backed-up data volumes instead of restoring the entire volume in case of data corruption. This capability enables users to recover specific files or related files and folders efficiently.

While you register a Kubernetes source on the Cohesity cluster and create a Protection Group, you can perform the backup of namespaces. This allows you to search and browse the backed-up PVC folders and files you want to recover by providing their names. Each file and folder is indexed within volumes of type PersistentVolumeClaims in Kubernetes namespaces from snapshots taken during Kubernetes backups. Once indexed, the files and folders are available for searching and browsing.

You have the option to either download the files or initiate the recovery of files and folders. You can specify the download path if you choose to download the files. If you choose the restore option, you can select one or more files and folders from a single object. The recovered files and folders can be restored to their original location (such as the source,

namespace, PVC, and file path) or an alternate location wherein the target source must be registered.

You can specify the recovery path and choose to preserve the original permissions and attributes of the recovered files and folders at the time of the backup. Additionally, you can overwrite files and folders or download them from selected snapshots created by a Cohesity Protection Group.

> **Note:**
> - For archived items, only downloading is supported.
> - If restoring to a different location, you must turn on the PVC inclusion/exclusion feature and enable the corresponding magneto flag. This is necessary to list the PVCs available for selection during recovery.

Considerations

- Granular recovery from archival is not supported. Only download is supported.
- If recovering to an alternate location, ensure that the file system of the target supports the recovery of files.
- Granular recovery is only supported for volumes of type PersistentVolumeClaims.
- Recovery of files and folders to an alternate location is restricted to already registered Kubernetes sources.
- Granular recovery does not support file and folder recovery involving multiple namespaces.
- Granular file recovery from the archive to the original sources is not supported. Only file downloads are allowed.
- Attempt to resubmit a failed Kubernetes restore job may fail with the following error message:

  "Error while calling FileStat for /cohesity-data/cohesity-data/pv-5tb: [kNotFound]: Bridge error: Directory not present."

  The issue occurs due to a known UI bug, which adds an extra "cohesity-data" to the file path with each resubmission. A fix for this issue is expected in a future release.

For more information about the recovery options:

- Recover Files or Folders to the Original Location
- Recover Files or Folders to a New Location within the original source

Recover Files or Folders to the Original Location

You can recover the files and folders within the PVCs to the original location. To restore the files and folders to the same location:

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** at the top right of the page and then select **Kubernetes Cluster** > **Files or Folders** as the recover source.

   The Files recovery page appears.
3. Select any one of the following options to search for the file or folder:
   a. **Files and Folders**: Allows you to search and recover files using file or folder names from any backup available on the Cohesity cluster.
   b. **Browse**: Allows you to search and recover files using the name of the server or Protection Group from any backup available on the Cohesity cluster.
4. Search for files and folders that contain the snapshots to recover from by entering characters of the files or folder name or by specifying the wildcard character *.
5. From the search results list, select one or more objects (files or folders or Protection Groups containing the snapshots to recover).
6. You have the option to select either **Download** or **Recover files**. To download, select the recovery point by choosing **Select Recovery Point** and then click on the **Download** option to download files and folders. To recover, proceed to the next step.
7. Click **Next: Recover Options**.
8. Select **Original Server**, to recover the files or folders to the original location.
9. Optional. Edit the default settings of the following **Recovery Options**: You can select any one of the Recovery options:
   a. **Overwrite Existing File/Folder**: Allows to overwrite the existing files and folders with new ones during recovery.
   b. **Preserve File/Folder Attributes**: Allows to preserve the attributes of the existing files and folders during recovery.
   c. **Continue on Error**: Allows to continue recovery even if one of the objects encounters an error
   d. **Cluster Interface**: Is auto-selected,
   e. **Task Name**: Change the default name of the recovery task.
10. Click **Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Recover Files or Folders to a New Location

To recover files and folders to a new location:

> **Note:** It is recommended that the file system at the new location be the same as the source.

1. Navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** located at the top right of the page and then select **Kubernetes Cluster** > **Files or Folders**.

   The FIles recovery page appears.
3. Select any one of the following options to search for the file or folder:
   a. **Files and Folders**: Allows you to search and recover files using file or folder names from any backup available on the Cohesity cluster.
   b. **Browse**: Allows you to search and recover files using the name of the server or Protection Group from any backup available on the Cohesity cluster.
4. Search for files and folders that contain the snapshots to recover from by entering characters of the files or folder name or by specifying the wildcard character *.
5. From the search results list, select one or more objects (files or folders or Protection Groups containing the snapshots to recover).
6. You have the option to select either **Download** or **Recover files**. To download, select the recovery point by choosing **Select Recovery Point** and then click on the **Download** option to download files and folders. To recover, proceed to the next step.
7. Click **Next: Recover Options**.
8. Select **New Server** , to recover the files or folders to the new location.
9. Select any of the registered source, namespace, persistent volume claim, and the path to save the recovered files or folders.
10. Optional. Edit the default settings of the following Recovery Options: You can select any one of the Recovery options:
    a. **Overwrite Existing File/Folder**: Allows to overwrite the existing files and folders with new ones during recovery.
    b. **Preserve File/Folder Attributes**: Allows to preserve the attributes of the files from the snapshot, regardless of their existence.
    c. **Continue on Error**: Allows to continue recovery even if one of the objects encounters an error.
    d. **Cluster Interface**: Is auto-selected,
    e. **Task Name**: Change the default name of the recovery task.
11. Click **Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Red Hat OpenShift Virtualization

Red Hat OpenShift Virtualization is a feature of Red Hat OpenShift that allows you to manage and run VMs and container workloads together. It is based on the open-source project KubeVirt and uses a Kernel-based VM (KVM) within Kubernetes.

OpenShift API for Data Protection (OADP)

Cohesity now supports the OpenShift API for Data Protection (OADP) operator, a Red Hat solution that simplifies the registration and maintenance of Velero and Plugin versions. OADP is based on the open-source tool Velero, which allows for effective metadata backup.

Plan and Prepare for Protecting Red Hat OpenShift Cluster

Before you register your Red Hat OpenShift cluster on the Cohesity platform, ensure that:

- Cohesity cluster supports the Red Hat OpenShift cluster version you plan to protect. For more information, see Supported Versions.
- The firewall ports required for the communication between the Cohesity cluster and Red Hat OpenShift cluster are open. For more information, see Network Firewall Considerations.
- You have the minimum permission required to register and manage your Red Hat OpenShift cluster. For more information, see Minimum Permissions.
- You meet the prerequisites to register and manage your Red Hat OpenShift cluster. For more information, see Prerequisites.
- You have read the considerations for the backup and recovery of the Red Hat OpenShift cluster. For more information, see Considerations.

Supported Versions

Cohesity cluster supports data protection and recovery of the Red Hat OpenShift cluster. For supported versions of the Red Hat OpenShift clusters, see Supported Versions.

Network Firewall Considerations

If there is a firewall between the Cohesity cluster and the Red Hat OpenShift cluster, the following ports need to be opened.

Cohesity cluster	Type:Port	Direction	Red Hat OpenShift cluster	Type:Port	Usage Notes
Cohesity cluster nodes	TCP:	Outgoing	Red Hat OpenShift cluster api-address	TCP: <Red Hat OpenShift API server port>	Red Hat OpenShift cluster and Velero API Access. For more details on Velero support, see the Considerations section.
Cohesity cluster nodes	TCP:	Outgoing	Red Hat OpenShift cluster worker nodes	TCP:30000-32767[1] TCP:32000-(32000+#<worker nodes>)[2]	Cohesity cluster to Cohesity Datamover communication
Cohesity cluster VIPs	TCP:3000	Incoming	Red Hat OpenShift cluster	TCP	Velero S3 communication for metadata backups and restores

1 TCP:30000-32767 are supported only on releases 6.6.0a to 6.6.0d_u1.

2 TCP:32000-(32000+#<worker nodes>) are supported only on releases 6.6.0d_u2 and later.

Minimum Permissions

To register the Red Hat OpenShift cluster with the Cohesity cluster, you must provide the Bearer token ID of the service account. Ensure that the service account has the cluster-admin role on the Red Hat OpenShift cluster.

Prerequisites

Ensure that you meet the following prerequisites to register and manage your Red Hat OpenShift cluster:

- **Valid Certificate with Subject Alternative Name (SAN) field** —On the Cohesity cluster, install a valid certificate with the SAN field. The SAN field is used to specify additional host names (such as sites, IP addresses, and common names) to be protected by a single SSL certificate, such as a Multi-Domain or Extend Validation Multi-Domain Certificate. For more information, see Update SSL Certificates Using Cohesity CA or Customer CA certificate.
- **Create a Cohesity service account**—For registering a Red Hat OpenShift cluster with the Cohesity cluster, you can either use a default service account with the cluster-admin role or a dedicated service account with the cluster-admin role account. Cohesity recommends you to create a dedicated account in the default namespace.

For example, to create a 'cohesity' service account, use the following command:

```
kubectl create serviceaccount cohesity -n default
```

Assign the cluster-admin role to the 'cohesity' service account using the following command:

```
kubectl create clusterrolebinding cohesity-admin --clusterrole=cluster-admin --serviceaccount=default:cohesity
```

The above example can be run from any client or workstation from which `kubectl` is typically run for a given Red Hat OpenShift cluster that is registered and protected by the Cohesity cluster.

- For current version of Red Hat OpenShift, run the following command to generate the Bearer Token ID or secret token for your service account.

```
kubectl apply -f - <<EOF
apiVersion: v1
kind: Secret
metadata:
  name: cohesity-token
  annotations:
    kubernetes.io/service-account.name: cohesity
type: kubernetes.io/service-account-token
EOF
```

Sample Ouput

```
secret/cohesity-token created
```

- **Extract the Bearer token ID**—To register the Red Hat OpenShift cluster with Cohesity cluster, you must have the Bearer token ID of the Kubernetes service account. Extract the Bearer token of the service account that has admin privileges on the Red Hat OpenShift cluster.

  Extract the Bearer token using the following command:

```
kubectl describe secrets -n default cohesity-token | grep token: | awk '{print $2}' | head -1

eyJhbGciOiJSUzI1NiIsImtpZCI6IjRtZzBkX0VRLXMwV05veFdvcjR3eGw1N2c4MUk0RXlhWFBPdXBHNUVoTlkifQ.eyJpc3MiOiJrdWJqcm5ldGVzL3NlcnZpY2VhY2NvdW50Iiwia3ViZXJuZXRlcy5pby9zZXJ2aWNlYWNjb3VudC9uYW1lc3BhY2UiOiJkZWZhdWx0Iiwia3ViZXJuZXRlcy5pby9zZXJ2aWNlYWNjb3VudC9zZWNyZXQubmFtZSI6ImNvaGVzaXR5LXRva2VuL2Y0ZG02Iiwia3ViZXJuZXRlcy5pbF9zZXJ2aWNlYWNjb3VudC9zZXJ2aWNlLWFjY291bnQubmFtZSI6ImNvaGVzaXR5Iiwia3ViZXJuZXRlcy5pby9zZXJ2aWNlYWNjb3VudC9zZXJ2aWNlLWFjY291bnQudWlkIjoiZDg4NmE5ZWMtMzQxYi00ZTM3LTg1MjktMzYxNGJiY2U

```

- **Obtain the Cohesity Datamover Docker Image**—To back up the PVCs of the Kubernetes namespaces, you must push the Cohesity Datamover image to an image registry accessible by your Red Hat OpenShift cluster.

  To install the Cohesity Datamover image:

  1. Obtain the Datamover image that matches closely with your Cohesity cluster version from the Cohesity Download page.
  2. To push the Datamover image to your Docker registry:
     1. Run the following command to log into your Docker image registry:

        ```
        docker login <your image registry server>.fqdn
        ```

        If prompted, enter the credentials that have the permissions to push the Cohesity Datamover image to your image registry. Skip this login command if your image registry does not require authentication to push images.
     2. Load the Datamover image:

        ```
        docker load --input cohesity-datamover-<your Datamover
        version>.tar
        ```

        Replace <your Datamover version> in the preceding command with the version in your Datamover image name.

        Example:

        ```
        docker load --input cohesity-datamover-6.6.0d_u6.tar
        ```

        ```
        docker load --input cohesity-datamover-6.8.1_u1.tar
        ```

     3. Run the following command, and from the command result, make a note of the Image ID of the Datamover image:

        ```
        docker images
        ```

     4. Tag the Datamover image with the Image ID you made a note of in step c:

```
docker image tag <ID of your image> <your image registry
server>.fqdn/path/cohesity-datamover:<your Datamover version>
```

5. Push the Datamover image to your Docker registry:

```
docker push <your image registry server>.fqdn/path/cohesity-
datamover:<your Datamover version>
```

> **Note:** The preceding example assumes you use Docker to load, tag, push, and pull the Docker images. If you use Podman, replace `docker` with `podman`.

Considerations

- Cohesity does not support incremental backup.
- While protecting VMs with Block mode, ensure that you are using the latest version of Datamover.
- Cohesity does not support the restoration of VMs with partially selected PVCs. As a result, the VMs will not get provisioned. Also, configuration change is required to remove the excluded disk configurations.
- PVCs not attached to any pods are protected if a CSI snapshot is available for the Volume.
- You must toggle ON the CSI snapshot for crash-consistent backups. If a CSI snapshot is not enabled on the Protection Group or fails during its creation, the backup may still proceed for the VM. However, this backup may be inconsistent.
- Cohesity does not support granular recovery of files and folders within VMs.
- Cohesity does not support quiescing VMs during backups.
- If SELinux is enabled on the VM, correct permissions should be set on qemu-agent to allow it to run guest-fsfreeze commands.
- Cohesity does not support recovery from backups if the storage class is deleted after the backup is made from the source and that same storage class is not present on the alternate cluster.
- If the Machine type is not supported on the alternate cluster then recovery is successful but the VM quits unexpectedly. Ensure that the required Machine type is available on the alternate location cluster.
- In scenarios where the Red Hat OpenShift cluster lacks external IP support, a configuration change may be needed to support backups and recoveries. Contact your Cohesity account team to enable the feature.
- During the backup process, metadata for all resources in the namespace is backed up, but only the volumes of the selected VMs are included in the backup.

- During the recovery process, if all VMs in a namespace are being recovered, the entire metadata for that namespace is also recovered along with the VMs and their associated volumes.
- If VMs are selectively recovered, only the metadata of the resources connected to those selected or backed up VMs, along with their volumes, will be restored.
- If the version of the Red Hat OpenShift cluster is lower than 4.17, the deployment of the OpenShift API for Data Protection (OADP) operator is not supported.
- During the deployment of the operator, the subscription channel is set to stable-1.4, which automatically manages any minor updates to the operator. If you have deployed another OADP operator with a different stable channel, then the Cohesity operator deployment is not supported.
- If the Velero CRDs are already present, you cannot deploy the OADP operator by default. You must delete the CRDs and click refresh on the OpenShift source in the Cohesity UI to deploy the operator.
- After restoring a VM with a hotplug disk, the disk appears in the VM configuration but is not visible within the VM. As a workaround, either restart the VM or remove the older hotplug pod that is currently running to detect the hotplug disk within the VM.
- Backups fail if the namespace contains a VM that is in a paused state. As a workaround, stop the paused VM and reinitiate the backup. As a workaround, for assured data consistency during backups, VMs should be powered down before initiating the backup.
- Backing up a VM that uses LVM or has a file system spanning multiple disks may result in data corruption. The issue occurs when the snapshots of the underlying volumes or PVCs are not captured at the same point in time, resulting in inconsistencies
- For IPv6 support, the Cohesity cluster must be configured with a preferred IPv6 address.
- Instant recovery feature is supported starting from OpenShift 4.18.
- VM recovery using the override option is not supported.
- When creating target data volumes for VM migration, the volume mode (Filesystem or Block) is not explicitly specified.
- A Velero backup may fail if the PVC associated with a VM is deleted before the backup is triggered. As a result, the Velero fails to backup deleted PVC and marks the metadata backup as failed:

  "Backup job failed by Velero."
- After upgrading the Cohesity cluster from version 7.2.2_u2 to 7.3.1, if an incremental backup is run using an existing Protection Group to generate a new snapshot, instant recovery of a VM from that snapshot may fail with the following error:

  "Failed to clone the namespace backup view."

Instant Recovery is supported starting from version 7.3.1. For existing Protection Groups, a forced full backup is required. Run a full backup of the affected Protection Group to ensure that subsequent backups create separate views.

- **For KubeVirt**

  Below are the considerations for KubeVirt. For more information, see limitations:

  - Migration of hot-plug disks is not supported.
  - Migration of shareable disks is not supported, as data consistency cannot be guaranteed with multiple writers.
  - Live migration is not supported when using virtiofs because it does not currently provide live migration capabilities.
  - Original disks may support the SCSI protocol, but the destination PVC storage class might not support it.
  - KubeVirt currently supports live migration only between separate nodes.

    > **Note:** After upgrading to version 7.3.1, ensure you run a full backup of all VMs in the existing protection jobs.

Register and Manage Red Hat OpenShift Cluster

To protect the namespaces of the Red Hat OpenShift cluster, you must first register your Red Hat OpenShift cluster as a source on the Cohesity cluster. After registering your source, you can also perform the following actions:

- Update the Red Hat OpenShift cluster source configuration.
- Refresh the source details.
- Unregister the Red Hat OpenShift cluster from the Cohesity cluster.

Register Red Hat OpenShift Cluster as a Source

Before you register the Red Hat OpenShift cluster as a source on the Cohesity cluster, ensure that you:

Review the requirements, considerations, and best practices.

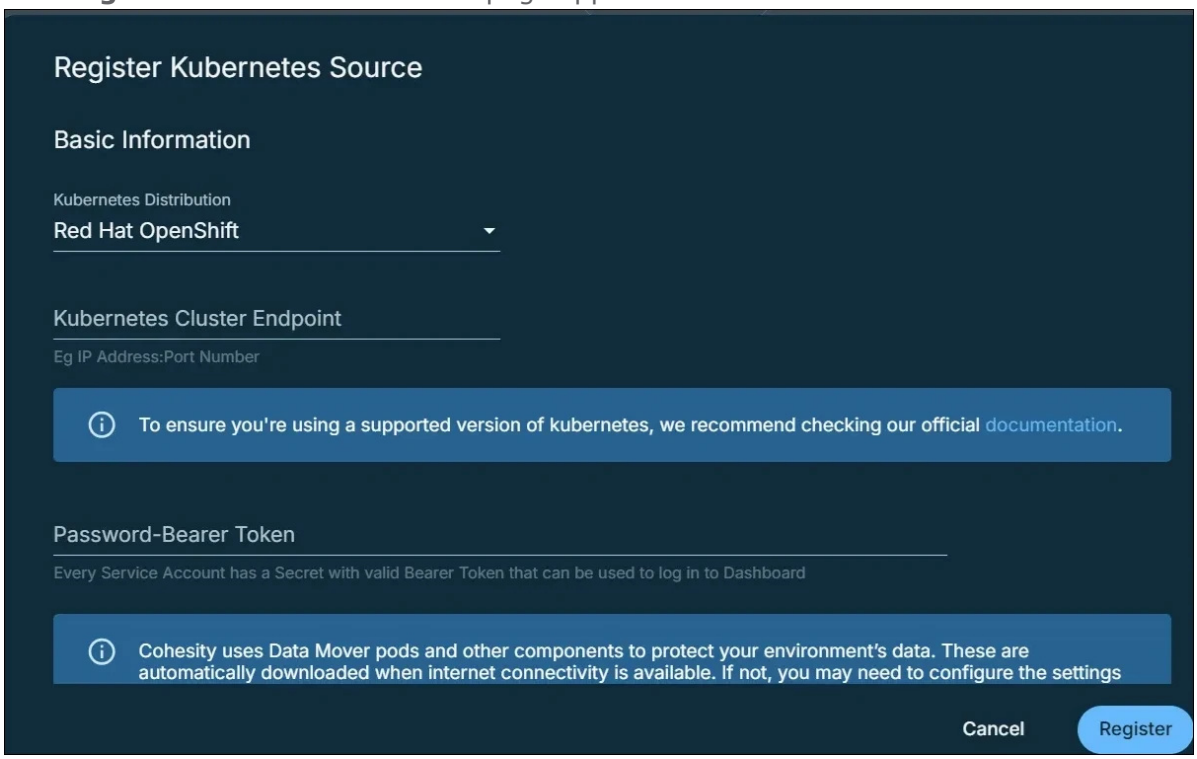
Perform the prerequisite tasks.

For more information, see Plan and Prepare for Protecting Red Hat OpenShift Cluster.

To register the Red Hat OpenShift cluster as a source on the Cohesity cluster:

1. Navigate to **Data Protection > Sources**.
2. Click **Register** and then select **Kubernetes Cluster**.

The **Register Kubernetes Source** page appears.



3. From the **Kubernetes Distribution** drop-down, select Red Hat OpenShift Kubernetes distributions to backup and recover.
4. In the **Kubernetes Cluster Endpoint** field, based on your requirements, enter the Kubernetes API Server endpoints in one of the following formats:

   https://<FQDN>:<port_number>

   IPv4

   Format: https://<IPv4 address>:<port_number>

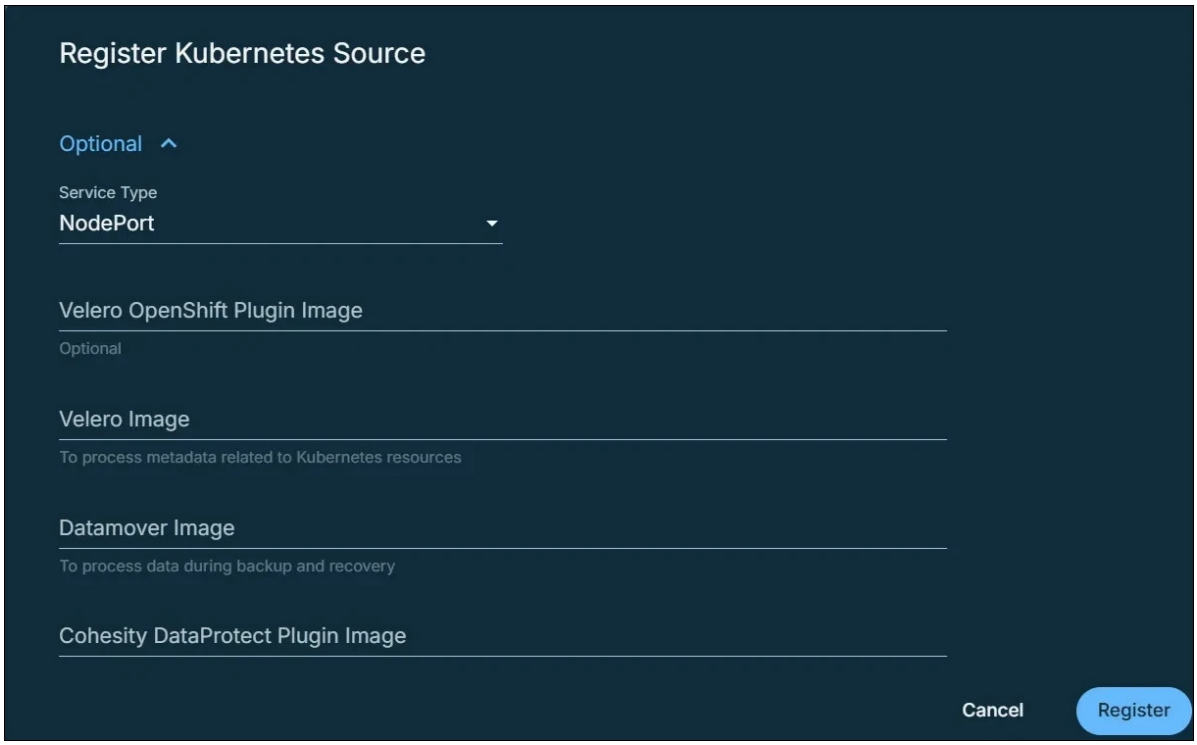
   Example: https://10.14.58.2:6443IPv6

   Format: https://[<IPv6 address>]:<port_number>

   Example: https://[2400::9000:0:0:500:12]:6443

   In the **Password-Bearer Token** field, enter the Bearer token ID of the Kubernetes service account. For information on obtaining the Bearer token ID, see Plan and Prepare for Protecting Red Hat OpenShift Cluster.
5. *(Optional)***Service Type**: Enable this field to route external traffic to your Red Hat OpenShift cluster node via dedicated VLANs.

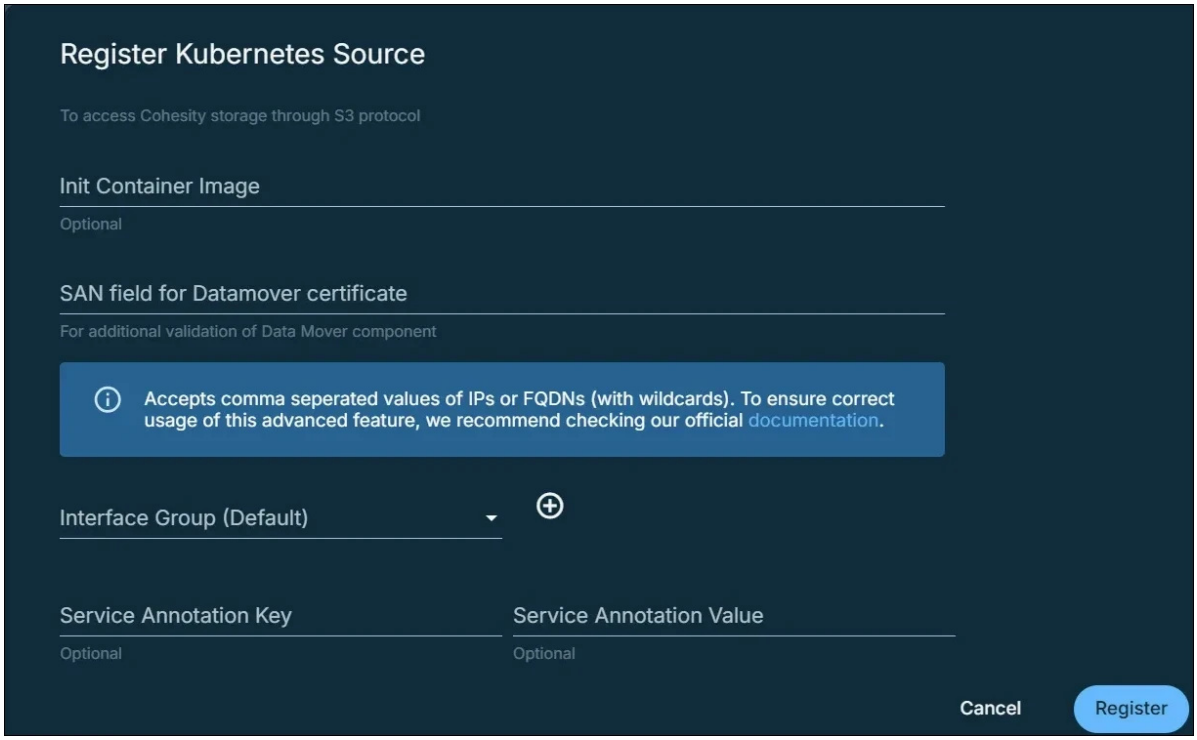
   From the drop-down, select one of the following service types:



- **NodePort** service type allows you to route external traffic through a fixed port (which you can set within the range of 30000-32767) on every Kubernetes node. In a NodePort setup, external traffic has direct access to the Kubernetes node.
- **Load Balancer** service type allows you to route external traffic via an external Load Balancer functionality. Load Balancers monitor the availability of your Kubernetes pods and route incoming service requests to the relevant pods. In a Load Balancer setup, external traffic has access to the Kubernetes node through the Load Balancer only.

6. *(Optional)***Velero OpenShift Plugin Image**: This plugin image will be deployed by the OADP operator for Red Hat OpenShift Virtualization.
7. *(Optional)***Velero Image**: This plugin image will be deployed by the OADP operator for Red Hat OpenShift Virtualization.
8. **Datamover Image**: Enter the location where you have the Datamover image saved in your registry accessible from the OpenShift cluster. The image must be entered in the format: `<Image_name>:<TAG>`.
9. *(Optional)***Cohesity DataProtect Plugin Image**: Enter the location where you have the Cohesity DataProtect Plugin image saved. This plugin is required when selecting the VM.
10. *(Optional)***Velero Kubevirt Plugin Image**: This plugin image will be deployed by the OADP operator for Red Hat OpenShift Virtualization.

11. *(Optional)***Velero AWS Plugin Image**: This plugin image will be deployed by the OADP operator for Red Hat OpenShift Virtualization.
12. *(Optional)***Init Container Image**: Enter the location where you have the Init Container image saved in your Docker registry. If you leave this field blank, then Cohesity will use the Datamover image as the Init Container image



13. **Interface Group (Default)**: Displays all the Interface Groups set in your cluster. Click the **+** icon to add as many Interface Groups as needed. Once the Interface Groups are created, the traffic of the Service Type (you selected in Step 8) will only flow through the Interface Group(s), creating a separate channel for the traffic.

    Vlan Annotation Key and **Vlan Annotation Value**: Displayed only if the **Load Balancer Service Type** is selected. Enter the key-value pair to specify a VLAN that the Load Balancer service deploys to.

    Load balancer services allow you to configure a specific kind of address pool (in this case VLAN). For example, if you use the MetalLB LoadBalancer service, you need to set the **Vlan Annotation Key** to "metallb.universe.tf/address-pool" and the **Vlan Annotation Value** should be the name of the address pool. For more information, see the documentation of your LoadBalancer service.

    > **Note:** The Interface Group field is an Early Access feature. Contact your Cohesity account team to enable it.

14. **Service Annotation Key** and **Service Annotation Value** Enter the Service annotation key-value pairs. These key-value pairs are utilized to store metadata that offers information about the selected Kubernetes service that Cohesity deploys. This metadata does not affect the behavior of the Red Hat OpenShift cluster.

    > **Note:** The Service Type field is an Early Access feature. Contact your Cohesity account team to enable it.

15. Click **Register**.

Post-Registration Task

Once you register the Red Hat OpenShift cluster with the Cohesity cluster, perform the following actions:

- Run the following command to view the ports associated with each node of the Red Hat OpenShift cluster.

  ```
  kubectl get services -n cohesity-<cluster-id>
  ```

  Ensure the ports associated with the nodes are open to enable communication between the Red Hat OpenShift cluster and the Cohesity cluster.

  For information on other required ports, see Network Firewall Considerations.

- Verify all of the pods in the Red Hat OpenShift cluster are in running state by running the following command:

  ```
  kubectl get pods -n cohesity-<cluster-id>
  ```

  The namespaces are displayed on the **Sources** page of the Cohesity Dashboard only after all the pods are either in the running state or error state.

- Refresh the Red Hat OpenShift source if there is an error on the source page. For more information, see Refresh the Red Hat OpenShift Source.

Update the Red Hat OpenShift Cluster Source Configuration

You can update the Red Hat OpenShift cluster details that you had provided during the registration process with the latest Red Hat OpenShift cluster configuration.

To edit the Red Hat OpenShift cluster source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Red Hat OpenShift cluster source and select **Edit**.
3. In the Register Kubernetes Source page, update the respective configurations.
4. Click **Register**.

Refresh the Red Hat OpenShift Source

You can refresh the Red Hat OpenShift and fetch the latest changes on the Red Hat OpenShift cluster. To refresh the Red Hat OpenShift cluster source configuration:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Red Hat OpenShift cluster source and select **Refresh**.

Unregister Red Hat OpenShift Cluster

If you plan to stop taking the backup of your Red Hat OpenShift cluster, you can unregister the Red Hat OpenShift cluster source from the Cohesity cluster.

Before unregistering, ensure to delete all the Protection Groups associated with the Kubernetes source.

To unregister the Red Hat OpenShift cluster:

1. Navigate to **Data Protection > Sources**.
2. Click the actions menu (⋮) next to the Red Hat OpenShift cluster source and select **Unregister**.

Perform a Manual Cleanup

To perform a manual cleanup:

1. Stop all the Red Hat OpenShift protection jobs that are currently running and ensure there are no active protection runs on the Red Hat OpenShift source.
2. Run the following command to delete the Cohesity namespace in the Red Hat OpenShift cluster:

   ```
   - oc delete ns <name of the Cohesity namespace>
   ```

   Example

   ```
   - oc delete ns cohesity-21234567891234
   ```

3. Run the following command to delete the CRDs specific to Cohesity:

   ```
   - oc delete crds -l operators.coreos.com/redhat-oadp-operator.<Cohesity namespace>
   ```

   Example

   ```
   - oc delete crds -l operators.coreos.com/redhat-oadp-operator.cohesity-21234567891234
   ```

4. Delete the operator from the cluster using the following command:

   ```
   - oc delete operator redhat-oadp-operator.<Cohesity namespace>
   ```

   Example

   ```
   - oc delete operator redhat-oadp-operator.cohesity-21234567891234
   ```

Upgrade to OpenShift API for Data Protection (OADP)

After upgrading the Cohesity cluster, make sure you follow steps to make use of the newly supported features. Additionally, update the Datamover image to the latest version to.

Upgrade When the Cohesity Namespace is Present

To upgrade from Velero deployment to OADP:

1. Stop all the Red Hat OpenShift protection jobs that are currently running and ensure there are no active protection runs on the Red Hat OpenShift source.
2. Run the following command to delete the Cohesity namespace in the Red Hat OpenShift cluster:

   ```
   - oc delete ns <name of the Cohesity namespace>
   ```

   Example

   ```
   - oc delete ns cohesity-21234567891234
   ```

3. Run the following command on any node of that Red Hat OpenShift cluster (or from a node in another Red Hat OpenShift cluster that has access to the OpenShift command-line tool) to delete the Velero CRD:

   ```
   - oc delete crds -l component=velero
   ```

4. To edit the Red Hat OpenShift cluster source configuration:
   a. Navigate to **Data Protection** > **Sources**.
   b. Click the Actions menu (⋮) next to the Red Hat OpenShift cluster source and select **Edit**.
   c. In the Register Kubernetes Source page, enter the locations of the new DataProtect Plugin and Data Mover images in the **Datamover Image** field, respectively.
   d. Click **Register**.

Backup Red Hat OpenShift Virtualization

Cohesity supports the backup of PVCs, VMs, Red Hat OpenShift cluster resources and metadata of the Kubernetes namespaces. Cohesity uses the Data Mover pod that will be deployed in the Red Hat OpenShift cluster for backing up the PVCs of the Kubernetes namespaces.

Cohesity supports the backup of PVCs with the volumeMode set to Filesystem or Block.

Cohesity uses the VM Snapshot API that enables taking a single snapshot of all volumes associated with a VM in one backup operation. PVCs that are not associated with the VM but exist within the same namespace will continue to use individual volume snapshots for backup purposes.

The supported file systems include ext3, ext4, xfs, vxfs, ReiserFS, autofs, cvfs, zfs, fuse, mfs, nfs, nfs3, cifs, gpfs, and mmfs.

Cohesity also supports the backup of PVCs with CSI drivers using CSI volume snapshotting capability.

> **Note:** Cohesity recommends that the entire namespace containing VMs should be protected, without any exclusions. Additionally, it is recommended to use CSI snapshots.

After registering the Red Hat OpenShift cluster as a source on the Cohesity cluster, you can start configuring your backups.

Protect Red Hat OpenShift Cluster

In the Cohesity cluster, Kubernetes namespaces are protected using a Protection Group and a Protection Policy. A Protection Group uses the schedules and settings defined in the policy to determine when and how backups are captured, archived, or replicated.

A Protection Policy is a reusable set of settings that define how and when objects are protected and replicated. You can select which standard or custom policy to use when creating a Protection Group.

To protect the namespaces of the Kubernetes containers:

1. In the Cohesity cluster UI, perform one of the following:
   - Select **Data Protection > Protection**. Click **Protect** displayed on the top-right of the page and then select Kubernetes Cluster.
   - Select **Data Protection > Sources**. Click the Actions menu (⋮) next to the Red Hat OpenShift source and then select Protect.
2. From the **Registered Source** drop-down list, select the registered Red Hat OpenShift source or click **Register Source** to register a Red Hat OpenShift source. For more information, see Register Red Hat OpenShift Cluster as a Source.
3. From the **Objects** list, select the namespaces that you plan to backup and click **Save Selection**.

> **Note:** You can use the advanced filters that are available to search and find the namespaces you plan to protect. Also, you can click the shield icon to enable Auto Protect at the Red Hat OpenShift cluster level or based on the namespace label(s). For more information, see Enable or Disable Auto Protect.

4. In the Protection Group section, perform one of the following:
   - Select **New Group** to create a new Protection Group. In the **Name** field, enter a name from the Protection Group and go to step 5.
   - Select **Existing Group** to use the settings of an existing Protection Group. From the **Group** list, select an existing Protection Group and click **Protect**.
5. From the **Policy** drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, see Create or Use an Existing Protection Policy .
6. Select the appropriate **Storage Domain**. For more information, see Manage Storage Domains.
7. In the **Start Time** field, select the time and time zone to start the protection run. This option is available only if the selected policy is set to Backup Daily. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting. The default time zone is the browser's time zone. You can change the time zone of the protection run by selecting a different time zone.
8. Cohesity supports protecting PVCs with the snapshot and restore feature of Container Storage Interface (CSI) drivers on CSI volumes. This option is disabled by default in your Cohesity protection job. To enable this feature, turn ON the **Leverage CSI snapshot** toggle. Once enabled, Cohesity clusters will begin utilizing snapshots captured by CSI drivers to protect the PVCs. These snapshots are crash-consistent, meaning that the PVC is in the same state as it was during the crash. If you are protecting entire namespaces, this setting must be enabled manually. When protecting individual VMs, the setting is applied automatically.
9. If you need to change any of the advanced settings on the Protection Group page, click the down arrow icon next to **Advance Settings** and click **Edit** on the right. For more information, see Advanced Settings.
10. Click **Protect**.

    Your new Protection Group is now active and running.

Advanced Settings

Advance Settings	Description
Pause Future Runs	Enable **Pause Future Runs** to stop protection runs of the Protection Group from executing. Once you enable this option, no protection runs will be scheduled for this Protection Group.
End Date	Enable **End Date** and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts prior to this date runs until completion even if it completes after this date.
QoS Policy	Select an appropriate quality of service (QoS) policy. **Note:** Cohesity recommends specifying **Backup HDD**, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Alerts	Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts.
Email Recipients	You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection run.

Advance Settings	Description
Priority	Select a priority for the Protection Group eProtection Groupxecution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks). • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. > **Note:** Users with similar SLAs can be grouped together and a custom policy and Protection Group can be created to achieve different SLAs.
Description	Enter a brief description about the Protection Group.

Advance Settings	Description
Include or Exclude PVC	Cohesity enables you to choose which PVCs to include or exclude in the Protection Group. To select the PVCs: a. Turn ON the **Enable PVC Inclusion/Exclusion** toggle. b. In the **Logical Rule** drop-down, select "Match Any of the following labels" or "All of the following labels". c. Select **Include** or **Exclude**. d. Click **+ Add**. e. Enter the PVC's label. The label is the unique identifier assigned to that PVC in the Red Hat OpenShift cluster. You can add more PVC until you have all the PVCs you want to be included or excluded for that Protection Group. **Note:** • PVC Inclusion or Exclusion settings of the Namespace take precedence over the settings of its Protection Group. • Do not modify these settings while protecting VMs.

Create or Use an Existing Protection Policy

A Protection Policy is a reusable set of settings. It enables you to define how and when Kubernetes namespaces are protected, replicated, and archived. A standard policy provides various settings that you can configure for a Protection Group.

Create a Protection Policy with the settings listed in the Policy Settings for Kubernetes. For detailed instructions on how to create a Protection Policy, see Create or Edit a Standard Policy.

Policy Settings for Red Hat OpenShift

The following table lists the applicable policy settings for Red Hat OpenShift:

Field	Description
DataLock	If applicable, add a DataLock for compliance and regulatory requirements, to ensure that your protected data, including local backups, archives, and replication, cannot be modified until the DataLock expiration. Once applied, a DataLocked Snapshot will be deleted only after its retention period expires. A DataLock prevents all users, including those who have the Data Security role in Cohesity Data Cloud, from modifying or deleting any Snapshots that were generated by the Protection Groups that use this Policy. Only users with the Data Security role can add, modify, or remove a DataLock from a Policy.
Backup	Defines when backups are captured, how long they are retained and the type of backup to capture.
Periodic Full Backup	Use this option to choose when to run a periodic full backup.
Extended Retention	Add this to retain a subset of snapshots (backups) for longer than defined by the protection schedule.
Quiet Times	Quiet times define time periods when new protection runs are not started. For example, you might want to configure hourly backups that run during weekdays but not on Saturdays or Sundays. Quiet times only prevent new protection runs from starting during the specified time period. The protection runs that started before the quiet times are not affected and will continue to run. For example, if a protection run starts at 12:45 AM on Saturday morning and there is a weekend quiet time that starts at 1 AM on Saturday morning, the protection run will continue to run past 1 AM. No new protection runs are started during the quiet times.
Retry Options	Use this option to customize the retry settings for capturing Snapshots. By default, the Cohesity cluster attempts to capture Snapshots three times before the Protection Group fails. The default time between retries is five minutes. You can customize the number of retries and how long to wait between each attempt.
Replication	To replicate snapshots to another, click the **Replication** icon from the floating menu. The copied snapshots are stored in the storage domain of the remote cluster.
Archival	To add an archive schedule, click the **Archival** icon from the floating menu.

Use an Existing Protection Policy

You can edit an existing Protection Policy and configure it with applicable policy settings for Red Hat OpenShift cluster. In this case, all the policy settings apart from the settings applicable to Red Hat OpenShift cluster are ignored.

To use an existing Protection Policy:

1. In the Cohesity cluster, navigate to **Data Protection > Policies**.
2. On the **Policies** page, select the policy that you plan to edit.
3. On the **Policy Details** page, click **Edit** and configure the applicable policy settings for Red Hat OpenShift cluster. For information on the applicable policy settings, see Policy Settings for Red Hat OpenShift.
4. Click **Save**.

The updated policy settings are applied to the Protection Group in the next protection run.

Manage the Red Hat OpenShift Backup Configuration

In Cohesity Data Cloud, a backup configuration includes a Protection Group and a Protection Policy. You can modify the existing Protection Group and the Protection Policy based on your requirements.

> **Note:** You cannot update the registered Red Hat OpenShift cluster and the assigned Storage Domain in the Protection Group settings.

Add Namespaces to the Protection Group

You can add new namespaces to the Protection Group for backup. The newly added namespaces are backed up from the next protection run, and it will be a full backup.

To add namespaces to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had created for the Red Hat OpenShift cluster.
3. Click the Actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the Kubernetes page, click the edit icon in the **Objects** section.
5. From the namespaces list, select the namespaces that you plan to add to the backup and click **Save Selection**.
6. Click **Save**.

Remove Namespaces from the Protection Group

You can remove the Kubernetes namespaces from the Protection Group that you do not want to back up in the next protection run. When you remove a namespace from the Protection Group, the incremental backup of this namespace is not performed from the future protection run. The existing backup for the namespace is preserved until the snapshot expires.

To remove namespaces from the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you had created for the Red Hat OpenShift cluster.
3. Click the Actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the Kubernetes page, click the edit icon in the **Objects** section.
5. From the namespaces list, unselect the namespaces that you plan to remove to the backup and click **Save Selection**.
6. Click **Save**.

Enable or Disable Auto Protect

You can enable the Auto Protect option at the:

- **Red Hat OpenShift cluster level**: Automatically protect the new namespaces that are added to the Kubernetes container.
- **Label level of the namespaces**: Automatically protect the new namespaces that are tagged with the same label you selected while enabling the auto protect.

When the Auto Protect option is enabled:

- All the namespaces that are added to the Red Hat OpenShift cluster or tagged with the same label in the future are automatically added to the Protection Group and are protected from the next protection run.
- All the namespaces that are removed from the Red Hat OpenShift cluster or untagged from the specified label in the future are automatically removed from the Protection Group and are not protected from the next protection run. The existing backup for the namespace is preserved until the snapshot expires.

When the Auto Protect option is disabled, you need to manually:

- Add newly added namespaces to the Protection Group.
- From the Protection Group, remove existing namespaces that are deleted on Red Hat OpenShift. The existing backups of the namespaces are preserved until the snapshot expires.

Enable or Disable Auto Protect at Red Hat OpenShift cluster level

To enable or disable Auto Protect at the Red Hat OpenShift cluster level:

1. Navigate to **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had created for the Red Hat OpenShift cluster.
3. Click the Actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the Kubernetes page, click the edit icon in the **Objects** section.

5. Click the icon in the cluster level to enable or disable Auto Protect and click **Save Selection**.
6. Click **Save**.

Enable or Disable Auto Protect at Label level

To enable or disable Auto Protect at the Kubernetes label level:

1. Navigate to **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had created for the Red Hat OpenShift cluster.
3. Click the Actions menu (⋮) next to the Protection Group and select **Edit**.
4. On the **Kubernetes** page, click the edit icon in the **Objects** section.
5. Select the label icon ( ) available on the top-right of the **Objects** section.
6. From the **label** drop-down list, select the label(s) for which you want to enable **Auto Protect**.
7. Click the icon in the enable or disable Auto Protect and click **Save Selection**.
8. Click **Save**.

Attach New Protection Policy to the Protection Group

A Protection Policy can be attached to multiple Protection Groups, and any changes in the policy settings impact all the Protection Groups that are associated with the Protection Policy. You can create and attach a new Protection Policy with the required policy settings to your Protection Group. The new policy is applied to the Protection Group from the next scheduled protection run.

To attach a new Protection Policy to the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had created for Red Hat OpenShift.
3. Click the Actions menu (⋮) next to the Protection Group and select **Edit**.
4. In the **Policy** drop-down list, select the new Protection Policy for the Protection Group.
5. Click **Save**.

Start an On-demand Protection Run

You can manually start a protection run of the Protection Group that you have created to back up the namespaces of the Red Hat OpenShift cluster. It provides you with options to:

- Back up all the objects or only selected objects in the Protection Group.
- Select an incremental or full backup.

- Add replication.
- Add Archival.

To start a protection run:

1. Navigate to **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had created for Red Hat OpenShift.
3. Click the Actions menu (⋮) next to the Protection Group and select **Run Now**.
4. In the pop-up window, perform the following:
    a. In the **Backup** drop-down list, select any one of the following:
        - **Backup all Objects in the Protection Group**
        - **Backup only selected Objects in the Protection Group**
    b. In the **Backup Type** drop-down list, select the backup type. By default, an incremental backup will be performed.
    c. Optional. In the **Replicate** section, select the replication target and the retention duration.
    d. Optional. In the **Archive** section, select the Archival target and the retention duration.
5. Click **Run Now**.

Pause Future Protection Runs

You can pause future protection runs for the Protection Group. However, if the Protection Group is currently executing a protection run, the current run continues to execute and only future runs of the Protection Group are paused.

To pause future protection run:

1. Navigate to **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had created for Red Hat OpenShift.
3. Click the Actions menu (⋮) next to the Protection Group and select **Pause Future Runs**.

Resume Paused Protection Runs

You can resume a paused protection run. When you resume a protection run, if the backup snapshots are expired then a full backup is triggered.

To resume a paused protection run:

1. Navigate to **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had paused.
3. Click the Actions menu (⋮) next to the Protection Group and select **Resume**.

Delete the Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups and the local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- Delete Protection Group Only: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- Delete Protection Group and Snapshots: Allows you to delete the Protection Group and all the local and archived Snapshots generated by the Protection Group.

  After deleting the Protection Group and Snapshots, the reclaimed storage space details are not displayed immediately. It will take some time to reflect on the Cohesity Dashboard.

To delete the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the Protection page, select the Protection Group that you had created for Red Hat OpenShift.
3. Click the Actions menu (⋮) next to the Protection Group and select **Delete**.
4. In the **Delete Protection Group?** dialog box, select any one of the following options:
   - **Delete Protection Group Only**
   - **Delete Protection Group and Snapshots**

Backup of Selected VMs

Cohesity supports the backup of selected VMs for Red Hat OpenShift Virtualization present in the Kubernetes namespaces. You can back up individual VMs or select groups of VMs, rather than backing up the entire namespace.

Cohesity uses the VM Snapshot API that enables taking a single snapshot of all volumes associated with a VM in one backup operation.

To protect the selected VMs:

1. In the Cohesity cluster UI, perform one of the following:
   - Select **Data Protection > Protection**. Click **Protect** displayed on the top-right of the page and then select Red Hat OpenShift Cluster.
   - Select Data Protection > Sources. Click the Actions menu (⋮) next to the Red Hat OpenShift source and then select Protect.

2. From the **Registered Source** drop-down list, select the registered Red Hat OpenShift source or click **Register Source** to register a Red Hat OpenShift source. For more information, see Register Red Hat OpenShift Cluster as a Source.
3. From the **Objects** list, select the VMs present in the namespace that you plan to backup and click **Save Selection**.

> **Note:** You can use the advanced filters that are available to search and find the namespaces you plan to protect. Also, you can click the shield icon to enable Auto Protect at the Red Hat OpenShift cluster level or based on the namespace label(s). For more information, see Backup of Selected VMs.

Exclude or Include VMs

Cohesity enables you to choose which VM to back up or exclude for Red Hat OpenShift Virtualization in a Kubernetes Namespace or Protection Group. Select the VM that is currently configured with a PVC. You can choose to either enable VM inclusion/exclusion or enable PVC inclusion/exclusion.

To include or exclude VMs for Red Hat OpenShift Virtualization in a Kubernetes namespace:

> **Note:**
> Ensure that you meet the following prerequisites:
>
> - On the Red Hat OpenShift cluster, enable Virtualization.
> - The OADP operator must install the kubevirt plugin.
> - The OAPD operator must install the Cohesity DataProtect plugin.

a. In the **New Protection** dialog, click the **Edit** ( ) icon next to that selected namespace.

> **Note:** To turn ON the **VM Inclusion/Exclusion** option to an existing Protection Group, click the Actions menu (⋮) for that Protection Group and select **Edit**. In the **Edit Protection** dialog, under **Objects**, select the namespace and click the **Edit** icon.

b. In the **Options** dialog, turn ON the **Enable VM Inclusion/Exclusion** toggle.
c. You can choose to either include or exclude the VMs. Select **Include** or

Exclude, and then select the VMs from the drop-down.

d. Click **Save**.

4. When you select the VM, the **Leverage CSI snapshot** toggle is enabled by default. This option is necessary for making a VM selection, as snapshots are essential for ensuring a consistent backup of the VM.
5. Click **Protect** to complete the configuration of the protection group.

   More information about the selected VMs is available in the protection run details.

> **Note:**
> - If any of the volumes attached to the VM are not backed up correctly or if it fails, then the backup for the VM will also fail, and a warning message will appear.
> - When an entire namespace is protected, individual VMs or groups can still be selected during recovery, provided that certain plugin and filter requirements are met, and CSI snapshots are enabled.
> - We can check the protection run details to determine if granular backups are being performed or skipped. If it indicates "Skipping," this means some requirements were not met.

Advanced Settings

Advance Settings	Description
Pause Future Runs	Enable **Pause Future Runs** to stop protection runs of the Protection Group from executing. Once you enable this option, no protection runs will be scheduled for this Protection Group.
End Date	Enable **End Date** and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts prior to this date runs until completion even if it completes after this date.

Advance Settings	Description
QoS Policy	Select an appropriate quality of service (QoS) policy. **Note:** Cohesity recommends specifying **Backup HDD**, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy. For best performance, Cohesity recommends the Backup Target SSD policy. If necessary, you can change the policy at any time later. But it doesn't change or take effect on the currently running task.
Alerts	Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts.
Email Recipients	You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection run.
Priority	Select a priority for the Protection Group eProtection Groupxecution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs

Advance Settings	Description
SLA	The service-level agreement (SLA) defines how long the administrator expects a Protection Group run to take. • **Full**: Enter the number of minutes you expect a full backup Protection Group run takes to complete. A full backup captures the entire object (all blocks). • **Incremental**: Enter the number of minutes you expect an incremental backup Protection Group run takes to complete. An incremental backup captures only the differences (changed blocks) since the last run. > **Note:** Users with similar SLAs can be grouped together and a custom policy and Protection Group can be created to achieve different SLAs.
Description	Enter a brief description about the Protection Group.
Include or Exclude Labels	Cohesity enables you to choose which PVCs or VMs to include or exclude in the Protection Group. To select the PVCs or VMs: a. Turn ON the **Enable PVC Inclusion/Exclusion** toggle. b. In the **Logical Rule** drop-down, select “Match Any of the following labels” or “All of the following labels”. c. Select either **PVCs** or **VMs**. d. Select **Include** or **Exclude**. e. Click **+ Add**. f. Enter the PVC’s or VMs label. The label is the unique identifier assigned to that PVC or VM in the Red Hat OpenShift cluster. You can add more PVC or VM until you have all the PVCs or VMs you want to be included or excluded for that Protection Group. > **Note:** > • PVC or VM Inclusion or Exclusion settings of the Namespace take precedence over the settings of its Protection Group. > • Do not modify these settings while protecting VMs.

Recover Red Hat OpenShift Virtualization

After you protect your Red Hat OpenShift Cluster, you can recover namespaces to the same or an aternate location.

Recovering Namespaces to the Same Location

When you are recovering the namespaces to the same or original location, then only the VMs, resources, PVCs, or the metadata of the Kubernetes namespaces that are missing or deleted from the original location are restored from the namespace snapshot you selected for recovery. Cohesity does not overwrite or restore the VMs, resources, PVCs, or the metadata of the Kubernetes namespace that already exists in the original location.

For example, a Kubernetes namespace you want to restore to the same location contains a deployment resource and a service account. When Cohesity initiates the restore to the original location and if the service account is missing from the original location, then Cohesity will restore only the service account. The restore of the deployment resource is skipped.

Cohesity supports the recovery of PVCs with the volumeMode set to Filesystem or Block.

To restore the namespaces of a Red Hat OpenShift cluster to the same location:

1. In the Cohesity cluster UI, navigate to **Data Protection > Recoveries**.
2. Click **Recoveries** on the top-right of the page and then select **Red Hat OpenShift Cluster** as the recovery source.

   The Kubernetes Namespaces page appears.
3. Search for a namespace or Protection Group that contains the snapshots to recover from by entering characters of the namespace name, Protection Group name, or by specifying the wildcard character *.

   You can optionally filter the search results by source, Protection Group, Storage Domain, or date.
4. From the list of search results, select one or more objects (namespaces) or Protection Groups that contain the snapshots to recover.

   > **Note:**
   > - If you have selected a Protection Group, then all the namespaces backed up in the latest protection run of this Protection Group will be selected for recovery. The option to select these namespaces individually will be greyed out in the search result list.
   > - You can only select Protection Groups and namespaces with snapshots stored in the same Storage Domain and belonging to the same source. Once you select a namespace or Protection Group, the **Storage Domain** and **Source** filters will automatically get locked.

   By default, the latest snapshot is selected for recovery.

5. To recover from a different snapshot, perform the following steps depending on the object selected:

> **Note:** In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

To choose a different snapshot for a..	Then..
Protection Group	a. From the selected lists, mouse over the snapshot, and then click the **edit** icon. b. From the **Protection Run** drop-down menu, select the snapshot from which you want to recover the namespaces. By default the snapshot is recovered from the local cluster. c. Optionally, you can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. d. Click **Select Recovery Point** and then go to step 6.
Namespace	a. From the selected lists, mouse over the snapshot, and then click the edit icon. The Edit recovery point for <namespace_name> page appears. By default, the page displays the snapshots available in the last one month. b. Optionally, you can also select a snapshot from a different date range or by selecting the date range from the **Date** drop-down list. Once you select the date range and then click **Apply**, the Edit recovery point page displays the available snapshots in the specified range. c. Select the snapshots to be recovered. By default, the snapshot is recovered from the local cluster. d. Optionally, you can also select snapshots archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. e. Click **Select Recovery Point** and then go to step 6.

6. Click **Next: Recover Options**.

7. From the **Recover To** options, select **Original Location** to recover the namespace to the original location.
8. From the **PVC Selection** option, select the PVCs of the namespace you want to recover.

   > **Note:** Do not modify these settings while protecting VMs.

9. Optional. Edit the default settings of the following **Recovery Options**:

   > **Note:**
   > - When you select the recovery of a namespace, existing resources will not be overwritten. Only the deleted resources will be replaced by the recovered VMs.
   > - Cohesity recommends that you follow the default settings.

   - **Rename**: Add Prefix and/or Suffix strings to the names of the new namespaces created by this task. For example, you could specify Prefix Test_ and Suffix _QA to the namespace's name WinOS and when the namespace is recovered, the new namespace that is created is called Test_WinOS_QA.
   - **Task Name**: Change the default name of the recovery task.
   - **Storage Class**: Enable the **PVCs will be recovered to mapped Storage Class.** option if you want to map the PVCs to be recovered to a different storage class. Click the **+Add** option and from the **Current Storage Class** drop-down, select the storage class you want the PVCs to be mapped.
10. Click **Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Recovering Namespaces to an Alternate Location

You can recover the namespaces of the Kubernetes to an alternate Red Hat OpenShift cluster that is registered with the Cohesity cluster. If you are recovering the Kubernetes namespace to an alternate location, then the entire namespace is restored. However, if you are restoring to this location again, then Cohesity will not restore the VMs, resources, PVCs, or the metadata of the Kubernetes namespace that already exist in the location.

To restore the namespaces of a Red Hat OpenShift cluster to the same location:

1. In the Cohesity cluster, navigate to **Data Protection > Recoveries**.
2. Click **Recoveries** on the top-right of the page and then select **Red Hat OpenShift Cluster** as the recovery source.

   The Kubernetes Namespaces page appears.

3. Search for a namespace or Protection Group that contains the snapshots to recover from by entering characters of the namespace name, Protection Group name, or by specifying the wildcard character *.

   You can optionally filter the search results by source, Protection Group, Storage Domain, or date.

4. From the list of search results, select one or more namespaces or Protection Groups that contain the snapshots to recover.

   > **Note:**
   > - If you have selected a Protection Group, then all the namespaces backed up in the latest protection run of this Protection Group will be selected for recovery. The option to select these namespaces individually will be greyed out in the search result list.
   > - You can only select Protection Groups and namespaces with snapshots stored in the same Storage Domain and belonging to the same source. Once you select a namespace or Protection Group, the **Storage Domain** and **Source** filters will automatically get locked.

   By default, the latest snapshot is selected for recovery

5. To recover from a different snapshot, perform the following steps depending on the object selected:

   > **Note:** In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

To choose a different snapshot for a..	Then..
Protection Group	a. From the selected lists, mouse over the snapshot, and then click the **edit** icon. b. From the **Protection Run** drop-down menu, select the snapshot from which you want to recover the namespaces. By default the snapshot is recovered from the local cluster. c. Optionally, you can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. d. Click **Select Recovery Point** and then go to step 6.
Namespace	a. From the selected lists, mouse over the snapshot, and then click the edit icon. The Edit recovery point for <namespace_name> page appears. By default, the page displays the snapshots available in the last one month. b. Optionally, you can also select a snapshot from a different date range or by selecting the date range from the **Date** drop-down list. Once you select the date range and then click **Apply**, the Edit recovery point page displays the available snapshots in the specified range. c. Select the snapshots to be recovered. By default, the snapshot is recovered from the local cluster. d. Optionally, you can also select snapshots archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. e. Click **Select Recovery Point** and then go to step 6.

6. Click **Next: Recover Options**.
7. From the **Recover To** options, select **New Location** to recover the namespace to a new location.
8. From the **Registered Source** drop-down list, select the registered Red Hat OpenShift source to which you want to recover the namespaces or click **Register Source** to register an Red Hat OpenShift source. For more information, see Register Red Hat OpenShift Cluster as a Source.
9. From the **PVC Selection** option, select the PVCs of the namespace you want to recover.

> **Note:** Do not modify these settings while protecting VMs.

10. Optional. Edit the default settings of the following **Recovery Options**:

> **Note:**
> - When you select the recovery of a namespace, existing resources will not be overwritten. Only the deleted resources will be replaced by the recovered VMs.
> - Cohesity recommends that you follow the default settings.

    - **Rename**: Add Prefix and/or Suffix strings to the names of the new namespaces created by this task. For example, you could specify Prefix Test_ and Suffix _QA to the namespace's name WinOS and when the namespace is recovered, the new namespace that is created is called Test_WinOS_QA.
    - **Task Name**: Change the default name of the recovery task.
    - **Storage Class**: Enable the **PVCs will be recovered to mapped Storage Class.** option if you want to map the PVCs to be recovered to a different storage class. Click the **+Add** option and from the **Current Storage Class** drop-down, select the storage class you want the PVCs to be mapped.
11. Click **Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Recover Selected VMs Present in the Namespace

Cohesity supports recovery of selected VMs for Red Hat OpenShift Virtualization present in the Kubernetes namespaces. You can recover individual VMs or a group of VMs from a backup, rather than recovering the entire namespace.

Recovering Selected VMs Present in the Namespace to the Original Location

You can restore the VMs present in the namespace of a Red Hat OpenShift cluster to the same location.

1. In the Cohesity cluster UI, navigate to **Data Protection > Recoveries**.
2. Click **Recoveries** on the top-right of the page and then select **Red Hat OpenShift Cluster** as the recovery source.

   The Kubernetes Namespaces page appears.

3. Search for a namespace that contains the snapshots to recover from by entering characters of the namespace name or by specifying the wildcard character *.

   You can optionally filter the search results by source, Storage Domain, or date.

4. From the list of search results, select one or more objects (namespaces) that contain the snapshots to recover.

   > **Note:** You can only select namespaces with snapshots stored in the same Storage Domain and belonging to the same source. Once you select a namespace, the **Storage Domain** and **Source** filters will automatically get locked.

   By default, the latest snapshot is selected for recovery.

5. To recover from a different snapshot, perform the following steps depending on the object selected:

   > **Note:** In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

To choose a different snapshot for a..	Then..
Namespace	a. From the selected lists, mouse over the snapshot, and then click the edit icon. The Edit recovery point for <namespace_name> page appears. By default, the page displays the snapshots available in the last one month. b. Optionally, you can also select a snapshot from a different date range or by selecting the date range from the **Date** drop-down list. Once you select the date range and then click **Apply**, the Edit recovery point page displays the available snapshots in the specified range. c. Select the snapshots to be recovered. By default, the snapshot is recovered from the local cluster. d. Optionally, you can also select snapshots archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. e. Click **Select Recovery Point** and then go to step 6.

6. Click **Next: Recover Options**.
7. From the **Recover To** options, select **Original Location** to recover the VMs to the original location.
8. Optional. Edit the default settings of the following **Recovery Options**:

> **Note:**
> - When you select the recovery of a namespace, existing resources will not be overwritten. Only the deleted resources will be replaced by the recovered VMs.
> - Cohesity recommends that you follow the default settings.

   - **Rename**: Add Prefix and/or Suffix strings to the names of the new namespaces created by this task. For example, you could specify Prefix Test_ and Suffix _QA to the namespace's name WinOS and when the namespace is recovered, the new namespace that is created is called Test_WinOS_QA.
   - **Task Name**: Change the default name of the recovery task.

- **Namespace Resources**: Allows you to change the namespace resources you want to recover. Enable this option to customize the following settings:
  - **Resources**: In the Resources you can select **VM Inclusion/Exclusion** and select the VMs to include or exclude from recovery. When you select a VM for recovery, you have the following options:
    a. **Instant Recovery**: The VMs will be instantly available after recovery in the target location. The data will be moved to the target storage later. The VM can be used in production during Instant Recovery when the data is being copied to the VMs target data volume from the Source PVC (backed by Cohesity NFS view). In such scenarios, the VM performance may be low as the Storage vMotion is still in progress.

       Cohesity recommends that you choose Copy Recovery for powered-off VMs for better performance.

    b. **Copy Recovery**: The VMs will be available in the target location only after all the data is copied to the target storage from the source location (Cohesity cluster or cloud). Once the restore is complete, the VM will be available to use.

       > **Note:** This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

  - **Storage Class**: Enable the **PVCs will be recovered to mapped Storage Class.** option if you want to map the PVCs to be recovered to a different storage class. Click the **+Add** option and from the **Current Storage Class** drop-down, select the storage class you want the PVCs to be mapped.

9. Click **Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page. More information about the selected VMs is available in the recovery details.

Recovering Selected VMs Present in the Namespace to an Alternate Location

You can restore the VMs present in the namespace of a Red Hat OpenShift cluster to a new location:

1. In the Cohesity cluster UI, navigate to **Data Protection > Recoveries**.
2. Click **Recoveries** on the top-right of the page and then select **Red Hat OpenShift Cluster** as the recovery source.

   The Kubernetes Namespaces page appears.

3. Search for a namespace that contains the snapshots to recover from by entering characters of the namespace name or by specifying the wildcard character *.

   You can optionally filter the search results by source, Storage Domain, or date.

4. From the list of search results, select one or more objects (namespaces) that contain the snapshots to recover.

   > **Note:** You can only select namespaces with snapshots stored in the same Storage Domain and belonging to the same source. Once you select a namespace, the **Storage Domain** and **Source** filters will automatically get locked.

   By default, the latest snapshot is selected for recovery.

5. To recover from a different snapshot, perform the following steps depending on the object selected:

   > **Note:** In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

To choose a different snapshot for a..	Then..
Namespace	a. From the selected lists, mouse over the snapshot, and then click the edit icon. The Edit recovery point for <namespace_name> page appears. By default, the page displays the snapshots available in the last one month. b. Optionally, you can also select a snapshot from a different date range or by selecting the date range from the **Date** drop-down list. Once you select the date range and then click **Apply**, the Edit recovery point page displays the available snapshots in the specified range. c. Select the snapshots to be recovered. By default, the snapshot is recovered from the local cluster. d. Optionally, you can also select snapshots archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. e. Click **Select Recovery Point** and then go to step 6.

6. Click **Next: Recover Options**.
7. From the **Recover To** options, select **New Location** to recover the VMs to the new location.
8. From the **Registered Source** drop-down list, select the registered Red Hat OpenShift source to which you want to recover the VMs present in the namespace or click **Register Source** to register an Red Hat OpenShift source. For more information, see Register Red Hat OpenShift Cluster as a Source.
9. Optional. Edit the default settings of the following **Recovery Options**:

> **Note:**
> - When you select the recovery of a namespace, existing resources will not be overwritten. Only the deleted resources will be replaced by the recovered VMs.
> - Cohesity recommends that you follow the default settings.

- **Rename**: Add Prefix and/or Suffix strings to the names of the new namespaces created by this task. For example, you could specify Prefix Test_ and Suffix _QA

to the namespace's name WinOS and when the namespace is recovered, the new namespace that is created is called Test_WinOS_QA.

- **Task Name**: Change the default name of the recovery task.
- **Namespace Resources**: Allows you to change the namespace resources you want to recover. Enable this option to customize the following settings:
  - **Resources**: In the Resources you can select **VM Inclusion/Exclusion** and select the VMs to include or exclude from recovery. When you select a VM for recovery, you have the following options:
    a. **Instant Recovery**: The VMs will be instantly available after recovery in the target location. The data will be moved to the target storage later. The VM can be used in production during Instant Recovery when the data is being copied to the VMs target data volume from the Source PVC (backed by Cohesity NFS view). In such scenarios, the VM performance may be low as the Storage vMotion is still in progress.

       Cohesity recommends that you choose Copy Recovery for powered-off VMs for better performance.

    b. **Copy Recovery**: The VMs will be available in the target location only after all the data is copied to the target storage from the source location (Cohesity cluster or cloud). Once the restore is complete, the VM will be available to use.

       > **Note:** This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

  - **Storage Class**: Enable the **PVCs will be recovered to mapped Storage Class.** option if you want to map the PVCs to be recovered to a different storage class. Click the **+Add** option and from the **Current Storage Class** drop-down, select the storage class you want the PVCs to be mapped.

10. Click **Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page. More information about the selected VMs is available in the recovery details.

Browse and Download Files and Folders in Red Hat OpenShift Virtualization

Cohesity supports file and folder browsing and download capabilities for Red Hat OpenShift Virtualization. This feature allows you to browse VM content and download single or multiple files or folders through the web interface.

Download Files and Folders

To donwload files and folders:

1. In the Cohesity cluster UI, navigate to **Data Protection > Recoveries**.
2. Click **Recoveries** on the top-right of the page and then select **Kubernetes Cluster > Files or Folders**.

   The Recover Files or Folders page appears.
3. Select any one of the following options to search for the file or folder:
   - **Files and Folders**: Allows you to search and recover files using file or folder names from any backup available on the Cohesity cluster.
   - **Browse or Specify Path for Search**: Allows you to search and recover files using the name of the server or Protection Group from any backup available on the Cohesity cluster.

If you select...	Then...
Files and Folders	1. Enter characters of the file name, path, or by specifying the wildcard character *. A list of items displays. You can optionally filter the search results by object type, source, object, Protection Group, Storage Domain, files only, or folders only. > **Note:** When entering the path of a Windows VM, be sure to reformat as shown in the example: Instead of *C:\Windows\System32\winevt* use *C:/Windows/System32/winevt/*. 2. From the list of search results, select the required files or folders to recover. 3. By default, the latest snapshot is selected for recovery. To recover from a different snapshot: > **Note:** The option to change the recover point is not available if multiple items were selected for recovery. 1. From the selected list, mouse over the snapshot, and then click the **edit** icon. The Edit recovery point page appears. 2. By default, only the snapshots that are indexed are displayed. To display all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. 3. Select a date range and the snapshot point for recovery. 4. By default, the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud (icon) by clicking this icon if available in the **Location** option. 5. When recovering from an archive, consider the following points: • The archive (external target) must be currently registered for the task to succeed. • (*Applies only for cloud archive incremental with periodic full*) Provisioned Capacity Units (PCU) are required for all file-level recoveries. Provisioned capacity ensures that your retrieval capacity for expedited retrievals is available when needed. Each unit of capacity guarantees that at least three expedited retrievals can be performed every five minutes and provides up

If you select...	Then...
	to 150 MB/s of retrieval throughput. 4. Click **Select Recovery Point** and go to step 4.

If you select...	Then...
Browse	1. Enter the full or partial server or Protection Group name. You can do this by specifying the wildcard character *. You can also optionally filter the search results by object type, source, object, Protection Group, Storage Domain. 2. From the list of search results, select the object whose files or folders are to be recovered. 3. By default, the latest snapshot is selected for recovery. To recover from a different snapshot, click the snapshots drop-down in the top-left corner and select the snapshot you need. 4. **Browse on Indexed Data**: Toggle on this setting to browse the indexed data. It helps to speed up browsing of recovery data. By default, it only displays the files and folders that are indexed. Hidden files, folders, paths such as /usr, /var, /sys , /Windows, /ProgramData etc. are excluded from indexing. To display all the available files and folders, including hidden files and folders toggle off the **Browse on Indexed Data** setting. **Note:** • Changing the snapshot after selecting the items (files or folder) removes the selected items from the cart. • Enabling or disabling the **Browse on Indexed Data** option after selecting the items (files or folder) removes the selected items from the cart. • Deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process. 5. Browse to the file or folder that you want to recover by clicking a folder and subfolders. 6. Click **Save**. 7. After saving the selection, if you want to recover from a different snapshot or change the location from where the snapshot is recovered, perform the following steps: 1. From the selected list, mouse over the snapshot, and click the edit icon. 2. The Edit recovery point page appears. 3. By default, only the snapshots that are indexed are displayed. To display

If you select...	Then...
	all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. 4. Select a date range and the snapshot point for recovery. 5. By default, the snapshot is recovered from the local Cohesity cluster. You can also select a snapshot archived to the cloud (icon) by clicking this icon if available in the **Location** option. When recovering from an archive, consider the following points: • The archive (external target) must be currently registered for the task to succeed. • (*Applies only for cloud archive incremental with periodic full*) Provisioned Capacity Units (PCU) are required for all file-level recoveries. Provisioned capacity ensures that your retrieval capacity for expedited retrievals is available when needed. Each unit of capacity guarantees that at least three expedited retrievals can be performed every five minutes and provides up to 150 MB/s of retrieval throughput. 8. Click **Select Recovery Point** and go to step 4.

4. Once you select the files and folder to recover, choose the **Download Files** option.

> **Note:** The **Next Recover Option** is not supported. Use **Download Files** to download files or folders.

Download Files: If you are recovering a single file, this option downloads the file to your browser's download folder. For all other selections, this creates a recover task. When the task is completed, from the Recoveries page, click the task name and then click **Download Files** to download the generated zip file.

Chapter 21: About Bare Machine Recovery

A Bare Machine Recovery (BMR) is the ability to recover a system, including the operating system, its configuration, applications running on the operating system, and its data back to a state it was at a given point.

Cohesity integrates with Cristie software to protect your servers for bare machine recovery (BMR). Cohesity supports two types of BMR:

- **Cristie Bare Machine Recovery (CBMR)**: In this integration, a separate schedule for BMR backup is required to be added to the protection policy.

  First, a block-based protection run is executed followed by a separate BMR run. The BMR run is always Full (no incremental). For more information, see CBMR.
- **Cohesity Bare Machine Recovery (CoBMR)**: In this integration, CoBMR leverages Cohesity's file-based and block-based physical server protection. No separate BMR schedule or protection run is required. For more information, see CoBMR.

> **Note:**
> - For BMR-based protection of a physical server, you must first install the Cohesity agent on the physical server followed by the BMR agent and register the physical server with the Cohesity cluster.
> - You can also deploy the Cohesity agent on a virtual machine and protect the VM as a physical server to perform BMR. For more information, see Deploy Cohesity Agent on Virtual Servers.

CBMR and CoBMR Comparison

Feature	CBMR	CoBMR
Supported physical servers	• Windows • Linux For more information, see Supported Software.	• Windows • Linux For more information, see Supported Software.
Protection Policy	You must add a BMR schedule to the policy.	Default Policy - No BMR schedules.
Protection Group	Block-based backup	File-based backup Block-based backup
Protection Run	First performs block-based protection run followed by a BMR run.	Leverages the physical file-based and block-based backup run (No separate BMR schedule)
System State Backup	For block-based backup: First Full followed by incremental backup. For BMR backup: Always full backup.	First full backup followed by incremental backup.
Recovery ISO	For Windows servers, you must install CRISP software and create a separate ISO. For Linux servers, Cristie provides pre-build recovery ISO.	Cristie provides pre-build recovery ISO.
Recovery Workflow	Initiate BMR recovery from Cohesity to fetch the recovery path (the SMB share has the “system.vtd” file, the Custom Virtual Device Driver file). Then mount the system.vtd file in the CBMR recovery wizard to complete the recovery.	Recovery is performed through CoBMR Recovery Environment.

CBMR

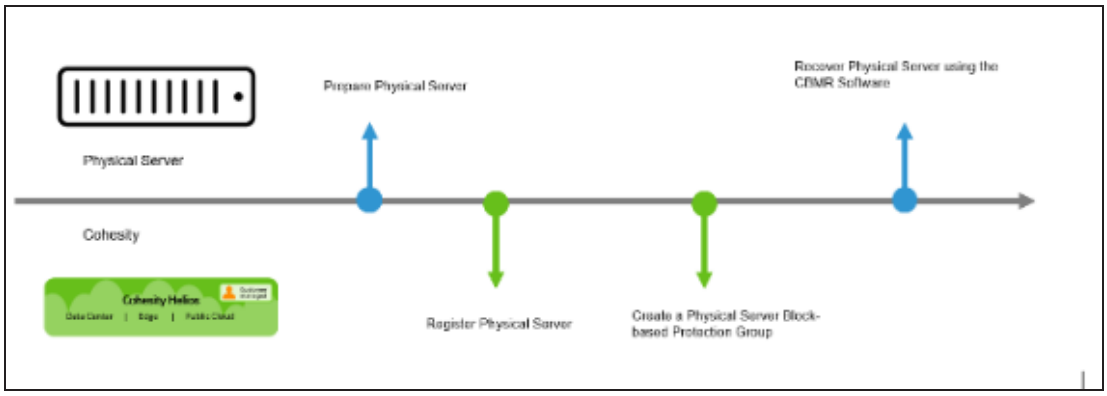
CBMR is required and must be licensed and installed separately from Cohesity. Cristie can be used for all supported platforms, but Cohesity's Cristie bare machine recovery (BMR) integration is supported for Windows and Linux. For Cristie product documentation, see CBMR Documentation.

Setup Protection with CBMR and Cohesity

The steps involved in setting up protection with CBMR and Cohesity are as follows:

- Plan and prepare the server for Cristie-Cohesity integration. For more information, see Plan and Prepare for CBMR Protection.
- Register your server as a Cohesity source. For more information, see Register the Server as a Cohesity Source for CBMR Protection.
- Create a block-based Protection Group for the server. For more information, see Protect the Server Using CBMR.
- Recover your server using the CBMR software. For more information, see Recover the Server Using CBMR.

The following figure illustrates the CBMR workflow:



Plan and Prepare for CBMR Protection

Before you register and protect your server for bare machine recovery, ensure that:

- You register as a user with Cristie and activate your Cristie license before your fully functional 30-day trial period expires
- Cohesity supports the server marked for BMR protection. For more information, see Supported Software.
- The firewall ports required for the communication between:
  - The Cohesity cluster and the server are open.
  - The Cohesity cluster and the recovery environment are open.

  For more information, see Firewall Ports Used for Communication.
- You have installed the Cohesity physical agent and CBMR software on the server. For more information, see Prepare the Server for Cristie-Cohesity Integration.

Supported Software

For more information on supported CBMR versions, see Supported Software.

Firewall Ports Used for Communication

Ensure all necessary ports are open in the firewall between Cohesity cluster and VMware VMs and Hypervisors. For more information, see Firewall Ports Used for Communication.

Prepare the Server for Cristie-Cohesity Integration

You must install and run the following software on the physical server you want to protect for BMR:

- Install Cohesity Agent
- Install CBMR

Install Cohesity Agent

Installing the Cohesity Agent on the server helps to establish the network path between the system image backup and Cohesity.

- For information on installing the Cohesity Agent on Windows servers, see Install and Manage the Agent on Windows Servers.
- For information on installing the Cohesity Agent on Linux servers, see Install and Manage the Agent on Linux Servers.
- For information on deploying Cohesity Agent on VMs to protect them as physical servers, seeDeploy Cohesity Agent on Virtual Servers.

Install CBMR

To enable the physical server for bare machine recovery, you must install the CBMR software on the server. You can download the CBMR installer to the server from the CBMR website. Registration is required to access the Cristie portal. For more information, see Cristie Portal Registration.

Install CBMR on Windows Server

To install CBMR on a Windows server:

1. On the Windows server, run the CBMR installer you downloaded.

   The **InstallShield Wizard for CBMR VA Suite <version>** page appears.
2. Select the language for the installation and click **Next>**.

   The **Welcome** page appears.
3. Select **Install CBMR Suite**.

   The **License Agreement** page appears.
4. Read the license agreement carefully and select the **I accept the terms in the license agreement** radio button to proceed with the installation steps and click **Next>**.

   The **Select install component** page appears.

5. Select **Install CBMR** to install the CBMR components.
6. Click **Install** to install the CBMR component. By default, the CBMR software is installed at C:\Program Files\Cristie\. Optionally, you can select a different location by clicking **Change**.

   > **Note:** Cristie recommends installing the software in the default installation location.

   You can also enter the IPv4 address of a Cristie Virtual Appliance if you want the CBMR to be managed by the virtual appliance.

When the installation completes, click **Finish** and reboot the server. For more information, see CBMR Windows Installation and Licensing Guide.

Install CBMR on Linux Server

To install CBMR, you must have the login credentials with root/sudo for the user on the Linux server.

To install CBMR:

1. Copy the downloaded installation file to a temporary location, for example, '/tmp.

   The CBMR installation binaries are available in three formats: RPM package (for RHEL & CentOS), Debian package (for Ubuntu), and Tar file (to install from the source).

   - To install CBMR from an RPM package, run the `rpm -ivh --nodeps` command.

     For example:

     ```
     rpm -ivh --nodeps cbmr-8.7.1008-1.x86_64.rpm
     ```

   - To install CBMR from a Debian package, run the `dpkg` command.

     For example:

     ```
     dpkg -i cbmr-8.7.1008-1_amd64.rpm
     ```

   - To install CBMR from a Tar file:
     - Extract the Tar file using the `tar xvzf` command.

       For example:

       ```
       tar xvzf cbmr-8.7.1008-1.linux.x86_64.tar.gz
       ```

     - Navigate to the extracted folder and run the following command to install CBMR:

       ```
       ./install
       ```

2. Check the status of the installation in the `/CBMRCFG/cbmrcfg.log` file.

3. Once the installation is complete, run the `licmgr` command to check the license and validate the CBMR installation.

   For example:

   ```
   licmgr -p cbmr
   ```

4. Copy the `ubax_monitor` file inside the `tar` package to `/usr/bin` to monitor the BMR protection status.

   For example:

   ```
   # cd cbmr
   ```

   ```
   cbmr]# cp ubax_monitor /usr/bin
   ```

For more information, see CBMR Linux CBMR Installation and Licensing Guide.

Register the Server as a Cohesity Source for CBMR Protection

For performing CBMR, you must first protect your server. To protect your server data, you need to register the physical server as a source on the Cohesity cluster. For more information see, Register or Edit a Physical Server.

You can also register VMware VMs and deploy the Cohesity agent on VMs to protect the VMs as physical servers and perform CBMR.

For information on registering VMware VMs, see Register or Edit a Hypervisor Source.

For information on deploying Cohesity agent, see Deploy Cohesity Agent on Virtual Servers.

Protect the Server Using CBMR

You can protect a server using a Protection Group and a Protection Policy.

A Protection Policy is a reusable set of settings that define how and when objects are protected and replicated.

A Protection Group uses the schedules and settings defined in the policy to determine when and how backups are captured, archived, or replicated.

When creating a Protection Group for protecting your server for CBMR, you must ensure to:

- Create a block-based Protection Group.
- Enable the **Take BMR backup** option for all the volumes you select to protect.
- If you want to back up all the volumes in a system, ensure to enable **Protect all local volumes** while selecting the physical servers for protection.
- Attach a Protection Policy with the **Add BMR Backup (Physical Server)** option configured to the Protection Group.

Recover the Server Using CBMR

To perform a CBMR from a Cohesity protected physical server, you require the following:

- A CBMR recovery ISO having the Cohesity agent and Cristie software installed.

  For Windows Server, you can use the Windows Preinstallation Environment (WinPE) 10 based recovery media.

  For Linux Server, you can download the recovery ISO from the Cristie website.
- A recovery target you can:
  - **Recover the server to the original machine**: You can choose this option if a malware attack deletes all the data on your server but the server is still accessible.
  - **Recover the server to a new machine**: You can choose this option if your server becomes unavailable due to a complete hardware failure.
  - **Recover the server as a VM**: You can choose this option if your physical server becomes unavailable due to a hardware failure.

For information on recovering Windows Server with CBMR, see the **Recover Your Server Using Cohesity with CBMR** section in the Bare Machine Recovery Using Cohesity & Cristie Solution Guide.

For information on recovering Linux Server with CBMR, see the **Recover Your Server Using Cohesity with CBMR** section in the Bare Machine Recovery for Linux Using Cohesity & Cristie.

CoBMR

Cohesity Bare Machine Recovery (CoBMR) is a licensed BMR software suite. Cohesity integrates with CoBMR to perform the bare machine recovery of the physical servers (Windows and Linux) by leveraging Cohesity's file-based backup and block-based backup for physical server protection.

With CoBMR, the system state information of the physical server is captured first, followed by the file-based or block-based backup for all drives, volumes, and partitions. This way, CoBMR recovers the physical server's original state using the recovery image and the protected data.

To obtain the CoBMR software and license, contact Cristie.

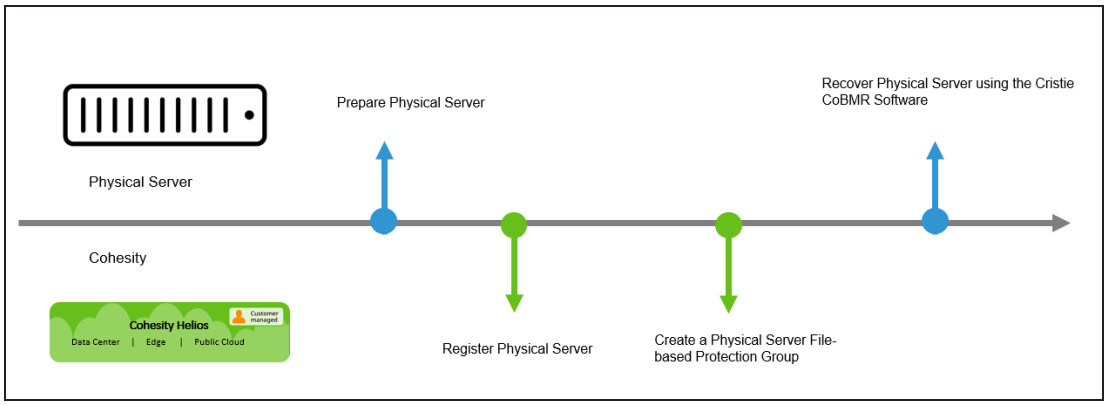
Setup Protection with CoBMR and Cohesity

Steps involved in setting up protection with CoBMR and Cohesity are as follows:

- Plan and prepare the server for Cristie-Cohesity integration. For more information, see Plan and Prepare for CoBMR Protection.

- Register your server as a Cohesity source. For more information, see Register the Server as a Cohesity Source for CoBMR Protection.
- Create a file-based or block-based Protection Group for the server. For more information, see Protect the Server using CoBMR.
- Recover your server using the Cristie CoBMR software. For more information, see Recover the Server Using CoBMR.

The following figure illustrates the CoBMR workflow:



Plan and Prepare for CoBMR Protection

Before you register and protect your server for bare machine recovery, ensure that:

- Cohesity supports the physical server marked for BMR protection. For more information, see Supported Software.
- The firewall ports required for the communication between:
  - The Cohesity cluster and the server are open.
  - The Cohesity cluster and the recovery environment are open.

  For more information, see Firewall Ports Used for Communication.
- You have installed the Cohesity physical agent and CoBMR software on the physical server. For more information, see Prepare the Server for Cristie-Cohesity Integration.
- You have added the executable file in the **user_scripts** directory to capture the system state. For more information, see Add Executable File in user_scripts Directory.
- You have reviewed and understood the considerations of the CoBMR process. For more information, see Consideration.

Supported Software

For more information on supported CoBMR versions, see Supported Software.

Firewall Ports Used for Communication

Ensure all necessary ports are open in the firewall between the Cohesity cluster and VMware VMs and Hypervisors. For more information, see Firewall Ports Used for Communication.

Prepare the Server for Cristie-Cohesity Integration

You must install and run the following software on the physical server you want to protect for BMR:

1. Install Cohesity Agent.
2. Install CoBMR Software.

Install Cohesity Agent

Installing the Cohesity agent on the server helps to establish the network path between the system image backup and Cohesity.

For information on installing the Cohesity agent on Windows servers, see Install and Manage the Agent on Windows Servers.

For information on installing the Cohesity agent on Linux servers, see Install and Manage the Agent on Linux Servers.

For information on deploying Cohesity agent on VMs to protect then as physical server, see Deploy Cohesity Agent on Virtual Servers.

Install CoBMR Software

> **Note:** The CoBMR installation can take some time so you may need to plan accordingly.

To enable the server for bare machine recovery, you must install the CoBMR software on the server. You can download the CoBMR installer to the server from the CoBMR site. Registration is required to access the Cristie portal. For more information, see Cristie Portal Registration.

> **Note:** To use CoBMR in DoDIN mode, contact Cristie team to obtain a suitable version of the CoBMR software.

Install CoBMR on Windows Server

To install CoBMR on a Windows server:

1. On the Windows server, run the CoBMR installer you downloaded.

   The **Welcome to the InstallShield Wizard for CoBMR VA Suite <version>** window appears.

2. Select **Install CoBMR Suite**.

   The **License Agreement** window appears.

3. Read the license agreement carefully and select the **I accept the terms in the license agreement** radio button to proceed with the installation steps and click **Next>**.

   The **Select install component** window appears.

4. Select **Install CoBMR** to install the CoBMR components.

5. Click **Install** to install the CoBMR component. By default, the CoBMR software is installed at `C:\Program Files\Cristie\`. Optionally, you can select a different location by clicking **Change**.

   > **Note:** Cristie recommends installing the software in the default installation location.

At the end of the installation, detailed machine configuration information is recorded in the **CoBMRcf.exe** executable file located at `:\Program Files\Cristie\CoBMR` on the Windows System drive. This executable captures the system recovery data.

Install CoBMR on Linux Server

For Linux servers, Cristie shares the CoBMR installation binary in the following formats:

- RPM package for RHEL & CentOS.
- DEB package for ubuntu machines.
- As gunzip tar file to install from the source.

These packages can be installed on the Linux servers using the command line. For example, the rpm package can be installed using the following command.

```
# rpm -i cobmr-9.1-1.x86_64.rpm
```

At the end of the installation, detailed machine configuration information is recorded in the cobmrcfg executable saved in `the /usr/bin` directory. This executable captures the system recovery data.

Add Executable File in user_scripts Directory

Once the CoBMR installation is complete, the **cobmrcfg** executable gets installed at the following location:

- For Windows Server: `\Program Files\Cristie\CoBMR`
- For Linux Server: `/usr/bin/`

This executable file must be run before every protection run to capture the latest System Recovery Data information. You can run this executable as a pre-script in the Cohesity's Protection Group by adding this executable file in the **user_scripts** directory available in

the Cohesity agent installation directory on the physical server. This pre-script captures the system state as a system recovery data file.

To add the executable in the user_scripts directory:

For Windows Server:

Create a batch file to trigger **CoBMRcfg.exe** from its installed location.

For example:

```
echo "C:\Program Files\Cristie\CoBMR\CoBMRCfg.exe" > c:\"Program Files"\Cohesity\user_scripts\<file_name>.bat
```

> **Note:**
> - You must execute the echo command using MS-DOS prompt. Executing the echo command using PowerShell inserts a special character causing the command to fail.
> - You must not copy the **CoBMRcfg.exe** script to the **INSTALL_DIR/user_scripts** directory.

For Linux Server:

On the Linux physical server, copy **cobmrcfg** from the `/usr/bin/` to the `<cohesity_agent_install>/user_scripts` directory.

For **RPM or Debian** installer, the path would be:

```
/opt/cohesity/agent/software/crux/bin
```

For a **Script-Based** installer, the path would be:

```
/home/cohesityagent/cohesityagent
```

For Example:

```
sudo cp /usr/bin/cobmrcfg /opt/cohesity/agent/software/crux/bin/user_scripts/
```

In the pre-script, you have to mention the path as `cobmrcfg`.

Consideration

When recovering a Linux server using CoBMR, the option for verifying the SSL certificate validity is auto-enabled. However, you must disable this option for achieving seamless recovery.

Register the Server as a Cohesity Source for CoBMR Protection

For performing CoBMR, you must first protect your server. To protect your physical server data, you need to register the server as a source on the Cohesity cluster. For more information see, Register or Edit a Physical Server.

Protect the Server using CoBMR

Protecting a physical server for CoBMR involves creating a **Protection Group** and a **Protection Policy**.

- A **Protection Policy** defines how and when objects are backed up, archived, or replicated. For details on creating a policy, see Create or Edit a Standard Policy.
- A **Protection Group** applies the schedules and settings defined in the policy to execute backups. For instructions, see Add or Edit a Protection Group for Physical Servers.

When setting up a Protection Group for CoBMR, follow the platform-specific guidelines below:

For Windows Servers

1. **Choose Backup Type**: Select either a file-based or block-based Protection Group.

   > **Note:** Recovery steps vary by backup type. File-based backups do not require local SMB user configuration, while block-based backups do. Refer to the CoBMR Windows User Guide for details.

2. **Include All Volumes**: If backing up all system volumes, enable Protect all local volumes during server selection.
3. **Enable Crash Consistent Backups**: Check the Crash Consistent Backups option in the Protection Group settings.
4. **Add Pre-Script**: Add CoBMRcfg.bat as a Pre Script in the Advanced Settings. In the Script Path field, specify the batch file that triggers CoBMRcfg.exe to capture the system state.

   For instructions on adding executable files, see Add Executable File in user_scripts Directory.
5. **Set Timeout**: Set Timeout (mins) to at least 45 minutes to account for script execution time.
6. **Disable Script Failure Option**: Uncheck Continue Backup if script fails.

For Linux Servers

1. **Choose Backup Type**: Select either a file-based or block-based Protection Group.

   > **Note:** Recovery steps vary by backup type. Refer to platform-specific documentation for details.

2. **Include All Volumes**: If backing up all system volumes, enable Protect all local volumes during server selection.
3. **Add Pre-Script**: Configure a pre-script that invokes cobmrcfg with the --cobmr_boot_backup flag to ensure the /boot partition is backed up correctly.

   For guidance on adding scripts, see see Add Executable File in user_scripts Directory.
4. **Set Timeout**: Set Timeout (mins) to at least 45 minutes to account for script execution time.
5. **Disable Script Failure Option**: Uncheck Continue Backup if script fails.

Recover the Server Using CoBMR

To perform a CoBMR from a Cohesity protected physical server, you require the following:

- A CoBMR recovery media (ISO) provided by Cristie having the Cohesity agent and Cristie software.
- A recovery target. you can:
  - **Recover the server to the original machine**: You can choose this option if a malware attack deletes all the data on your server but the server is still accessible.
  - **Recover the server to a new machine**: You can choose this option if your server becomes unavailable due to a complete hardware failure.
  - **Recover the server as a VM**: You can choose this option if your physical server becomes unavailable due to a hardware failure.

  During the recovery process, the CoBMR recovery environment connects to the Cohesity cluster to fetch the source details and the desired snapshot from Cohesity. Then, the discovery process starts to fetch the system data file that captures the system state and restores the system state. This is followed by restoring the boot drives and other mounted drives.

Minimum Permissions

The following table lists the minimum permissions required for CoBMR recovery.

Roles	Permissions
Cluster Management	View Alert Details
Data Protection	View Protection Groups Manage Sources
Recovery Management	View Recover Tasks Manage Recover Tasks
Source Management	Manage Physical Servers

Recover Windows Server

> **Note:** For information on Cristie Windows Server requirements, see CoBMR for Windows.

To recover the server using CoBMR, perform the following steps:

1. Boot the recovery ISO to start the CoBMR Recovery Environment.

   Depending on the recovery target speed and the ISO recovery media, the CoBMR window might take some time to appear.

   The **CoBMR Recovery Environment** window appears. Click **Recover System**.
2. (Optional) In the **Log Files Path** field, specify the path either as a share in UNC format or as a drive letter and path where the log files must be saved at the end of the recovery. By default, the log files are saved in the /COBMRCFG on the root drive.
3. Specify the **Domain, Username**, and **Password** of the UNC path to which the log files must be saved.
4. Click **Next**.
5. In the **Cohesity Server** field, enter the IPv4 address or the FQDN of the Cohesity cluster.
6. In the **Authentication** field, enter the Domain name, user name, and password of the Cohesity cluster. For more information on the permissions required for authentication, see Minimum Permissions.
7. In the **Registered Source** field, enter the IPv4 address or the FQDN of the physical server source as registered with the Cohesity cluster.
8. Enable **Point-in-time (PIT)** restore and select a time slot corresponding to the snapshot you want to restore. The CoBMR software will select the latest snapshot up to the time specified.

9. Click **Next**.

   The Window displays the status of the Cristie software attempting to connect to the Cohesity cluster, registering the recovery environment with the Cohesity cluster, and then extracting the Cohesity backup snapshots. The **Next** button is enabled once the BMR configuration is extracted.

10. Click **Next**.

    The CoBMR - Volume Layout window appears that displays a list of disks and partitions to be recovered. Depending on the volume layout (similar or dissimilar hardware) of the target server, you can perform one of the following actions:

    - **Similar Volume Layout**: If the recovery is back to the original server or a different server with the same volume layout (similar hardware), the disk mapping is similar. You can select the Proposed layout and click **Next**.
    - **Dissimilar Volume Layout**: When recovering to a different server with dissimilar hardware, the mapping is complex with the different disk geometry and capacity. In such cases, you can right-click the disks displayed in **Proposed layout** to select the disk to be partitioned or not. Then click **Next**.

    The **CoBMR - Select Volumes to Restore** window appears.

11. Select the datasets to be restored from the backup and click **Next**.

    The **CoBMR - Clone Settings** page appears.

12. Change the NeTBIOS name, host name, or IP address of the target server. You can use DHCP or enter a valid static IP address. Click **Finish**.

    The **Restore Status** window displaying the progress through the recovery process appears.

    The CoBMR recovery process transfers the system data and user volumes that were backed up on Cohesity and restores them on the target server with the system state maintained as that of the original server.

Recover Linux Server

> **Note:** For information on Cristie Linux Server requirements, see CoBMR for Linux.

To recover the server using CoBMR, perform the following steps:

1. Boot the CoBMR recovery environment from the ISO recovery media. You can recover back on the same physical server or onto a new physical server.

   The **CoBMR Recovery Environment** window appears.

2. Read and accept the end-user license agreement (EULA) to proceed with the recovery process.

3. Select **CoBMR** from the **Choose which product to recover** drop-down and then click **OK** to continue.
4. From Cristie Software menu options, select **Automatic Recovery**.

   The **Setup Cohesity VE Server information** window appears.
5. Enter the following information for accessing the Cohesity cluster:
   - IPv4 address or the FQDN of the Cohesity cluster
   - (Optional) Port number
   - Domain name
   - User name
   - Password

   > **Note:** The **Verify SSL certificate validity** option is enabled by default. However, you must disable this option to achieve seamless recovery.
6. Click Network Setup and validate the network setup and click **OK**.
7. Click **Next**.

   The **Get Configuration** window appears.
8. In the **Select Source** field, select the Linux server you want to recover.
9. In the **Select Backup** field, select a date and a time slot corresponding to the snapshot you want to restore. The CoBMR software will select the latest snapshot up to the time specified.
10. Click **Next**.

    The **Copy Configuration From Backup** window displays the status of the Cristie software downloading and installing the Cohesity Agent, connecting to the Cohesity cluster, registering the recovery environment with the Cohesity cluster, and then extracting the Cohesity backup snapshots. The **Next** button is enabled once the BMR configuration is extracted.
11. Click **Next**.

    The **Start Recovery** window appears.
12. Specify the restore settings and then click **Next**.

    The **Recovery Status** window appears.
13. Once the recovery is complete, a pop-up window will appear to remind you to copy the log files. Click **OK**.
14. From the Cristie Software menu options, click **Reboot** to restart your system. Once the system restarts, validate the recovered volumes.

The CoBMR recovery process transfers the system data and user volumes that were backed up on Cohesity and restores them on the target server with the system state maintained as that of the original server.

Chapter 22: Manage External Targets

The Cohesity cluster can move rarely used and inactive data to a designated external target, such as tape or cloud storage.

From the **External Targets** page, you can view, manage, and unregister the external targets that have been registered on the Cohesity cluster. For detailed instructions, see Register an External Target.

From the **Targets** tab of the external targets page, the following fields and options are available:

Column Name	Description / Action
Name	Drill-down on this link to view the following details about the target.
Purpose	The target's purpose, either Archival or Cloud Tier.
Type	The target's type, such as Google Nearline, AWS Glacier or Azure Standard.
Actions	To manage an existing target, use the following options: • **Edit** ( )–Configure the settings of the existing Target. For detailed instructions, see Register an External Target. • **Unregister**–You can unregister an external target. By unregistering, the associated metadata will be deleted from the target and will no longer be available for retrieval. For details, see Unregister an External Target.

From the **Settings** tab of the of the external targets page, you can:

- Register an External Target for Archival.
- Set Bandwidth throttling at Cluster-level for Tiering to External Targets.

CloudArchive Direct

CloudArchive Direct lets you archive data directly to an external target without retaining a copy of the data on the Cohesity cluster. In CloudArchive Direct, the Cohesity cluster acts as a local cache to stream the dataset to the external target, eliminating the need to store a full backup copy on the Cohesity cluster first.

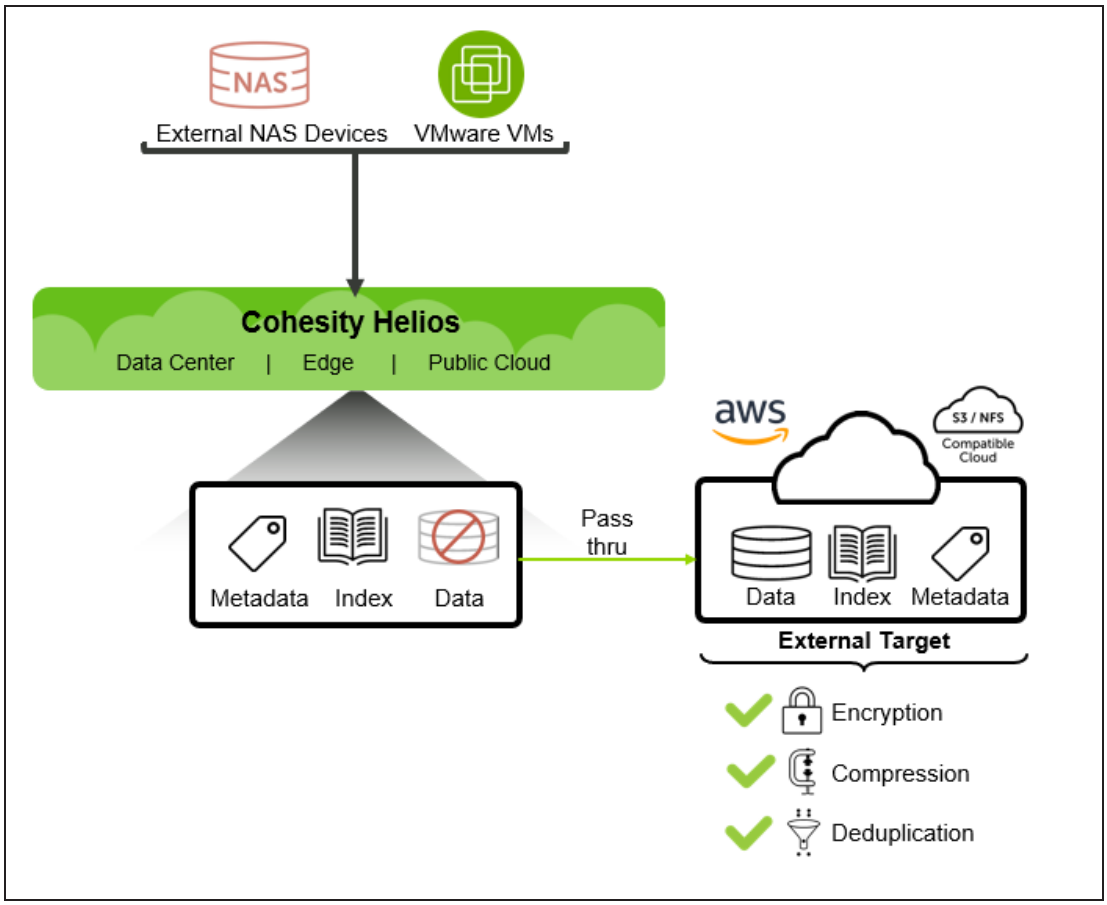
This approach reduces the capacity requirements on the local Cohesity cluster to a small cluster footprint, as only the metadata and index, and not the dataset itself are stored on the local cluster. Storing the metadata and index on the local cluster enables much quicker search and recovery down the road. The external target also stores the metadata and index, in addition to the data itself. On the Cohesity cluster, you can register a cloud storage, S3-compatible storage, or NFS-mounted servers as external targets.

> **Note:** For the first archival, depending on the size of data, the Cohesity cluster might experience significant capacity utilization, because the data first gets stored on the local storage (Storage Domain) and then aggressively gets down tired to the external target. During this time, the capacity utilization will increase till the data is garbage collected upon the successful transfer.

> **Important:**
> The option to enable CloudArchive Direct (native mode - no dedupe, no compression) from the NAS Protection Group page is deprecated in the 6.7 version.

How CloudArchive Direct Works

When you run a Protection Group for a registered source with CloudArchive Direct enabled, then according to the policy set for the Protection Group, the file system from NAS is read and stored on the external target as a streaming backup using the Cohesity cluster as a temporary cache.



CloudArchive Direct Characteristics

Feature	CloudArchive Direct
Supported Sources	• VMware • NAS sources • S3-compatible
Mode of enablement	While creating or editing a Protection Policy.
Deduplication	Supported
Number of Objects per Protection Group	Multiple
Data archival	Incremental forever

Feature	CloudArchive Direct
Metadata archival	Incremental forever
Granularity level of incremental archival	Block-level–Need to perform only incremental archival of a file if the data or metadata of the file is updated.
Native format as primary	No
Tiering of objects using Cohesity Data Movement	Supported–can choose to tier the archived data to a cheaper storage tier.
CloudRetrieve	Supported
Vault unregistration	Not supported

Supported External Targets

For the list of supported external targets, see Supported Software.

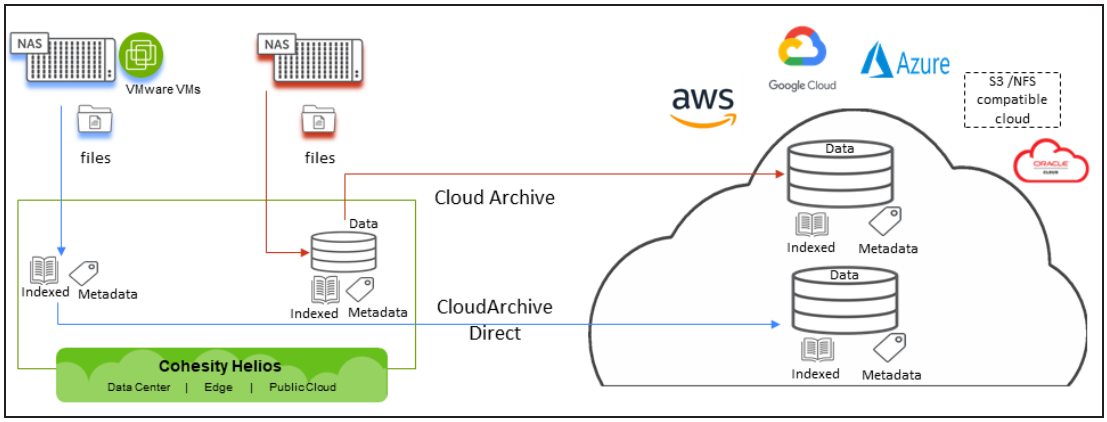
CloudArchive Direct Workflow	VMware			NAS		
	Standard Storage Tier	Archive Storage Tier	Hot Tier	Standard Storage Tier	Archive Storage Tier	Hot Tier
Direct Archival	Yes	Yes	Yes	Yes	Yes	Yes
Restore	Yes	Yes	Yes	Yes	Yes	Yes
File-level restore	Yes	No	Yes	Yes	Yes	Yes
Indexing	Yes	No	Yes	Yes	Yes	Yes
CloudRetrieve	Yes	Yes	Yes	Yes	Yes	Yes

*Indexing for VMware VMs in CloudArchive Direct-enabled Protection Groups may cause data egress from the external target, resulting in charges from the cloud provider.

Differences Between CloudArchive Direct and Cloud Archive

Term	Description
CloudArchive Direct	CloudArchive Direct copies the data from the supported source directly to any registered external target such as public cloud providers (AWS, Azure, Google Cloud Platform) or any S3-compatible external target to reduce storage costs and eliminate the need to store a full backup copy on-premises.
Cloud Archive	Cloud Archive sends a copy of the backup data (it contains the backup data, metadata, dedupe fingerprint, and index) stored on the Cohesity Cluster to any registered external target. To perform Cloud Archive, at least one full copy of the primary data needs to be stored on the cluster.

Figure X: CloudArchive Direct and Cloud Archive workflow



Considerations

- If **Encryption** is enabled at the cluster level, you must also enable encryption while registering the external target for CloudArchive Direct. Archiving directly to an external target may fail if encryption is enabled at the cluster level but not at the external target level.
- Review and understand the following considerations if you are performing CloudArchive Direct of NAS sources:
  - When you upgrade the Cohesity cluster from 6.6 or below versions to the latest version, the existing Protection Group created with CloudArchive Direct native mode will not automatically switch to the new CloudArchive Direct format. Therefore, you must pause the existing Protection Group and then create a new Protection Group for the objects with CloudArchive Direct new format.
- Review and understand the following considerations if you are performing CloudArchive Direct of VMware VMs to **Archive Storage tier** (AWS S3-Glacier, AWS

S3-Glacier-Deep-Archive, AWS S3-Glacier-Deep-Archive, AWS S3-Glacier-Deep-Archive Gov):

- File and folder recovery is not supported.
- Instant recovery of VMware VMs is not supported.
- Instant Volume Mount is not supported.
- Test & Dev (Cloning) is not supported.
- Virtual Disks (VMDK) recovery is not supported.
- Indexing is not supported.

Enable CloudArchive Direct

This topic provides information on how to enable CloudArchive Direct.

To enable CloudArchive Direct, perform the following steps:

1. Register any of the following sources:
   - NAS

     For more information, see Register or Edit NAS.
   - VMware Vcenter

     For more information, see Register or Edit a Hypervisor Source.
2. Register an external target with the **Archival Format** option as **Incremental Forever**. For more information, see Register an External Target for Archival.
3. Create a Policy with CloudArchive Direct Settings.
4. Create a Protection Group and Attach the CloudArchive Direct Policy.

Create a Policy with CloudArchive Direct Settings

A policy is a reusable set of settings that define how and when objects are protected, replicated, and archived. You can select which standard policy to use when configuring a Protection Group. A Protection Group uses the schedules and settings defined in the policy to determine when and how backups are captured, archived, or replicated.

For CloudArchive Direct, you must create a policy with the following settings:

1. Navigate to **Data Protection** > **Policies**.
2. Click **Create Policy** located at the top right of the page.

   To edit an existing policy in the list, click the actions menu (⋮) and select **Edit** (✎).
3. **Policy Name**: Specify a protection policy name. The name can contain alphanumerics, underscores, hyphens, periods, and spaces. This field is required and can be changed later.

4. Specify when backups are captured:
   - **Backup every xx**: Select the time unit for how often backups are captured by the Protection Group. This defines the protection schedule for capturing backups.
5. Under **Primary Copy**, specify the following:
   - **Keep On**: Select the external target that you have registered. You can also register a new target by clicking **Register External Target**.

     > **Note:** For CloudArchive Direct, you should not keep the primary copy on the Cohesity cluster (Local copy).

   - **Retain for xx days**: Specify how many days backups are retained on the external target before they are deleted.
6. If you want to change or configure any of the additional policy settings, then select **More Options** and perform the below steps, or else, click **Create**.
   1. **Periodic Full Backup**: Select this option from the **Backup Options** floating menu and specify the frequency for periodic full backup:
      - Day
      - Week
      - Month
   2. **Continuous Data Protection**: (*Applies only for VMware*) Select this option from the **Backup Options** floating menu and specify the time unit (hours) to capture and retain logs on the Cohesity cluster. This value defines the CDP schedule for capturing logs from the VMs.

      You can use this option to restore the VM applications to a point-in-time as opposed to periodic snapshots available with regular backups.
   3. **Quiet Times:** Select this option from the **Backup Options** floating menu to add a quiet time. Quiet Times define time periods when new protection runs are not started. For example, you may want to configure hourly backups that run during weekdays but not on Saturdays or Sundays. Quiet Times only prevent new protection runs from starting during the specified time period. Protection runs that started before the quiet time period are not affected and will continue to run. For example, if a protection run starts at 12:45 AM on Saturday morning and there is a weekend quiet time period that starts at 1 AM on Saturday morning, the protection run will continue to run past 1 AM. No new protection runs are started during the quiet times.

You can add multiple quiet times. For example, you could define a quiet time period for Saturday and Sunday and another quiet time period every morning from 9:00 AM to 11:00 AM.

> **Note:** If you update the Quiet Time periods in a policy for a running Protection Group, only new protection runs using the policy are affected and any existing Protection runs that have already started will use the original Quiet Time periods.

4. **Retry Options**: By default, the Cohesity cluster attempts to capture snapshots three times before the Job fails. The default time between retries is five minutes. You can optionally customize the number of retries and how long to wait between each attempt.
5. (Optional) Click the **Primary Copy** tile and configure the following **Backup Options** from the floating menu:
   - **Extended Retention**: Select this option to retain a subset of snapshots (backups) for a longer time period than defined by the protection schedule. Specify when to take the first snapshot and how long to retain it.
   - **Data Movement**: This option applies only when you have selected AWS Standard Storage Tier as the external target to store the primary copy. With this option, you can move the data (downtier) from the selected AWS Standard Storage Tier to an AWS Archive Storage Tier target after a specified time period. Data Movement helps in space reclamation on the external target. From the **Move Data** drop-down, you can select the data S3 target and specify after how many days, weeks, months, or years you want to move the data from the external target to the S3 bucket.

     > **Note:** As an AWS consideration, you cannot downtier from S3 Glacier to S3 Deep Archive. After downtiering to either S3 Glacier or S3 Deep Archive, you cannot perform any further downtiering.
6. Click **Create**.

Create a Protection Group and Attach the CloudArchive Direct Policy

A Protection Group uses the schedules and settings defined in the policy to determine when and how backups are captured.

For performing CloudArchive Direct on the supported sources, you must create a Protection Group and attach the policy created with the CloudArchive Direct settings.

- For information on creating a Protection Group for VMware VMs, see Add or Edit a Protection Group for Virtual Servers.
- For information on creating a Protection Group for NAS, see Protect NAS.

Use Cases for CloudArchive Direct

Use-Case 1: Perform CloudArchive Direct to a cold storage tier

1. On the AWS console, create an S3 bucket. Ensure that you do not set lifecycle management policy on the S3 bucket.
2. Log in to the Cohesity cluster, and perform the following steps:
    1. Register the S3 bucket as an S3-Glacier or S3-Glacier-Deep-Archive as an external target. While registering:
        - Select the **Archival Format** as **Incremental Forever**.
        - Download and execute the CloudFormation template in your AWS account to create the required resources for Garbage collection.

          For more information, see Register an External Target for Archival.
    2. Create a policy with the **Primary Copy** option set to the registered external target.

       For more information, see Create a Policy with CloudArchive Direct Settings.
    3. Create a Protection Group and Attach the CloudArchive Direct Policy. For more information, see Create a Protection Group and Attach the CloudArchive Direct Policy.

Use-Case 2: Perform CloudArchive Direct to hot storage tier (S3) with tiering to a cold storage tier (S3-Glacier or S3-Glacier-Deep-Archive)

1. On the AWS console, create an S3 bucket. You must not set the lifecycle management policy on the S3 bucket.
2. Log in to the Cohesity cluster, and perform the following steps:
    1. Register the S3 bucket as an S3-Glacier or S3-Glacier-Deep-Archive as an external target. While registering:
        - Select the **Archival Format** as **Incremental Forever**.
        - Execute the Cloud Formation template in your AWS account to create the required resources for Garbage collection.

          For more information, see Register an External Target for Archival.
    2. Create a policy with the following settings :

- The **Primary Copy** option is set to the registered external target.
- Add the **Data Movement** option in the policy and select the desired storage class to tier the snapshots.

For more information, see Create a Policy with CloudArchive Direct Settings.

3. Create a Protection Group and Attach the CloudArchive Direct Policy. For more information, see Create a Protection Group and Attach the CloudArchive Direct Policy.

Recover CloudArchive Direct Data

> **Note:** See the Considerations section before recovering the data directly archived to the external target.

For NAS, Cohesity supports both file-based and volume-based recovery of filesystem that is directly archived to the external target.

- For information about file-based recovery, see Recover Files or Folders.
- For information about volume-based recovery, see Recover NAS Storage Volumes.

For VMware VMs, Cohesity supports the recovery of VMs and virtual disks that are archived to the external target.

For more information, see:

- Recover VMs.
- Recover Virtual Disks.

CloudRetrieve of CloudArchive Direct Data

Cohesity supports retrieving the CloudArchive Direct data to an alternate Cohesity cluster. For more information on how to retrieve data to an alternate cluster, see About CloudRetrieve.

Archive Object Lock

> **Note:** This feature applies only to CloudArchive.

Cohesity stores immutable data at both the source cluster and external target levels. By configuring Object Lock, you can lock archives on external targets to prevent data from being modified, deleted, or overwritten. Object Lock can be configured during external target registration. For registering an external target, see Register an External Target for Archival.

Prerequisites for Object Lock

Before registering an external target with Object Lock enabled, ensure the following:

- **Confirm Object Lock support**: Verify that the target you select supports Object Lock. For the list of targets that support Object Lock, see Supported Workflows and External Targets.
- **For AWS external targets**: The Object Lock-supported AWS external target must have versioning and Object Lock enabled. For more information, see Using S3 Object Lock.
- **For Azure external targets**: The Object Lock-supported Azure external target must have version-level immutability enabled on the storage container, which indicates that the storage account must also have version-level immutability. For more information, see Enable version-level immutability support on a container.
- **For GCP external targets**: The Object Lock-supported GCP external target must have versioning and Object Retention Lock enabled. For more information, see Object Rentention Lock.

> **Note:**
> - The above properties must be set at the time of target creation and cannot be enabled after creation.
> - Avoid setting default retention on S3 buckets and Azure - this is not required as Cohesity locks the objects for the duration required. Large default retentions affect garbage collection and increase costs.
> - For AWS and S3-compatible targets, by default, the archived objects will be locked in the Governance retention mode. Support for enabling Object Lock in **Compliance** mode via the Cohesity UI will be introduced in an upcoming release.
> - For Azure targets, by default, the objects will be locked in the Locked mode.

Considerations for Object Lock

- If you registered an Object Lock-capable external target on a Cohesity cluster running version 6.8 or earlier and later upgraded the cluster to a version that supports Object Lock, you will not be able to enable Object Lock on those previously registered targets.
- When archiving data to versioned buckets, ensure that you do not edit the storage class of objects directly. Editing the storage class of objects directly will create a new

version of the object while the original version remains in the previous storage tier. Object-level locks will not be carried over to the new version.

- The Cohesity Data Movement feature, which can enabled during protection policy creation cannot coexist with Object Lock. An archival target can only have one of the settings enabled.
- The expiry of the object lock will match the expiry set for archived snapshots. However, the object lock will not update if you modify the expiry for archived snapshots after the Protection Group has run.
- You cannot disable Object Lock once you enable it on a target.
- **For archival with periodic full format**:
  - For the list of targets (S3-compatible, AWS, and Azure) that support Object Lock for archival with periodic full,

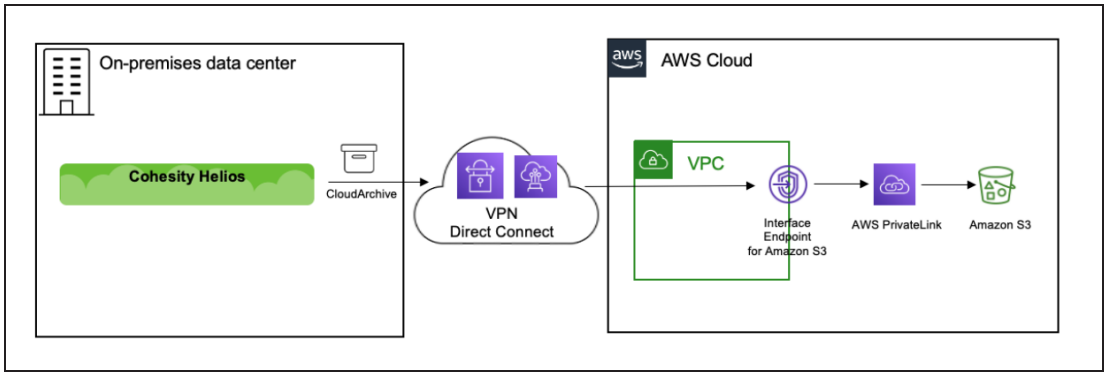
    see Supported Workflows and External Targets.
  - If Object Lock is not met for an archive, the archive is still considered successful and can be recovered.
  - After archival, to view the Object Lock status, perform the following:
    a. Click the **Protection** menu.
    b. Select the required Protection Group.
    c. Select the required run.
    d. Click the **Cloud Archive** tab.

       The **Object Lock Compliance** status and **Archive Object Lock Expiry Time** will be displayed.
- **For archival with incremental forever format**:
  - For the list of targets (S3-compatible, AWS, Azure, and GCP) that support Object Lock for archival with incremental full, see Supported Workflows and External Targets.
  - If Object Lock compliance is not met for an archive, then the archival will fail.
  - For on-prem clusters, Cohesity does not support Object Lock for CloudArchive Direct. However, for DataProtect for cloud clusters in AWS, GCP, and Azure, where the primary copy of data is down-tiered directly to an external target via CloudArchive Direct, support Object Lock for CloudArchive Direct of primary data.
  - With Object Lock enabled, the storage utilization of external targets may be higher.

Archive Data Over AWS PrivateLink

AWS PrivateLink allows AWS users to access Amazon services (S3, EC2, etc) through a private network. With AWS PrivateLink, you can create an interface endpoint in your VPC. These endpoints are directly accessible from applications that are on premises over VPN and AWS Direct Connect, or in a different AWS Region over VPC peering. For archiving your data to AWS S3, you can configure AWS PrivateLink to securely connect to the AWS external target over your private network.

The following diagram depicts how AWS PrivateLink is used to access Amazon S3 through a private network:



Configuring Amazon PrivateLink for Archive

Prerequisites

Before configuring Amazon PrivateLink for archive, ensure to have:

- AWS Direct Connect or AWS Virtual Private Network (AWS VPN) connection between the on-premise data center and AWS.
- AWS Virtual Private Cloud (VPC), VPC subnet, and security group.

To configure Amazon PrivateLink for archive, perform the following steps:

1. Create a PrivateLink Interface Endpoint for S3 in Your VPC.
2. Create an S3 Bucket in the AWS Console.
3. Register S3 Bucket as an External Target.

Create a PrivateLink Interface Endpoint for S3 in Your VPC

To support on-premise traffic for S3, you must create an interface VPC endpoint. To create an interface endpoint for S3, see AWS documentation.

Once you create an interface endpoint, Amazon S3 generates two types of endpoint-specific S3 DNS names that you can use to communicate with the AWS service from your VPC: *Regional* and *zonal*. Select **Regional S3 DNS name** to communicate with the AWS service.

Create an S3 Bucket in the AWS Console

To archive your data to Amazon S3, you must create an S3 bucket. While creating a bucket, Cohesity recommends you update the S3 bucket policy to restrict access only to the VPC endpoint. For more information on creating an SR bucket, see AWS documentation.

Register S3 Bucket as an External Target

Once you map the VPC endpoint IP address with the FQDN of the S3 bucket, for archiving your data over the private network, you can register the AWS S3 bucket with Cohesity as an external target. For more information, see Register an External Target for Archival.

If you have configured Amazon PrivateLink interface endpoints with the Cohesity cluster to access the AWS S3 external targets for archival, then you must provide values for the following parameters while executing CFT:

- **NetworkSecurityGroup**: The network security group name to use for the lambda function.
- **VPCSubnets**: The network security group name to use for the lambda function.

For more information, see CloudFormation Template.

Archive Data Over Azure Private Endpoints

This topic provides the requirements and the procedure to configure Incrementation Forever Archival using an Express Route and/or VPN from an on-premises Cohesity cluster to Azure Blob and Azure Function App using Azure Private Endpoints.

Prerequisites

Before configuring Azure Private Endpoint for archival, ensure the following:

- Azure ExpressRoute or Virtual Private Network (VPN) between the on-premises Cohesity cluster and Azure.
- Azure Resources:
    - Azure Resource Group
    - Virtual Network (VNET)
    - VNET subnets for private endpoints (Storage Account and Azure Function App)
    - Outbound subnet for Azure Function App
    - Network Security Group

Configuring Azure Private Endpoint for Archive

Perform the following configuration steps for archiving data over Azure Private Endpoints. The process includes creating necessary Azure resources and configuring the Cohesity

cluster.

1. Create an App Service Plan.
2. Configure Subnet for Outbound Azure Function App.
3. Create an Azure Storage Account with Private Endpoint.
4. Create an Azure Function App with Private Endpoint.
5. Configure Azure Function App for Incremental Forever Archival
6. Configure the Cohesity cluster to use Azure Private Endpoint.

Create an App Service Plan

The App Service Plan defines the compute resources for your Azure Function App.

Perform the following steps to create an App Service Plan:

1. In the Azure Portal, use the **Create App Service Plan** wizard to create the App Service Plan. Enter the following values:
    - **Operating System**: Linux
    - **Pricing Plan**: Select Basic, Standard, Premium, Isolated, or Elastic to support Azure Private Endpoint for App.
2. Click **Next: Tags** to optionally add tags to the App Service Plan.
3. Click **Review + create**.
4. Click **Create** to provision the App Service Plan.

Configure Subnet for Outbound Azure Function App

Perform the following steps to configure a subnet for outbound traffic from your Azure Function App:

1. In the Azure Portal, select the Virtual Network (VNET).
2. On the **Virtual Network** page, select **Subnets** from the left navigation under **Settings**. On the Subnets page, click **+ Subnet**.
3. On the **Add Subnet** screen, enter or select the required values for the subnet settings:
    - **Subnet Delegation**: Set to **Microsoft.Web/serverFarms** to enable outbound connectivity for the Azure Function App.
4. Click **Add** to create the subnet.

Create an Azure Storage Account

Create an Azure Storage Account with a private endpoint to archive data to Azure by following these steps:

1. In the Azure Portal, use the **Storage Account** wizard to create the storage account. Enter or select the required values for the storage account settings, then click **Next**.
2. In the **Advanced** tab, configure the advanced options as needed, then click **Next**.
3. On the **Networking** tab, configure the network settings for the storage account, then click **Next**:
   - **Network Connectivity**: Select the appropriate network access option. Refer to the Microsoft documentation for details.
   - **Add a Private Endpoint**: Enter or select the required values, then click **OK**.

     > **Note:** : The private endpoint must be included in DNS. You can use Azure DNS or your own DNS.
4. Configure **Data Protection** (optional), **Encryption**, and **Tags** (optional), then click **Review + Create**.
5. On the **Review + Create** tab, verify your settings and click **Create** to create the storage account.

Create Azure Function App

To archive data to an Azure target using the Incremental Forever archival format, you must create an Azure Function App in the Azure Portal. The Azure Function App enables cost-efficient garbage collection.

Perform the following steps to create an Azure Function App with private endpoints:

1. In the Azure Portal, use the **Create Function App** wizard to create a new Azure Function App. Choose either **App Service** or **Functions Premium** hosting plan, and then click **Select**.

   > **Note:** : Consumption or Flex Consumption hosting plans are not supported with private endpoints.
2. On the **Basics** tab, enter or select the following values, and then click **Next: Storage**:

Setting	Value
Try a secure unique default hostname	Toggle off

Setting	Value
Do you want to deploy code or container image	Code
Operating System	Linux
Runtime stack	Python
Version	3.9 or newer
Linux Plan	Select the Azure Service Plan that you created.

3. On the **Storage** tab, select the storage account you created, and then click **Next: Networking**.
4. On the **Networking** tab, enter or select the following values:

Setting	Value
Enable public access	Off
Virtual Network	Select the VNET
Enable private endpoints	On
Private endpoint name	Enter name
Inbound subnet	Select subnet
DNS	Select Azure DNS or your own DNS
Enable VNET integration	On
Outbound subnet	Select the outbound subnet created previously.

5. (Optional) On the **Monitoring** tab, configure monitoring settings, and then click **Next: Durable Function**.
6. (Optional) On the **Durable Functions** page, select the desired option, and then click **Next: Deployment**.

7. On the **Deployment** tab, configure **Basic authentication**, then click **Next: Authentication**.
8. On the **Authentication** tab, enter or select the following values, and then click **Next: Tags**:

Setting	Authentication type
Host storage (AzureWebJobsStorage)	Secrets

9. (Optional) On the **Tags** tab, enter values, and then click **Next: Review + create**.
10. On the **Review + create** tab, review the configuration, and then click **Create**.

Configure Azure Function App for Incremental Forever Archival

Perform the following steps to configure environment variables for your Azure Function App:

1. In the Azure Portal, select the Azure Function App.
2. On the **Function App** page, select Environment variables from the left navigation under **Settings**.
3. In **App settings**, click **Add** to add the required environment variables, then click **Apply**:

Name	Value	Notes
SCM_DO_BUILD_DURING_DEPLOYMENT	true	Required
ENABLE_ORYX_BUILD	true	Required
WEBSITE_DNS_SERVER	<IP address>	Optional - Set this variable to use Azure DNS for DNS resolution in the Azure Function.

4. Click **Confirm** to save the changes.

Configure the Cohesity Cluster to Use Azure Private Endpoint

To use the Azure Storage Account and Azure Function App through their Private Endpoints for archiving data, you must add the Private Endpoint IP addresses to the host mapping on the Cohesity cluster.

Perform To add host mapping for the VPC endpoint on the Cohesity cluster:

1. Navigate to **Settings > Networking > Host Mapping**.
2. Click **Add Host Mapping**.
3. In the **IP Address** field, enter the IP addresses of the private endpoint of Azure Storage account and Function App.
4. In the **Hostname** field, enter the FQDNs of the private endpoint of Azure Storage account and Function App.

   Example:

   - FQDN of Azure Storage account: <Azure Storage Account>.blob.core.windows.net
   - FQDN of Function App:

     <Azure Function App Name>.scm.azurewebsites.net

     <Azure Function App Name>.azurewebsites.net

Register Azure Account as an External Target

After mapping the Azure Storage Account and Azure Function App private endpoint IP addresses with their FQDNs, you can register the Azure Storage Account with Cohesity as an external target. This allows you to archive data over the private network using the Incremental Forever archival format.

For more information, see Register an External Target for Archival.

Register an External Target

You can register an external target with the Cohesity cluster for Cloud Archive, CloudArchive Direct, or for Cloud Tiering.

Supported External Target

The following table provides the mapping of external target types that can serve as Cloud Archive, CloudArchive Direct, and Cloud Tier:

Cloud Provider	Class of Storage	Cloud Archive			CloudArchive Direct	Cloud Tier
		With Periodic Full	With Incremental Forever	Always Full		
AWS	Glacier (Legacy) Standard	Supported	Not Supported	NA	Not Supported	Not Supported
	Glacier (Legacy) Gov	Supported	Not Supported	NA	Not Supported	Not Supported
	Glacier (Legacy) C2S	Supported	Not Supported	NA	Not Supported	Not Supported
	S3 Standard	Supported	Supported	NA	Supported	Supported
	S3 Gov	Supported	Not Supported	NA	Not Supported	Supported
	S3 C2S	Supported	Not Supported	NA	Not Supported	Supported
	S3-Glacier Standard (Currently S3 Glacier Flexible Retrieval)	Supported	Supported	NA	Supported	Not Supported
	S3-Glacier Gov	Supported	Supported	NA	Supported	Not Supported
	S3-Glacier-Deep-Archive Standard	Supported	Supported	NA	Supported	Not Supported
	S3-Glacier-Deep-Archive Gov	Supported	Supported	NA	Supported	Not Supported
	S3-IA Standard	Supported	Supported	NA	Supported	Not Supported

Cloud Provider	Class of Storage	Cloud Archive			CloudArchive Direct	Cloud Tier
		With Periodic Full	With Incremental Forever	Always Full		
	S3-IA Gov	Supported	Supported	NA	Supported	Not Supported
	S3-IA C2S	Supported	Not Supported	NA	Not Supported	Not Supported
	S3-Intelligent Standard	Supported	Supported****	NA	Supported****	Supported
	S3-Intelligent Gov	Supported	Supported****	NA	Supported****	Not Supported
	S3-One-Zone Standard	Supported	Supported	NA	Supported	Not Supported
	S3-One-Zone Gov	Supported	Supported	NA	Supported	Not Supported
	Snowball Edge*	Supported	Not Supported	NA	Not Supported	Not Supported
	S3 Glacier Instant Retrieval	Supported	Supported	NA	Supported	Not Supported
	S3 Glacier Instant Retrieval Gov	Supported	Supported	NA	Supported	Not Supported

Cloud Provider	Class of Storage	Cloud Archive			CloudArchive Direct	Cloud Tier
		With Periodic Full	With Incremental Forever	Always Full		
Azure	Archive Blob	Supported	Supported	NA	Not Supported	Not Supported
	Archive Blob-Gov	Supported	Not Supported	NA	Not Supported	Not Supported
	Cool Blob-Standard	Supported	Supported	NA	Supported	Not Supported

[*]**AWS Snowball and Snowball Edge**

- Cohesity does not support AWS legacy Snowball as an external target.
- AWS Snowball Edge can be used as a local S3 target by selecting **Snowball Edge** as the **Storage Class** while registering the AWS external target.
- Contact Cohesity Support if you want to ship the Snowball Edge device to AWS.

[**]**S3-Compatible Standard Tier and NAS**

With incremental forever archival format, the Cohesity cluster will download a portion of the data from the S3-compatible Standard tier and NAS external targets for the space reclamation process and reupload it after compaction. This leads to increased network bandwidth usage. Cohesity recommends having sufficient network bandwidth between the cluster and the external target, for example, hosting the external target within the same data center or network as the Cohesity cluster.

[***]**S3-Compatible Tape Based**

The archival format is Always Full and does not support deduplication and incremental forever archival.

[****]**AWS - S3-Intelligent**

Cloud Archive with incremental forever and CloudArchive Direct is supported for AWS - S3-Intelligent starting from the 7.2.2_u2 release.

S3-Compatible Object Storage - Standard Tier

Cohesity supports any S3-compatible device as an S3-Standard tier (Regular as storage class) external target with similar capabilities to an AWS S3-Standard. Any S3-compatible targets that use S3-Standard must be registered as a regular storage class. The S3-compatible uses S3-Standard APIs for archival and recovery. This Standard tier is supported for both incremental with periodic full and incremental forever archival formats. Compression and deduplication are supported for both archival formats.

With incremental forever archival format, the Cohesity cluster will download a portion of the data from the S3-compatible Standard tier external target for the space reclamation process and reupload it after compaction. This leads to increased network bandwidth usage. Cohesity recommends having sufficient network bandwidth between the cluster and the external target; for example, hosting the external target within the same data center or network as the Cohesity cluster.

> **Note:** Any S3-compatible targets that use Tape storage in the backend are not supported with the Standard tier; instead, you must register them as S3-compatible with the Tape-based Storage Class.

The following table provides the list of S3-Compatible Object Storage - Standard Tier and their details:

The S3-compatible table below contains a subset of supported S3-compatible targets. Refer to the S3 External Target Compatibility Tool to validate the S3-compatible targets.

Object Storage Vendor/ Cloud Provider	Product Names	Service URL	Port Number	Transport	AWS Signature Version	Additional Details
Backblaze	B2 Cloud Storage with v2 API version	s3.us-west-000 .backblazeb2.com	443	HTTPS	AWS Sign ver4	Requires V4 signing to provide S3 compatibility.
Cohesity	Cohesity Data Cloud	-	3000	HTTPS	AWS Sign ver4	-
Dell EMC	ECS	<fqdn-or-IP>: <portnumber>	9021	HTTPS	AWS Sign ver4	It is recommended to use AWS Sign ver4 with HTTPS port 9021.
			9020	HTTP	AWS Sign ver2	
Hitachi Vantara	Hitachi Content Platform	<fqdn-or-IP>	Not Required	HTTPS	AWS Sign ver4	Both v4 and v2 are supported for HTTPS.
		<fqdn-or-IP>:8080	8080	HTTP	AWS Sign ver2	-
Huawei Software Technologies Company	Object Storage Service	obs.ap-southeast-3.myhuaweicloud.com	Not required	HTTPS	AWS Sign ver2	-
IBM	Cloud Object Storage	s3.private.<region>-<site>.cloud-object-storage.appdomain.cloud	Not required	HTTPS	AWS Sign ver4	Both v4 and v2 work; v4 is the preferred version.

Object Storage Vendor/ Cloud Provider	Product Names	Service URL	Port Number	Transport	AWS Signature Version	Additional Details
11:11 Systems	11:11 Cloud Object Storage	us-central-1a.object.ilandcloud.com	Not required	HTTPS	AWS Sign ver4	-
		us-central-1b.object.ilandcloud.com				
		eu-west-1a.object.ilandcloud.com				
		eu-west-2a.object.ilandcloud.com				
		ap-southeast-1a.object.ilandcloud.com				
MInIO	MInIO Object Storage	<fqdn-or-IP>:9000	9000	HTTP	AWS Sign ver2	HTTP is the default protocol, but can be configured for HTTPS.
NetApp	StorageGrid	<fqdn-or-IP>:8082	8082	HTTPS	AWS Sign ver2	8082 via storage node.
	StorageGRID Webscale	<fqdn-or-IP>:18082	18082	HTTPS	AWS Sign ver2	18082 via gateway node.

Object Storage Vendor/ Cloud Provider	Product Names	Service URL	Port Number	Transport	AWS Signature Version	Additional Details
Pure Storage	Pure Flashblade	-	443	-	AWS Sign ver2	-
Wasabi	s3.us-east-1.wasabisys.com s3-<region>.wasabisys.com s3.wasabisys.com	-	Not required	HTTPS	AWS Sign ver4	Both v4 and v2 work; v4 is the preferred version.
Netdepot	-	us-central-1-s3.netdepot.com	Not required	HTTPS	AWS Sign ver4	-
IBM	IBM Storage Ceph	s3.cephlabs.com	443	HTTPS	AWS Sign ver4	-

S3-Compatible Object Storage - Tape-Based

Cohesity supports any S3-compatible targets that use tape storage in the backend as an external target and have capabilities similar to those of AWS S3 Glacier. Any S3-compatible targets that use Tape storage in the backend must be registered as Tape-based Storage Class. The tape-based Storage Class uses S3 Glacier APIs for archival and recovery. This supports always full with compression enabled by default and does not support deduplication and incremental archives.

> **Note:** S3-compatible Tape-based targets that deviate in their capabilities compared to AWS S3 Glacier tier are not supported. For the supported workflows of Tape-based, see Supported Workflows and External Targets.

Object Storage Vendor/ Cloud Provider	Product Names	Service URL	Port Number	Transport	AWS Signature Version	Additional Details
IBM	Storage Protect	<fqdn-or-IP>:9000	9000	HTTPS	V4	
Spectra Logic	Spectra Logic	<fqdn-or-IP>:443	443	HTTPS	V4	Solution Guide
PoINT Software & Systems	PoINT Archival Gateway	<fqdn-or-IP>:4443	4443	HTTPS	V4	Solution Guide

S3 External Target Compatibility Tool

The S3 external target compatibility tool validates whether the provided S3 compatible configuration has all the necessary permissions to execute the required APIs for successful archive and restore operations. This tool can validate S3-compatible storage targets and Tape-based S3 targets.

The S3 external target compatibility tool can be run from any linux environment and does not require a Cohesity cluster.

The S3 external target compatibility tool validates the following features:

- Incremental with periodic full
- Incremental with periodic full - versioning support
- Incremental with periodic full - object lock support
- Forever incremental
- Forever incremental - versioning support
- Forever incremental - object lock support

Install and Configure S3 Compatible Tool

To install the S3 compatibility tool:

1. Download the tool from the Cohesity Tools section on the Cohesity Download portal.
2. Run the following command to install the tool:

   ```
   ./s3_external_target_compatibility_tool_installer
   ```

   The installer is a self-extracting package that installs all required files under the following directory:

```
/tmp/s3_external_target_compatibility_tool
```

> **Note:** The dll_libs directory contains all dependent libraries. The installer automatically sets the correct interpreter and rpath.

3. Change the directory to `/tmp/s3_external_target_compatibility_tool`.
4. Run the following command to start the validation:

```
./s3_external_target_compatibility_tool --vault_config_file_path=<path_to_vault_config_file>
```

5. Run the following command to view the list of available options in the tool:

```
./s3_external_target_compatibility_tool
```

Configuration File Format

The S3 External Target compatibility tool requires the external target configuration file in the following format:

```
{
"access_key_id": "<Provide access key id>",
"secret_access_key": "<Provide secret access key>",
"host_name": "<Enter the hostname>",
"bucket_name": "<Enter the bucket name>",
"port_number": "<Optional: Default is 443. Specify only if different>",
"signature_version": <Optional: Default is 4. Values can be 2 or 4 (integer)>,
"use_https": <Optional: Default is true. Values can be true or false (boolean)>
"region": <Optional>
}
```

Parameters

The following table describes the external target configuration file parameters.

Parameter	Description
access_key_id	The access key ID for authentication.

Parameter	Description
secret_access_key	The secret access key for authentication.
host_name	The hostname of the S3-compatible storage system.
bucket_name	The bucket name where archives and restores will be performed.
port_number	(Optional) The port number to connect to the S3-compatible target (default: 443).
signature_version	(Optional) The signature version for API authentication (default: 4, possible values: 2 or 4)
use_https	(Optional) Boolean flag to indicate whether HTTPS should be used (default: true).
region	(Optional) Region of the bucket.

- Register an External Target for Archival
- Register an External Target for Cloud Tier

Prerequisites and Considerations for Registering External Targets

Before registering an external target, read and understand the following points:

- Ensure the external target is reachable. Verify by pinging the target from the Cohesity CLI.
- Check the network infrastructure and confirm it is not blocking connectivity.
- Check firewall policy settings. You may need to add the Cohesity node IP addresses to firewall rules.
- For AWS S3 or Glacier external targets, add the DNS names for the S3 and Glacier endpoints for the region to the allow list. For more information, see AWS service endpoints.
- For GCP, ensure that the Cloud Resource Manager API is enabled on the GCP project.
- Before registering GCP as external targets, ensure the following endpoints are accessible to the Cohesity cluster: "www.googleapis.com", "accounts.google.com".
- Cloud Tier targets cannot be unregistered currently.
- The target type cannot be modified once you register the target.

- You can register an external target either for Cloud Archive, CloudArchive Direct, or for Cloud Tier. You cannot register the same external target for Cloud Archive, CloudArchive Direct, and Cloud Tier purposes.
- The external targets that are registered for Cloud Tiering must have low latency. Therefore, high latency storage classes like glacier vault etc are not supported for Cloud Tiering.
- The same bucket can be registered as different external targets depending on the storage class.
- If you are using an S3 bucket with object versioning enabled as the external target, you must set up a Lifecycle Management Policy on the bucket to permanently delete non-current versions of objects. This is required to garbage-collect object versions. If there is a malware attack on the bucket that overwrites object versions, this policy could result in data loss in the absence of WORM locks on the object versions.
- To configure an HTTP proxy server for outbound internet connectivity from a Cohesity cluster to an external target, see this KB article.
- From the Cohesity UI, you cannot unregister an external target registered for CloudTier.
- For Cloud Archive with incremental forever and for CloudArchive Direct, Cohesity cluster may download a portion of the data from the S3-compatible and NAS external targets during each garbage collection process and reupload it after compaction. This can potentially lead to increased network bandwidth usage. To prevent additional network usage, Cohesity recommends using S3-compatible and NAS targets hosted within the same data center or network as the Cohesity cluster.
- If you have archived or plan to archive your data with "incremental forever" as the archival format to a bucket with versioning enabled, Cohesity recommends you skip upgrading your Cohesity cluster to 7.1 and wait until the upcoming Cohesity release or a subsequent patch for upgrade.
- If an external target you want to register for archival has object lock with a default retention period configured, then you must not select "incremental forever" as the archival format while registering this external target with the Cohesity cluster.

  Cohesity may require additional permissions to validate whether such a data lock policy is configured on the external target. For example, to validate the data lock configuration on AWS S3 targets, you must have the `s3:GetBucketObjectLockConfiguration` permission.
- If the **Object Key Pattern** of the S3 View is **Object ID**, then you must use the **Incremental Forever** archival format while archiving the S3 View. You cannot archive the S3 View using the **Incremental with Periodic Full** format.
- If you are planning to archive your data to Azure hot tier using the incremental forever archival format, then ensure that the storage account you create is accessible through a public network and not a private network.

- To avoid early deletion charges, garbage collection of objects archived to an external target is performed only after the minimum retention period is met. As a result, storage utilization at the target level may increase; however, the associated costs typically remain the same or may even be lower.
- For archiving data to **S3 Compatible - Tape Based Storage Class**:
  - The archival format is *Always Full* with compression enabled by default.
  - Cohesity does not support deduplication and incremental archive.
  - Cohesity does not support file-level recovery.
  - The S3 cache must have sufficient storage to hold the largest Protection Group while the cache is filled with the restored data.
  - The recovery workflow retains the restored data from the tape on the S3 cache for seven days. If you want to reduce the retention period of restored data on the S3 cache, contact Cohesity Support.
  - If multiple recoveries are triggered within a span of seven days, the cache size must be large enough to hold all the recovered snapshots.
  - By default, the number of parallel streams per cluster is set to 10. If you want to configure these values, contact Cohesity Support.
  - By default, the number of restore tasks per Tape Storage is set to 1.
  - Cohesity recommends not to add more objects in a Protection Group as the recovery workflow could hydrate the complete archive while restoring a single object.
  - To protect IBM Storage Protect S3 Compatible, you must contact IBM support.
- You must not set up a Lifecycle Management (LCM) Policy on the external target registered for Cloud Tier.
- If you are archiving data using Cloud Archive or CloudArchive Direct with the Incremental Forever archival format to Amazon S3 Intelligent-Tiering, ensure you do not explicitly configure a bucket lifecycle policy that down-tiers data to the Archive or Deep Archive tiers. Doing so will cause the external target registration to fail.

  Additionally, if such a policy is configured after the S3 Intelligent-Tiering target has been registered with the cluster, any data archived to that bucket may become unrecoverable
- Prerequisites for Registering AWS S3 Buckts as External Targets Using IAM Roles Anywhere:

  Before registering an AWS S3 bucket as an external target on the Cohesity cluster for archival using IAM Roles Anywhere, follow these steps:

1. Create a Certificate Authority (CA):
    - Ensure that the certificates are X.509 v3 compliant.
    - Set Basic Constraints to "CA" with the value "false".
    - Include the key usage for Digital Signature.
    - Use a signing algorithm such as SHA256 or stronger. Avoid MD5 and SHA1 algorithms.
2. Create a Trust Anchor in AWS:
    - Establish the relationship between the certificate authority and IAM Anywhere by creating a Trust anchor.
3. Create an IAM Role:
    - This role should have access to the AWS S3 bucket.
    - Implement a custom trust policy specifically for the IAM Anywhere service principal.
4. Create an IAM Anywhere Profile:
    - Specify which roles IAM Roles Anywhere can assume. This will define the permissions and restrictions associated with the roles used by IAM Roles Anywhere.

For more information about creating a Trust Anchor and Profile role, see the AWS documentation.

Minimum Permissions for Registering External Targets

This topic covers the minimum permissions required for registering the AWS, Azure, and GCP as external targets.

Minimum Permissions for registering AWS External Targets

The following tables list the AWS permissions required for registering AWS source as an external target. The description column in the table explains why the permissions are needed. The permissions are for both AWS and AWS GovCloud.

You can create an AWS policy to grant permissions. For more information, see Grant AWS Permissions.

A JSON file is also provided for each set of permissions.

The permissions listed for Cloud Archive and CloudTier are required for both the IAM user and the IAM role used for registering the external target.

Cloud Archive (Incremental with Periodic Full) and CloudTier - S3

"glacier:DescribeVault" and "glacier:DescribeJob" are required to describe the vault details and job details. "glacier:ListParts" is needed to list parts while retrieving objects.

Minimum Permissions for registering Azure External Targets

When registering Azure as an external target for archival or tiering, authentication is performed using storage access keys, so no additional permissions are required.

Minimum Permissions for registering GCP External Targets

The following tables list the GCP permissions required for registering GCP source as an external target.

Action	Permissions

Cloud Archive	`storage.buckets.get`
	`storage.multipartUploads.abort`
	`storage.multipartUploads.create`
	`storage.multipartUploads.list`
	`storage.multipartUploads.listParts`
	`storage.objects.create`
	`storage.objects.delete`
	`storage.objects.get`
	`storage.objects.list`
	`storage.objects.update`

Register an External Target for Archival

Before register an external target for archival, ensure you have:

- Met the pre-requirements to register an external target.
- Reviewed the considerations.
- The minimum permissions to register the external target.

To register an external target for Cloud Archive, perform the following steps:

1. Navigate to **Infrastructure > External Target**.
2. Click **Add External Target** located at the top right of the page.
3. Select **Archival** as the external target's **Purpose**.
4. From the **Storage Type** drop-down list, select the external target you want to register with the Cohesity cluster for Cloud Archive.
5. From the **Storage Class** drop-down, select the storage class of the storage type you selected.

> **Note:** For Cloud Archive with incremental forever and for CloudArchive Direct, Cohesity cluster may download a portion of the data from the S3-compatible and NAS external targets during each garbage collection process and reupload it after compaction. This can potentially lead to increased network bandwidth usage. To prevent additional network usage, Cohesity recommends using S3-compatible and NAS targets hosted within the same data center or network as the Cohesity cluster.

AWS S3 Standard or AWS Glacier(Legacy) Standard or AWS S3-Glacier Standard (Currently S3 Glacier Flexibel Retrieval) or AWS S3-Glacier-Deep-Archive Standard or AWS S3 Intelligent Standard or AWS S3 One Zone Standard

For IAM user, if you do not already have an access key to use with Cohesity, create a new one in the AWS Management Console (root account credentials required). In AWS, go to **IAM** (AWS Identity and Access Management) and create a new access key ID and secret access key ID. Use this access key ID and secret access key to complete the corresponding fields below.

> **Warning:** Do not apply an AWS Object Lifecycle Policy with the Expiration action to an AWS S3 External Target used for archiving data. Applying a policy with this action may result in data loss.

Field Name	Description
Bucket Name	Name of the existing bucket where you will store objects. This cannot be modified after you register the Target.

Field Name	Description
Region	Geographic area to use for Amazon storage. For example, if your region name is US West (N. California), the AWS Region value should be “us-west-1”. > **Note:** The AWS Region value is case-sensitive. It must be in lowercase and cannot contain uppercase letters. To know your AWS Region based on the Region name, see AWS Service Endpoints.
Bucket Owner Account Id	The AWS account ID of the Amazon storage you archive the data. This field is not applicable for AWS Glacier(Legacy) Standard.
Authentication Method: **IAM User** > **Note:** For more information on registering the AWS cloud source using IAM User, see Register an AWS Cloud Source.	
Access Key ID	Access key ID used to access Amazon storage.
Secret Access Key	Secret access key address to access Amazon storage.
Authentication Method: IAM Anywhere • Ensure you meet the prerequisites before registering the AWS S3 buckets using **IAM Anywhere Roles**. • Cohesity does not support IAM anywhere authentication for registering Glacier(Legacy) Standard with the Cohesity cluster.	
Trust Anchor ARN	ARN of the trust anchor.
Profile ARN	ARN of the IAM Roles Anywhere profile.
Role ARN	The ARN of the IAM role that trusts the IAM Roles Anywhere service principal.
Private Key	Private key of the Certificate Authority.

Field Name	Description
Authentication Method: **IAM Role** **Note:** To register the AWS Cloud Source using the IAM Role, you need to download the CloudFormation Template and execute on the AWS account. For more information, see Execute CloudFormation Template to Register AWS Using IAM Role.	
Account ID	The account ID where the CE is running
IAM Role	The IAM Role for external target registration. Example: `arn:aws:iam::<account>:role/<role-name-with-path>`.

For most regions, the Cohesity uses `s3-<region>.amazonaws.com` to construct the S3 endpoints instead of `s3.<region>.amazonaws.com`.

Example

`s3-us-east-2.amazonaws.com`, where `s3-us-east-2.amazonaws.com` is the CNAME for `s3.us-east-2.amazonaws.com`.

However, the Cohesity uses `s3.<region>.amazonaws.com` for regions listed below:

- China
- us-east-1
- S3 acceleration

For more information, see CloudArchive & CloudRetrieve Deployment & Recovery Guide for AWS.

You can archive data to Azure Data Box by registering Data Box as NAS External Target on Cohesity cluster. For more information, see How to use Cohesity Microsoft Azure Data Box Integration.

AWS S3 Gov or AWS Glacier(Legacy) Gov or AWS S3-Glacier Gov or AWS S3-Glacier-Deep-Archive Gov or AWS S3 Intelligent Gov or AWS S3 One Zone Gov

> **Note:** IAM Role for AWS S3 Gov is not supported.

Field Name	Description
Bucket Name	Name of the existing bucket where you will store objects. This cannot be modified after you register the Target.
Region	Geographic area to use for Amazon storage. For example, if your region name is US West (N. California), the AWS Region value should be “us-west-1”. **Note:** The AWS Region value is case-sensitive. It must be in lowercase and cannot contain uppercase letters. To know your AWS Region based on the Region name, see AWS Service Endpoints.
Bucket Owner Account Id	The AWS account ID of the Amazon storage you archive the data. This field is not applicable for AWS Glacier(Legacy) Gov.
Access Key ID	Access key ID used to access Amazon storage.
Secret Access Key	Secret access key address to access Amazon storage.

AWS S3 C2S or AWS Glacier(Legacy) C2S

You must contract with a Commercial Cloud Services (C2S) agency to provide a private instantiation of the AWS commercial cloud.

Field Name	Description
Base URL	URL of the Commercial Cloud Services (C2S) server that contains the Amazon storage provided by the C2S agency.
Agency	The name the agency that is providing the Commercial Cloud Services (C2S) server.
Mission	The account name for accessing the Commercial Cloud Services (C2S) server which is provided by the C2S agency.
Role	The IAM role to use when accessing the Amazon storage which is provided by the C2S agency.

Field Name	Description
Bucket Name	Name of the existing bucket where you will store objects. This cannot be modified after you register the Target.
Region	Geographic area to use for Amazon storage. For example, if your region name is US West (N. California), the AWS Region value should be “us-west-1”. **Note:** The AWS Region value is case-sensitive. It must be in lowercase and cannot contain uppercase letters. To know your AWS Region based on the Region name, see AWS Service Endpoints.
Bucket Owner Account Id	The AWS account ID of the Amazon storage you archive the data. This field is not applicable for AWS Glacier(Legacy) C2S.
Client Certificate Password	The password to read the Client Private Key when accessing the Commercial Cloud Services (C2S) server which is provided by the C2S agency.
CA Trusted Certificate	Upload the Certificate Authority Trusted Certificate file to access the Commercial Cloud Services (C2S) server which is provided by the C2S agency.
Client Certificate	Upload the Client Certificate file to access the Commercial Cloud Services (C2S) server which is provided by the C2S agency.
Client Private Key	Upload the Client Private Key file to use when accessing the Commercial Cloud Services (C2S) server which is provided by the C2S agency.

For more information, see CloudArchive & CloudRetrieve Deployment & Recovery Guide for AWS.

AWS S3-IA Standard or AWS-S3-Glacier-IR, or AWS-S3-Glacier-IR Gov

For IAM user, if you do not already have an access key to use with Cohesity, create a new one in the AWS Management Console (root account credentials required). In AWS, go to **IAM** (AWS Identity and Access Management) and create a new access key ID and secret access key ID. Use this access key ID and secret access key to complete the corresponding fields below.

> **Warning:** Do not apply an AWS Object Lifecycle Policy with the Expiration action to an AWS S3 External Target used for archiving data. Applying a policy with this action may result in data loss.

Field Name	Description
Bucket Name	Name of the existing bucket where you will store objects. This cannot be modified after you register the Target.
Region	Geographic area to use for Amazon storage. For example, if your region name is US West (N. California), the AWS Region value should be “us-west-1”. **Note:** The AWS Region value is case-sensitive. It must be in lowercase and cannot contain uppercase letters. To know your AWS Region based on the Region name, see AWS Service Endpoints.
Bucket Owner Account Id	The AWS account ID of the Amazon storage you archive the data.
Authentication Method: **IAM User** **Note:** For more information on registering the AWS cloud source using IAM User, see Register an AWS Cloud Source.	
Access Key ID	Access key ID used to access Amazon storage.
Secret Access Key	Secret access key address to access Amazon storage.
Authentication Method: IAM Anywhere • Ensure you meet the prerequisites before registering the AWS S3 buckets using **IAM Anywhere Roles**. • Cohesity does not support IAM anywhere authentication for registering **AWS-S3-Glacier-IR Gov** with the Cohesity cluster.	
Trust Anchor ARN	ARN of the trust anchor.

Field Name	Description
Profile ARN	ARN of the IAM Roles Anywhere profile.
Role ARN	The ARN of the IAM role that trusts the IAM Roles Anywhere service principal.
Private Key	Private key of the Certificate Authority.
Authentication Method: **IAM Role** **Note:** To register the AWS Cloud Source using the IAM Role, you need to download the CloudFormation Template and execute on the AWS account. For more information, see Execute CloudFormation Template to Register AWS Using IAM Role.	
Account ID	The account ID where the CE is running
IAM Role	The IAM Role for external target registration. Example: `arn:aws:iam::<account>:role/<role-name-with-path>`.

For more information, see CloudArchive & CloudRetrieve Deployment & Recovery Guide for AWS.

AWS S3-IA Gov

Field Name	Description
Bucket Name	Name of the existing bucket where you will store objects. This cannot be modified after you register the Target.
Region	Geographic area to use for Amazon storage. For example, if your region name is US West (N. California), the AWS Region value should be “us-west-1”. **Note:** The AWS Region value is case-sensitive. It must be in lowercase and cannot contain uppercase letters. To know your AWS Region based on the Region name, see AWS Service Endpoints.

Field Name	Description
Bucket Owner Account Id	The AWS account ID of the Amazon storage you archive the data.
Access Key ID	Access key ID used to access Amazon storage.
Secret Access Key	Secret access key address to access Amazon storage.

AWS S3-IA C2S

You must contract with a Commercial Cloud Services (C2S) agency to provide a private instantiation of the AWS commercial cloud. IA refers to an Amazon storage class that is infrequently accessed.

> **Warning:** Do not apply an AWS Object Lifecycle Policy with the Expiration action to an AWS S3 External Target used for archiving data. Applying a policy with this action may result in data loss.

Field Name	Description
Base URL	URL of the Commercial Cloud Services (C2S) server that contains the Amazon storage provided by the C2S agency.
Agency	The name the agency that is providing the Commercial Cloud Services (C2S) server.
Mission	The account name for accessing the Commercial Cloud Services (C2S) server which is provided by the C2S agency.
Role	The IAM role to use when accessing the Amazon storage which is provided by the C2S agency.
Bucket Name	Name of the existing bucket where you will store objects. This cannot be modified after you register the Target.

Field Name	Description
Region	Geographic area to use for Amazon storage. For example, if your region name is US West (N. California), the AWS Region value should be “us-west-1”. > **Note:** The AWS Region value is case-sensitive. It must be in lowercase and cannot contain uppercase letters. To know your AWS Region based on the Region name, see AWS Service Endpoints.
Bucket Owner Account Id	The AWS account ID of the Amazon storage you archive the data.
Client Certificate Password	The password to read the Client Private Key when accessing the Commercial Cloud Services (C2S) server which is provided by the C2S agency.
CA Trusted Certificate	Upload the Certificate Authority Trusted Certificate file to access the Commercial Cloud Services (C2S) server which is provided by the C2S agency.
Client Certificate	Upload the Client Certificate file to access the Commercial Cloud Services (C2S) server which is provided by the C2S agency.
Client Private Key	Upload the Client Private Key file to use when accessing the Commercial Cloud Services (C2S) server which is provided by the C2S agency.

For more information, see CloudArchive & CloudRetrieve Deployment & Recovery Guide for AWS.

Azure Archive Blob

After creating a storage account in Azure, if you have not done so already, go to Blob service and create a new container to use with Cohesity. Provide the container name, storage account name and either of the keys generated by Azure to the Cohesity Dashboard.

> **Note:** Cohesity recommends you to use the **Standard** (optimized for high capacity and high throughput) performance tier and not the Premium performance tier when creating a new Azure Blob storage account and container to register with the Cohesity cluster as an external target.

> **Warning:** Microsoft supports Azure Archive for block blobs in Blob storage accounts with replication set to Locally-redundant storage (LRS).

Field Name	Description
Container Name	Name of the existing container where you will store objects. This cannot be modified after you register the Target.
Storage Account Name	Account name used to access Azure storage.
Storage Access Key	Storage access key to access Azure storage.

> **Note:** When using archive tier on Azure Blob, Cohesity rehydrates the data from archive tier to hot tier instead of cool tier. Cool tier has a minimum retention duration of 30 days after which the data automatically moves to the archive tier. Hence, Cohesity uses hot tier. The data moves back to the archive tier after the restore job is deleted/expired.

> **Warning:** Do not apply an lifecycle management policy with the Expiration action to an Azure External Target used for archiving data. Applying a policy with this action may result in data loss.

For more information, see CloudArchive & CloudRetrieve Deployment & Recovery Guide for Azure.

Azure Cold Blob Standard or Gov

After creating a storage account in Azure, if you have not done so already, go to Blob service and create a new container to use with Cohesity. Provide the container name, storage account name and either of the keys generated by Azure to the Cohesity Dashboard.

> **Note:** Cohesity recommends you to use the **Standard** (optimized for high capacity and high throughput) performance tier and not the Premium performance tier when creating a new Azure Blob storage account and container to register with the Cohesity cluster as an external target.

> **Warning:** Do not apply a lifecycle management policy with the Expiration action to an Azure External Target used for archiving data. Applying a policy with this action may result in data loss.

Field Name	Description
Container Name	Name of the existing container where you will store objects. This cannot be modified after you register the Target.
Storage Account Name	Account name used to access Azure storage.
Storage Access Key	Storage access key to access Azure storage. **Note:** If you are planning to archive your data to Azure Cool Blob using the incremental forever archival format, then ensure that the storage account you create is accessible through a public network and not a private network.

For more information, see CloudArchive & CloudRetrieve Deployment & Recovery Guide for Azure.

Azure Hot Blob Standard or Gov

After creating a storage account in Azure, if you have not done so already, go to Blob service and create a new container to use with Cohesity. Provide the container name, storage account name and either of the keys generated by Azure to the Cohesity Dashboard.

> **Note:** Cohesity recommends you to use the **Standard** (optimized for high capacity and high throughput) performance tier and not the Premium performance tier when creating a new Azure Blob storage account and container to register with the Cohesity cluster as an external target.

> **Warning:** Do not apply a lifecycle management policy with the Expiration action to an Azure External Target used for archiving data. Applying a policy with this action may result in data loss.

Field Name	Description
Container Name	Name of the existing container where you will store objects. This cannot be modified after you register the Target.
Storage Account Name	Account name used to access Azure storage.
Storage Access Key	Storage access key to access Azure storage. **Note:** If you are planning to archive your data to Azure Hot Blob using the incremental forever archival format, then ensure that the storage account you create is accessible through a public network and not a private network.

For more information, see CloudArchive & CloudRetrieve Deployment & Recovery Guide for Azure.

GCP Coldline, GCP Multi-Regional, GCP Nearline or GCP Regional or GCP Standard

In the Google Cloud Platform Console, create a new bucket to use with Cohesity if you have not done so already. To create credentials to use with Cohesity, from the Dashboard go to **IAM & Admin > IAM** and create a service account. Give the service account the Role of Project Owner and select Google Nearline or Coldline. After you create the service account, download and open the credential (JSON) file and use the contents (copy the text in the fields between the double quotes) to complete the fields below.

> **Warning:** Do not apply a Google Cloud Object Lifecycle Policy with the Delete action to any GCP External Target used for archiving data. Applying a policy with this action may result in data loss.

> **Note:** Before registering GCP as external targets, ensure the following endpoints are accessible to the Cohesity cluster: "www.googleapis.com", "accounts.google.com".

Field Name	Description
Bucket Name	Name of the existing bucket where you will store objects. This cannot be modified after you register the Target.
Project ID	Project ID of the existing project where you will store objects. This cannot be modified after you register the Target.
Client Email Address	Email address used to access Google Cloud Storage.
Client Private Key	Private key used to access Google Cloud Storage.

For more information, see CloudArchive & CloudRetrieve Deployment & Recovery Guide for GCP.

You can archive data to Google Transfer Appliance by registering Google Transfer Appliance as NAS External Target on Cohesity cluster.

Oracle Archive Storage or Oracle Object Storage

A tenancy must be created by Oracle for your organization. In addition, an administer must set up the Tenancy and possibly create a compartment to hold your resources or a new user if required. Determine the best Oracle storage tier to use for your organization: Oracle Archival Storage (Archive Storage tier) or Oracle Object Storage (Object Storage tier). In the Oracle Cloud console, create a new bucket to use with Cohesity if you have not done so already. The Storage Tier specified for the bucket must match the specified Cohesity External Target Type (Oracle Archive or Oracle Object).

The user with which the bucket is registered must be associated with the following Oracle policy statements:

- Allow group <*group-name*> to manage buckets in tenancy
- Allow group <*group-name*> to manage objects in tenancy

To register OCI as an external target, Cohesity utilizes Amazon S3 Compatibility API keys for access to the OCI bucket. Use the OCI console to create the "**Customer Secret keys**" and then use the Access Key ID and Secret Access Key to complete the corresponding fields below.

Field Name	Description
Bucket Name	Name of the existing bucket where you will store objects. This cannot be modified after you register the Target. In the Oracle Cloud console, create a new bucket to use with Cohesity if you have not done so already. The Storage Tier specified for the bucket must match the specified Cohesity External Target Type (Oracle Archive or Oracle Object).
Region	Geographic area to use for Oracle storage. For more information, see Data Regions.
Access Key ID	Access key ID used to access the storage. For more information about create and copying the key, see create a secret key.
Secret Access Key	Secret access key address to access the storage. For more information about create and copying the key, see create a secret access key.
Tenancy	Enter the namespace to which the bucket belongs. You can obtain the **Namespace** name from the Bucket Details page of the Oracle Cloud Infrastructure console.

NAS

Only NFS is currently supported.

Field Name	Description
NAS Host	Hostname or host IP of the existing NAS host.
Mount Path	The mount path of the NAS host.
Share Type NFS	Only NFS is currently supported.

For more information, see CloudArchive & CloudRetrieve Deployment & Recovery Guide for NAS.

QStar Tape

To use QStar with Cohesity, QStar must be configured with the settings described in the Archive Data to Tape with QStar & Cohesity.

Field Name	Description
QStar Host	Hostname or host IP of the existing QStar host.
QStar Web Services Port	The QStar port that Cohesity communicates with. Port number 18082 is set on the QStar host by default. If your QStar host is not using the default Web Services Port, update the port number.
QStar Username	Account name used to access the QStar host.
QStar Password	Password used to access the QStar host.
QStar Integral Volumes	Names of the existing Integral Volumes where you will store objects. Cohesity supports the LTFS and TDO file systems for Integral Volumes. The Integral Volumes must have already been created on the QStar host with the necessary minimal configuration as recommended in the QStar Administrator's Guide. If you attempt to edit this list after the External Target was initially registered, be advised that the Cohesity cluster can only archive to and recover from Integral Volumes that are currently registered with Cohesity, that is, if you edit the External Target by adding an Integral Volume, it cannot be used by the Cohesity cluster. In this case, you must register a new External Target that includes the Integral Volume.

S3 Compatible - Regular Storage Class

- Cohesity supports any S3-compatible device as an S3-Standard tier (Regular as storage class) external target with similar capabilities to an AWS S3-Standard.
- With incremental forever archival format, the Cohesity cluster will download a portion of the data from the S3-compatible Standard tier external target for the space reclamation process and reupload it after compaction. This leads to increased network bandwidth usage. Cohesity recommends having sufficient network bandwidth between the cluster and the external target; for example, hosting the external target within the same data center or network as the Cohesity cluster.
- Do not apply an AWS Object Lifecycle Policy with the Expiration action to an AWS S3 Compatible External Target used for archiving data. Applying a policy with this action may result in data loss.

Field Name	Description
Bucket Name	Name of the existing bucket where you will store objects. This cannot be modified after you register the Target.
Access Key ID	Access key ID used to access the storage.
Secret Access Key	Secret access key address to access the storage.
Endpoint	The Endpoint mount path. Use the IP address or Fully Qualified Domain Name (FQDN). **Note:** Do not include 'http://' or 'https://' in the mount path.
Port	The S3 Compatible port that Cohesity communicates with.
Region	Geographic area to use for S3 Compatible.
Secure Connection (HTTPS)	Toggle **Secure Connection** on or off.
AWS Signature Version	Select the AWS signing process version for adding authentication information to requests.

To register other S3 compatible targets like Pure FlashBlade S3 bucket, IBM ICOS S3 bucket and Cohesity S3 bucket, see CloudArchive Deployment & CloudRetrieve Recovery for S3-Compatible Storage.

S3 Compatible - Tape Based Storage Class

- The archival format is *Always Full* with compression enabled by default.
- Cohesity does not support deduplication and incremental archive.
- Cohesity does not support CloudRetrieve of data archived to S3 Compatible-Tape Based.
- Cohesity does not support file-level recovery.
- The S3 cache must have sufficient storage to hold the largest Protection Group while the cache is filled with the restored data.
- The recovery workflow retains the restored data from the tape on the S3 cache for seven days. If you want to reduce the retention period of restored data on the S3 cache, contact Cohesity Support.

- If multiple recoveries are triggered within a span of seven days, the cache size must be large enough to hold all the recovered snapshots.
- By default, the number of parallel streams per cluster is set to 10. If you want to configure these values, contact Cohesity Support.
- By default, the number of restore tasks per Tape Storage is set to 1.
- Cohesity recommends not to add more objects in a Protection Group as the recovery workflow could hydrate the complete archive while restoring a single object.
- To protect IBM Storage Protect S3 Compatible, you must contact IBM support.

Field Name	Description
Bucket Name	Name of the existing bucket where you will store objects. This cannot be modified after you register the Target.
Access Key ID	Access key ID used to access the storage.
Secret Access Key	Secret access key address to access the storage.
Endpoint	The Endpoint mount path. Use the IP address or Fully Qualified Domain Name (FQDN). **Note:** Do not include 'http://' or 'https://' in the mount path.
Port	The S3 Compatible port that Cohesity communicates with.
Region	Geographic area to use for S3 Compatible.
Secure Connection (HTTPS)	Toggle **Secure Connection** on or off.
AWS Signature Version	Select the AWS signing process version for adding authentication information to requests.

6. (*Applies only for AWS S3 Targets*) To archive your data over a private network, enable Use Private Endpoint URL and provide the following details:
   - **Amazon S3 Endpoint URL** – The Regional S3 DNS name generated when creating the S3 interface endpoint. This interface endpoint must be created in the same VPC as the cluster and associated with the appropriate subnets and

security groups.

- **AWS Lambda Private Endpoint URL (Optional)** – The *Regional Lambda DNS name* generated when creating the Lambda interface endpoint. This endpoint must also be created in the same VPC as the cluster and associated with the correct subnets and security groups.

7. Provide a name in the **External Target Name** field.
8. In the **Archival Format** field, **Incremental Forever** is auto-selected for external targets that support it. For other targets, **Incremental with Periodic Full** is selected by default. This field cannot be modified. For more information, see Archival Formats.

   > **Note:** This field is not applicable for Tape Based external target.

9. Enable **Archive Object Lock** to lock the archives in the targets to prevent modification of data on the external target. For more information, see Archive Object Lock.
10. (*Applies only for AWS S3 targets with incremental forever archival*) Download and run the CloudFormation Template by clicking the **CloudFormation Template** link available in the product UI. For more information, see CloudFormation Template.

    > **Note:** This option is not available if you have enabled **Archive Object Lock**.

11. (*Applies only for Azure target (hot blob or cool blob) with incremental forever archival*) Enter the **Function App Name** and **Function App Deployment Key**. For information on obtaining the Function App name and Function App Deployment key, see the Azure Function App.

    > **Note:** This option is not available if you have enabled **Archive Object Lock**.

12. (**Applies only to S3-compatible and NAS external targets using Incremental Forever archival**) For Incremental Forever archival, the Cohesity cluster may download portions of data from S3-compatible and NAS external targets during each garbage collection process and reupload it after compaction. Choose a **Garbage Collection** option based on your optimization preference:

    - **Storage Optimized**: Selecting this option maintains a regular garbage collection frequency to optimize storage consumption on the archive. However, this results in higher network bandwidth usage. To minimize additional network

usage, Cohesity recommends using S3-compatible and NAS targets within the same data center or network as the Cohesity cluster.

- **Network Optimized**: Selecting this option reduces garbage collection frequency to minimize network bandwidth usage. However, this results in higher storage consumption on the cluster due to less frequent garbage collection.

13. By default, the **Encryption** option is enabled with **Internal KMS** as the **Key Management Service (KMS) Type**.You can also register an external KMS by selecting one of the following as the Key Management Service (KMS) Type:
    - AWS
    - KMIP Compliant

    For information on configuring external KMS, see External Key Management Service.

    If you have selected **Internal KMS** or **KMIP Compliant** as the **Key Management Service (KMS) Type** for encryption, then you can enable additional security for the external target. By enabling additional security, you can manage the key manually instead of Cohesity managing the encryption key for data that is transferred out. If you choose to manage the key manually, then after registering the external target with the Cohesity cluster, you must download the key from the external target's details page and store it in a secure location outside of the Cohesity cluster. With additional security, only the Cohesity clusters where you have explicitly provided the encryption key can download data from that external target. However, the source Cohesity cluster (the cluster that archived the data) does not require the encryption key of the external target.

    Cohesity recommends you keep the **Encryption** option as enabled in almost all cases, except when the data is already encrypted.

    > **Note:** If **Encryption** is enabled at the cluster level, you must also enable encryption while registering the external target for CloudArchive Direct. Archiving directly to an external target may fail if encryption is enabled at the cluster level but not at the external target level.

14. By default, the **Compression** option is enabled to send data to the external target in a compressed format. Disable this option to send data to the external target in uncompressed format.
15. By default, the **Source Side Deduplication** option is enabled to deduplicate data before sending it to the External Target. This improves cloud performance and reduces the amount of data transferred from the Cohesity cluster. This option is not applicable for:

- **Tape-based external targets** – Source-side deduplication is not supported.
- **Archival with Incremental Forever** – Deduplication is already enabled by default in the backend.

16. Enable **Bandwidth Throttling** to limit the maximum data transfer rate *from and to this External Target* during a time window.
    a. **Traffic:** Specify the direction of traffic to limit, by specifying a maximum bandwidth:
        - **Upload:** Limit the data transfer rate from the Cohesity cluster to this External Target.
        - **Download:** Limit the data transfer rate from this External Target to the Cohesity cluster.
    b. **Days**: Specify the days of the week to apply the window.
    c. **Time**: Specify all day or a time period for each day.
    d. **Throttle To**: Specify the maximum data transfer rate.Optionally change the rate type.
    e. Click **Add**.
    f. Repeat these steps to add more upload throttling windows.

    If overlapping windows are specified, the latest window that was created takes precedence. For example, if you first create a window from Monday 9 AM - 10 PM with a data rate of 50 Mbps and then a window from 5 PM to 12 PM with a data rate of 100 Mbps, during 5 PM -12 PM the data rate is limited to 100 Mbps.

    If both cluster-level override throttling window and an external-target override throttling window is set during the same time period, the lowest **Throttle To** number specified is the maximum allowed data transfer rate. For example, if a cluster-level override throttling window of 8-11 AM is set to 250 Mbps and an External-level override throttling window of 9-10 AM is set to 200 Mbps, during 9-10 AM the maximum allowed data transfer rate is 200 Mbps. Specifying transfer rate limits at the External-target level is described at the end of this procedure. For information on setting up cluster-level bandwidth throttling, see Register an External Target for Archival.

17. Click **Register**.

    The Cohesity cluster attempts to connect to the Target. A successful connection displays the External Targets page with the new Target included in the list.

> **Note:** When adding an AWS S3-compatible external target, you may encounter the following error:
> `"an internal component may be down"`
> Ensure the external target is reachable. Verify by pinging the target from the Cohesity CLI.

Archival Formats

Cohesity supports the following formats for archiving the data to an external target:

- **Incremental with Periodic Full**: Performs an initial full archive and then incremental archival of data with a periodic full every 90 days from the Cohesity cluster to an external target.
- **Incremental Forever**: Performs a first full archival and then incremental forever archival of data from the Cohesity cluster to an external target.

> **Important:** In version 7.2.2 and later, Cohesity enforces Incremental Forever as the default archival method for registering external target. If the target does not support Incremental Forever, Cohesity will automatically fall back to Incremental with Periodic Full. Note that if the target supports Incremental Forever, the option to switch to Incremental with Periodic Full is not available is not available.

Incremental with Periodic Full

An archived snapshot is referred to as an archive.

The first archive of a Protection Group is always a **Reference Full Archive.**

A *Reference Full* forms the basis for Incremental Archives.

With incremental archives, the next archive after a reference full is an **Incremental Archive**. It designates the Reference Full Archive as its reference.

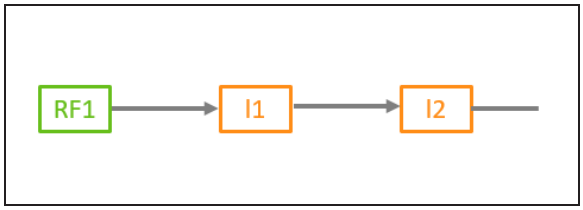
The Incremental Archive contains only data that is different between its reference's snapshot and the snapshot being archived. Change blocks are computed and then changed data is compared to the reference, and the necessary data is sent to the external target. If deduplication is enabled and data did not change, only metadata is transferred.

To reconstruct the snapshot of this incremental archive, both the incremental and the reference must be processed.

Then, the next Incremental Archive constitutes an increment on top of the previous incremental archive, i.e. it designates the previous Incremental Archive as its reference.

To reconstruct its snapshot, both Incremental Archives and the Reference Full Archive must be processed.

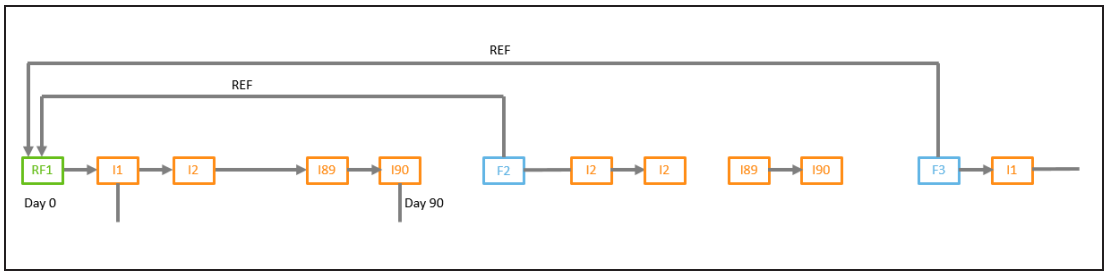
In this way, incremental archives form an "archival chain" that starts at the archive in question and ends with the Reference Full.



In order to limit the number of archives that must be processed to restore a snapshot, the chain is "broken" every 90 days. At that threshold, the next archive will not be an Incremental Archive, but rather a Full Archive. A regular, non-reference Full Archive is full in the sense that it covers all previous increments since the Reference Full Archive. However, it itself still refers to the Reference Full archive just like the first Incremental Archive.

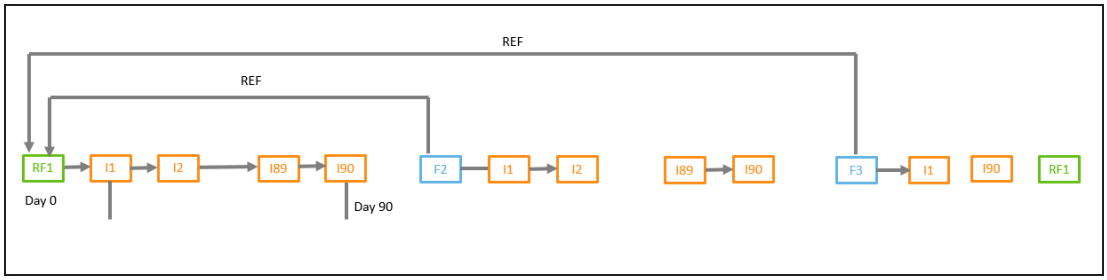
The next Incremental Archive after a Full Archive will use the Full Archive as a reference.

The threshold is not configurable through the web interface, and is always 90 days regardless of how many archivals have been performed.



During incremental archives, if the Reference Full Archive becomes too inefficient, mainly if its utilization as a reference drops below 50%, the Reference Full Archive is retired.

Retiring a Reference Full Archive means that the next time a Full Archive needs to be created, it is created as a Reference Full Archive, rather than a regular, non-reference Full Archive. The next Incremental then uses that new Reference Full Archive as its reference.



> **Note:** The web interface does not distinguish between Reference Full Archive and non-reference Full Archive.

Each archive, Whether Reference Full, Full, or Incremental, is retained as long as it is referred to by another archive, or as long as its own policy specifies.

For example, for a Protection Job with a 30-day retention policy on archives, on the 90th day, an Incremental Archive will be created, and set to expire on day 120. On day 119, it still refers to an entire archive chain going all the way to the Full Archive from day 1, and therefore even a 119-day old archive is not deleted from the external target.

Furthermore, if that Full Archive refers to a Reference Full Archive that is 6 months old, that Reference Full Archive is also not deleted.

The following table details an example archive workflow for 10 x 100 GiB VMs with a 3:1 deduplication ratio. Each row shows the archive type and amount of data transferred to the External Target based on a change rate.

Change Rate	Cumulative Change Rate	Timeline	Dedup On Incr On	Dedup Off Incr On
N/A	N/A	Day 0	Reference Full - 333 GiB	Reference Full - 1 TiB
1%	1%	Day 7	Incremental - 333 MiB	Incremental - 1 GiB
1%	1%	Day 14	Incremental - 333 MiB	Incremental - 1 GiB
1%	20%	Day 90	Full - 66 GiB	Full - 200 GiB
1%	21%	Day 97	Incremental - 333 MiB	Incremental - 1 GiB
1%	40%	Day 180	Full - 133 GiB	Full - 400 GiB
1%	41%	Day 187	Incremental - 333 MiB	Incremental - 1 GiB
1%	51%	Day 250	Incremental - 333 MiB	Incremental - 1 GiB
1%	60%	Day 270	Reference Full - 333 GiB	Reference Full - 1 TiB
1%	61%	Day 277	Incremental - 333 MiB	Incremental - 1 GiB
1%	80%	Day 360	Full - 66 GiB	Full - 200 GiB

> **Note:** If the **Object Key Pattern** of the S3 View is **Object ID**, you cannot archive the View using the **Incremental with Periodic Full** format.

For the list of external targets and the Protection Groups that supports incremental with periodic full, see Supported Workflows and External Targets.

Incremental Forever

Enable this option to perform a first full archival and then incremental forever archival of data from the Cohesity cluster to an external target. Incremental forever archival eliminates the need for periodic full archive and supports global deduplication, thereby improving the storage utilization of the target.

This option is enabled by default while registering a new external target. For an existing registered external target, you must edit the registered target and enable this option. The migration from **Incremental Archival** to **Incremental Forever Archival** takes place in the next reference archive.

> **Note:**
> - Ensure that the external target does not have WORM/Object Lock with a default locking period configured.

For the list of external targets and the Protection Groups that supports incremental forever archival, see Supported Workflows and External Targets.

Cloud Archive: Incremental with Periodic Full Vs Incremental Forever

The following table lists the differences between Cloud Archive incremental with periodic full archival and Cloud Archive Incremental forever archival.

	Cloud Archive using Incremental with Periodic Full	Cloud Archive with Incremental Forever Archival
Description	Performs an initial full archive and then incremental archive with a periodic full every 90 days. When 90 days elapse, the next archive is full with incremental performed for another 90 days.	Performs an initial full archive and then incremental forever archive. The data is archived from the Cohesity cluster to an external target.
Supported Source/workloads and Targets	See Supported Workflows and External Targets.	See Supported Workflows and External Targets.

	Cloud Archive using Incremental with Periodic Full	Cloud Archive with Incremental Forever Archival
File-level recovery	FLR is supported from the following targets for VMWare and NAS sources with provisioned capacity units: • AWS Glacier(Legacy) Standard • AWS Glacier(Legacy) Gov • AWS Glacier(Legacy) C2S File-level recovery back to the source *is not supported* from the following targets: • QStar Tape • Azure Archive Blob • AWS Glacier-Standard • AWS S3-Glacier-Deep-Archive	Supported
File download	File download is supported from the following target with provisioned capacity units: • Glacier-Standard • Glacier-C2S • S3-Gov-Glacier-Deep-Archive File download *is not supported* from the following targets: • QStar Tape • Azure Archive Blob • AWS Glacier-Standard • AWS S3-Glacier-Deep-Archive	Supported
Cloud Provider Life Cycle Management (LCM)	Entity recovery is supported with Cloud provider LCM from AWS S3 even if Cloud provider LCM is set on the S3 bucket. No recoveries (entity recovery or FLR) are supported from Azure if LCM is configured on the Azure container.	Not supported
CloudRetrive	Supported	Supported

	Cloud Archive using Incremental with Periodic Full	Cloud Archive with Incremental Forever Archival
Deduplication	Deduplication is performed at the Protection Group level thereby utilizing more storage space on the external target	Deduplication is performed at the external target level thereby utilizing less storage space on the external target.
Space reclamation	Does not require any external compute. Space reclamation for older snapshots is performed after a periodic full is done.	Requires external compute (lambda functions) for garbage collection. Continuous space reclamation using external compute is performed as soon as data expires.
WORM support*	Yes	Yes (Early Access feature)

*Cohesity does not support WORM for CloudArchive Direct.

For the list of targets that support WORM, see Supported Workflows and External Targets.

For information on configuring WORM, see Create or Edit a Standard Policy.

Migrate External Targets with Incremental with Periodic full to Incremental Forever

If you want to migrate an existing external target registered with Incremental with Periodic Full archival format in version 7.2.1 or earlier to Incremental Forever, perform the following steps:

1. Confirm the external target supports incremental forever archival format. For the list of supported external targets, see Supported workflow and External Targets.
2. From the Cohesity UI, navigate to the registered external target (**Infrastructure** > **External Target**).
3. Click the Actions menu (⋮) next to the target and select **Edit**.
4. Enable incremental forever as the archival format.
5. If you are enabling Incremental Forever on:
    a. Azure hot tier, you must create Azure Function App. For more information, see Function App.
    b. AWS S3 targets, you must run the **CloudFormation Template** on the AWS console using your AWS account. For more information, see CloudFormation template.
6. Click **Save**.

CloudFormation Template

If you are enabling incremental forever archival for AWS S3 targets, then you must run the **CloudFormation Template** on the AWS console using your AWS account. This will create

a Lambda function, *<S3BucketName>* for efficient garbage collection and an IAM role associated with it. You can download the template by clicking the **CloudFormation Template** link available in the product UI, just below the **Archive Object Lock** option, while registering AWS S3 as an external archival target.

> **Note:**
> - You can use the same or different IAM user to run the CloudFormation Template in your AWS account and to register the AWS target in the Cohesity cluster.
> - The CloudFormation template creates an empty Lambda function. This empty Lambda function will be populated with the Python code once the external target is registered with the Cohesity cluster.

When running the CloudFormation Template, ensure that:

- The IAM user running this template has the following permissions to create the necessary IAM roles and policies.
  - `s3:CreateBucket`
  - `s3:ListBucket`
  - `s3:PutObject`
  - `s3:GetObject`
  - `iam:CreateRole`
  - `iam:GetRole`
  - `iam:PassRole`
  - `iam:CreatePolicy`
  - `iam:PutRolePolicy`
  - `iam:GetRolePolicy`
  - `lambda:CreateFunction`
  - `lambda:GetFunction`
  - `cloudformation:CreateUploadBucket`
  - `cloudformation:CreateStack`
  - `cloudformation:ListStacks`
  - `cloudformation:GetTemplateSummary`
- For the list of permissions required for an IAM user to register an AWS S3 target for archival with incremental format, see Cloud Archive and CloudArchive Direct (Incremental Forever) - S3.

- The storage bucket name you specify while running this CloudFormation template should be the same name you used for AWS external target registration.

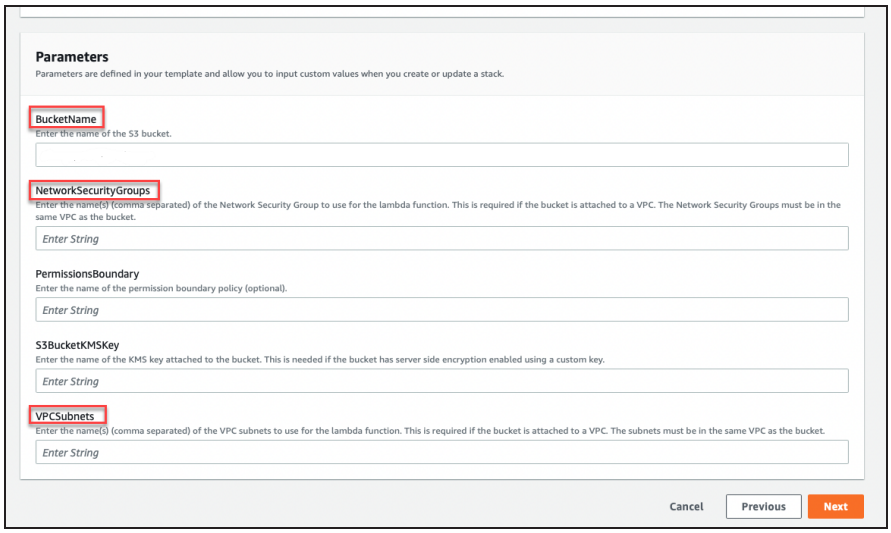
To run the CloudFormation template, perform the following steps:

1. In the **AWS Management Console**, navigate to **Services** and search for CloudFormation.
2. Click **Create stack** to create a stack under AWS CloudFormation using the downloaded CloudFormation Template.
3. In the **Prerequisite - Prepare template** page, select the **Template is ready** option and then select **Upload a template** file.
4. Click **Choose File** to browse and upload the JSON CloudFormation template that you have downloaded. Click **Next**.

   The Specify stack details page appears.
5. Provide a **Stack name**.
   1. Enter the Bucket name in the **BucketName** field. The bucket name should match the name you have provided while registering the external target.

      If you have configured **Amazon PrivateLink Interface Endpoints** with the Cohesity cluster to access the AWS S3 external targets for archival, then you must also provide values for the following parameters:

      - **NetworkSecurityGroup**: Enter the security group ID to associate with the lambda function.
      - **VPCSubnets**: Enter one or more subnet IDs in the VPC to use for the lambda function.
        The following screenshot highlights the parameters you need to configure for Amazon PrivateLink Interface Endpoints:



6. Click **Next** > **Next**.

You can skip the **Configure stack options** page.

7. Review the template and select the checkbox to acknowledge the creation of IAM resources, and click **Create Stack**.

On success the IAM resources are created and you can view the details under Resources tab of that stack. You can refresh the page to view the Lambda function, *<S3BucketName>* created for efficient garbage collection and an IAM role associated with it. Note that the Lambda function will be populated with the Python code only after the external target is registered with the Cohesity cluster.

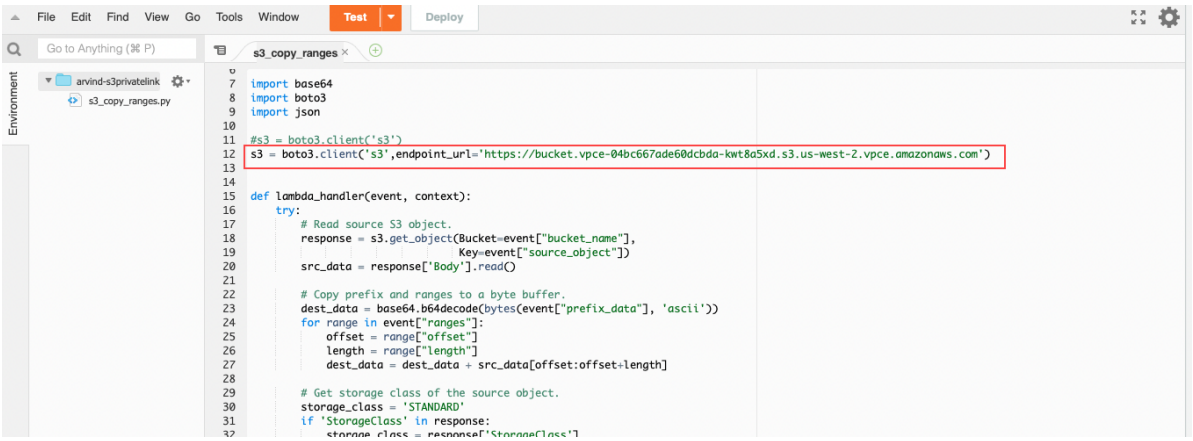
Update Lambda Function for Using Amazon PrivateLink Interface Endpoints

If you have configured **Amazon PrivateLink Interface Endpoints** with the Cohesity cluster to access the AWS S3 external targets for incremental forever archival, then you must update the Lambda function, *<S3BucketName>* as shown below:

Existing code in the lambda function	Update to

`s3 = boto3.client(S3)`	`s3 = boto3.client('s3',endpoint_url='https://bucket. <vpce-id>.s3-<region>.vpce.amazonaws.com')`
	For example:
	`s3 = boto3.client('s3',endpoint_url='https://bucket.vpce-04bc667ade60dcbda-kwt8a5xd.s3.us-west-2.vpce.amazonaws.com')`

Example of the updated lambda function:



Azure Function App

To archive data to an Azure target (Hot Blob or Cool Blob) using the Incremental Forever archival format, you must create an Azure Function App in the Azure portal using your Azure account.

The Azure Function App enables cost-efficient garbage collection. You can create the Function App in one of the following ways:

- Create the Function App directly from the Azure portal (recommended).
- Download the Azure Resource Template from the Register External Target page and upload it to the Azure portal.

> **Note:**
> DataProtect for cloud (legacy) and DataProtect for cloud clusters do not require an Azure Function App for Incremental Forever archival if the cluster and storage target are in the same region. Therefore, you can proceed with Azure external target registration without specifying a Function App Name or Function App Deployment Key—simply leave these fields empty or enter placeholder values. Validation for these fields is disabled for DataProtect for cloud and DataProtect for cloud (legacy) clusters.

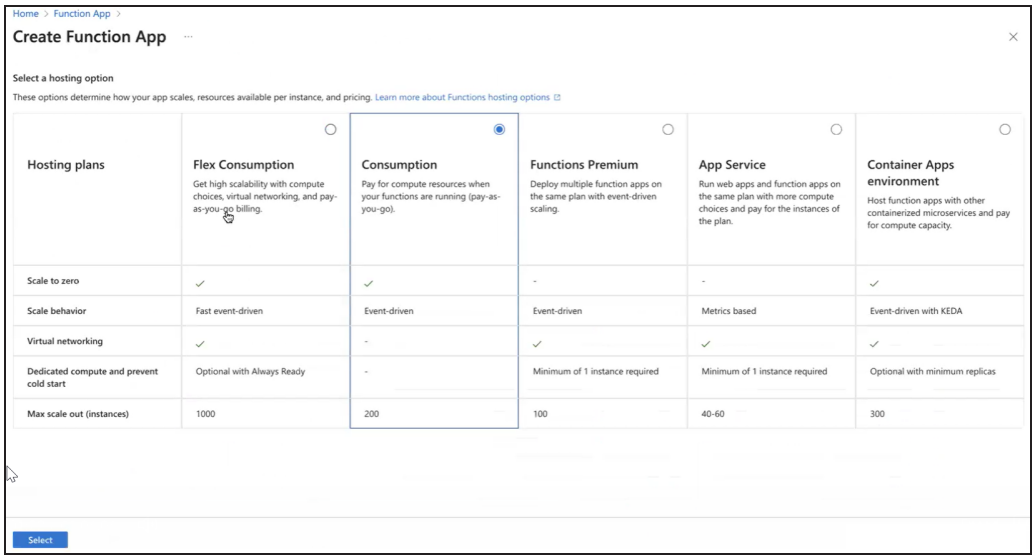
Option 1: Create Azure Function from the Azure Portal

Prerequisites:

- **Subscription** and **Resource Group**: The values you provide must be the same as the Azure storage account you are registering as an external target.
- **Runtime Stack**: Select **Python**.
- **Region**: The same region as the Azure storage account you are registering as an external target.
- **Plan Type**: Select **Consumption**. Cohesity currently supports only **Consumption** Plan Type.
- **Storage Account**: Should be of the Azure storage account you register as the external target.

To create the Azure Function App:

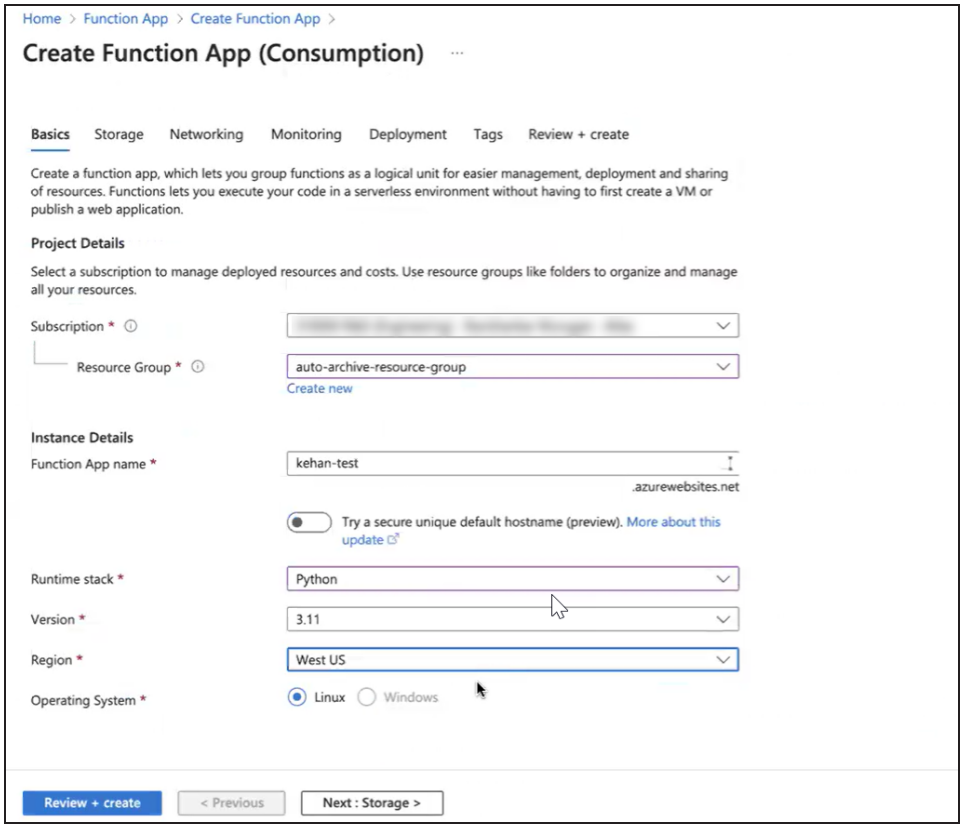
1. Log in to the Azure portal and select **Function App**.
2. Click **+Create**.
3. Select **Consumption** as the hosting option and click **Select**.



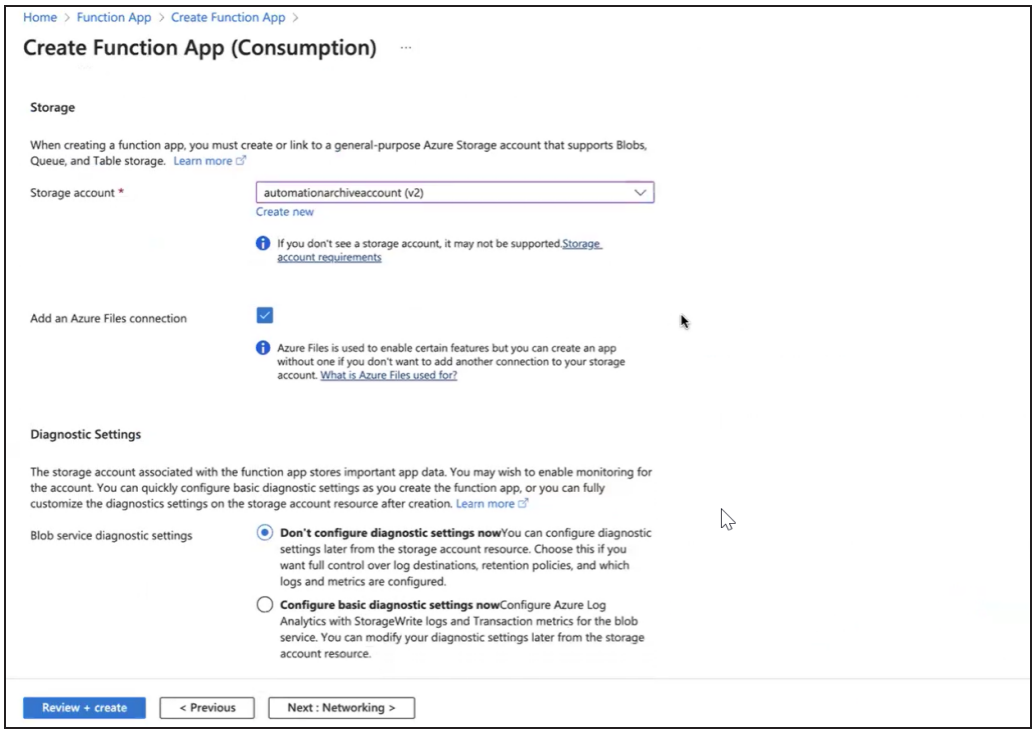
The Create Function App (Consumption) screen appears.

4. On the **Basics** Tab, provide the following information:
    - **Subscription** and Resource Group: Ensure the values you provide are the same as the Azure you register as an external target.
    - **Function App Name**: Provide a name for the Function App and disable the **Try a secure unique default hostname (preview)** option.
    - **Runtime Stack**: Select **Python**.
    - **Version**: Select the latest Python version.
    - **Region**: Ensure the Region you select for the Function App is the same as the Azure you register as the external target.
    - **Operating System**: The operating system is preselected based on the runtime

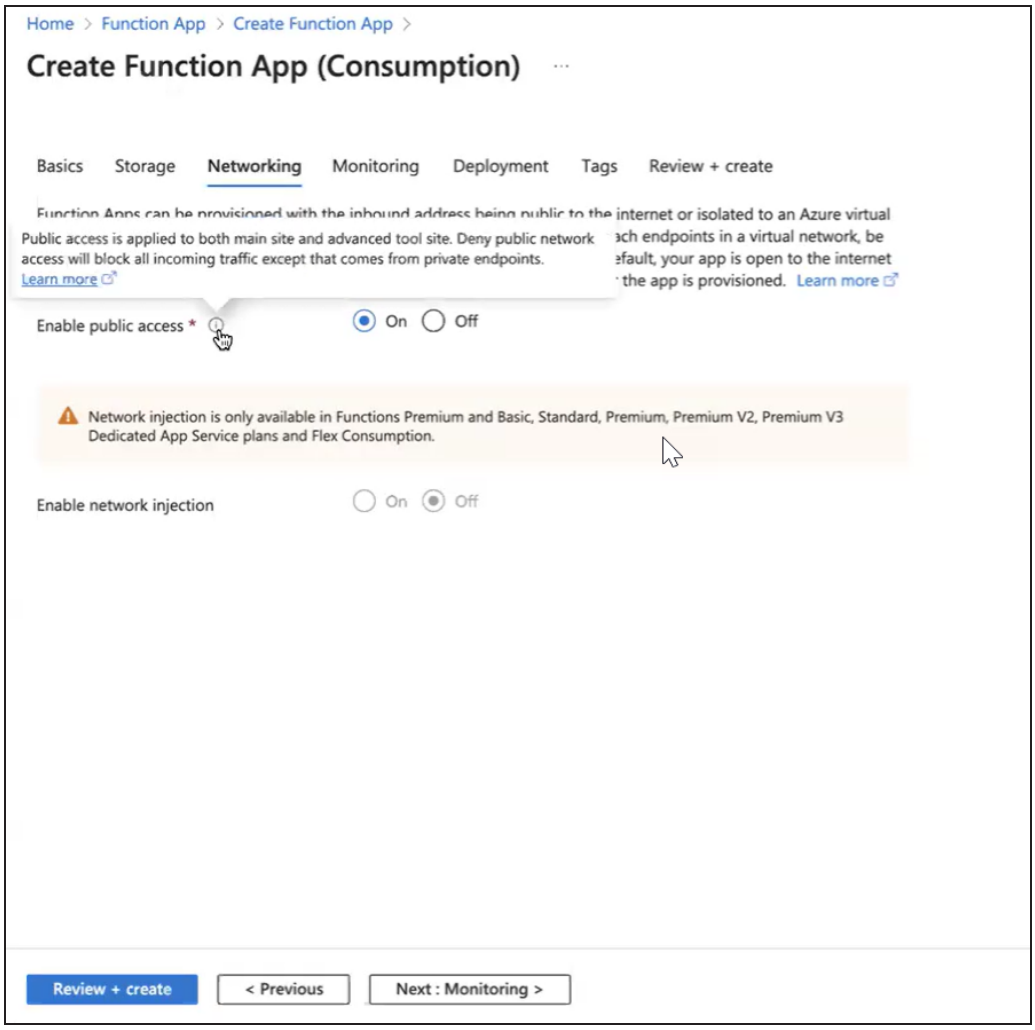
stack you select.



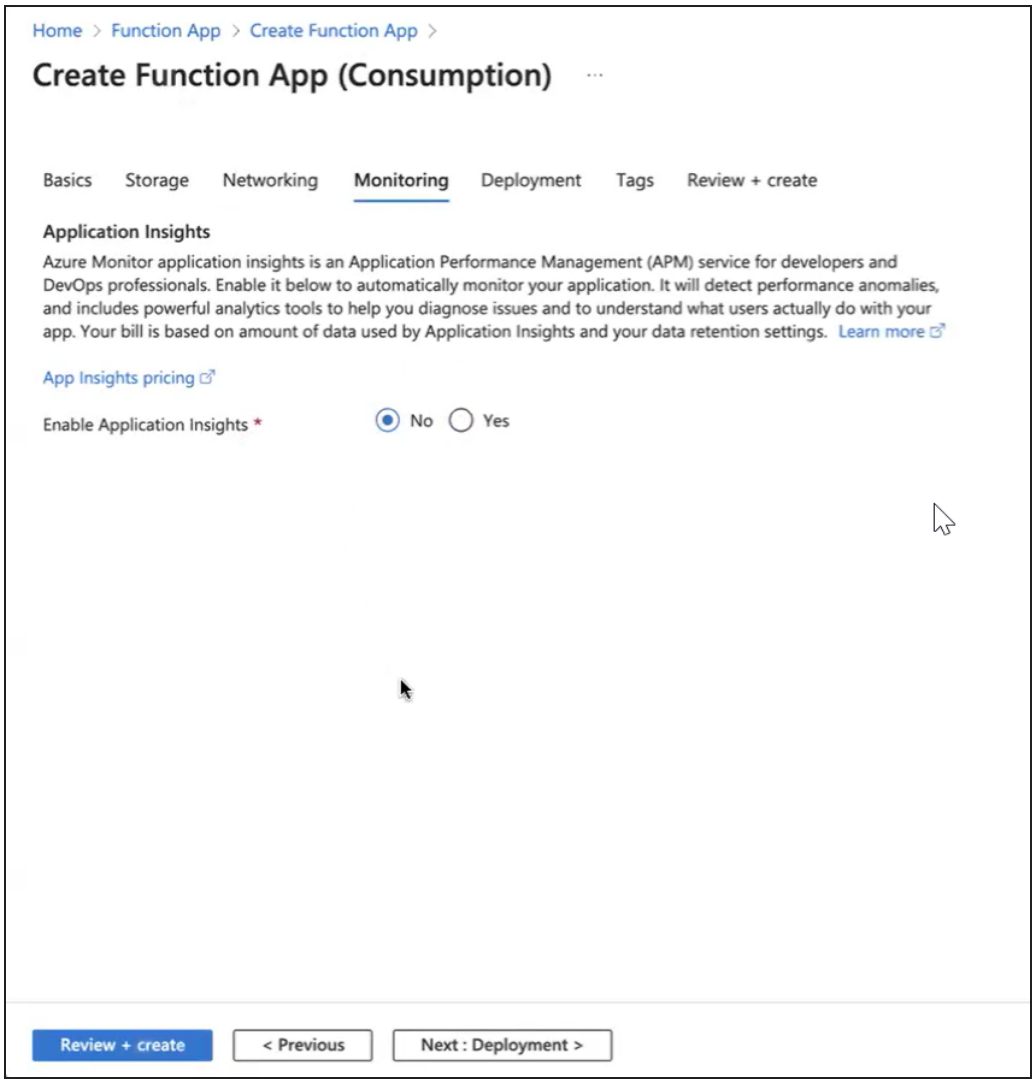
5. Click **Next: Storage >**.
6. On the **Storage** tab, the Storage Account you select must be of the Azure you register as the external target. You can retain the default values for all the other fields on the **Storage** tab.



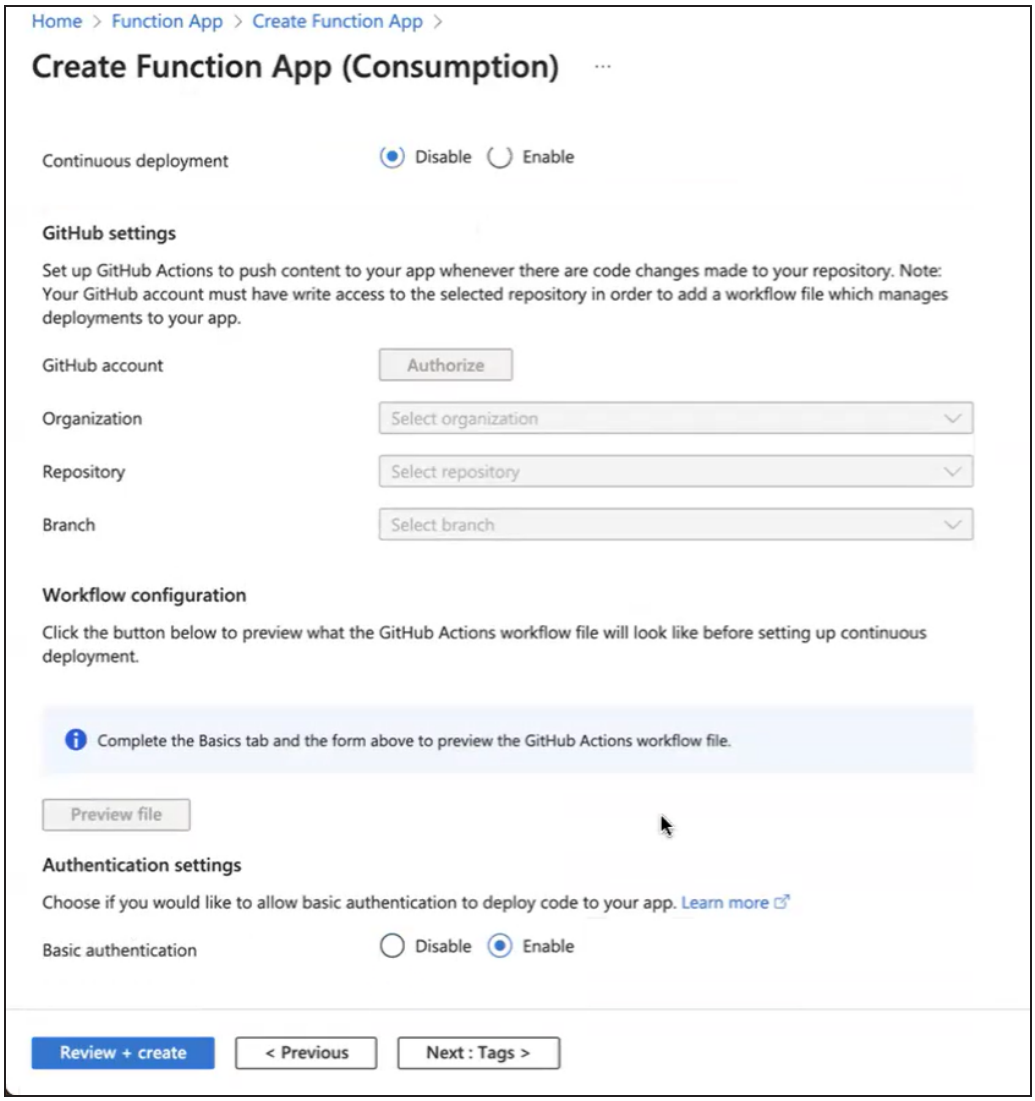
7. Click **Next : Networking >**.
8. On the **Networking** tab, set **Enable public access** to **On**.



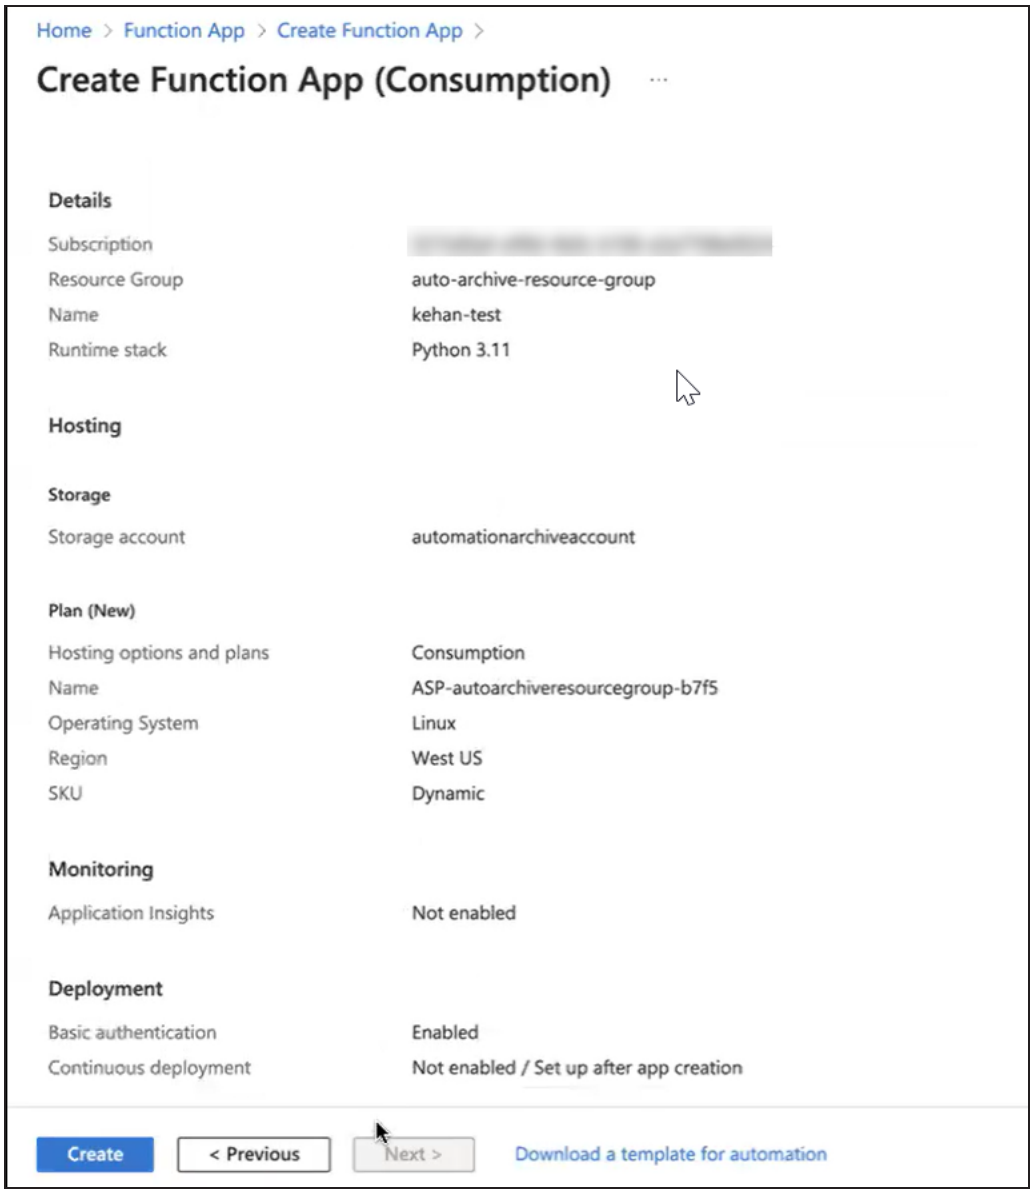
9. On the **Monitoring** tab, set **Enable Application Insights** to **No**.



10. Click **Next: Deployment >**.
11. On the **Deployment** tab, set **Basic authentication** to **Enable**. Retain the default values for all the other fields on the **Deployment** tab.



12. Click **Next: Tags >**. Retain the default values for all the fields on the **Tags** tab.
13. Click **Next: Review >**. Review the values configured and click **Create**.



The Function App deployment is initiated. Once deployed successfully, you can obtain the Function App keys required for registering the Azure as an external target with the Cohesity cluster. For more information, see Obtain the Function App Key of the Function App.

Option 2: Create Azure Function App using Azure Resource template

You can download the template from the Cohesity UI by clicking the **Azure Resource Template** link provided in the note admonition below the **Archival Format** option of the Register External Target page. The downloaded template zip file (**ART.zip**) contains two files: **template.json** and **parameters.json**.

Creating the Azure Function App using the Azure Resource template involves the following steps:

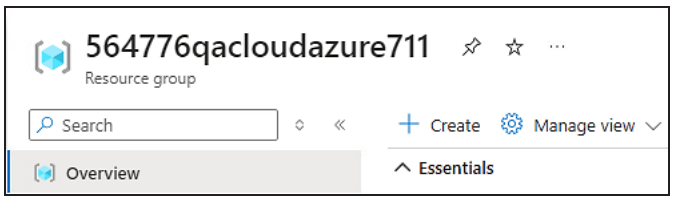
- Create Template Spec
- Deploy Template Spec

Create Template Spec

To create the Template Spec:

1. Log into Azure Portal.
2. Navigate to the resource group where you want to create the Function App.

   To simplify resource tracking and troubleshooting, it is recommended to create the Function App in the same resource group as the storage account used for the external target configuration.



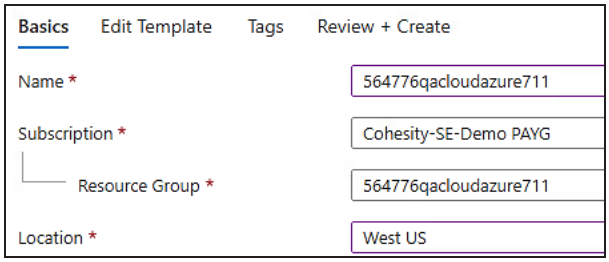
3. Click **+ Create**.
4. In the search field, search for **Template Specs** and select **Template Specs** from the result list.

5. From the **Template Specs** tile, click the **Create** drop-down, and then select **Template Specs**.

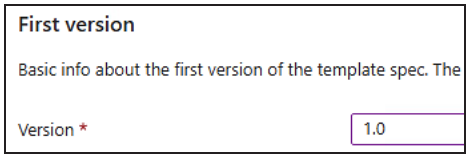
   The **Create new template spec** page appears.

6. On the **Basic** tab, provide the following information:

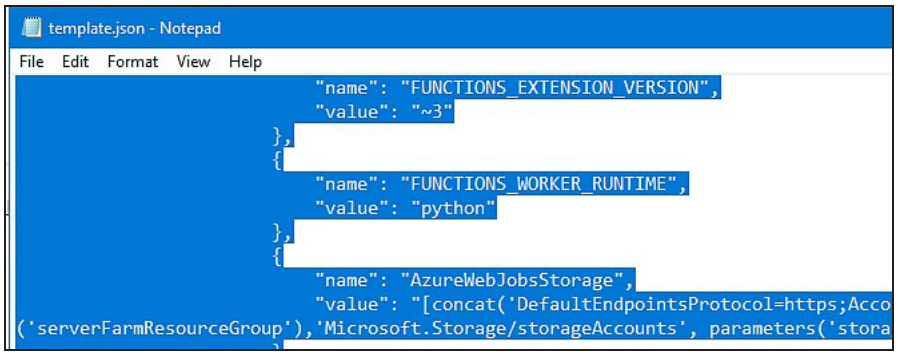
- **Name**: Name of the Template Spec.
- **Subscription** and **Resource Group**: These fields are auto-populated.
- **Location**: Region where the Template Spec is created.



- **Description**: (*Optional*) Provide a description.
- **Version**: (*Optional*) Enter a version for the Template Spec (e.g., 1.0).

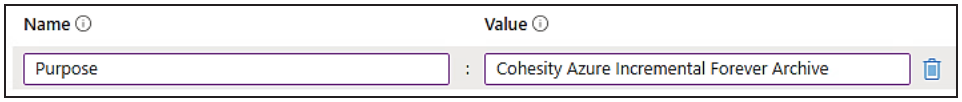


7. Click **Next : Edit Template**.
8. Unzip the downloaded template folder (**ART.zip**) and copy the content from the file **template.json**.



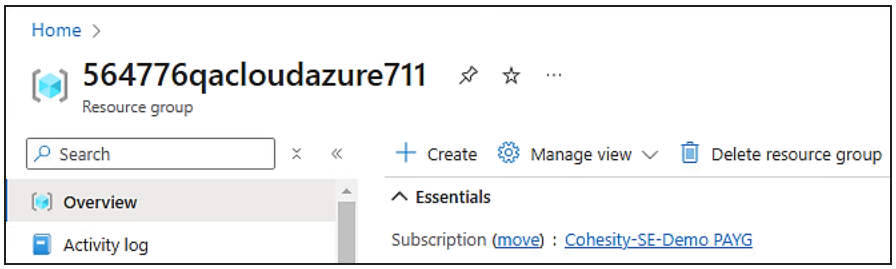
9. In the **Template Content** section of the **Edit Template** tab, replace the existing content with the content from the **template.json** file.

10. Click **Next: Tags**.
11. (*Optional*) On the **Tags** tab, add tags for the Template Spec.

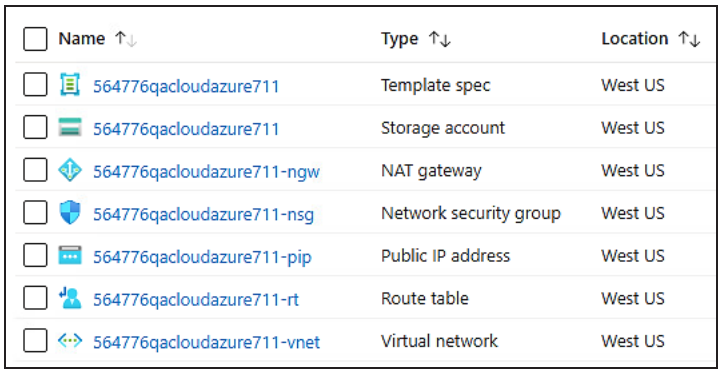


12. Click **Next: Review + Create** and review the summary page.
13. Click **Create**.

    The Template Spec creation is initiated.
14. Navigate to the Resource Group that contains the Template Spec.



15. Click **Refresh** on the Resource Group menu to view the newly created Template Spec.

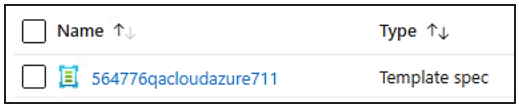


Deploy Template Spec

Once the Template Spec is created, it must be deployed.

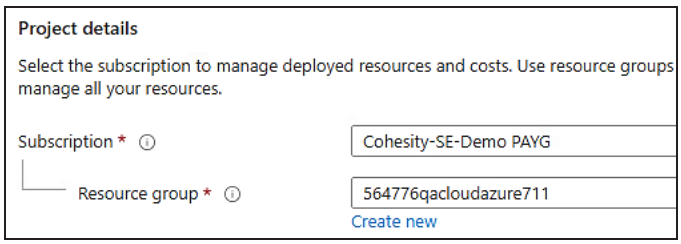
To deploy the Template Spec:

1. Navigate to the Resource Group that contains the Template Spec.
2. Click on the Template Spec you created using the above steps.



3. Click **Deploy**.
4. Verify the **Project details** section is correct.

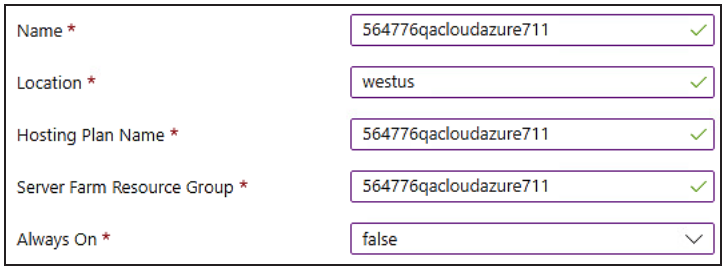
   The **Subscription** and **Resource Group** fields are auto-populated.



5. Under **Instance details**, verify the following:
   - **Region**: Verify the correct Azure region is selected. This field is auto-populated.
   - **Subscription Id**: Verify the correct Azure subscription is selected. This field is auto-populated.

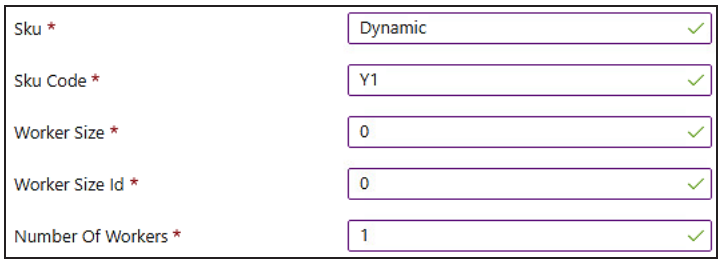
   - **Name**: Enter an appropriate name. The name must comply with standard Azure resource naming conventions.
   - **Location**: Enter the appropriate Azure region code.
   - **Hosting Plan Name**: This is a free-form field. For simplicity, use the Resource Group name.
   - **Server Farm Resource Group**: Enter the Resource Group name.

- **Always On**: Select false.



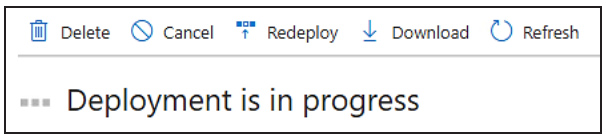
6. Configure additional fields:
   - **Storage Account Name**: Select the Storage Account that will be used for the external target.
   - **Use32Bit Worker Process**: Select **false**.
   - **Linux Fx Version**: Set to **Python|3.11**.

   - **Sku**: Enter **Dynamic**.
   - **Sku Code**: Set to **Y1**.
   - **Worker Size and Worker Size Id**: Enter **0**.
   - **Number of Workers**: Enter **1**.

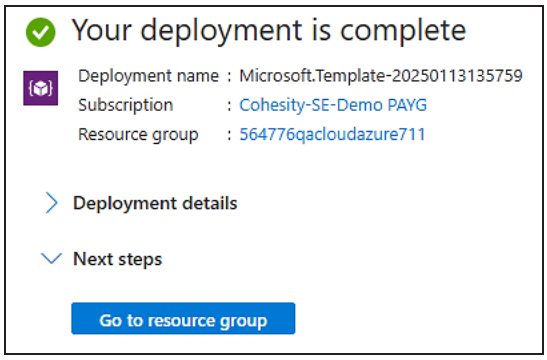


7. Click **Review + Create**.
8. Click **Create**.

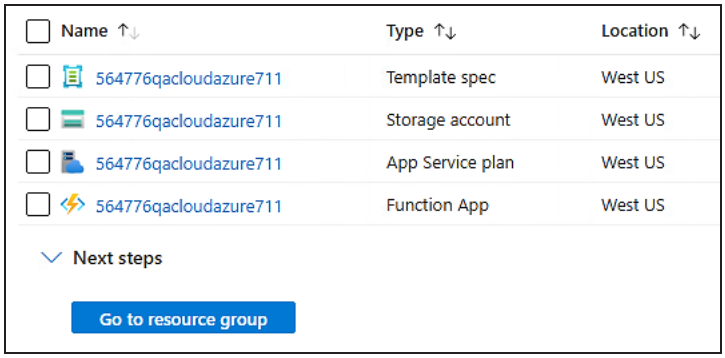
   Wait for the resource deployment to complete.



9. When the deployment completes, click **Go to resource group**.



The Resource Group now contains two new resources: an App Service Plan and a Function App.



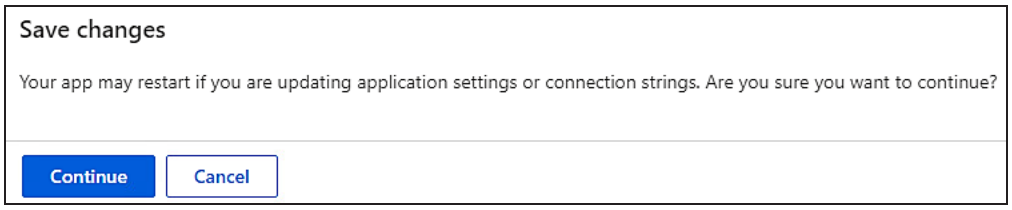
The Function App deployment is initiated. Once deployed successfully, you can obtain the Function App keys required for registering the Azure as an external target with the Cohesity cluster. For more information, see Obtain the Function App Key.

Obtain the Function App Key of the Function App

1. Click on the name of the Function App.

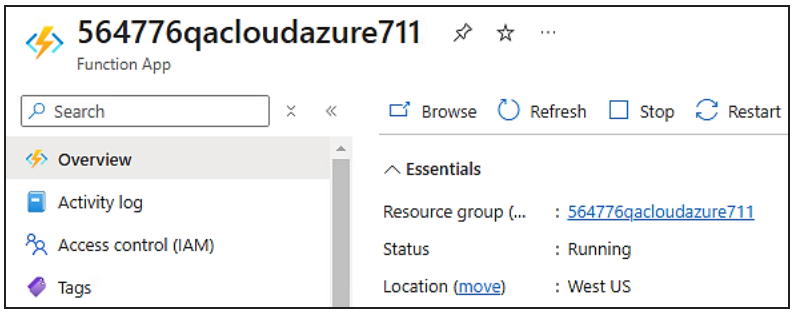
2. Under **Settings**, click **Configuration**.

3. For the **Runtime version** field, select **~4**.
4. Click **Save**, and then click **Continue**.



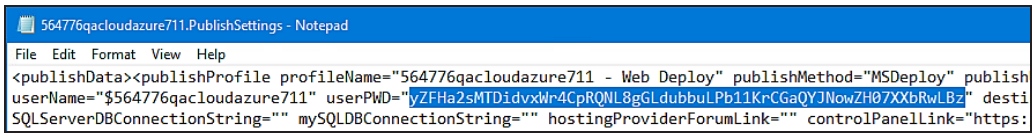
5. Click **Overview**.

   Verify the **Status** field displays **Running.**



6. Click **Get publish profile** to download the profile.
7. Open the downloaded file in a text editor and copy the value of **profileName** and **userPWD**.

   The **profileName** is the **Function App Name**, and **userPWD** the **Function App Deployment Key** you need to provide while registering the Azure as an external target.



Considerations

Cohesity does not support Azure virtual network integration and private endpoint configuration for the Azure Function App. Therefore, ensure the storage account you register for archival is accessible through a public network and not a private network.

Register an External Target for Cloud Tier

To register an external target for Cloud Tier, perform the following steps:

1. In the Cohesity Dashboard, select **Infrastructure > External Target**.
2. Click **Add External Target** located at the top right of the page.
3. Provide a name and add a description in the **New Target** and **Description** fields.
4. Select **Tiering** as the External Target's **Purpose**.

5. From the **Type** drop-down list, select the external target you want to register with the Cohesity cluster for Cloud Tiering and enter the information based on the target type you select..

AWS Glacier C2S

You must contract with a Commercial Cloud Services (C2S) agency to provide a private instantiation of the AWS commercial cloud.

Field Name	Description
Base URL	URL of the Commercial Cloud Services (C2S) server that contains the Amazon storage provided by the C2S agency.
Agency	The name the agency that is providing the Commercial Cloud Services (C2S) server.
Mission	The account name for accessing the Commercial Cloud Services (C2S) server which is provided by the C2S agency.
Role	The IAM role to use when accessing the Amazon storage which is provided by the C2S agency.
Bucket Name	Name of the existing bucket where you will store objects. This cannot be modified after you register the Target.
Region	Geographic area to use for Amazon storage. For example, if your region name is US West (N. California), the AWS Region value should be “us-west-1”. > **Note:** The AWS Region value is case-sensitive. It must be in lowercase and cannot contain uppercase letters. To know your AWS Region based on the Region name, see AWS Service Endpoints.
Client Certificate Password	The password to read the Client Private Key when accessing the Commercial Cloud Services (C2S) server which is provided by the C2S agency.
CA Trusted Certificate	Upload the Certificate Authority Trusted Certificate file to access the Commercial Cloud Services (C2S) server which is provided by the C2S agency.

Field Name	Description
Client Certificate	Upload the Client Certificate file to access the Commercial Cloud Services (C2S) server which is provided by the C2S agency.
Client Private Key	Upload the Client Private Key file to use when accessing the Commercial Cloud Services (C2S) server which is provided by the C2S agency.

For more information, see CloudArchive & CloudRetrieve Deployment & Recovery Guide for AWS.

AWS S3 Gov

For IAM user, if you do not already have an access key to use with Cohesity, create a new one in the AWS Management Console (root account credentials required). In AWS, go to **IAM** (AWS Identity and Access Management) and create a new access key ID and secret access key ID. Use this access key ID and secret access key to complete the corresponding fields below.

> **Warning:** Do not apply an AWS Object Lifecycle Policy with the Expiration action to an AWS S3 External Target used for archiving data. Applying a policy with this action may result in data loss.

Field Name	Description
Bucket Name	Name of the existing bucket where you will store objects. This cannot be modified after you register the Target.
Region	Geographic area to use for Amazon storage. For example, if your region name is US West (N. California), the AWS Region value should be “us-west-1”. **Note:** The AWS Region value is case-sensitive. It must be in lowercase and cannot contain uppercase letters. To know your AWS Region based on the Region name, see AWS Service Endpoints.
Access Key ID	Access key ID used to access Amazon storage.
Secret Access Key	Secret access key address to access Amazon storage.

Field Name	Description
(For IAM Role Only) **Account ID**	The account ID where the CE is running
(For IAM Role Only) **IAM Role**	The iAM Role for external target registration. Example: CohesityArchiveRole.

> **Note:** IAM Role for AWS S3 Gov is not supported.

For most regions, the Cohesity uses `s3-<region>.amazonaws.com` to construct the S3 endpoints instead of `s3.<region>.amazonaws.com`.

Example

`s3-us-east-2.amazonaws.com`, where `s3-us-east-2.amazonaws.com` is the CNAME for `s3.us-east-2.amazonaws.com`.

However, the Cohesity uses `s3.<region>.amazonaws.com` for regions listed below:

- China
- us-east-1
- S3 acceleration

For more information, see CloudArchive & CloudRetrieve Deployment & Recovery Guide for AWS.

You can archive data to Azure Data Box by registering Data Box as NAS External Target on Cohesity cluster. For more information, see How to use Cohesity Microsoft Azure Data Box Integration.

Azure Hot Blob Standard or Gov

After creating a storage account in Azure, if you have not done so already, go to Blob service and create a new container to use with Cohesity. Provide the container name, storage account name and either of the keys generated by Azure to the Cohesity Dashboard.

> **Note:** Cohesity recommends you to use the **Standard** (optimized for high capacity and high throughput) performance tier and not the Premium performance tier when creating a new Azure Blob storage account and container to register with the Cohesity cluster as an external target.

Field Name	Description
Container Name	Name of the existing container where you will store objects. This cannot be modified after you register the Target.
Storage Account Name	Account name used to access Azure storage.
Storage Access Key	Storage access key to access Azure storage.

For more information, see CloudArchive & CloudRetrieve Deployment & Recovery Guide for Azure.

GCP Multi-Regional or GCP Regional

In the Google Cloud Platform Console, create a new bucket to use with Cohesity if you have not done so already. To create credentials to use with Cohesity, from the Dashboard go to **IAM & Admin > IAM** and create a service account. Give the service account the Role of Project Owner and select Google Nearline or Coldline. After you create the service account, download and open the credential (JSON) file and use the contents (copy the text in the fields between the double quotes) to complete the fields below.

> **Warning:** Do not apply a Google Cloud Object Lifecycle Policy with the Delete action to any GCP External Target used for archiving data. Applying a policy with this action may result in data loss.

Field Name	Description
Bucket Name	Name of the existing bucket where you will store objects. This cannot be modified after you register the Target.
Project ID	Project ID of the existing project where you will store objects. This cannot be modified after you register the Target.
Client Email Address	Email address used to access Google Cloud Storage.
Client Private Key	Private key used to access Google Cloud Storage.

For more information, see CloudArchive & CloudRetrieve Deployment & Recovery Guide for GCP.

You can archive data to Google Transfer Appliance by registering Google Transfer Appliance as NAS External Target on Cohesity cluster.

Oracle Object Storage

A tenancy must be created by Oracle for your organization. In addition, an administer must set up the Tenancy and possibly create a compartment to hold your resources or a new user if required. Determine the best Oracle storage tier to use for your organization: Oracle Archival Storage (Archive Storage tier) or Oracle Object Storage (Object Storage tier). In the Oracle Cloud console, create a new bucket to use with Cohesity if you have not done so already. The Storage Tier specified for the bucket must match the specified Cohesity External Target Type (Oracle Archive or Oracle Object).

The user with which the bucket is registered must be associated with the following Oracle policy statements:

- Allow group <*group-name*> to manage buckets in tenancy
- Allow group <*group-name*> to manage objects in tenancy

If you do not already have an access key to use with Cohesity, create a secret key. Use the Access Key ID and Secret Access Key to complete the corresponding fields below.

Field Name	Description
Bucket Name	Name of the existing bucket where you will store objects. This cannot be modified after you register the Target. In the Oracle Cloud console, create a new bucket to use with Cohesity if you have not done so already. The Storage Tier specified for the bucket must match the specified Cohesity External Target Type (Oracle Archive or Oracle Object).
Region	Geographic area to use for Oracle storage. For more information, see Data Regions.
Access Key ID	Access key ID used to access the storage. For more information about create and copying the key, see create a secret key.
Secret Access Key	Secret access key address to access the storage. For more information about create and copying the key, see create a secret access key.
Tenancy	This is the Tenancy name that is displayed under TENANCY in the top menu bar of the Oracle Cloud Console. This is not the Oracle Cloud Identifier (OCID) for your Tenancy.

S3 Compatible

Cleversafe is a supported AWS S3 Compatible External Target.

When registering a Cleversafe External Target, complete the settings with the following information:

- Bucket Name - Use the vault name from Cleversafe.
- Access Key ID and Secret Access Key - As provided by Cleversafe.
- Endpoint - Use the endpoint of the Cleversafe appliance.
- AWS Signature Version - Select ver 4.

Do not apply an AWS Object Lifecycle Policy with the Expiration action to an AWS S3 Compatible External Target used for archiving data. Applying a policy with this action may result in data loss.

Field Name	Description
Bucket Name	Name of the existing bucket where you will store objects. This cannot be modified after you register the Target.
Access Key ID	Access key ID used to access the storage.
Secret Access Key	Secret access key address to access the storage.
Endpoint	The Endpoint mount path. Use the IP address or Fully Qualified Domain Name (FQDN), then a colon (:), followed by the port number. **Note:** Do not include 'http://' or 'https://' in the mount path.
Secure Connection (HTTPS)	Toggle **Secure Connection** on or off.
AWS Signature Version	Select the AWS signing process version for adding authentication information to requests.

To register other S3 compatible targets like Pure FlashBlade S3 bucket, IBM ICOS S3 bucket and Cohesity S3 bucket, see CloudArchive Deployment & CloudRetrieve Recovery for S3-Compatible Storage.

> **Note:** For Cloud Tiering, encryption and compression are always enabled and you cannot disable these options.

6. Enable **Bandwidth Throttling** to limit the maximum data transfer rate *from and to this External Target* during a time window.
   a. **Change Time Zone**: Optionally change the time zone that applies to all the override windows specified.
   b. **Traffic:** Specify the direction of traffic to limit, by specifying a maximum bandwidth:
      - **Upload:** Limit the data transfer rate from the Cohesity cluster to this External Target.
      - **Download:** Limit the data transfer rate from this External Target to the Cohesity cluster.
   c. **Days**: Specify the days of the week to apply the window.
   d. **Time**: Specify all day or a time period for each day.
   e. **Throttle To**: Specify the maximum data transfer rate.Optionally change the rate type.
   f. Click **Add**.
   g. Repeat these steps to add more upload throttling windows.

      If overlapping windows are specified, the latest window that was created takes precedence. For example, if you first create a window from Monday 9 AM - 10 PM with a data rate of 50 Mbps and then a window from 5 PM to 12 PM with a data rate of 100 Mbps, during 5 PM -12 PM the data rate is limited to 100 Mbps.

   If both cluster-level override throttling window and an external-target override throttling window is set during the same time period, the lowest **Throttle To** number specified is the maximum allowed data transfer rate. For example, if a cluster-level override throttling window of 8-11 AM is set to 250 Mbps and an External-level override throttling window of 9-10 AM is set to 200 Mbps, during 9-10 AM the maximum allowed data transfer rate is 200 Mbps. Specifying transfer rate limits at the External-target level is described at the end of this procedure. For information on setting up cluster-level bandwidth throttling, see Set Bandwidth throttling at Cluster-level for Tiering to External Targets.
7. Click **Register**.

   The Cohesity cluster attempts to connect to the target. A successful connection displays the external targets page with the new target included in the list.

Set Bandwidth throttling at Cluster-level for Tiering to External Targets

You can set bandwidth throttling at the cluster level to limit the data transfer rate to and from all the external targets registered for Tiering on this Cohesity cluster.

1. In the Cohesity Dashboard, navigate to **Inventory** > **External Target**.
2. Select the **Settings** tab.
3. Set the values of the fields displayed in the **Tiering** section:

Field Name	Description
Upload	Set the following options to limit the maximum data transfer rate from the Cohesity cluster to all the External Targets registered on this cluster: 1. **Throttle**: Enable this option and in the Throttle to field, specify the maximum data transfer rate. 2. **Throttling Overrides**: Enable this option and specify a time window during which the maximum data transfer rate you specified for in the above step must be overwritten: a. **Change Time Zone**: Optionally change the time zone that applies to all the override windows specified. b. **Days**: Specify the days of the week to apply the window. c. **Time**: Specify all day or a time period for each day. d. **Throttle To**: Specify the maximum data transfer rate. e. Click **Add**. f. Repeat these steps to add more upload throttling windows. **Note:** If overlapping windows are specified, the latest window that was created takes precedence. For example, if you first create a window from Monday 9 AM - 10 PM with a data rate of 50 Mbps and then a window from 5 PM to 12 PM with a data rate of 100 Mbps, during 5 PM -12 PM the data rate is limited to 100 Mbps.

Field Name	Description
Download	**Throttle**: Enable this option and in the Throttle to field, specify the maximum data transfer rate. 1. **Throttling Overrides**: Enable this option and specify a time window during which the maximum data transfer rate you specified for in the above step must be overwritten: a. **Change Time Zone**: Optionally change the time zone that applies to all the override windows specified. b. **Days**: Specify the days of the week to apply the window. c. **Time**: Specify all day or a time period for each day. d. **Throttle To**: Specify the maximum data transfer rate. e. Click **Add**. f. Repeat these steps to add more upload throttling windows. **Note:** If overlapping windows are specified, the latest window that was created takes precedence. For example, if you first create a window from Monday 9 AM - 10 PM with a data rate of 50 Mbps and then a window from 5 PM to 12 PM with a data rate of 100 Mbps, during 5 PM -12 PM the data rate is limited to 100 Mbps.

4. Click **Save**.

Things to remember

- **When specifying both cluster-level throttling and cluster-level Override throttling windows**: If both cluster-level throttling and a cluster-level override throttling window are set, then the rate specified in the cluster-level override throttling window takes precedence and is used during the specified time window. For example, if the cluster-level throttling is set to 100 Mbps and the cluster-level override throttling window of 9-10 AM is set to 200 Mbps, the maximum allowed data transfer rate during 9-10 AM is 200 Mbps but at any other time, the maximum allowed

data transfer is 100 Mbps.

- **When specifying both cluster-level Override throttling window and External-target Override throttling window**: If both cluster-level override throttling window and an External-target override throttling window is set during the same time period, the lowest Throttle To number specified is the maximum allowed data transfer rate. For example, if a cluster-level override throttling window of 8-11 AM is set to 250 Mbps and an External-level override throttling window of 9-10AM is set to 200 Mbps, during 9-10 AM the maximum allowed data transfer rate is 200 Mbps. Specifying transfer rate limits at the External-target level is described at the end of this procedure.

Add a New External Target for CloudTier

You can add a new external target for CloudTier while the existing external target registered for CloudTier is being removed.

Steps:

1. Verify whether the CloudTier is configured at the Cohesity cluster level or at the Storage Domain level.
    a. If the CloudTier is configured at the Storage Domain level, verify if the Storage Domain has physical storage available to uptier the data back to the Storage Domain with the physical quota being set. If the storage space is less, you must extend the physical quota to uptier the data completely.
    b. If the CloudTier is set at the cluster level, no action is required, proceed with step 2.
2. Remove the external target's disk if you want to remove the existing target from the entire Cohesity cluster. Skip this step if you want to remove the external target only from a set of Storage Domains as other Storage Domains might have data in this external target.
3. Contact Cohesity Support to remove the existing cloud_spill_vec depending on from where you want to remove the existing external target (from a set of Storage Domains or from the entire Cohesity cluster).
4. Wait until uptiering is complete. You can use the **Advanced Diagnostics** statistics (**System** > **Advanced Diagnostics**) on the Cohesity UI to confirm the status.

5. Register a new external target for CloudTier and designate the external target with Storage Domain(s).

   For more information, see Register an External Target for Cloud Tier and Create or Edit Storage Domains.

6. Once the disk of the previous external target is removed, unregister the previous external target. For more information, see Unregister an External Target.

Update Storage Key for Azure External Target

If your organization updates the Azure Storage Key on the Azure Storage Account used for Incremental Forever Archive, you must update the new key information at two places:

1. On the Cohesity cluster: Update the **Storage Access Key** field for the Azure target.
2. On the Azure Function App: Update the **AzureWebJobsStorage** environment variable with the new Azure Storage connection string.

Update Azure Target on the Cohesity Cluster

Perform the following steps on the Cohesity cluster:

1. Navigate to **Infrastructure > External Targets**.
2. Locate the Azure Target configured with Incremental Forever archival.
3. Next to the target, click the pencil icon to edit it.
4. In the **Storage Access Key** field, replace the old key with the new Azure Storage Access Key.
5. Enter the **Function App Name** and **Function App Deployment Key**.
6. Click **Save** to apply the changes.

Update the Azure Function App

Perform the following steps to update the Azure Function App with the New Azure Storage Connection String:

1. Get the New Azure Storage Connection String.
    - In the Azure Portal, navigate to the **Azure Storage Account > Security + Networking > Access Keys** page.
    - On the **Access keys** page, click **Show** next to the Connection string and copy the string.
2. Update the **AzureWebJobsStorage** Environment Variable.
    - In the Azure Portal, navigate to **Azure Function App > Settings > Environment Variables**.
    - Locate the **AzureWebJobsStorage** variable and replace its value with the new Azure Storage connection string.
    - Click **Apply** to save the changes.

AWS Security Token Service Support

Cohesity can secure AWS S3 External Targets with AWS Security Token Service (STS).

Supported S3 AWS Targets

Cohesity supports the following AWS S3 External Targets with AWS STS:

- S3 Intelligent-Tiering
- S3 One Zone-IA
- S3-Standard
- S3-GOV
- S3-C2S
- S3-IA-Standard
- S3-IA-C2S

Configure AWS STS Vault

You can configure the AWS STS vault by using the Cohesity CLI command.

Prerequisites

Before configuring the AWS STS vault, deploy a credentials service by ensuring the following:

- The HTTP endpoint is reachable by the Cohesity cluster.
- The HTTP endpoint accepts POST API requests.
- The HTTP endpoint validates the request body of a POST request and responds with a valid AWS STS token.

The response from the endpoint must generate the JSON output that matches the following syntax:

```
{
    "Version": 1,
    "AccessKeyId": "an AWS access key",
    "SecretAccessKey": "your AWS secret access key",
    "SessionToken": "the AWS session token for temporary credentials",
    "Expiration": "ISO8601 timestamp for when the credentials expire"
}
```

To configure the AWS STS vault:

```
iris_cli vault create name=<name> vault-type=Amazon usage-type=archival com-
pression-enabled=<true|false> encryption-enabled=<true|false> bucket-name-
e=<name> aws-region=<region> tier-type=Amazon-S3-Standard incremental-
enabled=true aws-credential-endpoint=<credential endpoint URL> aws-cre-
dential-blob=<path to local file>
```

To edit the AWS STS vault:

```
iris_cli vault edit id=<vault ID> aws-credential-endpoint=<credential end-
point URL> aws-credential-blob=<path to local file>
```

The following table provides the description of the parameters used for creating the AWS STS vault:

Parameter	Type	Description
`name`	string	Name of the vault.
`vault-type`	string	Type of the vault (Amazon).
`usage-type`	string	Usage purpose of the vault (Archival).
`compression-enabled`	bool	Flag to enable or disable the compression.
`encryption-enabled`	bool	Flag to enable or disable the encryption.
`bucket-name`	string	Name of the bucket or container inside the target vault.

Parameter	Type	Description
`aws-region`	string	AWS region (e.g. us-east-1, us-west-1 etc.) for AWS service account.
`tier-type`	string	Tier of the vault. For the list of supported tier types, see Supported S3 AWS Targets.
`incremental-enabled`	bool	Support incremental archive for archival vaults.
`aws-credential-endpoint`	URL	The endpoint of the credentials service.
`aws-credential-blob`	path	The absolute path of a local file containing the authentication string to send to the credential endpoint.

Kerberos Authentication for NAS External Target

Cohesity supports Kerberos authentication for registration of NAS volumes with NFS versions 4 and above as external targets with the Cohesity cluster.

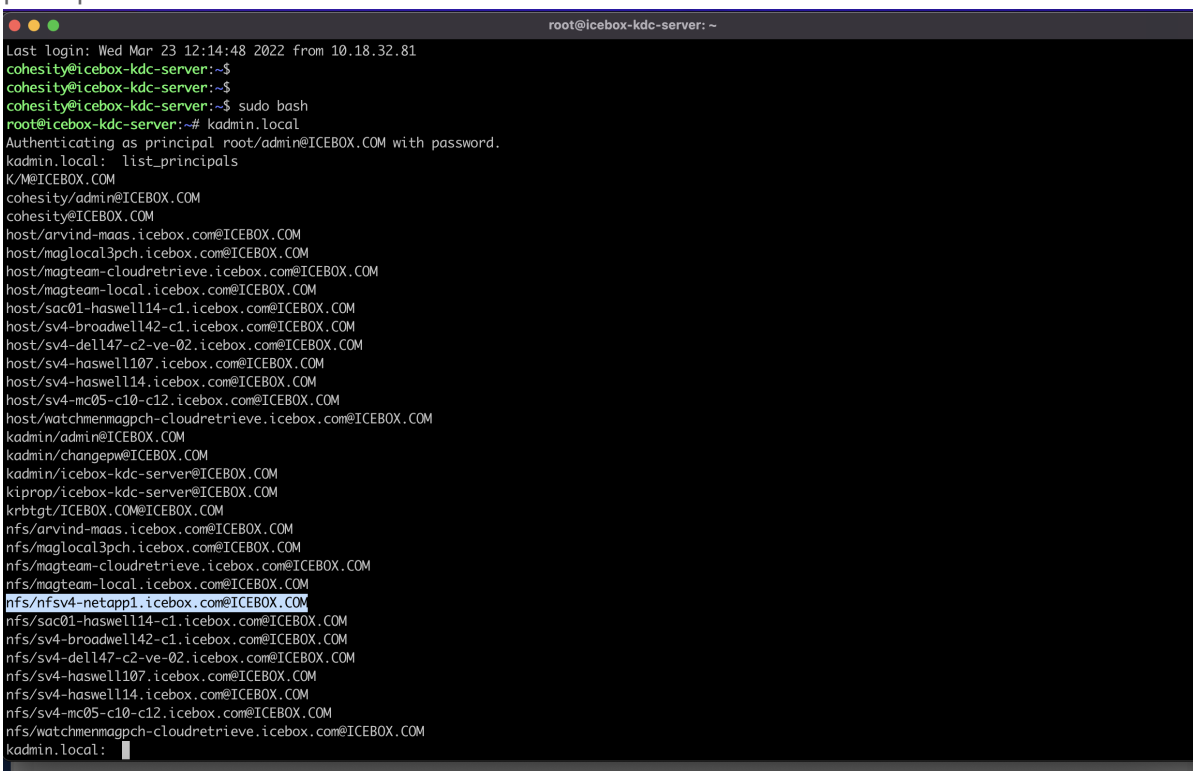
The following are the use cases supported:

- Using one MIT Kerberos security.
- Using two MIT Kerberos security.
- Cluster in AD using MIT Kerberos security.
- NetApp registered as NAS type of external target and accessed using NFSv4 protocol with Kerberos security.
  The following is the prerequisite procedure for this use case:
  - Login to NetApp.
  - Navigate to **Storage > Storage VMs**. The **Storage VMs** page is displayed.
  - Click the required Storage VM and click the **Settings** tab.
  - Click **Kerberos** and click **Add** to add a Kerberos Realm. The **Add Kerberos Realm** page is displayed.
  - Enter the Name, KDC IP Address, KDC Port, and KDC Vendor.

    When the Kerberos realm is registered, NetApp creates a Service Principal in the KDC.
  - Click **Add** to add a network interface to realm. Enter the Kerberos Interface, Service Principal Name (from Kerberos) , Admin Username, and Admin Password. Click **Save**.

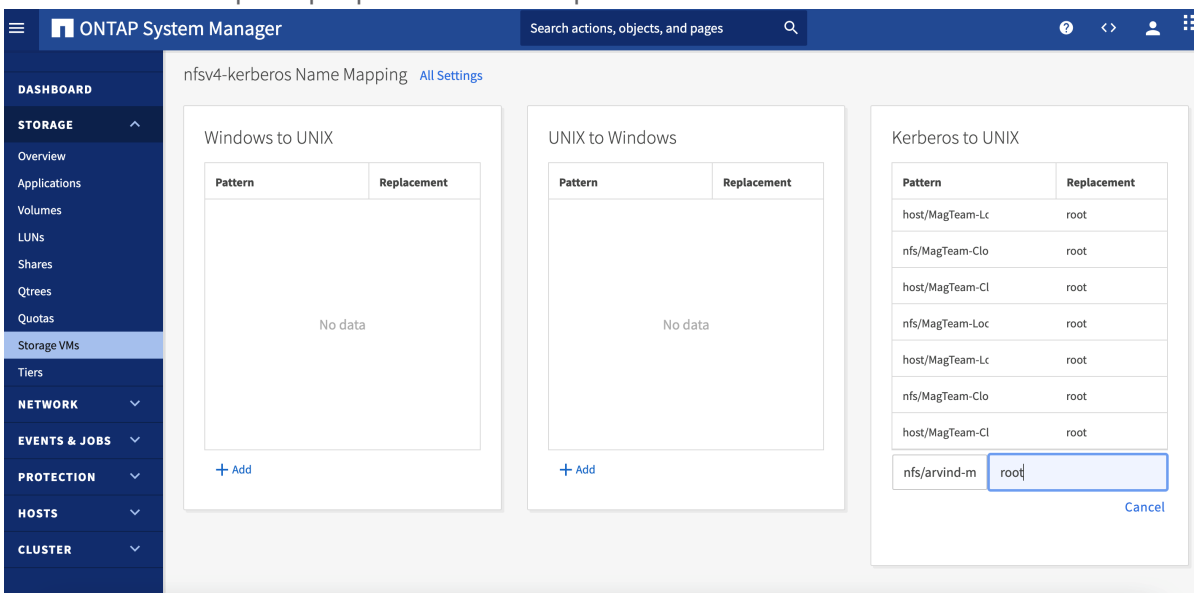
- Click **Save**. Now, the NetApp and KDC can communicate with each other.
- In the Cohesity cluster, Add Kerberos Provider to Cohesity cluster.

  The Cohesity cluster communicates with the KDC and creates two service principles in the KDC.



- In NetApp, navigate to **Storage > Storage VMs**.
- Click the required Storage VM. In the **Kerberos to UNIX** section, click **Add**.

- Enter the service principal patterns and map them to *root*.



The Kerberos to UNIX mapping will be added on NetApp.

Supported NAS External Targets for Kerberos Authentication

Cohesity supports all NAS volumes of NFSv4 and above versions for Kerberos authentication.

Kerberos Authentication Configuration Steps

Before you register an NFS volume as an external target with the Cohesity cluster using Kerberos authentication, you must perform the following steps:

1. Add Administrators to the Kerberos Database.
2. Add Administrators to the ACLs File.
3. Add Kerberos Provider to Cohesity cluster.

Add Administrators to the Kerberos Database

On the Kerberos database that you maintain, you must add an administrative principal (admin principal) with the required ACLs. You can also use an existing principal that has the required ACLs. This admin principal will be used by the Cohesity cluster during Kerberos provider registration.

> **Note:** The steps for adding admin principal to Kerberos may vary depending on the Kerberos environment.

The following is an example of adding admin principal on a standard Linux environment:

You can use kadmin.local on the Kerberos admin server to create the administrative principal `cohesity/admin`

```
shell% /usr/local/sbin/kadmin.local
kadmin.local: addprinc cohesity/admin@ENG.COHESITY.COM
//ENG.COHESITY.COM is the Realm name//
NOTICE: no policy specified for "cohesity/admin@ENG.COHESITY.COM";
assigning "default".
Enter password for principal cohesity/admin@ENG.COHESITY.COM:  <= Enter a
password.
Re-enter password for principal admin/admin@ENG.COHESITY.COM:  <= re-enter
the password.
Principal "cohesity/admin@ENG.COHESITY.COM" created.
kadmin.local:
```

Add Administrators to the ACLs File

The admin principal you created on the Kerberos database must be added to the Access Control List (ACL) file.

The principal used during Kerberos provider registration must have the following minimum permissions:

- All permissions except extract password for NFS and host principals
- All permissions including extract password for Cohesity principal

> **Note:** The steps for adding admin principal to the ACL file may vary depending on the Kerberos environment.

The following is an example of adding an admin principal to the ACL file on the Linux server:

1. Edit the access control list for Kerberos administration.

   ```
   $ sudo cat /etc/krb5kdc/kadm5.acl
   ```

2. Add the following:

   ```
   cohesity/admin@ENG.COHESITY.COM xe cohesity@ENG.COHESITY.COM
   cohesity/admin@ENG.COHESITY.COM x nfs/*@ENG.COHESITY.COM
   cohesity/admin@ENG.COHESITY.COM x host/*@ENG.COHESITY.COM
   ```

   Here,

   - `cohesity/admin@ENG.COHESITY.COM` is the admin principal that the Cohesity cluster uses to make changes to the Kerberos configuration.
   - `cohesity@ENG.COHESITY.COM`, `nfs/*@ENG.COHESITY.COM`, `host/*@ENG.COHESITY.COM` are the user principals.

- The user principal, `cohesity@ENG.COHESITY.COM` is shared among multiple clusters. The admin principal (`cohesity/admin@ENG.COHESITY.COM`) has read/write privileges (`x`) with respect to this user principal. The admin principal also has privileges to extract password (`e`) for this user principal. The reason to grant the admin principal the permission to extract the password for this user principal is that this user principal is shared among multiple Cohesity clusters in the same Kerberos realm.

  For example, in a multiple clusters environment, the first Cohesity cluster that registers with the Kerberos realm will create a user principal with a random password. This password is saved in its keytab. However, when the second cluster registers with the Kerberos realm, it does not know the password for the user principal that the first cluster created. Therefore, this password needs to be extracted and saved in the second cluster's keytab.
- `nfs/*@ENG.COHESITY.COM`, `host/*@ENG.COHESITY.COM` principals are not shared among clusters. These principles have more restrictive privileges but have wildcard associated with it. The names (`nfs/*` and `host/*`) of these principals are derived from the host alias provided during Kerberos provider registration with the Cohesity cluster and are assumed to be unique for each Cohesity cluster.

Add Kerberos Provider to Cohesity cluster

You need to add the Kerberos provider to the Cohesity cluster to authenticate the Cohesity user to access NAS volumes in a Kerberos environment. The Cohesity user is used for mounting the NFS volume onto the Cohesity cluster.

Prerequisites

- Realm name

  > **Note:** Realm is the domain over which a Kerberos provider can authenticate a user, host, or service. Realm name is the unique identifier of the Realm.

- KDC server name and credentials
- Admin server

To add Kerberos Provider to the Cohesity cluster, complete the following steps:

1. Log in to the Cohesity Dashboard, navigate to **Settings** > **Access Management** > **Kerberos**.
2. In the Kerberos tab, click **Add Kerberos Provider**.
3. In the Add Kerberos Provider screen, complete the following steps:

1. Type **Realm Name**.
2. Type **Host Alias**.

   Host alias is Cohesity cluster names. Default host alias is your Cohesity cluster name. You can add more than one host alias name. The host alias name will be associated with the admin principals that Cohesity creates in the Kerberos provider.
3. (Optional) Toggle the **Use existing Host Aliases**.
4. Type **KDC Servers** names.

   You can add multiple KDC Server hostnames. Use a comma to separate the names.
5. Add **Admin Server** (KDC).

   You can select one of the added KDC servers as an admin server.
6. Type **Admin Principal** you created on the Kerberos database.
7. Type **Admin password**.
8. Click **Add**.

Once the Kerberos provider is added to the Cohesity cluster,

- The Cohesity cluster creates certain principals with the Kerberos provider depending on the provided host aliases:
  - `host/<host_alias>.<realm_name_in_lowercase>@<realm_name>`
  - `nfs/<host_alias>.<realm_name_in_lowercase>@<realm_name>`
- If you have provided multiple host aliases, multiple principals will be created.
- Cohesity cluster additionally creates a Cohesity "user" principal, `cohesity@<realm name>`, which is used by the NFS client when mounting a Kerberos-secured NFS volume.
- The authentication of the principals created is restricted to AES-128/256 encryption types. These encryption types apply to the encryption applied to tickets and Kerberos client/server messages.
- The principals are created with a randomly generated password using the "`-randkey`" `kadmin` option.
- On each Cohesity node, a keytab is created containing the randomly generated passwords of each of the created principals.
  - This is a standard way to store Kerberos client authentication details.
  - Access to the keytab files is protected from non-Cohesity users by access control.

- The keytab contents are stored in the Cohesity cluster configuration and shared among nodes.

Register NAS Volume with Cohesity cluster using Kerberos Authentication

Prerequisites

Before you register an external target with Kerberos authentication, ensure the following:

- You must enable Kerberos security for the NFS volume you register.
- The volume must be accessible through NFS 4.0, 4.1, or 4.2.
- You must provide principals created by Cohesity permission to access the Kerberos-secured NFS volume.

> **Note:** The steps for configuring the prerequisites may be different for each NAS source.

To register an external target for Cloud Archive and CloudArchive Direct, or CloudTier using Kerberos authentication, perform the following steps:

1. In the Cohesity Dashboard, select **Infrastructure** > **External Target**.
2. Click **Add External Target** located at the top right of the page.

   The Register External Target screen appears.
3. Select the **Storage Type** as **NAS**.
4. Select the **NFS version** as **4.0**, **4.1**, or **4.2.**
5. Select one of the following as the **Security Type**:
   - **KRB5**: Provides Kerberos authentication.
   - **KRB5I**: Provides Kerberos authentication and integrity checking.
   - **KRB5P**: Provides Kerberos authentication, integrity checking (KRB5I), and privacy (encryption).
6. Type **Kerberos Realm Name**.
7. In the **NAS Host** field, type the hostname or IP address of the NAS host.
8. In the **Mount Path** field, type the mount path of the NAS host.

   > **Note:** Only NFS is currently supported.
9. Click **Register**.

The NAS volume is now registered with the Cohesity cluster using Kerberos authentication.

QStar Tape Configuration

You can archive backups to tape for long term data retention. Cohesity uses QStar Archive Storage Manager (ASM) from QStar Technologies as the media manager for your existing tape libraries. Cohesity provides the QStar software, license and technical support, but all media management is handled by the QStar software.

For supported tape libraries, requirements, installation and configuration information, see

Archive Data to Tape with QStar & Cohesity .

Unregister an External Target

Before you unregister an external target registered for archival, you must make sure that this external target is not used by any of the policies.

To unregister an external target registered for archival from the Cohesity cluster:

1. In the Cohesity Dashboard, navigate to **Infrastructure > External Target**.
2. Click the **Delete** icon.

   If the external target is used by any of the policies, then a prompt is displayed to remove the external target from the policies before unregistering.
3. In the **Unregister External Target** prompt, type **Unregister** for confirmation and optionally, toggle on **Delete Data**.

   By enabling the **Delete Data** option, all the data available at the target will be deleted before unregistering.

   If this is not enabled, then *only* the metadata will be deleted.
4. Click **Unregister**.

   Depending on the number of archives in that external target, the status moves to *Unregistering* along with the percentage displayed. On success, the external target will not be displayed on the External Targets page.

> **Note:** From the Cohesity UI, you cannot unregister an external target registered for CloudTier.

If you want to remove the external target registered for CloudTier from the cloud source, then you must:

1. Ensure to have enough storage space on the Cohesity cluster to uptier the data from the external target to the Cohesity cluster.
2. Gracefully remove the cloud disk.
3. Contact Cohesity Support to remove the external target from the Cohesity cluster.

Chapter 23: Disaster Recovery

Cohesity provides disaster recovery through replication and CloudRetrieve. To learn more, see the following topics:

About Replication 4003

Replication and Remote Access Setup 4021

About CloudRetrieve 4033

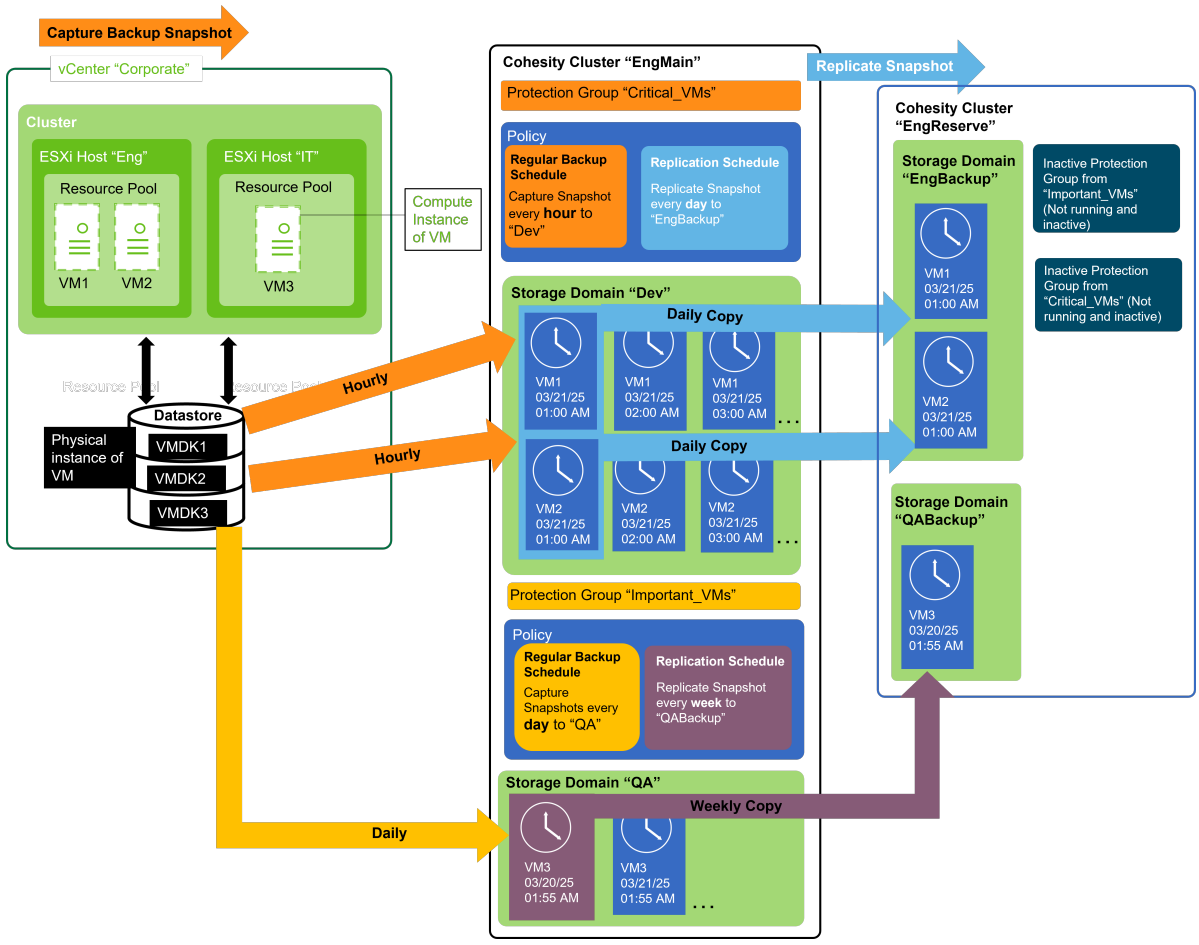
About Failover Ready 4038

Disaster Recovery Using CloudSpin 4039

Disaster Recovery Using CloudEdition 4039

About Replication

Organizations can achieve enterprise-level resiliency with site-to-site replication between Cohesity clusters. Replication can be configured at multiple granularity levels for maximum flexibility, including job-level or Cohesity View level (similar to a storage volume). All data on a single Cohesity cluster can be replicated to one or more clusters through the use of Protection Groups. The Protection Group specifies the objects (like databases, physical servers, VMs, Cohesity Views etc) to be backed up and replicated. Full and partial fail-over functions are fully automated using the Cohesity Orchestration workflow engine for simple, seamless recovery.



You specify a protection schedule in a Policy and that protection schedule defines how often a Protection Group using that Policy runs. In the example above, a Protection Group using a policy with an hourly protection schedule is capturing Snapshots of VM1 and VM2 and storing those Snapshots in the `Dev` Storage Domain. Another Protection Group using a policy with a daily protection schedule is capturing Snapshots of VM3 and storing those Snapshots in the `QA` Storage Domain.

You can optionally specify a replication schedule in a Policy. The replication schedule defines how often Snapshots are copied from a Storage Domain in the capturing Cohesity cluster and saved on a Storage Domain in the remote Cohesity cluster by a Protection Group using this Policy. In the example above, the Protection Group is making daily copies of the Snapshots in the `Dev` Storage Domain of the `EngMain` Cohesity cluster and storing those replicated Snapshots in the `EngBackup` Storage Domain of the remote Cohesity cluster called `EngReserve`. Another Protection Group with a different Policy is making weekly copies of the Snapshots in the `QA` Storage Domain of the `EngMain` Cohesity cluster and storing those replicated Snapshots in the `QABackup` Storage Domain of the remote Cohesity cluster called `EngReserve`.

The replication schedule for copying Snapshots cannot be more often than the protection schedule for capturing Snapshots. For example if Snapshots are captured hourly, the

Cohesity cluster cannot replicate them every 30 minutes but it can replicate them hourly or any value over one hour.

> **Note:** When replicating large files, if the replication process is slow for more than a day, contact Cohesity Support. For reference, see the KB Article.

> **Note:** After Snapshots of Objects (such as VMs) are created by a Protection Group with replication schedules, copy tasks are immediately created to replicate the Snapshots to the remote Cluster. The Cohesity cluster does not wait until the Snapshots of all the Objects protected by the Protection Group are captured, before it starts replicating.

Using the Replicated VM Snapshots

After VM Snapshots are replicated (copied) to a remote Cohesity cluster you can use the Snapshots to complete the following tasks:

- Recover VMs from the replicated Snapshots to a new location.
- Clone VMs from the replicated Snapshots.
- Recover files from the replicated Snapshots.
- Run the Analytics Workbench on these replicated Snapshots.
- Download VMX files from the replicated Snapshots.

The procedures for initiating these tasks are the same as initiating these tasks from Snapshots created by a Backup task of a Protection Group.

You can also use the Snapshots and Inactive Protection Group that were replicated to the remote Cohesity cluster for disaster recovery. To learn more, see Active Protection Group Replicating to Remote Cohesity cluster.

Using the Replicated View Snapshots

After View Snapshots are replicated (copied) to a remote Cohesity cluster you can use the snapshots to complete the following task:

- Clone a View From a Snapshot.

Using the Replicated SQL Server Snapshots

After SQL Server snapshots are replicated (copied) to a remote Cohesity cluster you can use the snapshots to complete the following task:

- Recover Microsoft SQL Server.

> **Warning:** For replicated MS SQL Server VM Snapshots, you can only restore MS SQL Server to a new location. (You cannot restore MS SQL Server to its original location.)

Object-based Replication

Object-based replication offers granular control by allowing replication at the individual object level. Instead of replicating all the runs in a protection group, you can replicate only the selected objects from a backup run to the target.

Follow these steps to perform object-based replication:

1. In the Cohesity cluster, select **Data Protection** > **Protection**.
2. On the **Protection** page, select the required Protection Group.
3. On the backup run details page, click the Actions menu (⋮) for the run and click **Edit Run**.
4. In the **Edit Run** dialog, click **Replication**.
5. From the **Replicate** dropdown, select the subset of objects in the backup run and click **Continue**.
6. From the **Replication** target dropdown, select the required target.
7. Toggle on **Modify Retention** if required.
    1. **Retention**: From the dropdown, select one of the following:
        1. **Extend**
        2. **Reduce**
    2. **Retain for**: Specify how many days, weeks, months, or years backups are retained on the cluster before they are deleted.
8. Click the save icon.

To add a new target to the backup run, click the plus icon.

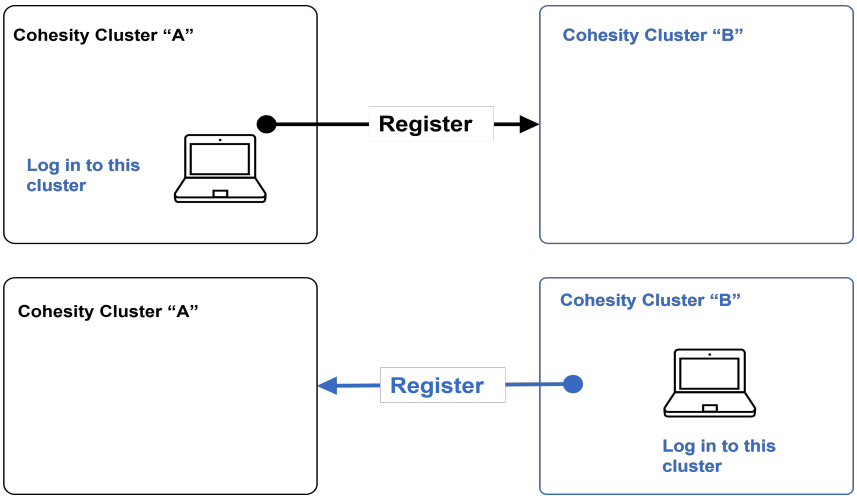
About Replication Setup

Replication automatically makes copies of snapshots captured by a Protection Group on one Cohesity cluster and copies them to a second Cohesity cluster.

To learn more about Replication, see About Replication. Before the Cohesity cluster can replicate Snapshots, you must register the Cohesity clusters with each other. For more information, see Replication and Remote Access Setup.

Register Cohesity clusters for Replication

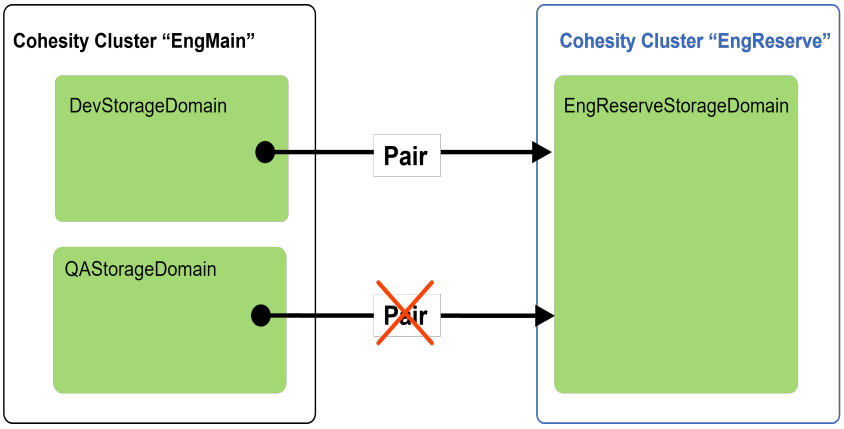
You must register the Cohesity clusters with each other and create at least one Storage Domain pairing between the Cohesity clusters. You can optionally specify a replication schedule in a Policy.



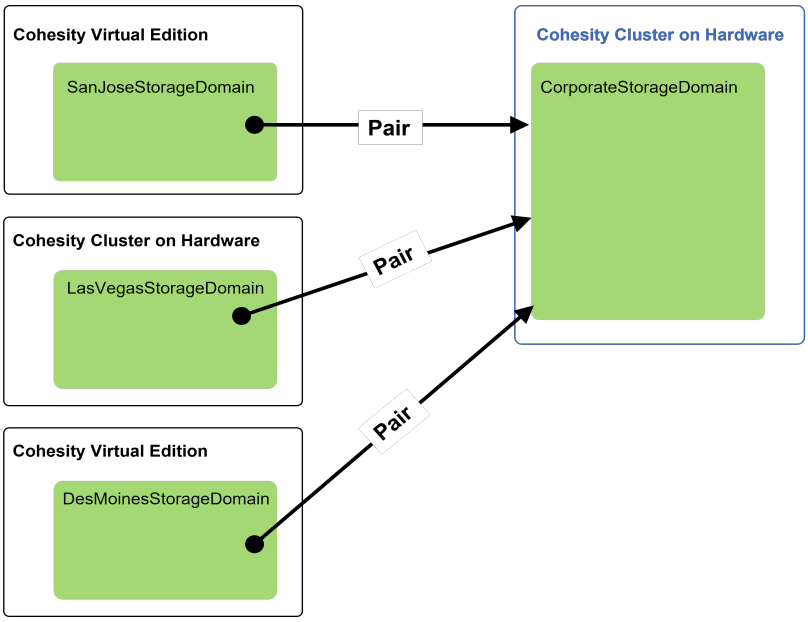
For more information on Replication Compatibility, see Replication Compatibility.

Pair Storage Domains for Replication

In addition, you must pair a Storage Domain on the capturing and replicating Cohesity cluster with a Storage Domain on the remote Cohesity cluster, as shown in the following figure. You cannot pair multiple Storage Domains on one Cohesity cluster to the same Storage Domain on the other Cohesity cluster. This is also shown in the following figure.



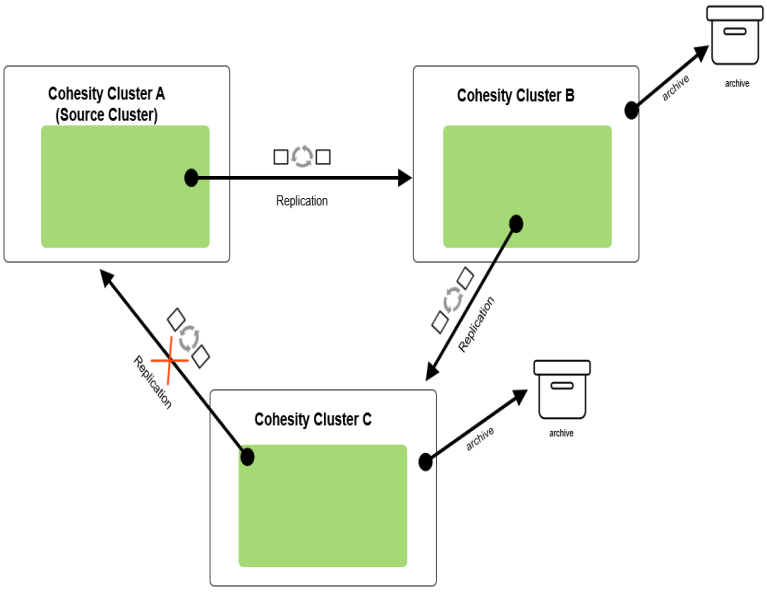
You can, however, pair multiple Storage Domains to a single Storage Domain if the source Storage Domains are on different Cohesity clusters as shown in the following figure.



Cascaded Replication and Archival policy

Cohesity now supports Cascaded Replication. You can use this feature to not only replicate your Protection Groups from the source to the target cluster but also from the target cluster to another cluster. Also, protection objects can be archived from any of these targets.

Cohesity supports cascaded replication through scripts only. You have to create a cascaded replication policy that is non-cyclic. For example, replicating data from A to B to C is supported but Cohesity doesn't support the replication of data from A to B to C to A. For more information, see Cascaded Replication, Archival, and Vaulting Policy.



About Replication and Disaster Recovery

When a Protection Group with a replication schedule starts replicating snapshots from a primary Cohesity cluster to a remote Cohesity cluster, a Protection Group in Failover Ready state is created on the remote Cohesity cluster. If the original capturing Cohesity cluster and/or the original Source are down because there is a planned maintenance outage or a disaster destroys them, you can failover the Protection Group in Failover Ready state and deactivate the original task on the capturing Cohesity cluster. As part of the Failover, you are prompted to optionally recover the VMs from the replicated snapshots stored on the remote Cohesity cluster.

> **Warning:** When you create a Protection Group on a Cohesity cluster with a replication schedule after the first snapshot is replicated, a Failover Ready copy of the Protection Group is created on the remote Cohesity cluster that is receiving the snapshot. For more information on Failover Ready, see About Failover Ready. You can failover the Protection Group of VMs. You cannot failover the Protection Group of Views or SQL Servers. You can, however, clone replicated Views and restore SQL Servers. For more information, see Failover a Protection Group.

The disaster recovery procedure consists of the following actions:

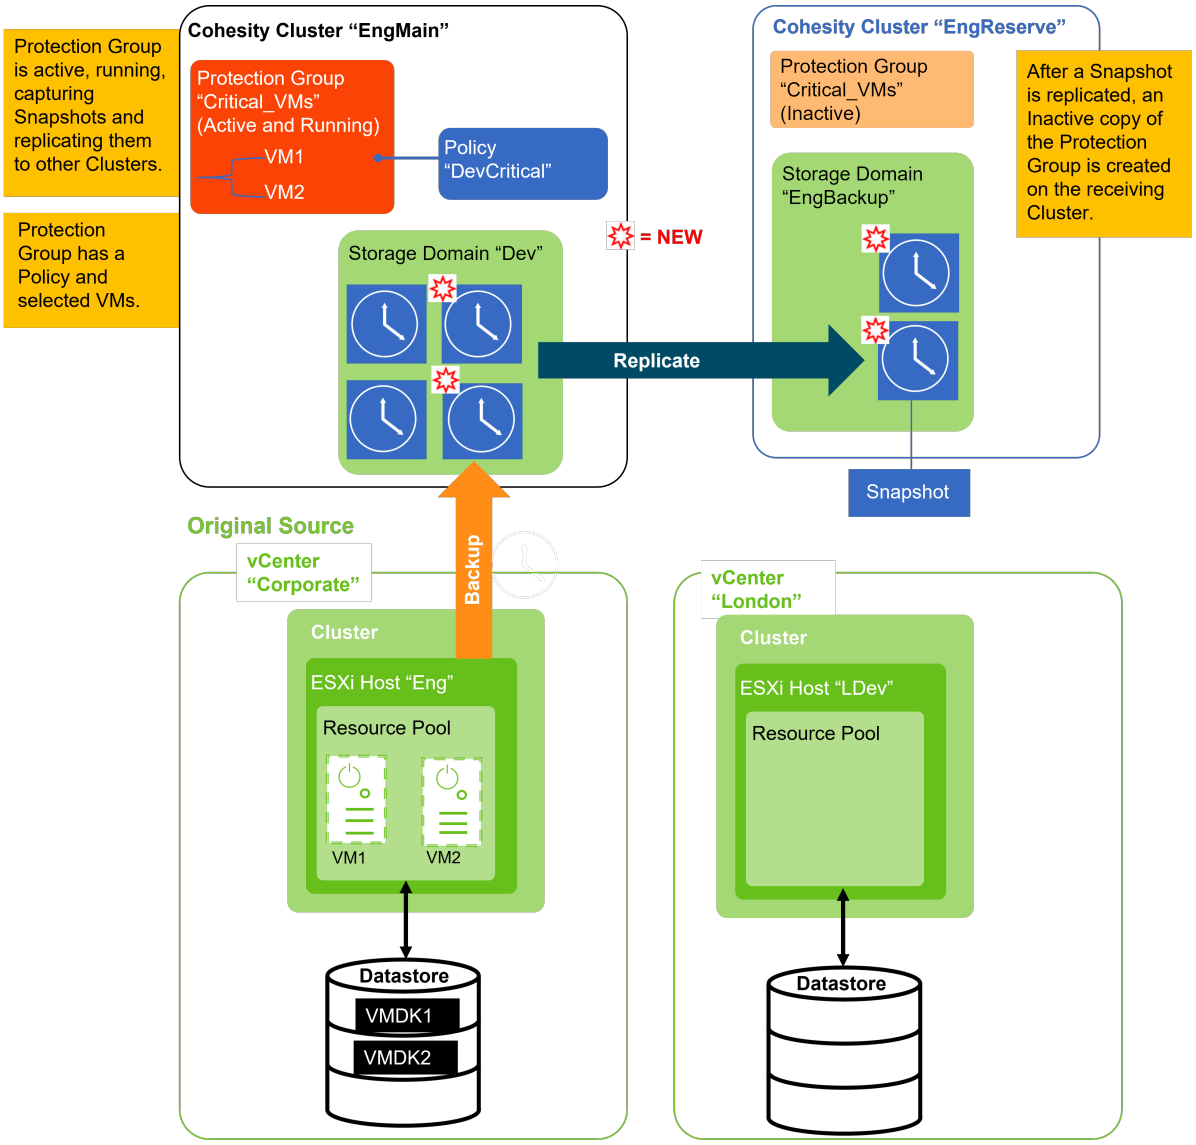
1. Active Protection Group Replicating to Remote Cohesity cluster. Protection Group on a Cohesity cluster is actively capturing Snapshots of VMs and replicating them to a remote Cohesity cluster. After the first Snapshot is replicated, an Inactive copy of the Job is also created on the remote Cohesity cluster.
2. Failover from Replicated Copies. Disaster strikes and you must recover from the replicated copies on the remote Cohesity cluster that received the Snapshots. This Failover activates the Job on the receiving (remote) Cohesity cluster. However, the Job is not running.
3. Deactivate Original VM Protection Group. If possible, deactivate the original Job on the Cohesity cluster that originally captured the Snapshots.
4. Restore Activated Protection Group. You can restore the state of the activated Job to running, by assigning a new Policy to the Job and selecting Objects (VMs) to back up.

Active Protection Group Replicating to Remote Cohesity cluster

A Protection Group on a Cohesity cluster is actively capturing Snapshots and replicating them to other remote Cohesity clusters. The Protection Group specifies Objects (such as VMs) to be backed up, replicated or archived. The Policy used by the Protection Group determines the protection schedule, the replication schedule and the archive schedule. The protection schedule determines when Snapshots of the Objects are captured. The replication schedule determines when the Snapshots are replicated to other remote Cohesity clusters. The backup Snapshots of the specified Objects are captured and saved on

a Storage Domain in the capturing Cohesity cluster as represented by the "Back Up" orange arrow in the figure below. The specified Snapshots are replicated from the Storage Domain in the capturing Cohesity cluster ("EngMain" below) to the Storage Domain in the remote Cohesity cluster ("EngReserve" below) as represented by the "Replicate" purple arrow in the figure below. After the first Snapshot is replicated, an Inactive copy of the Protection Group is created on the remote Cohesity cluster.

The example below shows the deactivation of a Protection Group protecting VMs. Deactivating a Protection Group protecting SQL Servers is similar but not all details are the same. For example, the transaction logs are not described or pictured.



Next learn about Failover from Replicated Copies.

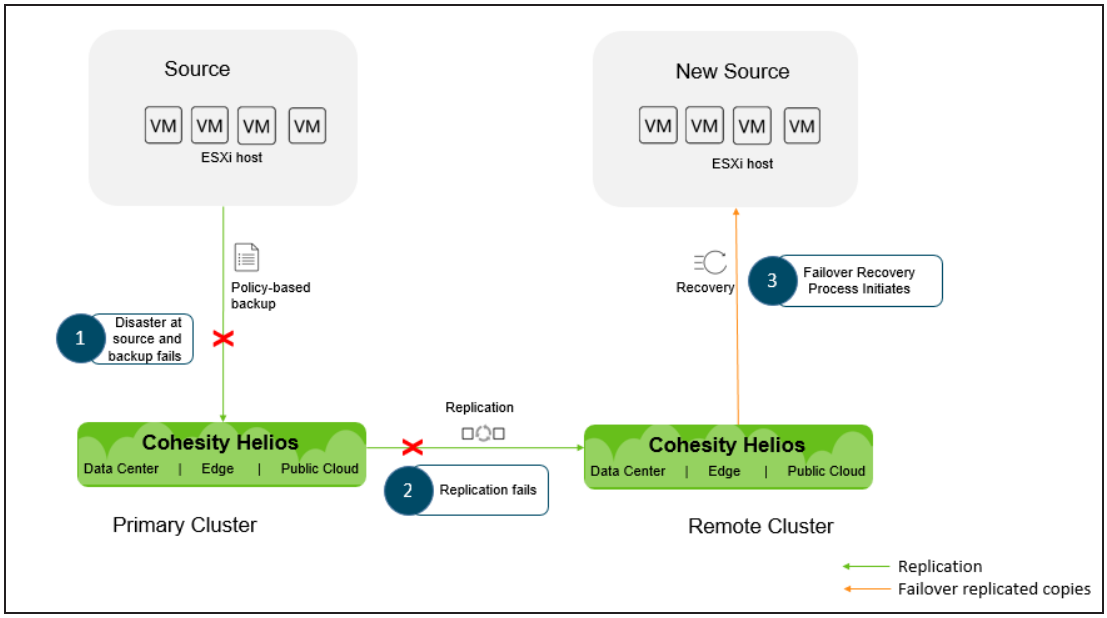
Failover from Replicated Copies

A disaster strikes the Source or there is a planned maintenance outage of the Source. The Cohesity cluster or the Source may be down or not available. From the Cohesity Dashboard, start the Failover procedure. For detailed instructions, see Failover a Protection Group. The example below shows the Failover of a task protecting VMs. Failover of a task protecting SQL Servers has transaction logs that are not pictured.

> **Note:** When you create a Protection Group on a Cohesity cluster with a replication schedule after the first snapshot is replicated, a Failover Ready copy of the Protection Group is created on the remote Cohesity cluster that is receiving the snapshot. For more information on Failover Ready, see About Failover Ready. You can failover the Protection Group of VMs. You cannot failover the Protection Group of Views or SQL Servers. You can, however, clone replicated Views and restore SQL Servers. For more information, see Failover a Protection Group.

During Failover, the following actions occur:

1. **Disaster at Source** - On the primary Cohesity cluster, the backup job fails to capture the snapshots of the source.
2. **Replication Fails** - As the source is down or unreachable, the replication job fails to replicate the snapshots onto the remote Cohesity cluster. The Failover Ready for VMs on the remote Cohesity cluster is activated and causes the rejection of the incoming replicated snapshots created by the associated job on the primary Cohesity cluster.
3. **Failover VMs** - You are prompted to optionally recover the VMs from the replicated snapshots on the remote Cohesity cluster to a new source.



Deactivate Original VM Protection Group

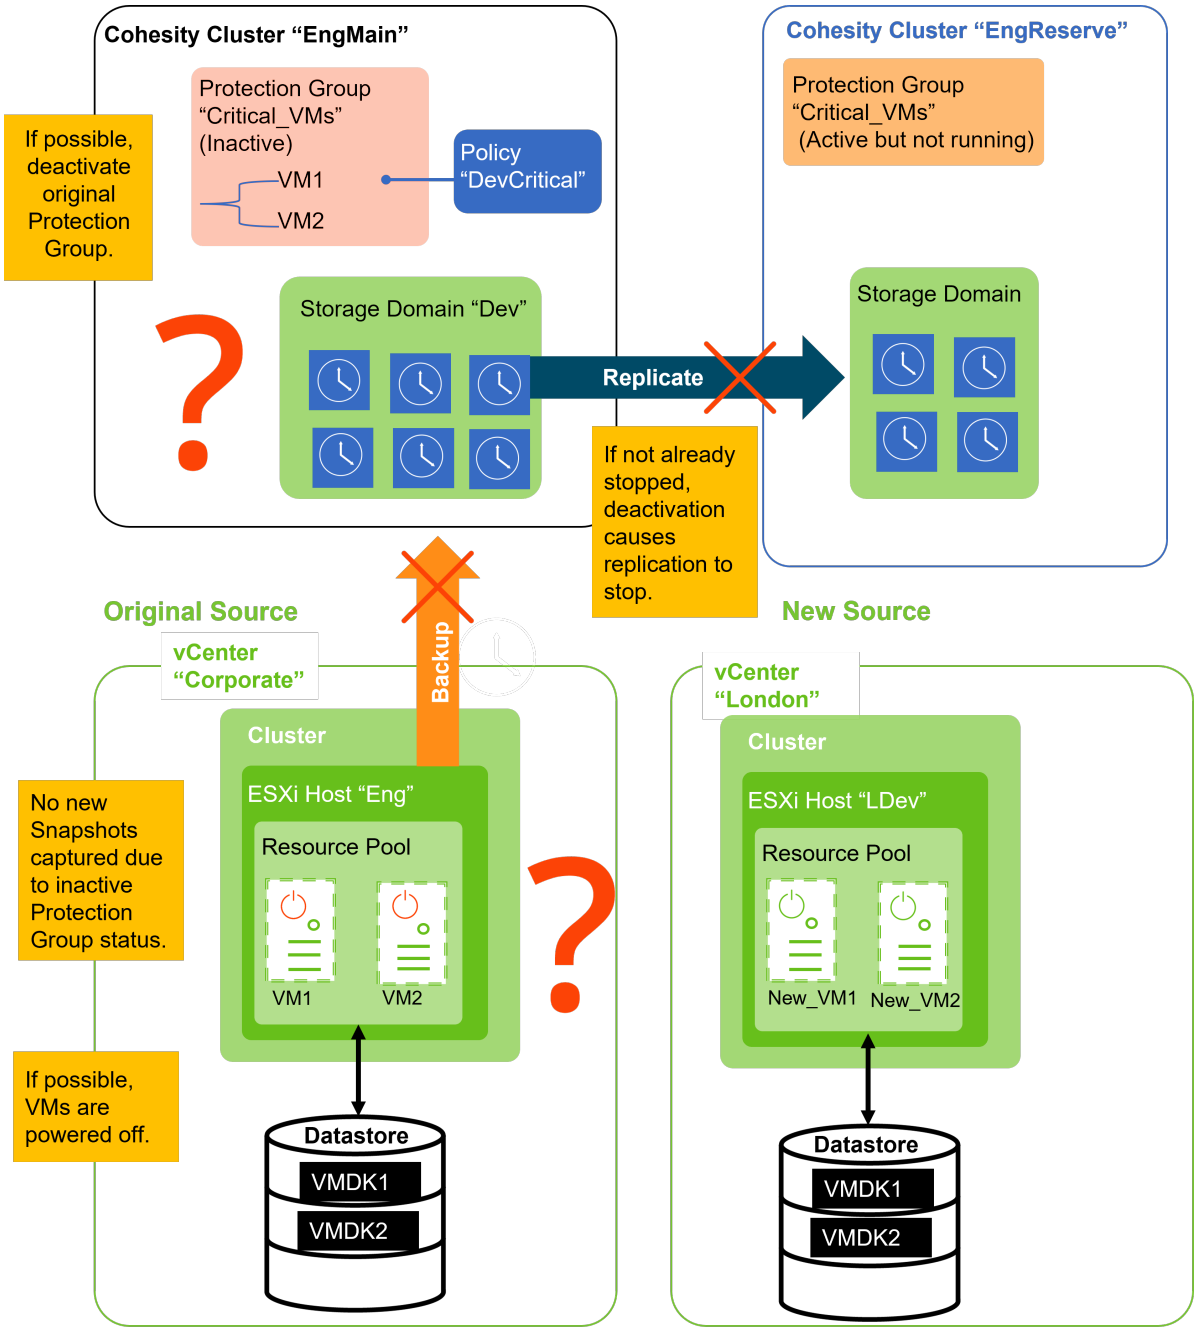
Only Protection Groups that are protecting VMs can be deactivated. Protection Groups that are protecting a view cannot be deactivated.

> **Note:** If possible, deactivate the original Protection Group on the original capturing Cohesity cluster. If the original Cohesity cluster that captured the Snapshots is down or unreachable, you may be unable to deactivate the Protection Group.

The example below shows the deactivation of a Protection Group protecting VMs. Deactivating a Protection Group protecting SQL Servers is similar but not all details are the same. For example, the transaction logs are not described or pictured.

During deactivation, the following actions occur:

1. Snapshots are no longer captured by the original Protection Group on the original capturing Cohesity cluster. However, the existing snapshots captured by the Protection Group remain in the storage domain. They are not deleted.
2. Snapshots created by the Protection Group are no longer replicated to the receiving (remote) Cohesity cluster. (If you have already initiated the failover procedure, the replication has already stopped.)
3. You can optionally choose that the VMs on the original source be powered off. The VMs and the VM files, however, are not deleted. (The Cohesity cluster may be unable to power off the VMs if the original source is down or unreachable.)



To deactivate the original Protection Group:

1. Log in to the Cohesity cluster where the original Protection Group was running.
2. Navigate to **Data Protection > Protection**.
3. Find the original Protection Group in the list, click on the actions menu ⋮ and select **Deactivate**.
4. Click **Deactivate and Power off VMs**, or click **Deactivate Only** if you do not want

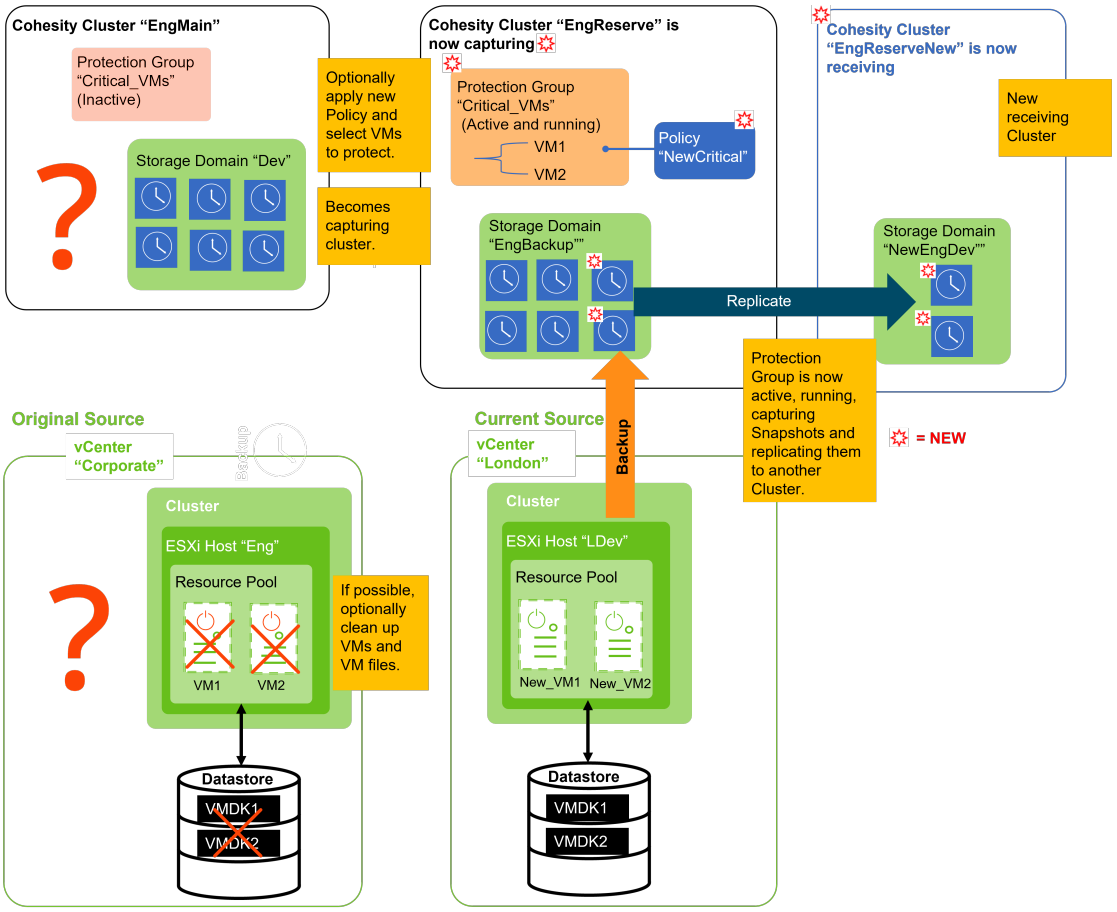
to power off the VMs.

5. Optionally delete the VMs and VM files using the VMware vSphere client.

Restore Activated Protection Group

You can restore the activated Protection Group to a running state by assigning a new policy to the Protection Group and selecting Objects (VMs) to back up. The original receiving (remote) Cohesity cluster becomes the new capturing Cohesity cluster. If the new policy defines a replication schedule, the new capturing Cohesity cluster starts replicating the snapshots to a new receiving (remote) cluster as shown in the following figure. If the original Source is still up, you can also optionally clean up the old VM files and VMs. For detailed instructions, see Restore VM Protection Group to Running.

The example below shows restoring an activated Protection Group protecting VMs. Restoring an activated Protection Group protecting SQL Servers is similar but not all details are the same, for example the transaction logs are not described or pictured.



Cascaded Replication, Archival, and Vaulting Policy

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

By default, Cohesity supports site-to-site replication of the Protection Groups, which includes objects such as databases, physical servers, VMs, and Cohesity Views. Cohesity now supports Cascaded Replication. You can use this feature to not only replicate your Protection Groups from the source to the target cluster, but also from the target cluster to another cluster. Also, protection objects can also be archived from any of these targets.

Prerequisites

Make sure the following prerequisites are met before creating a cascaded replication policy:

- Install Python on the Virtual machine on the cluster with the following modules:
  - `argparse`
  - `ast`
  - `copy`
  - `requests`
  - `logging`
  - `kson`
  - `sys`
  - `os`
  - `csv`
  - `time`
  - `re`
  - `datetime`
  - `subprocess`
  - `urllib3`

    > **Note:** Python 3.10 must have all the modules except for `requests`.

    Install the unavailable modules using the following command:

    ```
    pip install <modulename>
    ```

    Example pip command:

```
pip install request
```

For more information, see How to install pip on windows.

- Storage Domains of the source cluster and the target cluster must be paired.
- The Cohesity cluster version must be 6.8.1 and above.
- Download the **manage_cascaded_policy.py** and sample inputs file here.

Before you Begin

Cohesity provides the following files to create a cascaded replication policy:

- **manage_cascaded_policy.py**: The `manage_cascaded_policy.py` file contains the code and is used as the source file to create a cascaded replication policy. For more information, see Create a Cascaded Replication policy.

  > **Warning:** Do not edit the `manage_cascaded_policy.py` file.

- **user_friendly_policy.json**: The `user_friendly_policy.json` file contains the policy name, IP address, replication topology and other information required for the cascaded replication and archival.

  Topology is the connection between two nodes in a network and it represents the replication happening from the source cluster to the target cluster.

  In topology, where replication must be done from cluster A > B > C. While providing information for cluster A, mention the immediate cluster B and not C.

> **Note:** If you are creating a new `user_friendly_policy.json` file, pass the file path as `--user_friendly_json_file_path=<PATH>` while executing the `manage_cascaded_policy.py` script. By default, the `user_friendly_policy.json` file is in the same directory as the `manage_cascaded_policy.py` file.

Use the following format to create or modify the `user_friendly_policy.json` file.

Here is an example of the `user_friendly_policy.json` to create a cascaded policy named 'sample_policy_name' and the topology is A > B > C for replication where C is 'Sample_target_2' for archival.

The IP address should be in the following format:

<xxx.xxx.xxx.xxx>

- **log_in_credentials.json**: The `log_in_credentials.json` file contains the credentials of the IPs provided in the `user_friendly_policy.json` file. Provide the login credentials of the source and target clusters in the format given in the .json file.

Note:

- If you are creating a new `log_in_credentials.json` file, pass the file path as `--log_in_credentials_file_path=<PATH>` while executing the `manage_cascaded_policy.py` script . By default, the `log_in_credentials.json` file is in the same directory as the `manage_cascaded_policy.py` file.
- The login credentials are required only while creating the cascaded policy. The credential file can be deleted once the policy is created.

Supported Parameters

Parameters	Default	Description
`-m, --mode`		Mode of script execution. (generate-only-iris-json/ create-policy-from-user-friendly-json/ create-policy-from-iris-json)
`-t/ --target`		Specify the source cluster to create the policy. This is required while executing the script in the `create-policy-from-iris-json` mode.
`-u/ --username`	'admin'	Specify the generic username of the Cohesity cluster. You can also provide unique usernames in the `log-in_credentials.json` file.
`-p/ --password`	'Cohe$1ty'	Specify the generic password of the Cohesity cluster. You can also provide unique usernames in the `log-in_credentials.json` file.
`-bkp_skd_unit/ --backup_run_schedule_unit`	'Hours'	Period for scheduling protection runs [Hours, Days, Weeks, Months].
`-bkp_skd_freq/ --backup_run_schedule_frequency`	1	Frequency to perform the backup.

Parameters	Default	Description
`-bkp_ret_unit/ --backup_retention_unit`	'days'	Retention period for the protection Runs [Days, Weeks, Months, Years].
`-bkp_ret_freq/ --backup_retention_frequency`	28	Timeframe to retain the protection Runs.
`-rep_ret_unit/ --replication_retention_unit`	'days'	Retention period for the replication runs [Days, Weeks, Months, Years].
`-rep_ret_freq/ --replication_retention_frequency`	14	Timeframe to retain the replication runs.
`-arc_ret_unit/ --archival_retention_unit`	'days'	Retention period for the archival runs [Days, Weeks, Months, Years]
`-arc_ret_freq/ --archival_retention_frequency`	14	Timeframe to retain the archival runs.
`-path/ --iris_json_path`	`cascaded_protection_policy.json`	Specify the path of the cascaded policy creation request payload json file. This is required while executing the script in `create-policy-from-iris-json` mode.
`-auth_file_path/ --log_in_credentials_file_path`	`log_in_credentials.json`	Specify the path of the login credentials json file. The users are expected to provide the credentials in the `log-in_credentials.json` file, or pass the appropriate file path with the same format as the `log-in_credentials.json` file.

Parameters	Default	Description
`-user_json/ --user_friendly_json_file_path`	`user_friendly_policy.json`	Specify the path of the user-friendly json file. The users are expected to make the required changes in the `user_friendly_policy.json` or pass the appropriate file path with the same format as the `user_friendly_policy.json` file.
`-output_path/ --cascaded_policy_path`	`cascaded_protection_policy.json`	Specify the path of the generated `cascaded_protection_policy json` file. By default, the generated json file is saved as `cascaded_protection_policy.json`.

Manage Cascaded Replication Policy

You can create and edit a cascaded replication and archival policy through script only.

Create a Cascaded Replication policy

You can create a cascaded replication policy using any of the following methods.

Method 1

Generate a policy json file that can be used by the Cohesity Platform to create a cascaded protection policy.

1. Open the terminal (python must be accessible from this terminal) on the Virtual machine or the cluster .
2. Run the following command to create the `cascaded_protection_policy.json` file and click **Enter**:

   ```
   python ./manage_cascaded_policy.py --mode=generate-only-iris-json
   ```

   If the `user_friendly_policy.json` file and the `log_in_credentials.json` file are in different folders or the name of the `log_in_credentials.json` file is different from the default name, add the path of the `user_friendly_policy.json` and the `log_in_credentials.json` file along with the python command.

   ```
   --user_friendly_json_file_path=<json file path> --log_in_credentials_file_path=<log in file path>
   ```

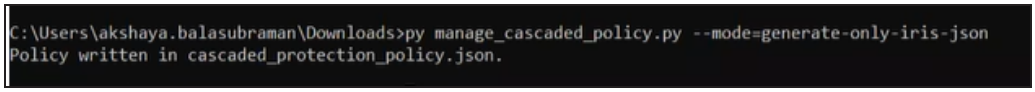
   If you want the `cascaded_protection_policy.json` file to be created in a different folder, add the following command along with the python command:

```
--cascaded_policy_path=<path_where_you_want_to_save_cascaded_policy>
```

If an error '**Can't open file <path of the manage_cascaded_policy.py file>: No such file or directory**', is displayed, run the following command and click **Enter**.

```
cd <path of the manage_cascaded_policy.py file>
```

On successful creation of the `cascaded_protection_policy.json`, the following message appears.



3. To create a policy in the Cohesity cluster using the `cascaded_protection_policy.json` file, run the following command and click **Enter**:

   ```
   python ./manage_cascaded_policy.py --mode=create-policy-from-iris-json
   --target=<source-cluster-ip>
   ```

   where *iris json* is the created cascaded replication policy.

   If the json file containing the cascaded replication policy is in a different folder, add the following along with the above python command.

   ```
   --iris_json_path=<path-to- iris-json>
   ```

Here is an example of the generated `cascaded_protection_policy.json` file.

The Cascaded replication policy is now created in the Cohesity Platform and you can view the policy by navigating to **Data Protection** > **Policies**.

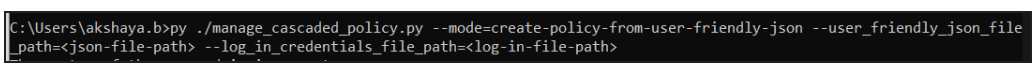
Method 2

1. Open the terminal on the Virtual machine or the cluster and to create a policy using the `user_friendly_policy.json` file, run the following command and click **Enter**:

   ```
   python ./manage_cascaded_policy.py --mode=create-policy-from-user-
   friendly-json
   ```

   If the `user_friendly_policy.json` file and the `log_in_credentials.json` file are in different folders, run the following commands along with the command above.

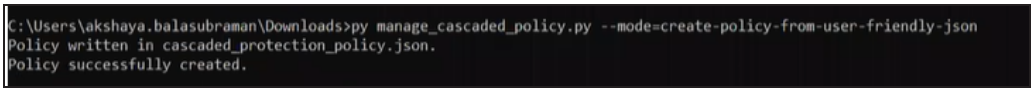
   ```
   --user_friendly_json_file_path=<json file path> --log_in_credentials_
   file_path=<log in file path>
   ```



If an error '**Can't open file <path of the manage_cascaded_policy.py file>: No such file or directory**', is displayed, run the following command and click **Enter**.

```
cd <path of the manage_cascaded_policy.py file>
```

On successful creation of the `cascaded_protection_policy.json`, the following message appears.



The json file is created in the directory where the `manage_cascaded_policy.py` file resides and the policy is created in the Cohesity Platform.

2. To view the created policy, log in to the Cohesity cluster, navigate to **Data Protection** > **Policies**.

> **Note:** You cannot edit the created cascaded policy from the Cohesity Platform.

Edit the Cascaded Replication Policy

To edit the cascaded replication policy, you require the cascaded replication policy ID.

Use the following URL format to fetch the created cascaded policy id:

```
https://<cluster IP address>/siren/v1/remote?remoteUrl=http%3A%2F%2F<IP address>%3A20000%2Fpolicyz
```

Considerations

- Cohesity supports cascaded replication through scripts only. Ensure to provide accurate data for the replication to be successful.
- Create a cascaded replication policy which is non-cyclic. For example, replicating data from A to B to C is supported but Cohesity doesn't support the replication of data from A to B to C to A.
- CloudRetrieve is not intended to be used to recover data to the source or target Cohesity clusters. CloudRetrieve can be used to retrieve data to an alternate location.

Replication and Remote Access Setup

On the Remote Cohesity clusters page, you can configure replication and remote access to another Cohesity cluster:

- Replication automatically makes copies of snapshots captured by a Protection Group on one Cohesity cluster and copies them to a second Cohesity cluster.You must register the Cohesity clusters with each other and create at least one Storage Domain

pairing between the Cohesity clusters. You can optionally specify a replication schedule in a Policy. A single Cohesity cluster can act as both a local and remote Cohesity cluster. For more information, see About Replication.

- Remote access lets you set up multi-cluster access and manage remote Cohesity clusters from the local Cohesity cluster. The Cohesity clusters must be the same version (6.0 or later). Once you add a remote Cohesity cluster to the local Cohesity cluster, you can switch to the remote Cohesity cluster by selecting its name from the drop-down list on the top left of the Cohesity Dashboard. The drop-down is not displayed until you add at least one remote Cohesity cluster. You can also display the consolidated statistics for all the remote access Cohesity clusters by selecting **All Clusters Dashboard** from the drop-down.

Note that replication and remote access are independent of each other; you can enable either or both for a remote Cohesity cluster. One does not require the other.

From the Remote Cohesity cluster's Dashboard page, you can begin setting up replication and remote access by clicking **Register Remote Cluster**. For detailed instructions, see Create a Connection to the Remote Cohesity Cluster.

To configure the Cohesity cluster's 1G interface for remote replication, see Set Up the Secondary Interface for Replication.

Note the following about replication:

- For information about using replication between Cohesity clusters running different versions, see Replication Compatibility.

  For the latest notes about replication compatibility, prerequisites and limitations, see the *Release Notes*.
- If you have a Protection Group that is capturing and replicating Snapshots multiple times a day, Cohesity recommends configuring the replication schedule to copy Snapshots daily instead of replicating Snapshots after each protection run. If the replication schedule is too frequent, the replication may lag behind the capturing of Snapshots resulting in a backlog of replication tasks.
- If Snapshots of a VM are replicated to a remote Cluster and the VM is renamed in the vCenter Server, the Cohesity Dashboard on the remote Cluster displays the original VM name in the protection run Details page. However, you can search for new VM name while recovering or cloning and the search results display the new VM name. Replication is not affected by this issue.
- In production environments, Cohesity recommends not replicating from one single node Cohesity cluster Virtual Edition to another single node Cohesity cluster Virtual Edition. Cohesity recommends replicating from Cohesity cluster Virtual Editions to Cohesity clusters running directly on hardware.

Prerequisites:

- When registering a remote Cluster, log in to the local Cluster with a user in the default LOCAL domain that has an Admin Role such as the default `Admin` account. Do not use users or groups that were added to the Cohesity cluster for Active Directory principals to register a remote Cluster.
- Ensure that the required firewall ports (443, 11111, 20000, and 23335) are accessible for replication to a remote Cohesity cluster.

  > **Note:** If both the local and remote Cohesity clusters support TLS, port number 23335 is utilized for TLS communication during replication.

- Verify the IP reachability for both VIP and Node IPs between the Cohesity cluster capturing and replicating Snapshots and the Cohesity clusters receiving the replicated Snapshots.
- If the cluster replication is configured, verify that the network connectivity is functioning properly during the upgrade to ensure the cluster replication relationship is successfully upgraded to use AES-256-GCM for encryption.
- In a replication environment, if either the transmitting or receiving cluster is a multitenancy-enabled, both clusters must be running version 6.1 or later. Storage domain pairing must be set up on the source cluster. One or both clusters can be multitenancy-enabled.
- When replicating data between multitenancy-enabled Clusters, the same organization ID and matching storage domain(s) must exist on both the transmitting and receiving Clusters prior to running replication tasks.

  > **Note:** Organization IDs are case-sensitive.

Note the following about multi-cluster access:

- Both the local Cohesity cluster and the remote access Cohesity cluster must be running the same version (6.0 or later) of the Cohesity cluster software.
- On the local Cohesity cluster for which multi-Cluster access is configured, verify that firewall port 443 (TCP outbound) is open to all the remote access Cohesity clusters.
- If a Cohesity cluster is configured for multi-Cluster access and then the Cohesity cluster is re-imaged or re-installed, Cohesity recommends deleting and re-adding the remote access configurations to ensure that multi-Cluster access functions properly.

The columns on the Remote Cohesity clusters page are described below.

Column Name	Description / Action
Cluster Name	The name of the Cohesity cluster that will be accessed remotely and/or used to store replicated (copied) Snapshots. If the Cohesity cluster is auto-registered at the target, then the **Auto Registered** tag will be displayed next to the Cohesity cluster name. For more information, see Create a Connection to the Remote Cohesity Cluster.
Remote Access	Whether remote access has been configured for the Cohesity cluster.
Replicate	Whether replication has been configured for the Cohesity cluster. • **Yes** indicates replication is enabled and at least one Storage Domain pairing between the Cohesity clusters is configured. • **No** indicates replication might be enabled, but there are no Storage Domain pairings between the Cohesity clusters.
Actions	To manage a remote Cohesity cluster, select one of the following options: • **Edit** ( )–Change the connection settings for the remote Cohesity cluster. Follow the instructions provided in Create a Connection to the Remote Cohesity Cluster. • **Delete** ( )–Delete the connection between the local and remote Cohesity cluster. When you delete a connection: ◦ If replication was configured, all Storage Domains Pairings in this connection are deleted. In addition, any Replication Tasks created by Protection Groups that are using this connection will fail and Snapshots will not be copied to the Storage Domains on the remote Cohesity cluster. ◦ If remote access was configured, the remote Cohesity cluster cannot be managed from the local Cohesity cluster.

Create a Connection to the Remote Cohesity Cluster

If you are setting up replication on the Cohesity cluster that contains the original snapshots to replicate, you must register the connection to the remote Cohesity cluster that will store the replicated snapshots. The capturing (local) Cohesity cluster captures the snapshots and replicates them to the remote Cohesity cluster.

> **Note:** A remote cluster is reachable by the source cluster only after the registration is complete because the firewall ports on the remote cluster are open after the registration.

To register a connection to a remote Cohesity cluster for replication and remote access:

1. Log in to the Cohesity cluster on which the original snapshots are stored.
2. Navigate to **Infrastructure > Remote Clusters**.
3. On the **Remote Clusters** page, click **Register Remote Cluster**.

   The **Register Remote Cluster** dialog is displayed.
4. **VIP or Node IP Addresses**—Specify one of the following:
   - One or more Virtual IP (VIP) addresses of the remote Cohesity cluster. Cohesity recommends specifying VIPs because of their ability to failover to other nodes in the Cohesity cluster if a node is down or unreachable.
   - One or more node IP addresses of the remote Cohesity cluster.

     If **All Cluster Node IPs are Reachable** is enabled for replication, a single node is specified in this field and the primary Cohesity cluster can establish an initial connection to the specified remote node, and the Cohesity cluster distributes the network traffic to other nodes in the remote Cohesity cluster. Cohesity recommends specifying VIPs. However, if you specify node IP addresses, Cohesity recommends specifying multiple node IP addresses. By specifying multiple node IP addresses, if the network traffic cannot reach a node, the Cohesity cluster can try a different node to establish the initial connection.

     If network traffic is restricted in your environment, specify the VIP or node IP addresses of the Cohesity cluster that are configured to receive network traffic in your environment and turn off the **All Cluster Node IPs are Reachable** toggle.

     > **Note:** To add more IP addresses after the remote connection is configured, edit the remote connection, click **Change**, enter the addresses in the **VIP or Node IP Addresses** field, and click **Connect** to verify connectivity to the addresses.
5. **Username**—Specify a local Cohesity user.
   - For remote access, Cohesity recommends you specify an admin user. Ensure you disable the MFA for this user.

- For replication, Cohesity recommends you specify a local user with only the **Replication** role on the remote Cohesity cluster. Ensure you disable the MFA for this user. For more information see Disable MFA for Local Users.

  > **Note:**
  > - The local user with only the **Replication** role on the remote Cohesity cluster does not have access to the Cohesity UI and can only perform replication.
  > - The audit log records the user specified while setting up the remote Cohesity cluster and not the user logged in to the remote Cohesity cluster. All the actions done on a remote Cohesity cluster are done on behalf of the remote user configured while setting up the remote Cohesity cluster.

6. **Password**—Specify the password of the user specified.

   > **Note:** The password must adhere to the ISO-8859-1 character set; otherwise, the cluster registration will fail.

7. Select **Interface Group**—Select one of the following:
   - Select **Automatically** if you want the Cohesity cluster to select the interface group.
   - Select **Manually** to select the associated interface group from the dropdown list.
8. Click **Continue** to specify the cluster options.

   The cluster connection status is displayed.
9. Turn on the **Remote Access** toggle to manage the remote Cohesity cluster from the Cohesity cluster you are currently using. Remote access is not required for replication. After remote access is enabled, you can select the remote Cohesity cluster name from the dropdown in the top left of the Cohesity cluster.
10. **Replication**—Starting from the 6.8 release, replication is enabled by default. Configure replication settings to the remote Cohesity cluster.
11. **Pair Storage Domains for Replication**—Select the storage domains:

    > **Note:** The paired storage domains must be associated with the same organization ID on both clusters.

a. Select a local storage domain. This storage domain contains the original snapshots that will be replicated.

> **Note:** You cannot pair multiple storage domains on one Cohesity cluster to the same storage domain on the other Cohesity cluster. You cannot pair a storage domain to two different storage domains on the same remote cluster. You can pair a storage domain to two different storage domains if they are in different remote clusters. For more information, see Pair Storage Domains for Replication.

b. Select a remote storage domain. This storage domain is where the copies of the replicated snapshots are stored.

12. Outbound compression is enabled by default. Cohesity recommends keeping this option enabled so that this Cohesity cluster can compress the replication data before sending it to another Cohesity cluster.
13. **All Cluster Node IPs are Reachable**—Turn on the toggle if traffic can be distributed to all nodes. Turn off if your network environment requires restricting network traffic to the subset of IP addresses listed in the **Node IP Address** field. For example, if your environment has a firewall that is limiting the network traffic to the remote Cohesity cluster and if **All Cluster Node IPs are Reachable** is enabled, the Cohesity cluster automatically distributes the network traffic to other nodes in the remote Cohesity cluster.

> **Note:** If there is Network Address Translation (NAT) between two clusters, ensure that the **All Cluster Node IPs are Reachable** option is disabled. This prevents communication issues due to translated IP addresses that may not be directly routable across the clusters.

14. Turn on the **Encryption** toggle to encrypt the replication data generated by this Cohesity cluster. Click **Generate New Key**. The encryption key is displayed. The Cohesity cluster that is receiving encrypted data must enable encryption and specify the same encryption key as the Cohesity cluster that sent the replication data. Copy the encryption key to the clipboard, so you can paste it while creating the connection from the capturing Cohesity cluster back to the remote Cohesity cluster as described in Create Connection Back to the Capturing Cohesity cluster.
15. Turn on the **Throttle** toggle to set a replication data transfer rate limit from this Cohesity cluster to another Cohesity cluster. Specify the data rate in Megabits per second. For this connection, this value limits the data transfer rate when copying replication data such as snapshots from this Cohesity cluster to another Cohesity

cluster.

16. Turn on the **Quiet Times and Throttle Overrides** toggle to specify one or more replication override windows. These windows override the setting in the **Data Transfer Rate Limit** field during the time period specified for the window.
    - You can optionally change the time zone that applies to all the override windows specified for the connection between the local Cohesity cluster and the remote Cohesity cluster.
    - Select the days of the week when the override window must be applied.
    - Specify a time period in a day when the override window must be applied.
    - Specify a type for the window:
        - **Quiet Time**—A window when data is not replicated from the local Cohesity cluster to a remote cluster. This value overrides the **Data Transfer Rate Limit** value specified.
        - **Throttle**—A window when this data transfer rate overrides the **Data Transfer Rate Limit** value specified. This window sets the maximum data transfer rate between the local Cohesity cluster and the remote Cohesity cluster during the specified time period.
    - If you selected **Throttle**, enter the replication maximum data transfer rate for this window in Megabits per second. For this connection, this value limits the rate that replication data such as snapshots are copied from the local Cohesity cluster to the remote Cohesity cluster during this window.

    > **Note:** If overlapping windows are specified, the latest one that was created takes precedence. For example, if you first create a quiet time window from Monday 9 AM to 10 PM and then a throttle window from 5 PM to 12 PM with a data rate of 100 megabits per second, from 5 PM to 12 PM the data rate is limited to 100 megabits per second.

17. Click **Continue** to view the summary.
18. Verify the details and click **Register** to register the remote Cohesity cluster.

> **Note:** If you configured replication, ensure that you set up replication on the remote Cohesity cluster. For more information, see Create Connection Back to the Capturing Cohesity cluster.

Edit Remote Cohesity Cluster Details

To edit a remote Cohesity cluster connection:

1. Navigate to **Infrastructure > Remote Clusters**.
2. On the **Remote Clusters** page, hover over the remote cluster that you want to edit and click the edit icon.

   The **Edit Remote Cluster** dialog is displayed.
3. Modify the remote cluster details as needed and click **Save**.

Delete the Remote Cohesity Cluster Connection

To delete a remote Cohesity cluster connection:

1. Navigate to **Infrastructure > Remote Clusters**.
2. On the **Remote Clusters** page, hover over the remote cluster that you want to delete and click the delete icon.
3. Click **Delete** to confirm.

   After you delete, all storage domain pairings in this connection are deleted and any replication task using this connection fails.

Create Connection Back to the Capturing Cohesity cluster

On the remote Cohesity cluster that will store the replicated snapshots, you must register the Cohesity cluster that is capturing the original snapshots. The capturing (local) Cohesity cluster captures the snapshots and replicates them to the remote Cohesity cluster.

To register a connection back to the Cohesity cluster that is capturing the original snapshots:

1. Log in to the Cohesity cluster that will store the replicated snapshots.
2. Navigate to **Infrastructure > Remote Clusters**.
3. On the **Remote Clusters** page, click **Register Remote Cluster**.

   The **Register Remote Cluster** dialog is displayed.

   > **Important:** In this procedure, you are logged in to the remote Cohesity cluster and registering the capturing Cohesity cluster. Specify the IP address and user credentials of the local Cohesity cluster.
4. In the **VIP or Node IP Addresses** field, specify one of the following:
   - One or more Virtual IP (VIP) addresses of the local Cohesity cluster. Cohesity recommends specifying VIPs because of their ability to failover to other nodes in the Cohesity cluster if a node is down or unreachable.
   - One or more node IP addresses of the capturing Cohesity cluster. If **Distribute Load** is enabled for replication, a single node is specified in this field and this

Cohesity cluster can establish an initial connection to the specified primary node, and the Cohesity cluster distributes the network traffic to other nodes in the capturing Cohesity cluster. Cohesity recommends specifying VIPs. However, if you specify node IP addresses, Cohesity recommends specifying multiple node IP addresses. By specifying multiple node IP addresses, if the network traffic cannot reach a node, the Cohesity cluster can try a different node to establish the initial connection.

If network traffic is restricted in your environment, specify the VIP or node IP addresses of the Cohesity cluster that are configured to receive network traffic in your environment and disable **Distribute Load**.

> **Note:** To add more IP addresses after the remote connection is configured, edit the remote connection, click **Change**, enter the addresses in the **VIP or Node IP Addresses** field, and click **Connect** to verify connectivity to the addresses.

5. **Username**—Specify a local Cohesity user.
   - For remote access, Cohesity recommends you specify an admin user.
   - For replication, Cohesity recommends you specify a local user with only the Replication role on the remote Cohesity cluster. Ensure you disable the MFA for this user. For replication, Cohesity recommends you specify a local user with only the **Replication** role on the remote Cohesity cluster. Ensure you disable the MFA for this user. For more information, see Disable MFA for Local Users.

   > **Note:**
   > - The local user with only the **Replication** role on the remote Cohesity cluster will not have access to the Cohesity UI and can only perform replication.
   > - The audit log records the user specified while setting up the remote Cohesity cluster and not the user logged in to the remote Cohesity cluster. All the actions done on a remote Cohesity cluster are done on behalf of the remote user configured while setting up the remote Cohesity cluster.

6. **Password**—Specify the password of the user specified.

   > **Note:** The password must adhere to the ISO-8859-1 character set; otherwise, the cluster registration will fail.

7. Click **Continue** to specify the cluster options.

   The cluster connection status is displayed.

8. Turn on the **Remote Access** toggle to manage the capturing Cohesity cluster from the remote Cohesity cluster. Users will be able to select the remote Cohesity cluster name from the drop-down in the top left of the Cohesity Dashboard.
9. **Replication**—Starting from the 6.8 release, replication is enabled by default. Configure replication settings to the remote Cohesity cluster.
10. **Pair Storage Domains for Replication**—The storage domain paring that was configured on the capturing Cohesity cluster is displayed. You can add additional parings as needed, but only one pairing is required. To add more pairings:
    a. Select a local storage domain. This storage domain contains the original snapshots that will be replicated.

    > **Note:** You cannot pair multiple storage domains on one Cohesity cluster to the same storage domain on the other Cohesity cluster. You cannot pair a storage domain to two different storage domains on the same remote cluster. You can pair a storage domain to two different storage domains if they are in different remote clusters. For more information, see Pair Storage Domains for Replication.

    b. Select a remote storage domain. This storage domain is where the copies of the replicated snapshots are stored.
11. Outbound compression is enabled by default. Cohesity recommends keeping this option enabled so that this Cohesity cluster can compress the replication data before sending it to another Cohesity cluster.
12. **Distribute Load**—Turn on the toggle if traffic can be distributed to all nodes. Turn off if your network environment requires restricting network traffic to the subset of IP addresses listed in the **Node IP Address** field. For example, if your environment has a firewall that is limiting the network traffic to the capturing Cohesity cluster and if **Distribute Load** is enabled, the Cohesity cluster automatically distributes the network traffic to other nodes in the capturing Cohesity cluster.
13. **Encryption**—If encryption was enabled on the capturing Cohesity cluster that is sending replication data to this remote Cohesity cluster, complete the following steps:
    a. Turn on the **Encryption** toggle.
    b. Paste the encryption key copied from the capturing Cohesity cluster. The Cohesity cluster that is receiving encrypted data must specify the same encryption key as the capturing Cohesity cluster that sends the replication data.

> **Note:** If you do not have the encryption key in your clipboard, log in to the capturing Cohesity cluster, select **Infrastructure > Remote Clusters**, select **View Details** ( ) and click **Copy Key to Clipboard**.

14. **Throttle:** Turn off if this Cohesity cluster is only receiving replicated data. If this Cohesity cluster is also copying replicated data, turn on the **Throttle** toggle to set a replication data transfer rate limit from this cluster to another cluster. Specify a data rate in Megabits per second. For this connection, this value limits the data transfer rate when copying replication data (such as snapshots) from this Cohesity cluster to another Cohesity cluster.
15. **Quiet Times and Throttle Overrides**—Turn off the toggle if this Cohesity cluster is only receiving replicated data. Turn on the **Quiet Times and Throttle Overrides** toggle to specify one or more replication override windows. These windows override the setting in the **Data Transfer Rate Limit** field during the time period specified for the window.
    - You can optionally change the time zone that applies to all the override windows specified for the connection between the local Cohesity cluster and the remote Cohesity cluster.
    - Select the days of the week when the override window must be applied.
    - Specify a time period in a day when the override window must be applied.
    - Specify a type for the window:
        - **Quiet Time**—A window when data is not replicated from the local Cohesity cluster to a remote cluster. This value overrides the **Data Transfer Rate Limit** value specified.
        - **Throttle**—A window when this data transfer rate overrides the **Data Transfer Rate Limit** value specified. This window sets the maximum data transfer rate between the local Cohesity cluster and the remote Cohesity cluster during the specified time period.
    - If you selected **Throttle**, enter the replication maximum data transfer rate for this window in Megabits per second. For this connection, this value limits the rate that replication data such as snapshots are copied from the local Cohesity cluster to the remote Cohesity cluster during this window.

> **Note:** If overlapping windows are specified, the latest one that was created takes precedence. For example, if you first create a quiet time window from Monday 9 AM to 10 PM and then a throttle window from 5 PM to 12 PM with a data rate of 100 megabits per second, from 5 PM to 12 PM the data rate is limited to 100 megabits per second.

16. Click **Continue** to view the summary.
17. Verify the details and click **Register** to register the capturing Cohesity cluster.

You can now add a replication schedule to a policy. For more information, see Create or Edit a Standard Policy.

About CloudRetrieve

CloudRetrieve provides the ability to download data that was archived from a Cohesity cluster to an alternate (non-original) Cohesity cluster. For example: You have Cohesity cluster A, which archives data to a cloud external target, but you want to download that archived data to Cohesity cluster B.

> **Note:** CloudRetrieve is not intended to be used to recover data to the original Cohesity cluster. To restore data to the original Cohesity cluster, see About Recovering VMs.

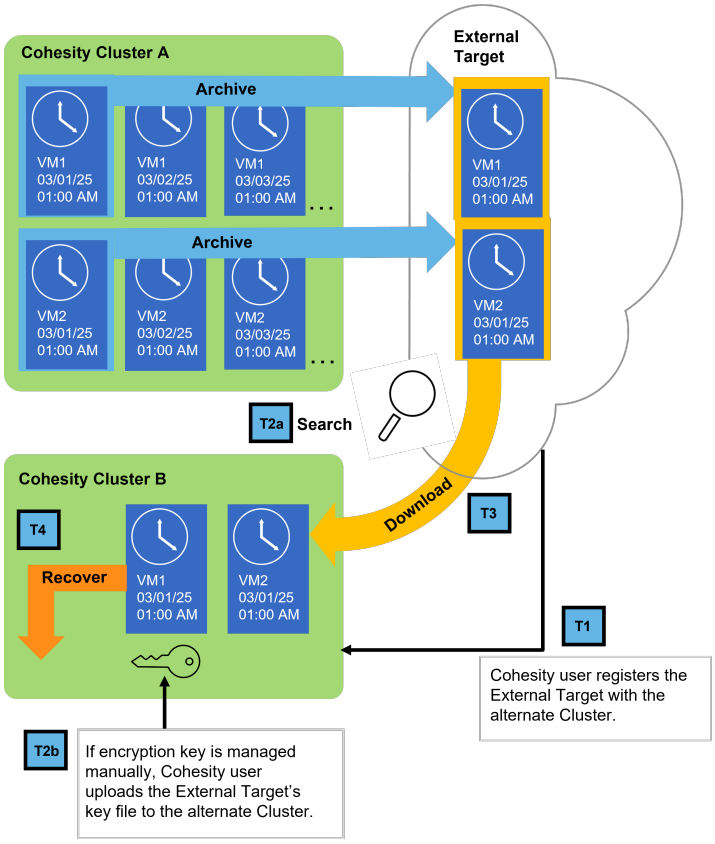
Download to an Alternate Cohesity cluster

The following example depicts one source Cohesity cluster archiving data to a cloud external target followed by an alternate Cohesity cluster retrieving the archived data from that external target. The action steps in the following procedure are represented in the figure below with blue numbered time squares:

.

1. Register the external target that contains the data you want to download to the alternate Cohesity cluster.
2. Submit a search for Protection Groups that contain the data you want to download from the cloud external target. The search may take a few hours to complete. If the job to be downloaded is from a particular Cohesity cluster, specify the job name and Cohesity cluster name to narrow the results.
3. If the external target's encryption key file is managed manually, upload the key file to the alternate Cohesity cluster before triggering the search. See Create a CloudRetrieve Search Task for more details.

4. Download a snapshot from any of the Protection Groups in the search results. You can also build a local index of Protection Groups that ran during a specified date range. Downloading can take a few hours to complete. See Create a CloudRetrieve Download Task for more details.
5. Recover or clone any downloaded objects using the Cohesity recovery or clone workflows. See CloudRetrieve Downloaded Protection Groups for more details.



Considerations

- It is recommended that the Cloud Retrieve cluster runs a newer software version than the source cluster. The version of archives performed increases across releases and the older clusters cannot retrieve newer versions.
- Cohesity recommends not registering the same AWS S3 bucket, Azure storage container, or GCP bucket more than once for CloudRetrieval, even if the storage class differs.

CloudRetrieve Searches

The Searches tab lists search tasks and their status. Click a search task name to set up a download task.

Create a CloudRetrieve Search Task

> **Note:** CloudRetrieve is not intended to be used to recover data to the original Cohesity cluster.

In this section you create a task to search for Cohesity clusters and Protection Groups that were archived to the selected external target. To learn more, see About CloudRetrieve.

Before you can submit a search, an external target must be registered. See Register an External Target.

Search Cohesity clusters and Protection Groups

1. Select an external target. You may need to register an external target if the one you want to search is not registered with the Cohesity cluster.
2. In the **Task Name** field, you can optionally change the default name for the task.
3. Change the **Date Range** by clicking the date range link (for example: 06/30/2017 - 07/06/2017), and adjusting the time period. A larger date range results in a longer search time. The default date range is one year.
4. Optionally provide a **Cohesity Cluster Name** to search for. This is the Cohesity cluster where the Protection Groups originated.
5. Optionally provide a **Protection Group Name** to search for.

   > **Important:** Wildcard characters (like '*') are NOT supported.

   > **Note:**
   > - If you enter search terms for both **Cohesity Cluster Name** and **Protection Group Name**, your search must find matches for the Protection Group within clusters that match.
   > - If your search is too narrow, try entering a search term for **Cohesity Cluster Name** or **Protection Group Name**, or leave one or both empty.

6. If the external target is protected by a manually managed key, click **Attach** to upload the encryption key file to the Cohesity cluster.
7. Click **Search**.

   The search can take up to several hours to complete.

> **Note:** The success of a CloudRetrieve search does not guarantee that the search found any matches. It only means that the search operation was completed successfully. If your search results are empty, broaden your search with partial names for the cluster and/or Protection Group, leave them blank, and/or extend the date range.

8. Go to searches on the CloudRetrieve page and click the name of the search task to create a download task. See Create a CloudRetrieve Download Task for more details.

Create a CloudRetrieve Download Task

In this section, you can create a task to download data from an external target. To learn more, see About CloudRetrieve.

Download Data

1. If desired, filter search results by Protection Group type or Cohesity cluster. You can also narrow results by searching for a Protection Group or Cohesity cluster.
2. Select the Protection Groups to download. Selecting the check box adjacent to Protection Group selects all filtered jobs.
3. For each selected Protection Group, you can edit download options by clicking Edit ( ). Or click **Edit Selected** to set download options for all selected Jobs together.

   Select the **Download Job Meta-Data** check box to fetch and index Job meta-data for the specified range. After the Protection Groups are indexed, they are listed as inactive Protection Groups on the Manage Protection Groups page. Jobs protecting VMs can be activated using the failover action. For more information, see Failover a Protection Group.

   Select the **Download Snapshot** check box to download the specified snapshot to the Cohesity cluster. Selecting a specific Snapshot is not available when editing multiple Protection Groups together (you clicked **Edit Selected**); the latest snapshot is always downloaded for these Protection Groups.

   > **Note:** In addition to the selected archive, a download fetches job meta-data for all archives that the currently selected archive depends on. This results in all the dependent protection runs displaying on the Job Details page. Additionally, selecting only a snapshot for download also downloads job meta-data.

4. Select or create a storage domain to contain the downloaded objects.

> **Note:** Selected archived Protection Groups that are linked to Protection Groups on this Cohesity cluster use the local Protection Group's storage domain for their download location. Selected archived Protection Groups without a known local Protection Group are downloaded to the selected storage domain.

5. Click **Download**.

   Downloads may take up to several hours to complete.

   (*Applies only for cloud archive incremental with periodic full*) Provisioned Capacity Units (PCU) are required for all file-level recoveries. Provisioned capacity ensures that your retrieval capacity for expedited retrievals is available when needed. Each unit of capacity guarantees that at least three expedited retrievals can be performed every five minutes and provides up to 150 MB/s of retrieval throughput.

   Glacier Expedited retrieval offers a significantly improved latency (1-5 minutes) over Standard/Bulk retrievals (3-12 hours). As part of this, AWS may fail expedited Glacier requests with a lack-of-resources response:

Option	Description	HTTP Status Code	Client
uri	Returned if there is insufficient capacity to process the expedited request. This error only applies to expedited retrievals and not to standard or bulk retrievals.	503 Service Unavailable	Server

   The Cohesity Bridge warning logs will return the following error when the cloud provider cannot process the expedited request.

```
curl_http_rpc_executor.cc:226] Response for the failed RPC: 9173 is
{"code":"InsufficientCapacityException","message":"There is
insufficient capacity to process this Expedited
request.","type":"Server"}
```

6. Go to Downloaded Jobs on the CloudRetrieve page and choose an action to perform from the actions menu.

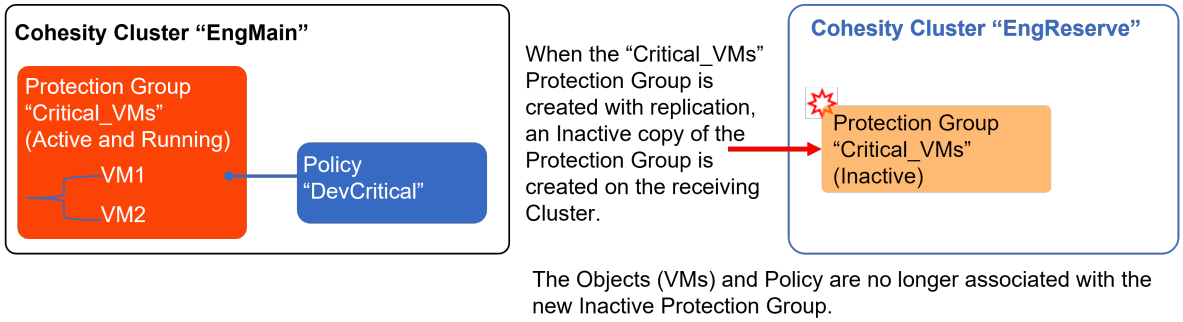
CloudRetrieve Downloaded Protection Groups

The Downloaded Job tab lists Protection Groups that were previously downloaded. Mouse over the actions menu and choose an action to perform.

About Failover Ready

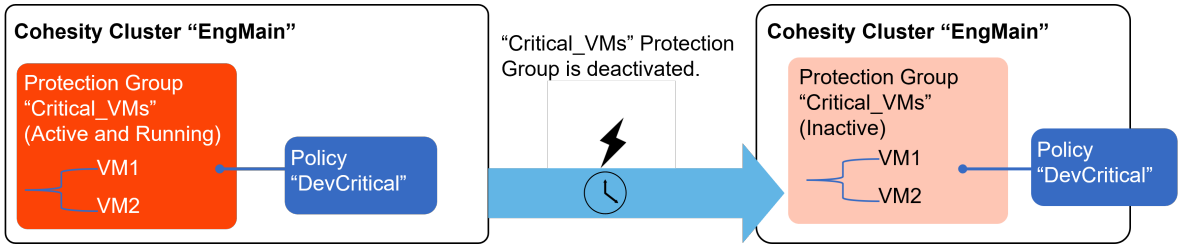
The state of a Protection Group protecting VMs can be "Failover Ready" for any of the following reasons:

- When you create a Protection Group on a Cohesity cluster with a replication schedule after the first snapshot is replicated, a Failover Ready copy of the Protection Group is created on the remote Cohesity cluster that is receiving the snapshot.



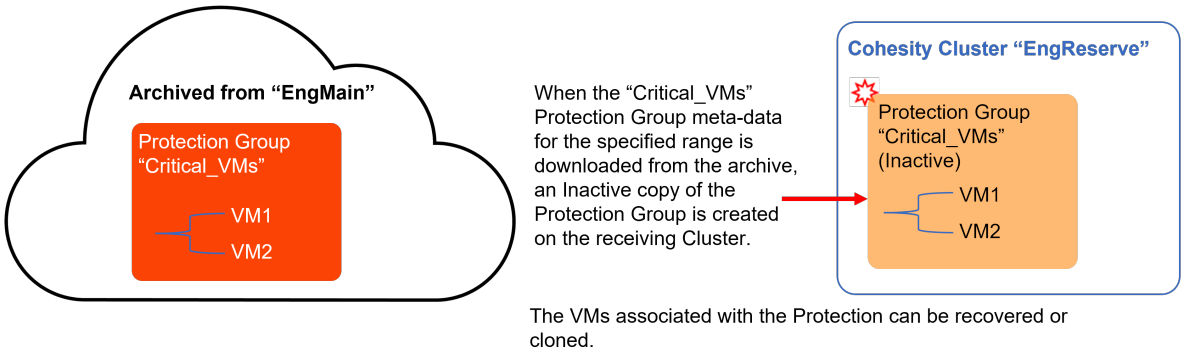
- When an active Protection Group is deactivated ( ), the Protection Group becomes Inactive and the selected VMs and Policy are still associated with the Protection Group.

> **Warning:** Cohesity recommends only deactivating a Protection Group as part of the failover process made possible by replication. Deactivate the original Protection Group running on the Cluster that captured the Snapshots before the failover and restoration of the Protection Group on the remote Cluster receiving the Snapshots. For more information, see Deactivate Original VM Protection Group and Failover from Replicated Copies.



- When the Protection Group meta-data is downloaded during CloudRetrieve, meta-data for the specified range is fetched and indexed. After the Protection Groups in this range are indexed, they are listed as Inactive Protection Groups on the Manage

Protection Groups page.



> **Note:** Only Protection Groups that are protecting VMs can be deactivated. Protection Groups that are protecting a view cannot be deactivated.

Disaster Recovery Using CloudSpin

You can use Cohesity's CloudSpin for disaster recovery. For more information, see Clone VMs to AWS Cloud Using CloudSpin.

Disaster Recovery Using CloudEdition

You can use Cohesity's Cloud Edition for disaster recovery. For more information, see Disaster Recovery of VMs Using AWS Cloud Edition.

Chapter 24: Manage Sources

From the Sources page, you can start the following actions:

- Add (register) a new source that contains objects to protect
- Back up objects in a source
- Download agents to physical or virtual servers.

The Sources page also provides an overview of the sources that have already been registered to the Cohesity cluster. Display modes can show VMs in a hierarchy or a flat list of all VMs.

Sources are organized by type and you can search on the source name. To get details and protection statistics about a source, click a source link in the source column of the table.

To register a new source on the Cohesity cluster, the host settings checker checks the health of different types of hosts. Host registration is not affected by the failure of any or all checks, but it is recommended that users address all error messages according to the instructions below.

Note the following about sources:

- The host settings checker is currently supported only for MS SQL hosts.
- For MS SQL FCI clusters, health checks are run only on the primary node. If a failover causes the primary node to change, health checks will begin to run on the new primary and stop on the previous node.
- If a Virtual Distributed Switch is created *after* the vCenter Cohesity user was created, then ensure that the Cohesity user has privileges to access the vCenter datacenter and its children objects (ESXi hosts, clusters, distributed switches, etc.). Without these privileges, some children ESXi hosts and clusters will not display in the object protection status hierarchy.

Manage Existing Sources Using Actions Menu Options

For a multitenancy Cohesity cluster, you can only modify the objects that belong to your organization.

- **Protect** ( )—Create a Protection Group using this source.
- **Edit** ( )—Configure the settings of a registered source. For detailed instructions, see Register or Edit a Hypervisor Source.
- **Unregister** ( )—Unregister this source. The Cohesity Dashboard prevents you from unregistering a source that is currently being used by a Protection Group.
- **Refresh** ( )—Manually force a refresh of the object hierarchy. The Cohesity cluster tracks all the objects (for example VMs, resource pools, datacenters, folders, and ESXi hosts) found within a source in an object hierarchy. This object hierarchy is automatically refreshed every four hours. If a new object such as a VM is added to the source, the Cohesity Dashboard does not list the new VM until the object hierarchy is refreshed, either manually or automatically after four hours.
- **Register Applications** —For more information, see the Manage Registered Applications Running on Virtual Servers section.
- **Deploy Cohesity Agent**—For more information, see the Manage Cohesity Installed Agents Running on Virtual Servers section.
- **Maintenance**—For more information, see the Maintenance Mode section.

Maintenance Mode

With your Cohesity cluster, you can easily enable Maintenance mode for registered sources. Enabling Maintenance mode for your Cohesity cluster's registered source will skip any scheduled activities or manually initiated operations, such as protection runs, restores, and upgrades. Ongoing backups will be canceled, but ongoing restores will continue without any interruptions.

> **Note:** You can only apply the maintenance mode at the level at which you registered it with the Cohesity cluster. For example, if you registered a vCenter, the entire vCenter will be put into maintenance mode. You won't be able to place individual ESXi hosts or VMs within that vCenter exclusively into maintenance mode.

To place a registered source in maintenance mode:

1. Navigate to **Data Protection** > **Sources**.
2. From the Action Menu (⋮) of the source, select **Maintenance**.

3. You have the option to initiate the maintenance mode immediately or later. To initiate the maintenance mode immediately:
   a. Select **Start Now**. The **Start Maintenance Now** dialog displays the list of Protection Groups available in that source.
   b. Review the list of Protection Groups and enter yes to confirm.
   c. Optionally, you can enter a note.
   d. Click **Confirm**.

   To schedule the maintenance mode:
   a. Select **Schedule**.
   b. On the **Schedule Maintenance** dialog, enter the start date and time and the end date and time.
   c. Optionally, you can enter a note.
   d. Click **Save**.

Register Applications Running on Virtual Servers

If a server is running MS SQL Server and/or MS Exchange, you can register these applications with the Cohesity cluster.

Navigate the hierarchy to the server, mouse over its actions menu and click **Register Applications** (+). See Set Up MS SQL on VMs as a VMware vCenter application with the Installed Agent and Register Exchange on a VM.

Manage Registered Applications Running on Virtual Servers

- **Edit Application Registration** ( )—Configure the settings of a registered application.
- **Unregister All Applications** ( )—Unregister all applications on the server.

Manage Cohesity Installed Agents Running on Virtual Servers

To upgrade the Cohesity agents on VMware, see Upgrade the Agent on VMware.

To upgrade Cohesity agents on Hyper-V, see Upgrade the Agent on SCVMM and Hyper-V Hosts.

To upgrade Cohesity agents on RHV, see Upgrade the Linux Agent.

Manage Existing Physical Servers Using the Actions Menu

For a multitenancy Cohesity cluster, you can only modify the objects that belong to your organization.

- **Edit Server** ( )—Configure the settings of a registered server. For detailed instructions, see Register or Edit a Physical Server.
- **Unregister Server** ( )—Unregister this server from the Cohesity cluster.
- **Refresh Server** ( )—Manually force a refresh of the object hierarchy.

  > **Note:** The refresh operation only collects information about the agent version, new objects, and deleted objects. No agent restart is initiated during this process

- **Register as MS SQL Server** ( )—If a physical server is running MS SQL, you can register it as MS SQL Server with the Cohesity cluster. Before registering, see Set Up MS SQL on Virtual or Physical Servers using the Agent or Set Up Microsoft SQL Server FCI.
- **Unregister MS SQL Server** ( )—If MS SQL Server is already registered with the Cohesity cluster, you can unregister it.
- **Upgrade Agent** ( )—Upgrade the Cohesity agent on the server if an upgrade is available. If an agent upgrade is requested while backup jobs or recover tasks are active, the upgrade starts after the jobs and tasks finish. This page also displays any agent upgrades that are in progress and if you must manually re-install an agent.

Health Check for SQL Sources

The health checks are run when a source is refreshed, automatically or manually. The current automatic source refresh interval is 8 hours.

Health Check Name	Error Message	Corrective Action
Cohesity Agent service **Description** Checks whether the cohesity agent service is running.	Error querying service status for Cohesity Agent Service.	1. Ensure that the Cohesity Agent is installed. 2. Provide local administrator rights to the CohesityAgent service.
	The service Cohesity Agent Service is not running. Current state: <current_state>	Ensure that the Cohesity Agent service is running. If yes, try restarting it.
SQL Server VSS Writer **Description** Checks whether the SQL Server VSS Writer service is running.	Error querying service status for SQL Server VSS Writer.	1. Ensure that the Cohesity Agent is installed. 2. Provide local administrator rights to the CohesityAgent service.
	The service SQL Server VSS Writer is not running. Current state: <current_state>	Ensure that the Cohesity Agent service is running. If yes, try restarting it.

Health Check Name	Error Message	Corrective Action
SQL Server (SQL2012), SQL Server (SQL2016), SQL Server (SQL2017) **Description** Checks if all SQL instances are running.	Error querying service status for <display name>.	1. Ensure that the Cohesity Agent is installed. 2. Provide local administrator rights to the Cohesity Agent service. 3. Ensure the SQL instance <display name> is correctly installed.
	Querying registry for SQL instance names failed.	Provide local administrator rights to the CohesityAgent service.
	Inactive SQL instances detected: <display names>	Start the SQL instances if required.

Health Check Name	Error Message	Corrective Action
SQL Server (SQL2012), SQL Server (SQL2016), SQL Server (SQL2017), SQL Server VSS Writer, Cohesity Agent Service **Description** Validates that the required permissions have been granted to the logons for the services being checked.	Querying registry for SQL instance names failed.	Provide local administrator rights to the CohesityAgent service.
	Error querying service status for <display name>	1. Ensure that the Cohesity Agent is installed. 2. Provide local administrator rights to the CohesityAgent service. 3. Ensure the SQL instance <display name> is correctly installed.
	The service <display name> is not using a local admin or service logon.	Provide either admin rights or a default system service account to the service login.
	The logon <logon name> for the service <display name> is not a sysadmin of the SQL instances(s) <SQL display name>.	Assign the logon the sysadmin role in the specified SQL Server instance.

Chapter 25: Manage Protection Groups

From the Protection page, you can start the backup process by clicking **Protect** in the upper right corner. You can also view protection group settings, run a protection group, edit protection group settings, delete a protection group, deactivate a protection group or failover a protection group using the icons listed in the actions column of the table. (See below for details.)

This page also provides the following information:

- Overview of the protection groups that are already created. You can filter these protection groups based on:
  - Groups
  - Group types
  - Policies
  - SLA
  - Status
  - Organizations
- The run status for all the protection groups in the Cohesity cluster that meet the specified filter criteria.

The columns for the table at the bottom of this page are described below.

Column Name	Description / Action

Group Name	Drill down on this link to get statistics about this Protection Group such as throughput, megabytes read, a list of job runs, job details and a job audit trail.
	You can view these details either in the details view or in calendar mode.
	• To view the details in the details view mode, click the icon on the right.
	• To view the details in calendar mode, click the icon displayed on the right corner of the page.
	  • You can view the status of the protection group based on the date you select from the calendar.
	  • If there is no protection group run scheduled on a day, then that day will be greyed out in the calendar.
	  • If there is a protection group run scheduled on a day, then that day will be highlighted in the calendar.
	  • If the scheduled protection group run fails, then the icon will be displayed against the scheduled day.

Organizations	Drill-down on this link to get details of the organization that is associated with the protection group.
Start time	The start time and date of the last run of this protection group.
Duration	The time duration taken to complete the last run of this protection group.
SLA	Reports the SLA status. –The last run of this Protection Group completed within the SLA time period specified for this protection group. –The last run of this Protection Group did not complete within the SLA time period specified for this protection group .

Column Name	Description / Action
Status	For the last run of this protection group, this column reports the current status: • **Succeeded**–The protection group run completed without error. • **Canceled**–A protection group run started and then was canceled in the Cohesity Dashboard The protection group run did not complete. • **Canceling**–In the Cohesity Dashboard, the cancel option was selected for the protection group run and the cluster is in the process of canceling the run but the run is not yet canceled. • **Failed**–The protection group run did not complete due to an error. •  –The protection group run is currently running but is not completed yet. Additional information about some protection run issues may be available here.

Cancel Replication and Archive Copy Tasks of a Protection Run

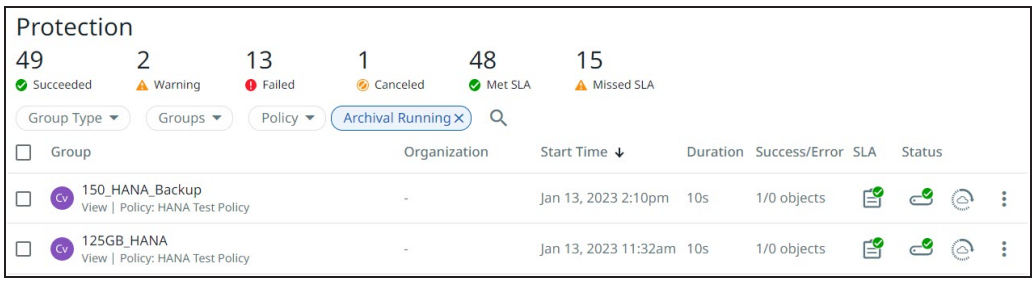
A Protection Group with replication and/or archive schedules creates copy tasks that copy Snapshots to remote Cohesity cluster or External Targets. You can cancel these copy tasks for a specific protection run using the Cohesity Dashboard. Here are some example scenarios when you may want to cancel copy tasks:

- A protection run takes a lot of time to complete and you want to free the resources used by Runs of this Protection Group:
  1. Pause the protection run.
  2. Cancel the replication and archive tasks of past Runs of this Protection Group.
- You delete a Job that is replicating or archiving Snapshots and not all of the Snapshots captured by this Job have been copied to the remote Cohesity cluster or the External Target, the Cohesity cluster continues to replicate and archive the remaining captured Snapshots even after the Job has been deleted. Before or after deleting this Job, you may want to cancel the replicate and archive tasks of existing protection runs that copy the remaining captured Snapshots.

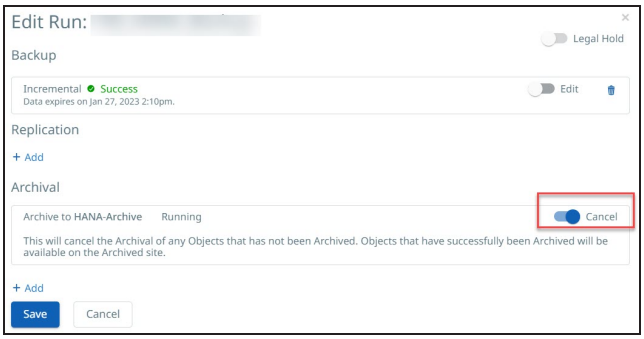
To cancel the copy tasks of a Protection Group Run:

1. Navigate to **Data Protection > Protection**.
2. From the list of Protection Groups, click on the Protection Group that has replication or archival running to view that Protection Group's details.

> **Tip:** Use the Status filter's Replication Running or Archival Running options to filter the Protection Groups.



3. The Group Details page lists the runs for that Protection Group. Click the Actions menu (⋮) for a protection run and select **Edit Run**.
4. On the Edit Run page:
   - To cancel a replication copy task, under Replication, select **Cancel**.
   - To cancel an archive copy task, under Archival, select **Cancel**.



5. Click **Save**.

Delete Protection Groups, Snapshots and Objects

You can delete a Protection Group from the local Cohesity cluster where the Protection Group is running. As part of the Protection Group deletion, you can optionally delete the snapshots captured by the Protection Group. You can also delete snapshots or individual Objects for protection runs (without deleting the Protection Group) as described in Deleting Snapshots or Objects. However, the deletion of snapshots is possible only if they're not protected by the DataLock policy or if the DataLock policy has expired.

> **Note:** DataLock policy can be changed at any time. After you change the policy, the snapshots that were taken earlier will continue to follow the previous policy time and only the new snapshots will follow the time defined in the updated policy. This means if you've set a 15-day DataLock policy for the snapshots and you change it to 7 days, then the old snapshots, which were taken before the policy change, will continue to be protected for 15 days from the day of its creation. However, any new snapshots that are taken after the policy change will be protected for 7 days.

Deleting a Protection Group

You can delete a Protection Group if you:

- Do not want to retain the backups, local and archived snapshots that are generated by the Protection Group.
- Want to reclaim the storage space utilized by the Protection Group.

Cohesity provides the following ways to delete a Protection Group:

- **Delete Protection Group Only**: Allows you to delete the Protection Group. All the backups generated by the Protection Group are preserved till the snapshots expire.
- **Delete Protection Group and Snapshots**: Allows you to delete the Protection Group and all the local and archived snapshots generated by the Protection Group.

> **Note:**
> - After deleting the Protection Group, the reclaimed storage space details will not be displayed immediately. It will take some time to reflect on the Cohesity Dashboard.
> - If a Protection Group is deleted manually while preserving the snapshots, all the unexpired snapshots will be available for recovery. However, when the snapshots expire as per the saved policy or by manual expiry, those expired snapshots will not be available for recovery.

Delete a Protection Group

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, select the Protection Group that you want to delete, click the actions menu (⋮), and select **Delete**.

or

3. Drill down on a Protection Group name in the **Group** column of the list. In the Protection Group Details page, click the actions menu (⋮) and select **Delete**.
4. In the **Delete Protection Group?** dialog box that appears, select any one of the following options:
   - **Delete Protection Group Only**
   - **Delete Protection Group and Snapshots**

   If you select **Delete Protection Group and Snapshots**, any local snapshots captured by this Protection Group and stored on the Cohesity cluster are deleted. In addition, any archived snapshots stored on External Targets that were captured by this Protection Group are also deleted. (To selectively delete the snapshots for specific protection runs without deleting the Protection Group, see Deleting Snapshots or Objects).

   If the current Protection Group is replicating snapshots to a remote cluster or archiving snapshots to an external target, you should probably cancel these replication or archive tasks before deleting the Protection Group. For instructions, see Cancel Replication and Archive Copy Tasks of a Protection Run.

   If the Protection Group on the local cluster is replicating to a remote cluster, the snapshots that were replicated (copied) from the local cluster will also be deleted. Archived snapshots are also deleted.

Deleting Snapshots or Objects

You can delete the Snapshots or individual Objects for specific protection runs of a Protection Group without deleting the entire Protection Group. This feature is useful if a long retention time was specified for Snapshots and the disk space on the Cohesity cluster is getting low. You can clean up Snapshots to reclaim space on the Cohesity cluster.

Delete Snapshots for Protection Runs on the Protection Group Details page

1. Log in to the Cohesity cluster that is storing the snapshots that you want to delete.
2. Select **Data Protection > Protection**.
3. On the **Protection** page, drill down on a Protection Group name in the **Group** column of the list.

   In the Protection Group Details page, a checkbox appears in the **Start Time** column. In addition, check boxes also appear next to the protection runs.
4. Select protection runs by clicking the check boxes in the **Start Time** column. All the snapshots that were captured by the *selected* protection runs will be marked for deletion. (Some limitations apply, see below.) To select all the protection runs displayed on the current page, click the check box in the **Start Time** header. If you

cannot select a check box, the snapshots for the protection run are already marked for deletion or the protection run has not been completed.

> **Note:** If there are multiple pages of protection runs, selecting the check box in the **Start Time** header does not select the protection runs on the other pages. It only selects the protection runs on the current page.

5. Click the **Delete All Snapshots** icon. If possible, all the snapshots that were captured by the *selected* protection runs are marked for deletion. Note the following about the snapshot deletion process:
    - The Cohesity cluster runs the Snapshot deletion tasks asynchronously in the background. Snapshots that are marked for deletion may continue to appear in the Cohesity Dashboard until the deletion tasks are complete. The deletion task takes only a few minutes to complete. Once the snapshot is deleted, it is marked as a "deleted snapshot" in the Cohesity Dashboard. You cannot restore the deleted Snapshot.The Cohesity cluster reclaims the space utilized by the deleted snapshot asynchronously in the background. You can increase the priority of the space reclamation by throttling the system activities running in the background. For more information, see Throttling Background System Activities.
    - If a selected protection run spawns copy tasks that replicate or archive Snapshots and those copy tasks have not been completed before the request for deletion is received, the Snapshots for the protection run are not deleted even after the copy tasks are complete. If other protection runs are selected and those runs do not have these restrictions, the snapshots captured by these protection runs are marked for deletion.
    - If the Protection Group on the local cluster is replicating to a remote cluster, the snapshots that were replicated (copied) from the local cluster will also be deleted. Archived snapshots are also deleted.

Delete Snapshots for a single Protection Run on the Run Details page

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, drill down on a Protection Group name in the **Group** column of the list. The Protection Group Details page appears.
3. In the **Start Time** column, drill down on a protection run. The Run Details page appears.
4. Click **Delete All Snapshots**. If possible, all the snapshots captured by the selected protection run are marked for deletion. Note the following about the snapshot deletion process:
    - The Cohesity cluster runs the Snapshot deletion tasks asynchronously in the background. Snapshots that are marked for deletion may continue to appear in

the Cohesity Dashboard until the deletion tasks are complete. The deletion task takes only a few minutes to complete. Once the snapshot is deleted, it is marked as a "deleted snapshot" in the Cohesity Dashboard. You cannot restore the deleted Snapshot.The Cohesity cluster reclaims the space utilized by the deleted snapshot asynchronously in the background. You can increase the priority of the space reclamation by throttling the system activities running in the background. For more information, see Throttling Background System Activities.

- If a selected protection run spawns copy tasks that replicate or archive Snapshots and those copy tasks have not been completed before the request for deletion is received, the Snapshots for the protection run are not deleted even after the copy tasks are complete.
- If the Protection Group on the local cluster is replicating to a remote cluster, the snapshots that were replicated (copied) from the local cluster will also be deleted. Archived snapshots are also deleted.

Delete individual Objects within a Snapshot

> **Note:** Deleting a single MS SQL database within a snapshot is not supported.

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the Protection page, drill down on a Protection Group name in the **Group** column of the list. The Protection Group Details page appears.
3. In the **Start Time** column, drill down on a protection run. The Run Details page appears.
4. Select Objects by clicking the checkboxes in the Object name column. To select all the Objects displayed on the current page, click the check box in the Object name header.
5. Click the **Delete Snapshots** icon.

   If the Protection Group includes replication, the confirmation includes the following additional information:

   - The Cohesity clusters that the snapshot was replicated to.
   - Replicated snapshots are not deleted through this workflow. To delete them, you must log in to those remote Cohesity clusters and delete the snapshots there.

   > **Note:** You cannot delete individual objects within an archived snapshot.

6. Click **Delete** to confirm.

Protection Group Run Issues

If a protection run fails, additional information may be available below:

- If backing up MS SQL Server fails with the following error: Backup task failed with error: [kGuestOperationsError]: Error while pushing the agent file, it means Cohesity was unable to push its agent file to the VM. Possible causes: VMware Tools went into a bad state, VM was not running in high performance mode.

  Possible fix - Restart VMware Tools and ensure the VM is running in high performance mode.

- Lingering VSS shadows on the VM can cause backups to fail with the following error: "Backup task failed with error: [kDatabaseBackupMismatch]: Incompatible LSN numbers for..." Running `vssadmin list shadows` in elevated mode in the CLI of the VM encountering issues shows the VM's existing shadows.

  Workaround - If no other backup apps are running on that VM, you can delete all VSS shadows using this command:

  ```
  PS C:\Windows\system32> vssadmin delete shadows /All
  ```

  If the previous command does not work, open DiskShadow and use this command:

  ```
  DiskShadow> delete shadows all
  ```

- If you encounter SOAP errors between Cohesity cluster and VMware vSphere, refer the Knowledge Base article, Troubleshooting SOAP errors between Cohesity cluster and VMware vSphere to troubleshoot the commonly seen errors during the SOAP exchange.
- If you encounter any VSS errors in a Cohesity environment, refer the Knowledge Base article, Troubleshooting VSS issues in a Cohesity environment. These error messages generally point to an environment issue and not a Cohesity protection or recovery issue.

Add or Remove a Legal Hold to a Snapshot

Users who are assigned the Data Security role can put a legal hold on existing Snapshots to preserve them for legal purposes. Legal hold Snapshots cannot be deleted until the legal hold is removed. Legal hold can be added to unlocked and DataLocked Snapshots. Cohesity recommends that their data security user enable Legal Hold for business-critical workloads after a ransomware attack is confirmed.

You can add a legal hold to Backup, Replication, and Archival targets in the protection run or individual objects in a protection run:

- If you add a legal hold to a protection run, it applies to all the Snapshot objects that were backed up by that protection run.
- You must manage the legal hold status on the remote replication Cluster manually.

> **Note:** Legal hold prevents Snapshots from being deleted until the legal hold is removed. Using legal hold for long periods of time may result in the cluster running out of space

To add a legal hold:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. Click a Protection Group name.
3. To add a legal hold for Backup, Replication and Archival targets in a protection run:
   a. Click the Actions Menu (⋮) and select **Edit Run**.
   b. Toggle on **Legal Hold** for the target that requires a legal hold. This option is enabled only if you have the Data Security role. Users assigned with other roles can only view the Legal Hold status.
   c. Click **Save**.
4. To add a legal hold to objects in the protection run:
   a. Drill-down on a protection run start time.
   b. Click the checkbox next to objects and then click the **Add Legal Hold** gavel icon ( ) displayed at the top of the list. The icon is enabled only if you have the Data Security role and you have selected at least one object.

   The legal hold is not added to the replicated objects. Consider adding legal hold manually to objects on the remote replication cluster.

A gavel icon ( ) indicates that a protection run or object has a legal hold on it.

To remove a legal hold:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. Click a Protection Group name.
3. To remove legal hold from Backup, Replication and Archival targets in a protection run:
   a. Click the Actions Menu (⋮) and select **Edit Run**.
   b. Toggle off **Legal Hold** for targets that do not require a legal hold. This option is displayed only if you have the Data Security role.
   c. Click **Save**.
4. To remove legal hold from objects in the protection run:
   a. Drill-down on a protection run start time.

      Legal hold objects have a gavel icon ( ) next to the object name.

b. Click the checkbox next to the objects and then click the **Remove Legal Hold** gavel icon ( ) displayed at the top of the list. The icon is displayed only if you have the Data Security role and have selected at least one object.

The legal hold is not removed from the replicated objects. Consider removing legal hold manually from objects on the remote replication cluster by signing on to the remote cluster and following the procedure above.

Considerations

- Only users assigned with a Data Security role can add and remove Legal Hold. Users with other roles can only view the Legal Hold status.
- Synchronization of Legal Hold happens only from the local cluster to the replication cluster and not from the replication cluster to the local cluster.
- The Legal Hold toggle for the whole local copy is enabled only if all the objects are on Legal Hold.
- The legal hold cannot be applied at the object level for SQL objects; it is only supported at the run level.

Failover a Protection Group

If you are failing over a Protection Group for VMs, follow the steps in Failover Protection Group for VMs.

You cannot failover the Protection Group of views and SQL servers.

You can, however, clone a view from a view snapshot stored on the remote Cohesity cluster. For detailed instructions, see Clone a View From a Snapshot.

You can also restore SQL servers from a SQL server VM snapshot stored on the remote Cohesity cluster. To learn more, see About Restoring Microsoft SQL Server Databases.

> **Warning:** For replicated MS SQL Server VM Snapshots, you can only restore MS SQL Server to a new location. (You cannot restore MS SQL Server to its original location.)

Failover Protection Group for VMs

> **Note:** Failover of Protection Groups is only supported for VMware VMs.

When a Protection Group with a replication schedule starts replicating snapshots from a primary Cohesity cluster to a remote Cohesity cluster, a Protection Group in Failover Ready state is created on the remote Cohesity cluster. If the original capturing Cohesity cluster and/or the original Source are down because there is a planned maintenance outage or a disaster destroys them, you can failover the Protection Group in Failover Ready state and deactivate the original task on the capturing Cohesity cluster. As part of the Failover, you are prompted to optionally recover the VMs from the replicated snapshots stored on the remote Cohesity cluster.

> **Note:** When you create a Protection Group on a Cohesity cluster with a replication schedule after the first snapshot is replicated, a Failover Ready copy of the Protection Group is created on the remote Cohesity cluster that is receiving the snapshot. For more information on Failover Ready, see About Failover Ready. You can failover the Protection Group of VMs. You cannot failover the Protection Group of Views or SQL Servers. You can, however, clone replicated Views and restore SQL Servers. For more information, see Failover a Protection Group.

During Failover, the following actions occur:

1. **Disaster at Source** - On the primary Cohesity cluster, the backup job fails to capture the snapshots of the source.
2. **Replication Fails** - As the source is down or unreachable, the replication job fails to replicate the snapshots onto the remote Cohesity cluster. The Failover Ready for VMs on the remote Cohesity cluster is activated and causes the rejection of the incoming replicated snapshots created by the associated job on the primary Cohesity cluster.
3. **Failover VMs** - You are prompted to optionally recover the VMs from the replicated snapshots on the remote Cohesity cluster to a new source.

The state of a Protection Group may also become "Failover Ready" when an active Protection Group is deactivated. For more information, see About Failover Ready.

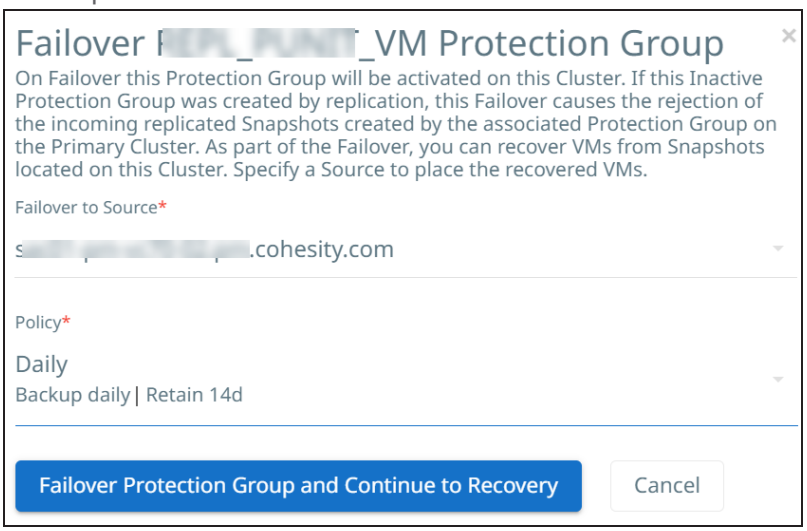
For more information about what happens during a Failover, see Failover from Replicated Copies.

For more information on disaster recovery of VMs using the Cloud Edition, see Back Up VMs to On-Prem, Replicate and Failover to AWS Cloud.

To Failover a Protection Group on the remote Cluster:

1. Navigate to **Data Protection > Protection**.
2. Find the Protection Group in the Failover Ready state in the list, click on the actions menu ⋮, and select **Failover**.

3. Select a source to place the recovered VMs and click **Failover Job and Continue to Recovery**.



4. Set Recover Options for VM Failover.
5. View VM Failover Confirmation.
6. Deactivate Original VM Protection Group. The Failover of the Protection Group in the Cohesity Dashboard does not automatically deactivate the original task on the original cluster that captured the snapshots. To deactivate, you must follow the instructions in Deactivate Original VM Protection Group
7. Restore VM Protection Group to Running. The Failover of the Protection Group in the Cohesity Dashboard does not automatically restore the task to running on the new cluster. To restore the task to a running state, you must follow the instructions in Restore VM Protection Group to Running.

Set Recover Options for VM Failover

In this section, you select the recover options while recovering VMs as part of the Failover of an Inactive Protection Group.

To set recover options:

1. Toggle **Rename Recovered VMs** on if you want to add Prefix and/or Suffix strings to the VM names of the new VMs created by this task. For example, you could specify Prefix `Test_` and Suffix `_QA` to the VM name `WinOS` and when the VM is recovered, the new VM that is created is called `Test_WinOS_QA`.
2. Select the appropriate **Recovery Location** option
   - **Recover back to original location**—Select this option to recover the VM files (such as the VMDK files) to their original datastores and create new instances of the VMs in the original location in the original source. For more information, see Recover to the Original Location.
   - **Recover to a new location**—Select this option to recover the VM files (such as the VMDK files) to an alternate datastore and create new instances of the

VMs in a new location of a registered Source. For more information, see Recover to a New Location. For details about virtualization or cloud platform-specific options, see the respective section.

- Acropolis
  a. **Source:** Select a registered Source to recover the VMs to.
  b. **Storage Container:** Select a storage container to store the recovered VMs.
- AWS
  a. **Source:** Select a registered Source to recover the VMs to.
  b. **Region:** Select a region in the project to recover the VMs.
  c. **VPC:** Select an Amazon Virtual Private Cloud (VPC) to store the recovered VMs.
  d. **Subnet:** Select a subnet in the Amazon VPC to store the recovered VMs.
  e. **Key Pair:** Select an Amazon key pair that has permission to log in to the recovered VMs.
  f. **Network Security Group:** Select the associated network security group.
- Azure
  a. **Source:** Select a registered Source to recover the VMs to.
  b. **Resource Group, Storage Account:** Select the corresponding Resource Group and Storage Account to which the recovery has to be done.
  c. **Storage Container:** Select the storage container in which page blobs will be created.
  d. **Virtual Network:** Select the virtual network where the VM must be placed.
  e. **Subnets:** Subnets in the virtual network where VMs must be placed.
- GCP
  a. **Source:** Select a registered Source to recover the VMs to.
  b. **Project:** Select a Google Cloud Platform (GCP) project to recover the VMs to.
  c. **Region:** Select a region in the project to recover the VMs to.
  d. **Availability Zone:** Select an availability zone in GCP to recover the VMs.

e. **VPC:** Select a Virtual Private Cloud (VPC) to store the recovered VMs.

- Hyper-V
  a. **Source:** Select a registered Source to recover the VMs to.
  b. **Compute:** Select the compute host for the recovered VMs.
  c. **Volume:** Select a volume to store the recovered VMs.

  When recovering to a standalone Hyper-V host as a new location, SMB volumes are not supported locations.
- RHV
  a. **Source:** Select a registered Source to recover the VMs to.
  b. **Data Center:** Select a data center to store the recovered VMs.
  c. **Cluster:** Select an RHV to store the recovered VMs.
  d. **Storage Domain:** Select an RHV storage domain to store the recovered VMs.
- VMware
  a. **Source:** Select a registered Source to recover the VMs to.
  b. **Resource Pool:** Select a Resource Pool to store the recovered VMs.

  > **Note:** When protecting a VMware Source, if you select a Resource Pool that is not part of the ESX cluster, all datastores in the vCenter are displayed. Ensure you select a datastore that is part of the selected Resource Pool. If you select the wrong datastore, storage migration fails, but the VM remains attached to the ESX Host and runs from the Cohesity datastore. You can manually migrate the VM to the desired datastore at a later time.

  c. **Datastore:** Select one or more available target datastores. The VM files (such as VMDK files) extracted from the Snapshots are stored in the selected datastores. The number of target datastores you select must be equal to or less than the number of VMs selected for recovery.

  Cohesity also displays each datastore's amount of free space and total capacity. For more information about recovering VMs to multiple datastores, see Recover VMs to Multiple Datastores.

> **Note:** Not applicable when recovering to a standalone ESX host. After recovery, VMs continue to run on the Cohesity datastore because Storage vMotion is not supported.

d. **VM Folder** Optionally select a logical VM folder in the datacenter in which to create the VMs.

> **Note:** Not applicable when recovering to a standalone ESX host.

- vCloud Director
  a. **Source:** Select a registered vCloud Director source to which you plan to recover the VMs or vApp.
  b. **Organization VDC:** Select the target organization VDC.
  c. **vApp:** Optional. Select the target vApp. If not specified, VMs are recovered as standalone VMs inside the target organization VDC.
  d. **Storage Profile:** Select the target Storage Profile. The Cohesity cluster chooses any compliant datastore associated with the Storage Profile to store the VM files. If you are recovering multiple VMs, the Cohesity cluster chooses one or more datastores associated with the Storage Profile.

3. Select the appropriate **Recovery Type** option.
   - **Instant Recovery**: if you select this option, the VM(s) will be usable instantly in the target environment and will be moved to target storage later. The VM can be used in production during Instant Recovery when data is copied to the VM from the Cohesity cluster. In such scenarios, the VM performance may be low as the Storage vMotion is still in progress.

     When recovering VMware VMs, by default, the selected VM is always instantly available after recovery.

     > **Note:** For instant recovery to Standalone ESXi, the VM(s) will be available immediately in the target environment and will have to be moved to the target storage manually.

   - **Copy Recovery**: You can select this recovery type for **VMware** sources only. If you select this option, the recovered VMs will be usable in the target environment only after all the data is copied from Cohesity to the target

storage. Once the restore is complete, the VM will be available to use and the performance of the VM will be normal.

> **Note:** You should have `VirtualMachine.Config.Rename` permission on your user account to use this recovery option.

Considerations when using the Copy Recovery option to recover VMware sources

- This is the only option to recover data from VMware cloud solutions.
- Copy recovery is not supported on Hybrid Extender deployments. Only vCenter and stand-alone ESXi hosts are supported.

4. Specify the networking options.
The network options displayed depend on the Recovery Location option that was selected.
   - **Keep original**—For each recovered VM, keep the original virtual Network Interface Cards (vNICs) and attach them to the original network connections. This option is only supported when VMs are recovered back to their original location.
   - **Start Connected**—For each recovered VM, connect to the original or new network when the VM reboots. If this option is not selected, the VMs are not connected to any network on reboot.
   - **Detach network**—For each recovered VM, the virtual Network Interface Card (vNIC) is removed from the VM.
   - **Attach to a new network**—For each recovered VM, attach the virtual Network Interface Card (vNIC) to a new network. The new network might be a standard port group or a distributed port group.

     When recovering VMware VMs, the selected Network port group will be attached to all the network interfaces of the VMs being recovered.

     When recovering Hyper-V VMs, the selected virtual switch will be attached to all the network interfaces of the VMs being recovered.

> **Note:**
> - Recovering a network attached CentOS VM on VMware or Hyper-V does not attach the VM to the network. Attach the VM to the network manually.
> - If the VMware Resource Pool is not part of the ESX cluster, all networks available to the Datacenter are displayed. Ensure you select a network available to the selected Resource Pool. If you select the wrong network, VM creation and recovery will fail.

5. **Auto Select:** When enabled, the recovery task automatically selects the correct VLAN.
6. Select **Instant Recovery** if you want to change the Hyper-V recovery mechanism so that VMs become available instantaneously after recovery. Applicable to Hyper-V only.

   Select **Preserve VMs UUID** if you want to preserve the UUID for the recovered VMs. Applicable to Hyper-V only.
7. Select **Leave recovered VMs powered off** if you want the recovered VMs to remain powered off after they are created.

   If you recover VMs from a Storage Domain that has Cloud Tier enabled, Cohesity recommends leaving the VMs powered off.
8. Select **Continue recovery even if errors occur when recovering VMs** if you want the Recover task to continue even if errors occur when recovering the VMs. For example, if one of the VMs cannot be created, the Cluster will still attempt to create the other VMs. If this is unselected, then the Recover task is discontinued only if VM creation fails, so if VM creation succeeds, but VM storage migration fails, the task continues.
9. In the Selected Objects section, click **Show VMs** to view the VMs associated with the Failover Job. By default, the VM Snapshots of the last Run of the Job are recovered.

   Click Edit ( ) to select Snapshots captured by a different protection run.
10. Click **Finish**.

The next step is View VM Failover Confirmation.

View VM Failover Confirmation

In this step, you can view a summary of the options for the current Failover task and a list of objects that will be recovered by the task.

The next step is to Deactivate Original VM Protection Group

Deactivate Original VM Protection Group

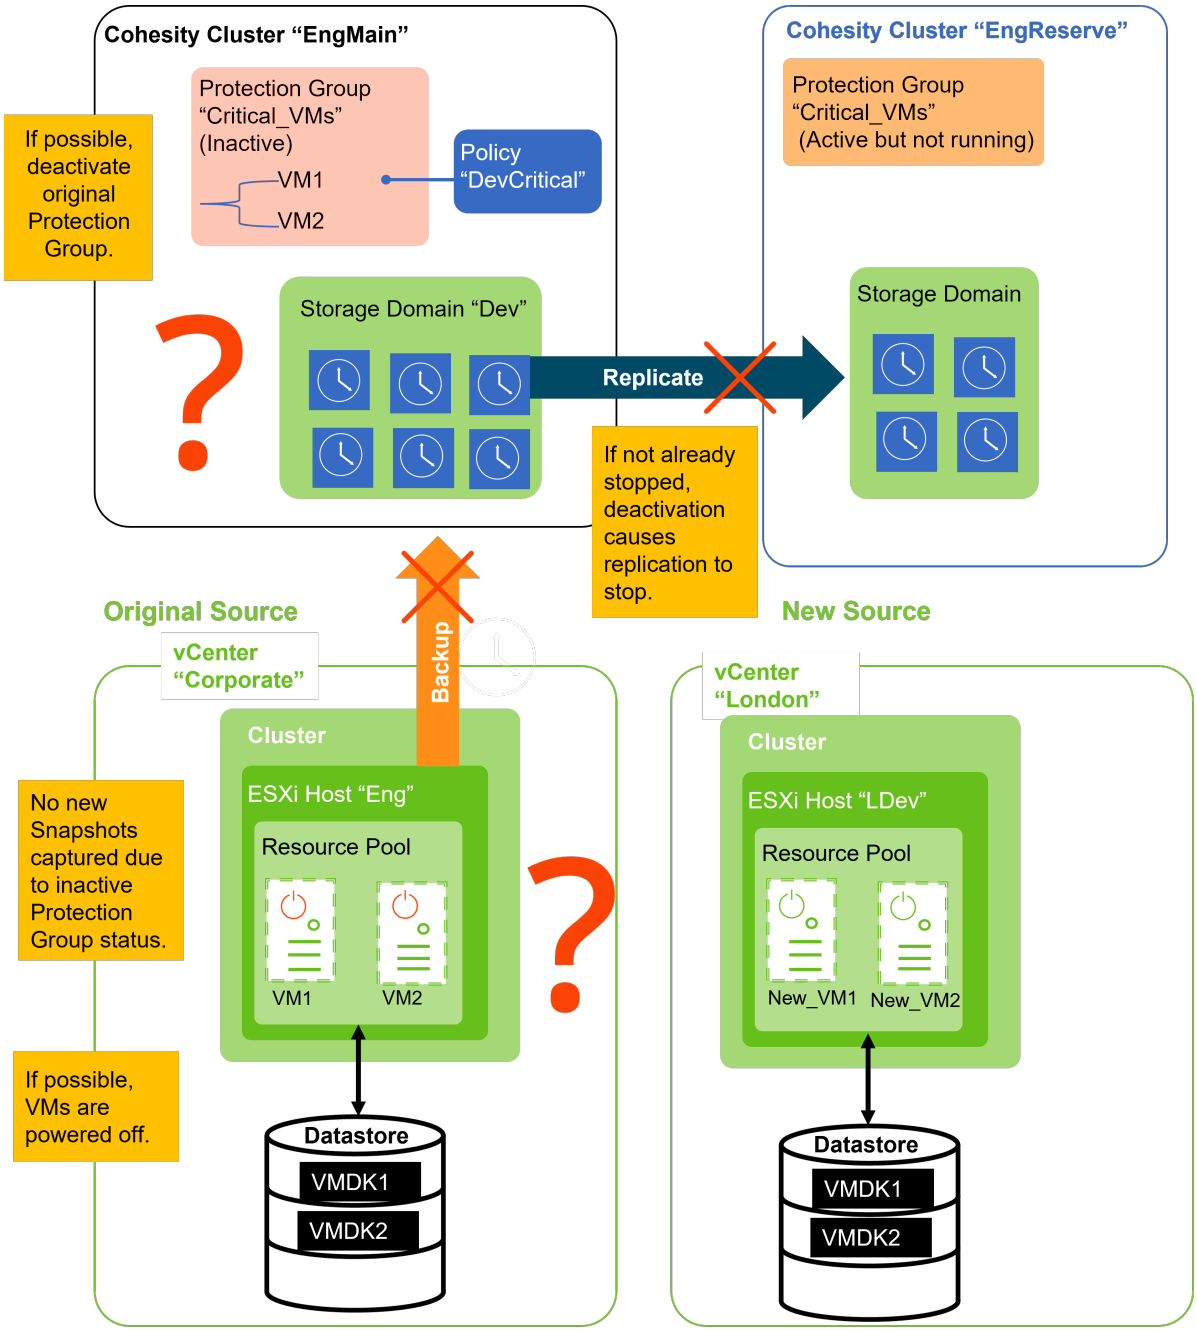
Only Protection Groups that are protecting VMs can be deactivated. Protection Groups that are protecting a view cannot be deactivated.

> **Note:** If possible, deactivate the original Protection Group on the original capturing Cohesity cluster. If the original Cohesity cluster that captured the Snapshots is down or unreachable, you may be unable to deactivate the Protection Group.

The example below shows the deactivation of a Protection Group protecting VMs. Deactivating a Protection Group protecting SQL Servers is similar but not all details are the same. For example, the transaction logs are not described or pictured.

During deactivation, the following actions occur:

1. Snapshots are no longer captured by the original Protection Group on the original capturing Cohesity cluster. However, the existing snapshots captured by the Protection Group remain in the storage domain. They are not deleted.
2. Snapshots created by the Protection Group are no longer replicated to the receiving (remote) Cohesity cluster. (If you have already initiated the failover procedure, the replication has already stopped.)
3. You can optionally choose that the VMs on the original source be powered off. The VMs and the VM files, however, are not deleted. (The Cohesity cluster may be unable to power off the VMs if the original source is down or unreachable.)



To deactivate the original Protection Group:

1. Log in to the Cohesity cluster where the original Protection Group was running.
2. Navigate to **Data Protection > Protection**.
3. Find the original Protection Group in the list, click on the actions menu ⋮ and select **Deactivate**.
4. Click **Deactivate and Power off VMs**, or click **Deactivate Only** if you do not want

to power off the VMs.

5. Optionally delete the VMs and VM files using the VMware vSphere client.

Restore VM Protection Group to Running

You can restore the Protection Group activated by the Failover, by assigning a new policy to the Protection Group and selecting Objects (VMs) to back up. These actions restore the Protection Group to a running state on the new cluster. To learn more, see Restore Activated Protection Group.

To restore the Protection Group:

1. Navigate to **Data Protection > Protection**.
2. On the **Protection** page, find the inactive Protection Group (created by replication).
3. From the Actions menu (⋮) of that Protection Group, select **Resume**.

This is the last step in the Failover process.

Chapter 26: Manage Recovery

This chapter includes the following topics:

Use Wildcard * in Search for Recovery 4071

Cancel a Recovery 4072

Use Wildcard * in Search for Recovery

You can optionally use the Wildcard `*` in any location in the search string. The following table shows some example searches.

Example Search	Finds	Description
`*`	All the files, Protection Group Names, or Server names	
`test*`	`vol1/usr/bin/test` `vol1/usr/share/setup/test.ps`	Note that this search does not find: `vol1/usr/memtest.ext`

`*test*`	`vol1/usr/bin/test`
	`vol1/usr/share/setup/test.ps`
	`vol1/usr/memtest.ext`	

`*xml`	`usr/local/firefox/searchplugin/yahoo.xml`	When searching for file extensions, do not enter the period in the search string. For example if searching for all files that end in the `.txt` extension, enter `*txt` and not `*.txt`.

Example Search	Finds	Description
`search* *xml`	`usr/searchplugins/dsl.xml`	Enter `search* *xml` with a space and not `search*xml`. However, when you add spaces between search terms, only files that match all the search terms are found, for example searching with the string: `search* *xml` does not find: `usr/searchplugins` Entering just `search` does not find `usr/searchplugins/dsl.xml`.
`*plug* *xml`	`usr/searchplugins/dsl.xml`	Only files that match all the search terms are found.

> **Note:** Ensure to follow the standard regular expression rules. Specify a dot '.' before asterisk '*' to match all characters, for example, L:.*.ndf.

Cancel a Recovery

The recovery of any objects that have not yet been recovered is canceled. Note the following:

- Canceling a recovery might require some manual cleanup. For example, if you cancel a folder recovery, any files copied prior to the cancellation will not be deleted.
- When canceling a VMware VM recovery, the cancellation will occur after the VM is created, the datastore is mounted and the Storage vMotion migration process begins. You will need to manually clean up the VM that was created and unmount the datastore.

Cancel a Running Recovery

1. In the Cohesity Dashboard, select **Data Protection > Recoveries**.
2. Click the recover task you want to cancel. The task details page is displayed.
3. Click **Cancel** in the upper right corner of the details page.
4. Respond to the confirmation prompt.

Chapter 27: Cohesity Agents

Data protection is paramount in today's complex IT environments, whether for physical servers, virtualized infrastructure, or databases. Cohesity provides a comprehensive solution to safeguard data across different systems using specialized software components known as agents. These agents are crucial in streamlining the data protection process across various platforms, ensuring smooth backup and recovery operations tailored to each environment.

What are Cohesity Agents?

Cohesity agents are lightweight software applications installed on target machines running supported operating systems—whether to protect physical servers, virtual environments, or databases. In particular, when Cohesity agents are used to protect filesystem data, they are referred to as **Cohesity Physical Agents**.

Once installed, these agents enable the Cohesity platform to manage backup and recovery through block-based or file-based **Protection Groups**. These Protection Groups determine how data is protected, while the agents facilitate interaction between the Cohesity cluster and the protected workloads.

The Physical agents also contain modules to protect other data, such as MS SQL databases. Additionally, the agents protect other workloads, such as SAP HANA, in conjunction with other Cohesity modules described in the documentation for the respective integrations.

What Do Cohesity Agents Do?

The core purpose of Cohesity agents is to enable seamless data protection by performing key tasks specific to the environment in which they are deployed:

- **Backup and Recovery**: Agents handle the backup of system, application, and database data, securely storing it within the Cohesity platform for fast recovery when needed.

- **Block-Based or File-Based Protection**: The Cohesity cluster can support block-based and file-based backups, depending on the type of agent and the system it protects.
- **Application Consistency**: Cohesity agents capture application-consistent backups for critical workloads like databases, ensuring data is protected without the risk of corruption.
- **Data Management**: Agents manage the scheduling, execution, and monitoring of backups, integrating with the Cohesity platform for centralized control and reporting.
- **Efficiency**: Using technologies such as deduplication and compression, agents optimize data transmission, reducing storage consumption and bandwidth usage.

Cohesity Agents Deployment in Different Scenarios

Physical Server Environments

In physical environments, **Cohesity Agents** are installed directly onto the operating system. These agents ensure that all critical data from the server, including file systems, applications, and system state, is fully protected. Administrators can use block-based or file-based **Protection Groups** to define backup schedules and policies depending on the system's configuration. This is particularly useful for traditional systems or workloads that are not virtualized, as the agents protect the entire physical infrastructure. It is important to note that nothing precludes the agents from being used inside virtual environments, which are described in the next section.

Virtual Environments

In virtualized environments, such as **VMware** or **Hyper-V**, Cohesity supports both agentless and agent-based protection. When using agents, they are typically installed on virtual machines (VMs) requiring more granular control over backup operations, such as specific applications or critical data. Cohesity can also perform agentless protection by interacting with the hypervisor directly, to allow for better management of workloads at scale.

In cases where the agent-based approach makes sense, the Cohesity agent ensures that the VM and its underlying applications are backed up in an application-consistent manner, providing the option for individual VM restores or more complex recovery scenarios.

Databases

Cohesity offers specialized agents for database environments, particularly for SQL Server, Oracle, and other enterprise databases. These agents are designed to work closely with database applications to ensure consistent and reliable backups. For example:

- **SQL Server**: The agent interfaces with the SQL Server application to take application-consistent snapshots, enabling log truncation, point-in-time recovery, and rapid restoration of databases.
- **Oracle Databases**: Similarly, the Cohesity agent integrates with Oracle RMAN (Recovery Manager) to perform both full and incremental backups, ensuring fast recovery and minimal impact on performance.

For databases, ensuring data consistency is critical. Cohesity agents allow administrators to leverage granular control over backup policies, ensuring that the databases can be restored to a specific state without loss of data integrity.

In summary, Cohesity agents are versatile tools designed to protect data in **Physical**, **Virtual**, and **Database** environments. They are essential for enabling tailored data protection strategies, ensuring that regardless of the infrastructure, backups are consistent, efficient, and easily recoverable. Whether protecting a traditional physical server, a modern virtual environment, or an enterprise-grade database, Cohesity agents provide the backbone for robust, reliable data protection.

Install and Manage Cohesity Agents

Installing the Cohesity Agent is required to protect physical servers and some hypervisor environments. The following topics discuss Agent installation and management.

Cohesity Java Agent Upgrade

> **Note:**
> - The Cohesity Java agent upgrade steps are common for all the platforms.
> - Automatic upgrades are available from the Cohesity cluster UI and for manual updation follow the steps listed below.

To upgrade the Cohesity Java Agent follow the steps listed below.

You can download the Cohesity agent installer from the Cohesity UI or manually download the agent from the Cohesity Package Download and install the agent using CLI.

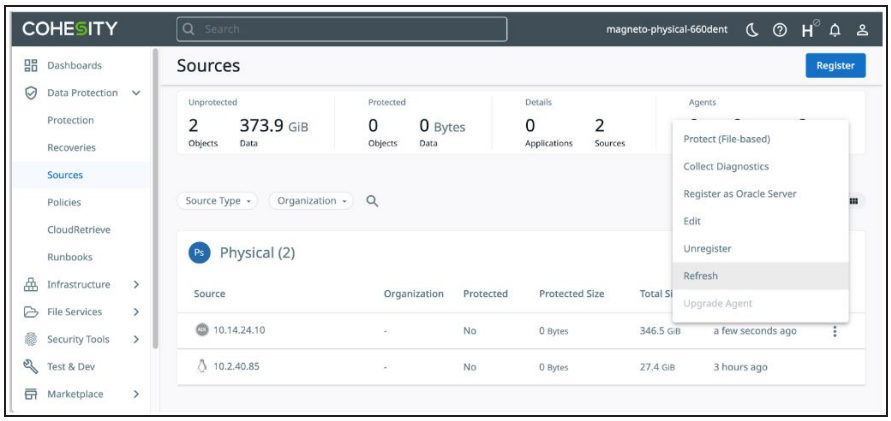
1. Download the installer:
    a. Using the Cohesity cluster UI

       Navigate to **Data Protection** > **Sources** and click **Download Cohesity Agent**.

    b. Using the Cohesity Package Download site

i. Download the agent installer to the protected server.

ii. Refresh the agent from the Cohesity Dashboard to ensure that the current agent is connected to the Cohesity cluster.



iii. Note down the current agent version and the last refresh time from the Cohesity Dashboard.

iv. Login to the server and upgrade the agent using the platform-specific command as per the below table.

Platform	Upgrade Command
Solaris	`pkgadd -d <installer>`
AIX*	`installp -ac -d <installer> all`
Linux (PowerPC)	`rpm -U <installer>`
Linux (z/Architecture)	`rpm -U <installer>`
Linux (ARM)	`rpm -U <installer>`
HP-UX	`swinstall -s <installer absolute path> -x reinstall=true \*`

*If the AIX agent upgrade fails due to version mismatch, then use the `force install` command:

```
installp -F -ac -d <installer> all
```

v. Refresh the agent from the Cohesity Dashboard and verify that refresh time and agent version are updated.

For more information on how to install and manage agents, see Manage Agents.

Install and Manage the Agent on Windows Servers

> **Note:** If the Windows firewall is active upon installing the Cohesity Agent, you need to add a rule in the firewall to open the port 50051 for communication with the Cohesity nodes. For more information, see Manage Firewall Ports.

Cohesity Agent Component Requirements

Refer to the following table to determine which components to install with the agent service for the server type you want to register/protect.

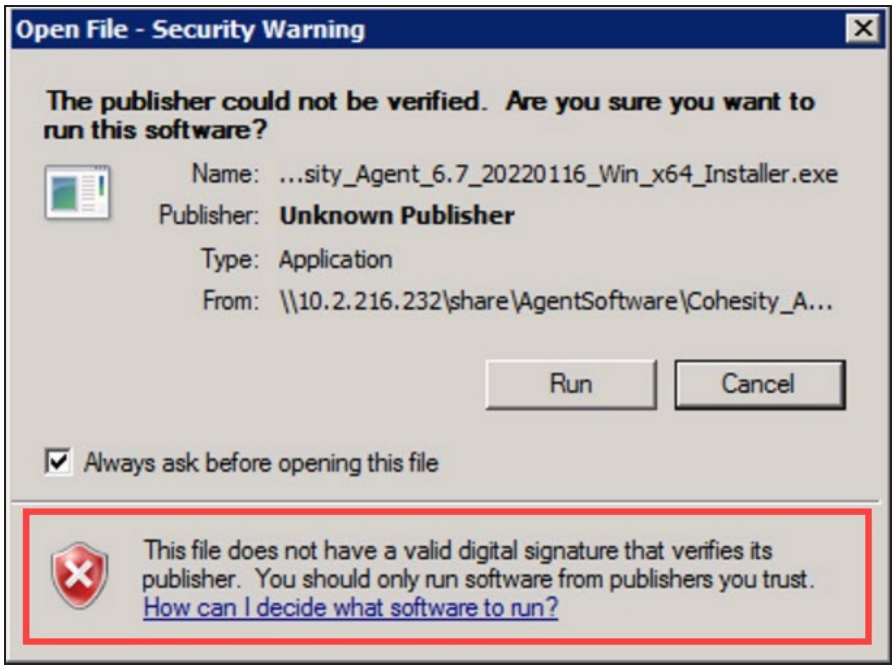
Server	Install Volume CBT	Install File System CBT
Physical Server without MS SQL	Yes (allows incremental backup)	No
Physical Server with MS SQL	Yes (allows incremental backup)	Yes (allows file-based SQL backup)
MS Exchange Server	No	Yes
VMware VM (using Installed agent) with MS SQL	No	No
Hyper-V SCVMM server	No	No
Hyper-V 2016 host	No	No
Hyper-V 2012 R2 host	No	Yes
Nutanix AHV	No	No

Free Space Requirement for Block-based Backup

For block-based backup of Windows physical server, the space must be at least equal to the calculation (Initial disk size*Churn rate*Backup window time). If you're running multiple backups on a cluster, you'll need enough storage capacity to accommodate the snapshots for each of the machines using this calculation.

Download and Install the Agent

Because of weaknesses in the SHA-1 algorithm and to align to industry standards, starting from the Cohesity version 6.7 onwards, sha1 signing of Cohesity artifacts is dropped. Windows Agent installer which was previously signed with sha1 and sha256 hashing algorithms is now signed with only sha256 algorithm. Due to this, legacy OS (Windows 2008 R2) users will notice the following warning when installing the Cohesity Windows agent.



To avoid this warning, install sha2 code signing support on the system where you are installing the agent.

> **Note:** This is only a warning, and you can click **Run** to continue with the installation.

To download and install the Cohesity Windows Agent:

1. Navigate to **Data Protection > Sources**.
2. Click **Download Cohesity Agent**. Ensure the agent has been downloaded to the appropriate server.

   Note that the Cohesity Windows Agent does not support file path names that are not compliant with UNICODE or UTF-8 encoding. The table below lists the encodings that are not supported.

Language	Locale	Windows Code Page
Simplified Chinese	zh_CN	936
Traditional Chinese.	zh_TW	950
Japanese-SJIS	ja_JP	932
Japanese-EUC	ja_JP	20932
Korean	ko_KR	949

The Cohesity Windows agent installation may fail even if the encodings are not supported.

3. As an administrator with local system privileges on that server, run the executable with **Run as administrator** and complete the installation wizard.Install the **Volume CBT (Changed Block Tracker)** component to perform incremental backups. Installing this component requires a reboot. Without a reboot, only full backups can be performed. Not installing this component means only full backups can be performed.The Cohesity Volume CBT driver creates the **Cohesity_Bitmap.cty** file at the root of each volume. There are multiple ways to backup Windows physical server but the **Cohesity_Bitmap.cty** file will be available on the system only if the Volume CBT driver is installed. This file is used to maintain the CBT data for incremental block-based backups across Windows server reboots. Do not move or delete the "**.cty**" file.

   The **File System CBT (Changed Block Tracker)** component is not required. Install this component if you require file-based SQL backup.

4. The agent starts automatically.

Note:

- The installation wizard may contain references to **user certificates**. This is not currently supported and reserved for future releases.
- This installation does not require a restart. You can wait until a normal maintenance window (such as a Patch Tuesday) to restart. However, until you do, some Protection Groups that depend on Volume CBT will run in full backup mode.
- When installing the Cohesity agents, usage of **Port 21213** is reserved for Cohesity's use with IANA. This is an Early-Access feature. Contact your Cohesity account team to enable the feature.

Silently Install the Cohesity Agent on Windows Physical Servers

You can install the Windows Cohesity agent on multiple Windows servers by running the following command in an Administrator CMD shell or Administrator PowerShell. (The servers must have access to the agent file.)

```
 <InstallerExeFile> [/type=<onlyagent|volcbt|fscbt|allcbt>]
[/log="<absolute-path-to-log-file>"] [/dir="<absolute-path-to-install-
location>"] [/username=<value> [/password=<value>]] [/verysilent]
[/suppressmsgboxes] [/norestart] [/firewallrule=<value>] [/configfile
<value>] /deleteconfigfile <value>] [/enforceusecustomcert=<value>]
[/cohesitycustomcertpath=<Value>]
```

The default name for `<InstallerExeFile>` is `Cohesity_Agent_<Version>_Win_x64_Installer.exe`.

A sample command is shown below:

```
Cohesity_Agent_5.0.0.0_Win_x64_Installer.exe /log="C:\logs\install logs.txt"
/verysilent /suppressmsgboxes /norestart /dir="F:\CohesityAgent"
```

The command parameters are described below.

Parameter	Description
`/type=<onlyagent|fscbt|allcbt|volcbt|onlyagent|volcbtwithsbt|fscbtwithsbt|agentwithsbt>`	Specifies the type of installation. • `volcbt` - Installs the Windows Agent Service and Volume CBT component. • `fscbt` - Installs the Windows Agent Service and File System CBT component. This parameter enables incremental backups of Windows Server 2012 R2 or individual databases hosted by MS SQL Server. • `allcbt` - Installs the Windows Agent Service, Volume CBT component and File System CBT component. This parameter enables incremental backups of Windows Server 2012 R2 or individual databases hosted by MS SQL Server. • `onlyagent` - Installs only the Windows Agent Service and not the Volume CBT or File System CBT components. • `onlyagent`- Installs only the Windows Agent Service and not the Volume CBT or File System CBT components. • `volcbtwithsbt`- Agent, Volume CBT and Oracle SBT Library • `fscbtwithsbt`- Agent, File System CBT and Oracle SBT Library • `allcbtwithsbt`- Agent, File System CBT, Volume CBT and Oracle SBT Library • `agentwithsbt`- Agent and Oracle SBT Library **Note:** The `/type` parameter is supported only for a fresh installation. It is not supported for upgrades. You cannot add or remove components during an upgrade. **Note:** If the `volcbt` parameter is not specified, volume based backups will always be full. Similarly, if the `fscbt` parameter is not specified, SQL and exchange file based backups will be full.
`/log="<absolute-path-to-log-file>"`	Records the events during installation and helps to debug the errors, if any, during the installation process.

Parameter	Description
`/username=<value> [/password=<value>]`	The Cohesity Windows Agent Service is installed, by default, in the Local System account. Use these parameters to change the account under which the service will run. Note that the specified user account must have local administrator privileges on the server and should have the `Log on as a service` right.
`/verysilent`	Suppresses the installation progress window. **Note:** If you specify this option during the agent installation, you should review the default values for all the other parameters such as `/type, /dir, /username,` etc., and explicitly add them with relevant values if the defaults are not acceptable.
`/suppressmsgboxes`	Suppresses any message boxes if `/verysilent` is specified.
`/norestart`	Prevents the setup from restarting the system following a successful installation, or after a `Preparing to Install` failure that requests a restart.
`/dir="<absolute-path-to-install-location>"`	Specifies the directory path in which the Cohesity Windows Agent Service should be installed. **Note:** The installer will create the necessary folders if they do not exist. If this parameter is not specified, the system will install the Windows Agent Service in the default directory path: `"%SystemDrive%\Program Files\Cohesity"`.

Parameter	Description
`/firewallrule=<yes | no>`	Specifies whether or not to open Agent port in the firewall. The default value is 'yes'. **Note:** The installer creates an inbound rule in the local firewall of the Windows machine for port 50051 and is bound with the Cohesity Agent Service. Any domain policy settings that may negate this effect will have to be handled at the domain policy level. The installer creates rules only in the Windows Firewall application. If any other firewall application is in force on the machine then the user will have to create appropriate rules in the active firewall application.

`/configfile <value>`	Specifies the path to INI file containing credentials for Agent service user account.
	
	Note: If the `configfile` parameter is not specified, the username and password command line parameters are ignored.
	
	To pass the credentials in the config file, follow the steps below:
	
	Create a `config.ini` file with username and password and specify the same in `/configfile` option.
	
	Example
	
	`[credentials]`
	`username=<user_name>`
	`password=<password>`

`/deleteconfigfile <yes | no>`	Specifies whether to delete the configfile upon successful installation.
`[/enforceusecustomcert=<yes>]`	Enforce the user to use a custom certificate while installing the agent. If this is set to YES, then the subsequent fields should have valid values, else the agent will not start. If the custom certificate is not found then the agent would not start.

Parameter	Description
`[/cohesitycustomcertpath=<path-to-agent-certificate-in-Cohesity-format>`	To be used only when **/customcertstype = cohesitycustomcerts**. Specifies the directory path in which the Cohesity custom certificate for the agent is present.

> **Note:** On Windows physical servers, the Cohesity agent logs are stored in C:/programData/cohesity/.

Upgrade the Agent on VMware

Windows Agent

Cohesity recommends using the agent installer when installing the persistent agent. If the persistent agent is manually installed, use the following workaround to upgrade the agent:

1. Log on to the server from which the persistent agent must be upgraded.
2. Open an elevated command window, and then stop the earlier persistent agent service:

   ```
   net stop cohesityagent
   ```

3. Download the Cohesity agent installer from the Cohesity UI.
4. Double-click the installer .exe file to initiate the installation. Follow the installer UI prompts.
5. Do not choose to install any CBT drivers. Only upgrade the agent binary.

   This procedure upgrades the Cohesity agent and creates an entry in **Control Panel** > **Uninstall Program**.

VMware VMs that are not registered as a source on the Cohesity cluster need to upgrade the installed Cohesity agent manually.

1. Download the Cohesity agent installer from the Cohesity UI.
2. Double-click the installer .exe file to initiate the installation. Follow the installer UI prompts.
3. Do not choose to install any CBT drivers. Only upgrade the agent binary.

Download and Install the Agent on the SCVMM Server

Before registering SCVMM, you must install the Cohesity agent on the SCVMM server or on an existing proxy endpoint that is connected to an SCVMM server.

1. Navigate to **Data Protection > Sources**.
2. Click **Download Cohesity Agent**. Ensure the agent has been downloaded to the appropriate server.
3. As an administrator with local system privileges, run the executable and complete the installation wizard.

   Install the agent without additional components.
4. The agent starts automatically. Now you can register the Hyper-V SCVMM server as a source.

Download and Install the Agent on Hyper-V Hosts

Ensure you install the Cohesity agent on any Hyper-V hosts that you want Cohesity to protect.

1. Navigate to **Data Protection > Sources**.
2. Click **Download Cohesity Agent**. Ensure the agent has been downloaded to the appropriate hosts.
3. As an administrator with local system privileges, run the executable and complete the installation wizard.

   For Hyper-V 2016 servers, install the agent without additional components.

   For incremental backups of individual VMs hosted by Hyper-V on Windows Server 2012 R2, install the **File System CBT (Changed Block Tracker)** component.
4. The agent starts automatically.

Guest Windows VM minimum recommended specifications: 2 GB RAM and the equivalent of a 1 GHz processor.

Best practice: For Hyper-V 2016, configure all VMs' Automatic Stop Action to shut down or turn off, instead of save. This results in all powered-on VMs having minimal size .vmrs files. Because Cohesity does not back up .vmrs files that are greater than 10 MB (.vmrs file size, if set to save, scales to the amount of memory assigned to the VM). VMs in the saved state, by definition, generally have .vmrs files greater than 10 MB. This Cohesity Windows Agent registry value entry determines the maximum size of the .vmrs file supported per backup: agent_hyperv_max_vm_config_file_size_mb. Set it to zero to back up .vmrs files of all sizes.

Upgrade the Agent on SCVMM and Hyper-V Hosts

You can use the Cohesity UI to upgrade agents on a non-SCVMM cluster.

1. Select **Data Protection > Sources**.
2. Click the Hyper-V source name.

3. If an upgrade is available, click **Upgrade Agents**.

   This upgrades eligible agents, such as a singleton SCVMM node or a proxy SCVMM.

To upgrade an agent individually, mouse over the corresponding actions menu and click **Upgrade Agent** (⬆).

Agents on hosts that belong to an SCVMM cluster must be updated manually. Download a new Cohesity agent and run the installer.

Download and Install the Agent on Nutanix AHV

File or folder-level recovery of VMs in a Nutanix Acropolis Hypervisor requires a Linux or Windows Cohesity agent installed on the target VM. Follow these steps to install the Cohesity agent.

1. Navigate to **Data Protection > Sources**.
2. Click **Download Cohesity Agent**. Ensure the agent has been downloaded to the appropriate server.
3. As an administrator with local system privileges on that server, run the executable and complete the installation wizard. Do not install any CBT components.

   If you use the Windows command prompt to install the agent, you can use a command similar to this sample:

   ```
   Cohesity_Agent_6.3.0.0_Win_x64_Installer.exe /type=onlyagent
   ```

   For more information about command parameters, see Silently Install the Cohesity Agent on Windows Physical Servers.
4. The agent starts automatically.
5. Configure the firewall and ports as necessary. For more information, see Manage Firewall Ports.

Upgrade the Windows Agent on a Physical Server

> **Note:** Scheduled upgrades of agents are supported on the Cohesity cluster.

You can use the Cohesity UI to upgrade agents on a physical server.

1. Navigate to **Data Protection** > **Sources**.
2. If an upgrade is available, click **Upgrade Agents**.

To upgrade an agent individually, mouse over the corresponding actions menu (⋮) and click **Upgrade Agent**.

Auto-upgrade of the Cohesity Windows Agent

Cohesity upgrade process supports auto-upgrade of the agents running on sources.

> **Note:** The option to auto-upgrade Cohesity Agent is not available on the Cohesity cluster with multi-tenancy configured. The auto-upgrade option is available only during cluster upgrade.

To enable auto-upgrade:

1. In the Cohesity UI, navigate to **Settings** > **Update**, and select the **Upgrade** tab.
2. Select the **Upgrade Cohesity Agent on all servers in Sources** checkbox to upgrade the agents on the source automatically after the cluster upgrade.

Uninstall the Agent

The following uninstallation methods are available:

- Use the Add/Remove Programs in the Control Panel and Start Menu shortcuts in Windows versions where it is supported.
- Use the uninstaller executable. The details of the uninstaller executable are available in the registry value "HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Uninstall\{99246986-0300-4B21-9A1C-DE278D8EC715}_is1\UninstallString". The default value is "C:\Program Files\Cohesity\Installer\unins000.exe", assuming C: is the default operating system installation volume and "C:\Program Files\Cohesity" is the default Cohesity Agent install location.

Preserve registry settings when uninstalling the agent

Uninstalling the Cohesity agent normally clears registration settings from the registry. You can preserve registration settings in the registry by using the `/preservesettings` flag when uninstalling from the command line. Preserving registry settings is not supported when uninstalling from the UI.

Sample command:

```
unins000.exe /preservesettings
```

Install and Manage the Agent on Linux Servers

The Cohesity Linux agent is now available with different installer packages, providing support on multiple Linux distributions. The following table lists the installer packages and Linux distributions on which the installer package is supported.

Installer package	Linux distribution
(Default) RPM	RHEL and its derivative
SUSE RPM	SUSE
Script Installer	All supported Linux operating systems

Linux agent has dependencies on the following packages, which must be installed on the Linux server:

Command/Package	Linux distribution				
	RHEL	SUSE	CentOS	Ubuntu	Debian
rsync	rsync	rsync	rsync	rsync	rsync
mount	mount	mount	mount	mount	mount
lsof	lsof	lsof	lsof	lsof	lsof
umount	umount	umount	umount	umount	umount
cp	cp	cp	cp	cp	cp
chown	chown	chown	chown	chown	chown
chmod	chmod	chmod	chmod	chmod	chmod
mkdir	mkdir	mkdir	mkdir	mkdir	mkdir
rm	rm	rm	rm	rm	rm
tee	tee	tee	tee	tee	tee
hostname	hostname	hostname	hostname	hostname	hostname
stat	stat	stat	stat	stat	stat
blkid	blkid	blkid	blkid	blkid	blkid
ls	ls	ls	ls	ls	ls

Command/Package	Linux distribution				
	RHEL	SUSE	CentOS	Ubuntu	Debian
losetup	losetup	losetup	losetup	losetup	losetup
dmsetup	dmsetup	dmsetup	dmsetup	dmsetup	dmsetup
timeout	timeout	timeout	timeout	timeout	timeout
lvs	lvs	lvs	lvs	lvs	lvs
vgs	vgs	vgs	vgs	vgs	vgs
lvcreate	lvcreate	lvcreate	lvcreate	lvcreate	lvcreate
lvremove	lvremove	lvremove	lvremove	lvremove	lvremove
lvchange	lvchange	lvchange	lvchange	lvchange	lvchange
libpcap-progs	null	libpcap-progs	null	null	null
nfs-utils **Note:** Required for Instant Volume Mount, file-folder recovery from block-based backup and VMware backup.	nfs-utils	nfs-utils	nfs-utils	nfs-utils	nfs-utils
wget	wget	wget	wget	wget	wget

Installing the Linux agent as an LDAP user is supported.

Free Space Requirement for Volume-based Backup

For block-based backup of Linux physical server, the space must be at least equal to the calculation (Initial disk size*Churn rate*Backup window time). If you're running multiple

backups on a cluster, you'll need enough storage capacity to accommodate the snapshots for each of the machines using this calculation.

You can run the `vgdisplay` command on the physical server to check the free space in a Volume Group in LVM.

If the volume-based backup fails due to insufficient free space in a Volume Group, then the following error message is displayed on the Cohesity UI.

```
Volume group "rhel" has insufficient free space (0 extents): 1 required.
```

Download and Install the Linux Agent

Installing the agent on a server allows actions such as registering the agent as a source with the Cohesity cluster or performing file-level recovery.

Install the Agent

1. Navigate to **Data Protection > Sources**.
2. Click **Download Cohesity Agent**.

   The Download Agents window appears.
3. Follow the installation instructions for the corresponding installer package.
4. Configure the firewall and ports as necessary. For more information, see Manage Firewall Ports.

Install RPM, Debian or SUSE RPM Installer Package

The following table explains the action to be performed for installing the RPM, Debian or SUSE installer package:

> **Note:** In the following commands, replace the Cohesity agent version with the desired agent version.

Action	How to
Download the Agent installer	From the Download Agents window, based on your Linux distribution, select **RPM**, **Debian**, or **SUSE RPM** and download it to the server you want to protect.
Navigate to the downloaded directory	As the root user with local system privileges on that server, change the directory to the location of the installer package.

Action	How to
Install the Custom certificates	**LINUX** If you are using a Cohesity certificate then run the following commands to install the user certificate followed by agent installation: `export ENFORCE_USE_CUSTOM_CERTS=true && export AGENT_CERT_FILE=<path-to-agent-certificate-in-Cohesity-format>`
Install the Agent	Run the following command depending on the installer package: • RPM: `rpm -i el-cohesity-agent-7.3.1-1.x86_64.rpm` or `yum localinstall ./el-cohesityagent-7.3.1-1.x86_64.rpm` • Debian: `dpkg -i cohesity-agent_7.3.1-1_amd64.deb` • SUSE RPM: `rpm -i cohesity-agent-7.3.1-1.x86_64.rpm`
Install the agent as root user	Run the executable file with the following command syntax: `/<path_to_installer_file> -- --install -c 0 -S root -G root` Followings are the command options in details: 1. **-S** this is the user to run the agent, specify root. 2. **-G** this is the group permission the Agent will use for files and directories installed by the agent, specify root. 3. **-c** this boolean switch controls if the OS user and group should be created. 0 means do not create the OS user and group, 1 means the agent installation will create the specified OS user and group. (When choose to run with the root user, specify '-c 0' as 'root' already exists)

Action	How to

Install the agent as non-root user	To start the service as a non-root user, create a new user or use an existing user with sudo permission and run the following command:
	• RPM: `export COHESITYUSER=<username> ; rpm -i el-cohesity-agent-7.3.1-1.x86_64`
	• Debian: `COHESITYUSER=<username> dpkg -i cohesity-agent_7.3.1-1_amd64`
	• SUSE RPM: `export COHESITYUSER=<username> rpm -i cohesity-agent-7.3.1-1.x86_64`
	Where, *<username>* is the user name with sudo permission.
	Note:
	By default, the installation uses the root user permission for all the files, and the service is started as root. Therefore, it is required to add non-root users to the sudoers list by making the following changes in the `/etc/sudoers` file:
	`<user_name> ALL=(ALL) NOPASSWD:ALL`
	`Defaults:<user_name> !requiretty`
	An example of the sudoers file is as given below:
	dgoble ALL=(ALL) NOPASSWD:ALL
	Defaults:dgoble !requiretty
	cohbackup ALL=(ALL) NOPASSWD:ALL
	Defaults:cohbackup !requiretty

Action	How to

	Note:
	You can add sudo privileges for non-root users using the syntax given below:
	`<user_name> ALL=(ALL) NOPASSWD:/path/to/command1, /path/to/command2, /path/to/command3`
	Remove `NOPASSWD` from the command above if you do not want to authenticate every sudo commands with password.
	The example below shows the sudo commands for user cohesityagent:
	`cohesityagent ALL=NOPASSWD: /bin/mount,/bin/umount,/bin/chmod,/bin/chown,/bin/hostname, /bin/mkdir,/bin/rm,/usr/bin/tee,/usr/bin/stat,/bin/cp,/bin/sed,/usr/bin/touch,/sbin/blkid,/usr/bin/lsof,/bin/ls,/sbin/losetup,/sbin/dmsetup,/usr/bin/rsync,/usr/bin/timeout,/usr/bin/getfacl,/usr/bin/setfacl,/tmp/installer_ch_cohesity_linux_ agent,/home/cohesityagent/installer,/home/cohesityagent/cohesityagent/data/agent/tmp/installer_ch_cohesity_linux_ agent,/bin/systemctl,/home/cohesityagent/cohesityagent/software/crux/bin/cohesity_linux_agent.sh`
	The actual paths for each command may vary in each system. Cohesity keeps adding or removing commands across releases.

Location	• Installation directory: `/opt/cohesity` • Log file: `/var/log/cohesity`

Install script installer package

The following table explains the action to be performed for installing the script installer package:

> **Note:** In the following commands, replace the Cohesity agent version with the desired agent version.

Action	How to
Download the Agent installer	From the Download Agents window, based on your Linux distribution, select **Script Installer** and download it to the server you want to protect.

Action	How to
Navigate to the downloaded directory	As the root user with local system privileges on that server, change the directory to the location of the installer package. For SLES 11 SP4, installing the agent as the root user is required.
Make the installer executable	Make the installer executable, for example: `chmod +x cohesity_agent_7.3.1_linux_x64_installer`
Install the Agent	Run the executable: `sudo /cohesity_agent_6.6.0d_u2_linux_x64_installer - --install`
Location	• Installation directory:`/home/<username>/cohesityagent` or `/root/cohesityagent` • Log file: `/home/cohesityagent/cohesityagent/logs` **Note:** You can specify the option `-log-dir <installtion_path>` to specify the directory path where the agent logs will be saved. If this option is not provided, the logs will be saved in the default path

Install Cohesity Agent for Linux PowerPC

> **Note:** To use the Linux PowerPC agent (Java based), Java Runtime Environment (JRE) 8 needs to be installed on the source system.

The following section explains the action to be performed for installing the Linux PowerPC Agent as a ROOT user:

1. Select **Data Protection** > **Sources**.
2. Click **Download Cohesity Agent**.
3. From the **Download Agents** window, select **PowerPC** and download it to the server you want to protect.
4. Change the directory to the location of the installer package and run the following command to install the rpm based installer package for PowerPC distribution:

   ```
   cohesity-java-agent-7.0.1-1.ppc64le.rpm
   ```

   The agent will be installed in the following directory `/opt/cohesity` and the logs files can be found in `/var/log/cohesity`.

5. To uninstall the agent, run the following command:

```
rpm -e cohesity-java-agent
```

For information about all Cohesity Linux agent installer options, see Linux Script Installer Options.

The agent starts after installation completes.

Agent startup behavior following a machine reboot:

- CentOS and RedHat (distributions with the "systemd" init system) - The agent starts automatically.
- Ubuntu (distributions with the "upstart" init system) - The agent starts automatically.

If a Linux server's `/etc/sudoers` file is managed by a deployment engine such as Chef, Puppet or others, this could impact Cohesity cluster's interaction with servers that have the Linux agent installed. Take the corresponding actions below:

Agent Installation - User type	Action required

As default cohesityagent user	The Cohesity Linux agent is installed using the cohesityagent user by default. For default installations, the cohesityagent is created by the installer. During installation, the installer updates the `/etc/sudoers` file to allow cohesityagent sudo and no-tty sudo access. Ensure the following settings in the /etc/sudoers file for the cohesityagent user are preserved:
	`cohesityagent ALL=(ALL) NOPASSWD:ALL`
	`Defaults:cohesityagent !requiretty`
	An example of the sudoers file is as given below:
	#includedir /etc/sudoers.d
	dgoble ALL=(ALL) NOPASSWD:ALL
	cohbackup ALL=(ALL) NOPASSWD:ALL
	Defaults:cohbackup !requiretty

As non default user, example foo	Ensure the above settings in the `/etc/sudoers` file for the foo user are preserved by replacing the occurrences of cohesityagent with foo.
As root user	No changes required

Install Cohesity Agent for Linux on z/Architecture

> **Note:** To use the Linux on z/Architecture agent (Java-based), Java Runtime Environment (JRE) 8+ (JRE 8, 11, 17) needs to be installed on the source system.

The following section explains the action to be performed for installing the Linux on z/Architecture Agent as a ROOT user:

1. Select **Data Protection** > **Sources**.
2. Click **Download Cohesity Agent**.
3. From the **Download Agents** window, select **s390x** and download it to the server you want to protect.
4. Change the directory to the location of the installer package and run the following command to install the rpm based installer package for z/Architecture distribution:

   ```
   rpm -i cohesity-java-agent-0.0.0-1.s390x.rpm
   ```

   The agent will be installed in the following directory `/opt/cohesity` and the logs files can be found in `/var/log/cohesity`.
5. To uninstall the agent, run the following command:

   ```
   rpm -e cohesity-java-agent
   ```

Install Cohesity Agent for Linux on on ARM (aarch64)

> **Note:** To use the Linux on on ARM (aarch64) agent (Java-based), Java Runtime Environment (JRE) 8+ (JRE 8, 11, 17) needs to be installed on the source system.

The following section explains the action to be performed for installing the Linux on on ARM (aarch64) Agent as a ROOT user:

1. Select **Data Protection** > **Sources**.
2. Click **Download Cohesity Agent**.
3. From the **Download Agents** window, select **aarch64** and download it to the server you want to protect.
4. Change the directory to the location of the installer package and run the following command to install the rpm based installer package for z/Architecture distribution:

   ```
   rpm -i cohesity-java-agent-7.3.1-1.aarch64.rpm
   ```

   The agent will be installed in the following directory `/opt/cohesity` and the logs files can be found in `/var/log/cohesity`.
5. To uninstall the agent, run the following command:

   ```
   rpm -e cohesity-java-agent
   ```

cohesity_linux_agent.sh

The table lists how `cohesity_linux_agent.sh` interacts with various `init` systems to issue `start/stop/status` commands.

If Cohesity does not detect any of the `init` systems, the installer uses the **undetected** `init` system commands.

init system	Commands

systemd	`sudo systemctl start cohesity-agent`
	`sudo systemctl stop cohesity-agent`
	`sudo systemctl status cohesity-agent`

upstart	`sudo initctl start cohesity-agent`
	`sudo initctl stop cohesity-agent`
	`sudo initctl status cohesity-agent`

SysV	`sudo /etc/init.d/cohesity-agent start`
	`sudo /etc/init.d/cohesity-agent stop`
	`sudo /etc/init.d/cohesity-agent status`

undetected	`sudo /etc/init.d/cohesity-agent start`
	`sudo /etc/init.d/cohesity-agent stop`
	`sudo /etc/init.d/cohesity-agent status`

Download and Install the Cohesity Agent on RHV Hosts

> **Note:** Cohesity supports RHV only until version 6.8.1. While you can still protect your RHV sources, the Cohesity Support team will not provide assistance.

Ensure you install the Cohesity Agent on any RHV hosts that you want Cohesity to protect. For installing the agent on RHV hosts, follow the steps described in the Download and Install the Cohesity Agent on Linux Physical Servers" section based on the Linux distribution

Run the following command on all the RHV hosts after they are connected and configured by the oVirt Manager:

```
# iptables -I INPUT `iptables -L INPUT --line-numbers | grep REJECT | awk '{
print $1 }'` -p tcp --dport 50051 -j ACCEPT

# service iptables save
# service iptables restart
```

If the firewall is enabled on RHV 4.1 hosts, open the following port 50051 to accept traffic.

To open the ports, run the following command:

firewall-cmd --permanent --add-port 50051/tcp

Linux Script Installer Options

The Cohesity Linux agent installer has the following options available.

Option	Description
`--agent-options, -a [options]`	Options to pass to the Cohesity agent. Used with single mode operation only.
`--create-user, -c [0|1]`	Whether to create `--service-user` or not. [Default: 1] Used with `--install` option only.
`--debug, -d`	Enable shell script debugging with set `-x` [Default: off]
`--full-uninstall, -U`	Uninstall the Cohesity Linux agent including service-user account and its home directory contents. Destructive operation. Use with care.
`--help, -h`	Print this help.
`--install, -i`	Install/uninstall the Cohesity Linux agent.
`--install-dir, -I [dir]`	Cohesity agent installation dir. [Default: `/home/<username>/cohesityagent or /root/cohesityagent`]
`--install-log-file, -L [file]`	Filename where installer logs should be saved. [Default: */tmp/cohesity_agent_installer_<time_in_seconds>_<pid>.log*]
`--log-dir`	Cohesity agent log installation directory. [Default: `/home/cohesityagent/cohesityagent/logs`]
`--service-group, -G [group]`	Groupname to use for service. [Default: `cohesityagent`]
`--service-user, -S [user]`	Username to use for service. [Default: `cohesityagent`]

Option	Description
`--single-mode, -s`	Install the Cohesity Linux agent for single mode operation. This installs the agent for one time usage/run only. It does not install the Agent to run as service or daemon to run continuously. This copies all required binaries/files to a location and runs the agent. Example use case: You want to recover files to a Linux VM. Cohesity pushes the Cohesity agent and starts it. After performing the usual file/folder recovery by talking to Cohesity Agent and file copying is done, the Agent is removed. The agent is not installed to run as service. It runs for the duration of the recover task only.
`--skip-lvm-check`	**1** - Skip LVM related checks during installation and start the agent in non-lvm mode (only file-based backup will be supported). **0** - Flag is not set. > **Note:** The default value is **0**.
`--skip-mountpoint-check`	Skip checks performed on installation directory's filesystem mountpoint.
`--target`	Extract directly to a target directory. Directory path can be either absolute or relative. [Default: `/tmp`]
`--update-uninstall, -u`	Uninstall the Cohesity Linux agent. Preserve user, group and agent config. Useful when upgrading software.
`--yes-all, -y`	Accept 'yes' answer to all questions in installer. [Default: off] This is useful for performing silent install/uninstall.

Install the Cohesity Agent to run with the Root User

Follow the steps below to install the Cohesity agent to run with the root user:

> **Note:** In the following command, replace the Cohesity agent version with the desired agent version.

For example, run the following command: `sudo ./cohesity_agent_7.3.1_linux_x64_installer -- --install -S root -G root -c 0 -I /opt -y`

The above example does the following:

- `-S root -G root` sets user "root:root" user:group for the agent.
- `-c 0` instructs the installer that user `root` already exists on the system, so do not create it.
- `-I /opt` installs the agent in the /opt directory. If you do not specify the directory, then the default home directory of the user will be used, /root/ in this case.

Sudo Privileges for Linux Users

The Linux system administrator can allowlist set of commands that do not need the root rights to be executed from the Cohesity agent deployed on the Linux servers.

The following tables list the commands that can be allowlisted for Oracle database, volume backups, and file restores for the Cohesity agent.

Oracle Database

Argument	Default Behavior	Allowlist Commands

`--skip-oracle-check`	The default value is 0. We will allowlist commands required by Oracle database.	`mkdir`
		`rm`
		`tee`
		`stat`
		`cp`
		`srvctl (from Oracle home)`

	If set to 1, we will not add any commands to the allowlist.	

Volume Backup

Argument	Default Behavior	Allowlist Commands

`--skip-lvm-check`	The default value is 0. We will allowlist commands required by volume backup.	`lvs`
		`vgs`
		`lvcreate`
		`vgcreate`

	If set to 1, we will not add any commands to the allowlist.	

File Restore

Argument	Default Behavior	Allowlist Commands

`--skip-restore-check`	The default value is 0. We will allowlist commands required by file restore.	`blkid`
		`lsof`
		`ls`
		`losetup`
		`dmsetup`
		`rsync`
		`timeout`

	If set to 1, we will not add any commands to the allowlist.	

> **Note:** During a Linux agent upgrade:
> If **NOPASSWD:ALL** entry is present in the sudoers file, then all commands can be executed without the root rights.
> If **NOPASSWD:ALL** entry is removed from the sudoers file, then you can add the commands listed in the table above for allowlisting.

Upgrade the Linux Agent

You can upgrade the Linux agent either from the Cohesity UI or using the CLI.

> **Note:** In the following commands, replace the Cohesity agent version with the desired agent version.

Upgrade from the Cohesity UI	Upgrade using CLI

1. Navigate to **Data Protection > Sources**.
2. Click **Download Cohesity Agent**.
3. Stop the Agent service on the server.
4. Click **Upgrade Agents**.
5. Restart the Agent service.
	1. Navigate to the Agent installation directory.
	2. Run the following command to install the script installer package:
	`sudo cohesity_agent_7.3.1_linux_x64_installer -- --install`
	3. Run the following command to install the RPM package:
	`rpm -U el-cohesity-agent-7.3.1-1.x86_64.rpm`
	4. Run the following command to install the Debian package:
	`dpkg -i cohesity-agent_7.3.1-1_amd64.deb`
	5. Run the following command to install the SUSE RPM package:
	`rpm -U cohesity-agent-7.3.1-1.x86_64.rpm`
	6. Run the following command to install the PowerPC RPM package:
	`rpm -U cohesity-java-agent-7.0.1-1.ppc64le.rpm`
	7. To install the Linux on z/Architecture package on Linux variants running on the x64 platform:
	`rpm -U cohesity-java-agent-0.0.0-1.s390x.rpm`
	8. To install the Linux on ARM (aarch64) package on Linux variants running on the x64 platform:
	`rpm -U cohesity-java-agent-7.3.1-1.aarch64.rpm`

Auto-upgrade of the Cohesity Linux Agent

Cohesity supports auto-upgrade of the Cohesity Linux Agent running on physical servers.

> **Note:** The option to auto-upgrade Cohesity Agent is not available on the Cohesity cluster with multi-tenancy configured.

To enable auto-upgrade:

1. Navigate to **Settings** > **Update**, and select **Upgrade** tab.
2. Select the **Upgrade Cohesity Agent on all servers in Sources** checkbox.

Uninstall the Script-Based Agent

To uninstall script-based agent, follow one of the methods listed below:

- If the Cohesity agent is installed in the default installation directory, run the "uninstall" script that is included with the installed software. For example:

```
cd <bin_directory>
[default=/home/cohesityagent/cohesityagent/software/crux/bin]
sudo ./uninstall
```

- Use the agent installer itself. For example:

```
sudo ./cohesity_agent_7.3.1_linux_x64_installer -- --full-uninstall
```

> **Note:** Replace the Cohesity agent version with the desired agent version.

Uninstall RPM/PKG Agents

To uninstall the RPM/PKG agents, follow the steps listed below:

- To uninstall the SUSE RPM/RPM package, run the following command:

```
rpm -e cohesity-agent
```

- To uninstall the Debian package, run the following command:

```
dpkg -r cohesity-agent
```

- To uninstall the PowerPC package, run the following command:

```
rpm -e cohesity-java-agent
```

- To uninstall the PowerPC Linux on z/Architecture package, run the following command:

```
rpm -e cohesity-java-agent
```

- To uninstall the PowerPC Linux on ARM (aarch64) package, run the following command:

```
rpm -e cohesity-java-agent
```

Sample Ubuntu Linux Installation Output

Sample output for the following command:

```
sudo ./cohesity_linux_agent_installer -- -i -y
```

```
Verifying archive integrity... All good.
```

```
Uncompressing Cohesity Linux Agent  100%
```

```

Troubleshoot

For troubleshooting information, see Troubleshooting Cohesity Agent issues on Linux physical servers.

Log in to the Cohesity support site to see more knowledge base articles.

Install and Manage the Agent on Hyper-V Linux VMs

To allow file-level recovery to a guest Linux VM running on Hyper-V, the guest VM must have the following installed:

- Cohesity Linux Agent
- Linux Integration Services
- Ubuntu
- CentOS or RHEL

Limitations

- Efficient file-level recovery does not support recovering from multiple Linux volumes.

Free Space Requirement for block-based Backup

For each virtual machine backup, you'll need free space on the volume hosting the virtual hard disk files to allow Hyper-V enough room for differencing disks (AVHDs) during backup. The space must be at least equal to the calculation Initial disk size*Churn rate*Backup window time. If you're running multiple backups on a cluster, you'll need enough storage capacity to accommodate the AVHDs for each of the virtual machines using this calculation.

Cohesity Linux Agent

Follow these steps to download and install the agent.

1. Navigate to **Data Protection > Sources**.
2. Click **Download Cohesity Agent**.

   The Download Agents window appears.

3. Manually install the agent on the Linux VM you want to recover to.

   Follow the installation instructions in this topic: Install and Manage the Agent on Linux Servers.

Linux Integration Services

The Linux Integration Services package must be installed on the Linux VM. For more information, see Linux Integration Services. Without Linux Integration Services installed, the Linux VM hostname and IP addresses are not visible to SCVMM and the VM cannot be selected as a recovery target.

Ubuntu

Ensure the VM is running a supported release. For more information, see Supported Ubuntu Virtual Machines on Hyper-V.

Install these additional packages:

- hv-kvp-daemon-init
- linux-tools
- linux-cloud tools

1. The following example command installs the packages:

   ```
   sudo apt-get update && sudo apt-get install hv-kvp-daemon-init linux-tools-$(uname -r) linux-cloud-tools-$(uname -r) -y
   ```

2. After you install the packages, test the daemons by running the following commands:
   - hv_fcopy_daemon
   - hv_kvp_daemon
   - hv_set_ifconfig
   - hv_vss_daemon
   - hv_get_dns_info
3. Shutdown the VM (not just a reboot).

   ```
   sudo shutdown -h now
   ```

4. Power on the VM using PowerShell or SCVMM.

   The IP address should be visible in the Networking tab.

CentOS or RHEL

Ensure the VM is running a supported release. For more information, see Supported CentOS and Red Hat Enterprise Linux virtual Machines on Hyper-V.

> **Note:** Ensure that **Guest Services** is enabled on Hardware Configuration > Integration Services on the selected VM.

Install the hyperv-daemons package.

1. The following example command installs the package:

   ```
   sudo yum install hyperv-daemons
   ```

2. Enable hypervvsd and hypervkvpd by running the following commands:

   ```
   sudo systemctl enable hypervvssd
   sudo systemctl enable hypervkvpd
   ```

3. Reboot the VM.

   ```
   sudo shutdown -r now
   ```

   The IP address should be visible in the Networking tab.

Install and Manage the Cohesity Java Agent on AIX Servers

You can install the Cohesity Java Agent on AIX server to protect:

- AIX server as a physical server
- Oracle database running on AIX server

Install the Cohesity Java Agent on AIX Physical Server

Prerequisites

Ensure that the AIX physical server meets the following requirements:

- To use the AIX agent (Java based), Java Runtime Environment (JRE) 8 needs to be installed on the source system.
- AIX agent (Java based) being installed should be a higher version than the existing version of GoAgent.
- Install 64-bit version 8 of IBM-supported AIX compatible Java.
- 1.5 GB of free RAM (at run time) to account for JRE overhead.
- Sudo package must be installed.
- Latest version of Bash must be installed. For more information, see AIX Toolbox for Linux Applications.
- Java version for the Agent must be JRE 1.8.0 AIX ppc-64 bit.

Considerations

- Only file-based Protection Groups are supported.
- IVM (Instant Volume Mount) is not supported.
- Cohesity does not support source-side deduplication of AIX server.
- AIX clustering is not supported.

Install the Cohesity Java Agent

For information on supported AIX versions on Cohesity cluster, see Supported Software.

To install the Cohesity Java agent:

You can download the Cohesity agent installer from the Cohesity UI or manually download the agent from the Cohesity Package Download and install the agent using CLI.

1. Download the installer:
   a. Using the Cohesity cluster UI

      Navigate to **Data Protection** > **Sources** and click **Download Cohesity Agent**.

   b. Using the Cohesity Package Download site

      Download the Cohesity Java Agent package (a **.bff** file) from Cohesity Package Download. Ensure the Java Agent is on the AIX server you want to protect.
2. To Install the Custom certificates, follow the below steps:

   ```
   echo ENFORCE_USE_CUSTOM_CERTS=true >> /usr/local/cohesity/set_env.sh
   ```

   If you are using a Cohesity certificate then run the following commands to install the user certificate:

   ```
   echo AGENT_CERT_FILE=<path-to-agent-certificate-in-Cohesity-format> >>
   /usr/local/cohesity/set_env.sh
   ```

   > **Note:**
   > - ENFORCE_USE_CUSTOM_CERTS, if this parameter is set to true, then the agent will try to load the specified certificate and fail to start in case of an invalid file or files.
   > - AGENT_CERT_FILE specifies the path to the agent certificate file in the Cohesity format
3. Install the package:

   Log in to the AIX server as a root user and run the following command to install the package:

   ```
   installp -ad <path_to_downloaded_agent_package> all
   ```

For example:

```
installp -ad cohesity_agent_6.6_aix_java.bff all
```

The Cohesity Java Agent starts automatically. Now you can register the server with the Cohesity cluster. Reboot is not required. The Cohesity Java Agent starts after any future reboots.

Install the Cohesity Java Agent on the Oracle AIX Server

Prerequisites

Before you install the AIX Java agent on the server, make sure the following software is installed on the server:

- The latest Bash package. For more information, see AIX Toolbox for Linux Applications.
- Java version, JRE 1.8.0 AIX ppc-64 bit for the agent.

> **Note:** Before installing the AIX Java agent, Cohesity recommends logging in to SQL Plus and RMAN using appropriate credentials (OS Auth or User Based). If the login is successful, proceed with the installation. If not, obtain the required user credentials and verify that you can log in.

Considerations

The mount point used for Oracle DB cloning is not persistent across reboots. To resolve this issue, manually update the **/etc/filesystem** file using any editor and update the mount path information.

Install the Cohesity Java Agent

To install the Cohesity Java agent on Oracle AIX sever:

You can upgrade the Cohesity agent installer from the Cohesity UI or manually download the agent from the Cohesity Package Download and install the agent using CLI.

1. Follow steps 1 and 2 from Install the Cohesity Java Agent section to download the agent and install Custom certificates.
2. Install the package:

   Log in to the AIX server as an Oracle ROOT user and run the following command to install the package.

   ```
   sudo install_with_oracle_adapter_support=true installp -ad <path_to_
   downloaded_agent_package> all
   ```

   For example:

```
bash-4.2$ id
uid=204(oracle) gid=54321(oinstall) groups=54322(dba),54323(oper)

bash-4.2$ sudo install_with_oracle_adapter_support=true installp -ad
cohesity_agent_6.6_aix_java.bff all
```

The Cohesity Java Agent starts automatically. Now you can register the server with the Cohesity cluster. Reboot is not required. The Cohesity Java Agent starts after any future reboots.

For a non ROOT user, run the following command:

```
sudo install_with_oracle_adapter_support=true install_oracle_adapter_
user_name=<oracle-username> install_oracle_adapter_dba_group_name=<DBA-
GROUP-NAME> installp -ad <path to .bff> all
```

> **Note:**
>
> - You should set the AIX NFS block size to 512K after installing the AIX java agent on the server. For more information, contact Cohesity Support.
> - `/var/log/cohesity/agent` is the default location where logs are stored.
> - For a non ROOT user, user should have **SETENV** enabled for the installp command in the `/etc/sudoers`.

Upgrade the Cohesity Java Agent

Cohesity supports auto-upgrading the Cohesity Java Agent.

> **Note:** If the existing Cohesity agent version is 6.4 and earlier versions, to upgrade the agent you need to uninstall the agent and install the new Cohesity Java Agent. For Cohesity agent 6.4.1 and higher versions, you can upgrade the agent from the Cohesity UI or CLI.

To upgrade the Cohesity Java agent

You can upgrade the Cohesity agent installer from the Cohesity UI or manually download the agent from the Cohesity Package Download and install the agent using CLI.

1. Using the Cohesity cluster UI

   Navigate to **Data Protection** > **Sources**. Click the action icon (⋮) next to the registered source and then click **Upgrade Agents**, if an upgrade is available.

2. Upgrading the Cohesity agent installer using CLI

   a. Download the latest Cohesity Java Agent package (a .bff file). Ensure the Java Agent is on the AIX server you want to upgrade.

   b. Install the package:

      Log in to the AIX server as a root user and run the following command to upgrade the agent:

      ```
      installp -ac -d <path_to_downloaded_agent_package> all
      ```

      For Example:

      ```
      installp -ac -d cohesity_agent_6.5.1_aix_java.bff all
      ```

Uninstall the Cohesity Java Agent

Uninstallation stops the running Agent and removes the libraries and other artifacts that were created during installation.

To uninstall the Cohesity Java agent, run the following command:

```
installp -u cohesity_agent.rte
```

Cohesity Java Agent Command-line Options

To start, stop and to get the status and version of the Cohesity Java agent, run the following command:

```
/usr/local/cohesity/agent/aix_agent.sh start|stop|status|version
```

Install and Manage the Agent on Solaris Servers

Install the Cohesity Agent on Solaris Physical Servers

To install the Cohesity agent on the Solaris server:

You can download the Cohesity agent installer from the Cohesity UI or manually download the agent from the Cohesity Package Download and install the agent using CLI.

1. Download the installer:
    a. Using the Cohesity cluster UI

       Navigate to **Data Protection** > **Sources** and click **Download Cohesity Agent**.

    b. Using the Cohesity Package Download site

       Download the Solaris 10 Agent here.

       > **Note:** Solaris 10 and 11 agents can also be installed in non-global zones. We can register a non-global zone as a physical server and perform file-level backups or recoveries.

    c. Run the following commands to create a custom installer option file to install with custom certificates:

       ```
       echo ENFORCE_USE_CUSTOM_CERTS=true >> /usr/local/cohesity/set_
       env.sh
       ```

       > **Note:**
       > - ENFORCE_USE_CUSTOM_CERTS, if this parameter is set to true, then the agent will try to load the specified certificate and fail to start in case of an invalid file or files.
       > - AGENT_CERT_FILE specifies the path to the agent certificate file in the Cohesity format.

    d. Install the package:

       Run the following command to install the package:

       ```
       sudo /usr/sbin/pkgadd -d <cohesity_agent_file_path>
       ```

       If sudo is not installed, install the package as the root user.

       The agent starts automatically after installation and does not require server reboot. Now you can register the server with the Cohesity cluster. The agent will start automatically after every reboot of the server.

    e. Run the following command to know the agent version on the source:

       `/usr/local/cohesity/agent/solaris_agent.sh` version

Additional Agent

This section lists the additional CLI commands that can be used with the Solaris agent.

View Agent status:

```
/usr/bin/svcs -x svc:/application/cohesity-agent:default
```

Start the Agent:

```
/usr/sbin/svcadm enable svc:/application/cohesity-agent:default
```

Stop the Agent:

```
/usr/sbin/svcadm disable svc:/application/cohesity-agent:default
```

Upgrade the Agent

To upgrade the agent using the CLI, follow the steps below:

You can upgrade the Cohesity agent installer from the Cohesity UI or manually download the agent from the Cohesity Package Download and install the agent using CLI.

1. Upgrade the installer:
    a. Using the Cohesity cluster UI

       Navigate to **Data Protection** > **Sources**. Click the action icon (⋮) next to the registered source and then click **Upgrade Agents**, if an upgrade is available.

    b. Using the Cohesity Package Download site
        i. Download the latest Solaris 10 Agent here.
        ii. Run the following command to upgrade the package:

```
sudo /usr/sbin/pkgadd -d <cohesity_agent_file_path>
```

The Agent restarts automatically. Reboot is not required.

Uninstall the Agent

Uninstallation stops the running Agent and removes the libraries and other artifacts that were created during installation.

To uninstall agent, run the following command:

```
sudo /usr/sbin/pkgrm cohesity-agent
```

Install and Manage the Agent on HP-UX Servers

For information on supported HP-UX versions on the Cohesity cluster, see Physical Servers.

Prerequisites

Ensure that the HP-UX server meets the following requirements:

- **OS Version**: HP-UX 11i v3 (B.11.31)
- **Architecture**: Intel Itanium (IA64)
- **Cohesity Version**: Cohesity cluster and agent version must be version 6.8.1 or later.
- **Java Version**: Java 8 installed on HP-UX and it should be installed in either PATH or `/usr` or `/opt`.
- **Minimum Space Requirements**:
  - 200MB in /var and /usr directories
  - 100MB in /tmp directory
  - 10KB in /etc directory
- **Memory Requirements**: Minimum memory of 2GB is recommended.

Consideration

- The Cohesity software version and the Cohesity Agent version should be 6.8.1 or later for HP-UX servers.
- Cohesity supports only file-based backup and recovery on HP-UX servers.
- Cohesity supports only the VxFS filesystem on HP-UX servers.

Download and Install the HP-UX Agent

To download and install the HP-UX agent:

You can download the Cohesity agent installer from the Cohesity UI or manually download the agent from the Cohesity Package Download and install the agent using CLI.

1. Download the installer:
   a. Using the Cohesity cluster UI

      Navigate to **Data Protection** > **Sources** and click **Download Cohesity Agent**.

   b. Using the Cohesity Package Download site

      Download the Cohesity HP-UX Agent package.
2. To install the Custom certificates, follow the below steps:

   ```
   echo ENFORCE_USE_CUSTOM_CERTS=true >> /usr/local/cohesity/set_env.sh
   ```

   If you are using a Cohesity certificate then run the following commands to install the user certificate:

   ```
   echo AGENT_CERT_FILE=<path-to-agent-certificate-in-Cohesity-format> >>
   /usr/local/cohesity/set_env.sh
   ```

> **Note:**
> - ENFORCE_USE_CUSTOM_CERTS, if this parameter is set to true, then the agent will try to load the specified certificate and fail to start in case of an invalid file or files.
> - AGENT_CERT_FILE specifies the path to the agent certificate file in the Cohesity format.

3. Install the package:

   Run the following command to install the package as a Root user:

   ```
   swinstall -s <installer absolute path>  -x reinstall=true \*
   ```

   The Agent starts automatically. Now you can register the Server with the Cohesity cluster. Reboot is not required. The Agent starts after any future reboots.

Backup and Restore on HP-UX Server

Cohesity supports only file-based backup and restores on HP-UX servers.

To backup and restore on HP-UX server:

1. For creating backup jobs on the HP-UX server, see Add or Edit a Protection Group for Physical Servers.
2. To restore files and folders on the HP-UX server, see Recover Files or Folders to the Original Location and Recover Files or Folders to a New Location.

Consideration

- Cohesity supports only file-based backup and restores on HP-UX servers.

Upgrade the Agent

To upgrade the agent, follow the steps below:

You can upgrade the Cohesity agent installer from the Cohesity UI or manually download the agent from the Cohesity Package Download and install the agent using CLI.

1. Upgrade the installer:
   a. Using the Cohesity cluster UI

      Navigate to **Data Protection** > **Sources**. Click the action icon (⋮) next to the registered source and then click **Upgrade Agents**, if an upgrade is available.

   b. Using the Cohesity Package Download site

i. Download the latest Cohesity HP-UX Agent package.

ii. Run the following command to install the package as a Root user:

```
swinstall -s <installer absolute path>  -x reinstall=true \*
```

Uninstall the Agent

Uninstallation stops the running Agent and removes the libraries and other artifacts that were created during installation.

To uninstall the agent, run the following command:

```
swremove cohesity_agent
```

Additional Agent Commands

This section lists the additional HP-UX agent commands:

View Agent status

```
/usr/local/cohesity/agent/hpux_agent.sh status
```

Start the Agent

```
/usr/local/cohesity/agent/hpux_agent.sh start
```

Stop the Agent

```
/usr/local/cohesity/agent/hpux_agent.sh stop
```

Restart the Agent

```
/usr/local/cohesity/agent/hpux_agent.sh restart
```

Deploy Cohesity Agent from the Cohesity UI

Cohesity provides the ability to deploy Cohesity Agents on Windows or Linux servers from the Cohesity UI. The server can be a physical server or a virtual server. This section provides information on deploying Cohesity Agent on physical and virtual servers, and its use cases.

Supported Software

The following table lists the supported server on which you can deploy Cohesity Agent from the Cohesity UI.

Supported Server	Operating systems
Physical server	• Windows • Linux
VMware vCenter Server and ESXi standalone host	• Windows • Linux

For information on the supported version of the servers and operating systems, see Supported Software.

Deploy Cohesity Agent on Physical Servers

For protecting a physical server using Cohesity, you must first deploy the Cohesity agent on the physical server. You can deploy the Cohesity agent on a physical server:

- By downloading the Cohesity agent installer from the Cohesity UI and then running the installer on the server you want to protect.
- Directly from the Cohesity UI.

This section provides information on deploying the Cohesity agent on physical servers from the Cohesity UI.

You can use one of the following options to deploy the Cohesity agent on the physical servers from the Cohesity UI:

- **Enter Hostname/IP**: You can choose this option to deploy the Cohesity agent on multiple physical servers having the same credentials for server authentication.
- **Upload CSV**: You can choose this option to deploy agents on multiple physical servers having different credentials for server authentication.

Plan and Prepare

Before you deploy the Cohesity agent on a physical server, ensure the following prerequisites:

- The required firewall ports are open to enable communication between the Cohesity cluster and the physical server.
- Minimum permission required to deploy the Cohesity agent.
- WinRM is enabled on the Windows physical servers.
- SSH server is installed on the Linux physical servers.

Ports Used for Communication

Ensure the following ports are open based on the server you want to deploy the Cohesity agent:

Port	Usage	Windows	Linux
50051	To enable communication between the Cohesity cluster and theCohesity agent running on the physical server.	Yes	Yes
22	To enable communication between Cohesity nodes and Linux sources.	No	Yes
5985/5986	WinRM HTTP connectivity HTTPS	Yes	No

Minimum Permissions

Ensure you have the following permissions for deploying the Cohesity agent.

For Windows server

For deploying the Windows agent, you can either use the LOCAL SYSTEM account or an account that meets the following requirements to install the Cohesity agent:

- The account must be a member of the local Windows Administrators group. For example, qa01\tme-backup is an Active Directory user account in the data center. If the backup admin plans to use this account, qa01\tme-backup must be part of the local Windows Administrators group on the Windows server.
- The account must have Log on as a service in the User Rights Assignment on the Windows server to deploy the Cohesity agent.

For Linux Server

If you are deploying the Linux agent using an existing user, the user must have sudo permission. For sudo permission, you must add the user to the sudoers list by making the following changes in the **/etc/sudoers** file:

```
<user_name> ALL=(ALL) NOPASSWD:ALL
```

```
Defaults:<user_name> !requiretty
```

Deploy Cohesity agent by Entering Hostname or IP Address

If the physical servers on which you deploy the Cohesity agent have the same credentials for server authentication, then you can perform the following steps:

> **Note:** If the physical servers have different credentials, then you can deploy the Cohesity agent using the Upload CSV option. For more information, see Upload CSV.

To deploy the Cohesity agent on multiple physical servers having the same credentials:

1. Navigate to **Data Protection** > **Sources**.
2. Click the plus icon on the top-right of the page and then select **Deploy Cohesity Agent**.

   The Deploy Cohesity agent page appears.
3. Select **Enter Hostname/IP** as the option to deploy the Cohesity agent.
4. Select the operating system of the server from the drop-down list.
5. In the **Hostname or IP Address** field, enter one or more comma-separated IP addresses or hostnames of the servers with the same type of operating system. Ensure that the servers specified have the same username and password for authentication.
6. Click **Select**.
7. For server authentication, enter the username and password. For Linux server, you can optionally select the **SSH Key** tab and enter the user name and SSH key.
8. Disable the **Register as a Physical Server** option if you do not want to register the servers with the Cohesity cluster. If you disable this option, then to protect the physical servers, you must register the servers as described in the Register a physical server topic. By default, this option is enabled.
9. Optional. Click the down-arrow icon next to the **More Options** setting, and then click the **edit** icon to change the default settings if required:

Option	Description	
	Windows OS	**Linux OS**

Deployed As	By default, the Cohesity agent will be deployed using the **Local System account**.
	
	To change the default account, click the **edit** icon, select **User Account**, and then provide the credentials of a user account having local administrator privileges on the server with "Log on as a service" permission.
		By default, the Cohesity agent will be deployed using the `cohesityagent` user and group. During the agent deployment, the installer updates the **/etc/sudoers** file of the Linux server to allow `cohesityagent` sudo and no-tty sudo access.
		
		To change the default service user, click the **edit** icon, and then provide the user name and group name.
		
		For a new user type:
		
		If you have specified a new user, , then select the **Create the user if it does not exists** checkbox. By selecting this option, the installer updates the **/etc/sudoers** file of the Linux server to allow the specified user sudo and no-tty sudo access.
		
		For an existing user type:
		
		If the user you specified already exists, then you must add the user to the sudoers list by making the following changes in the **/etc/sudoers** file:
		
		`<user_name> ALL=(ALL) NOPASSWD:ALL`
		`Defaults:<user_name> !requiretty`
		
		An example of the sudoers file is as given below:
		
		`#includedir`

Option	Description	
	Windows OS	Linux OS
		`/etc/sudoers.d dgoble ALL=(ALL) NOPASSWD:ALL cohbackup ALL=(ALL) NOPASSWD:ALL Defaults:cohbackup !requiretty`
Deployment Path	By default, the Cohesity agent is deployed in the **C:\Program Files\Cohesity** directory. To change the default path, click the **edit** icon and specify the path.	By default, the Cohesity agent is deployed in the **/opt/cohesity/agent/** directory. To change the default path, click the **edit** icon and specify the path.
Components	• **Volume CBT (Change Blocks Tracker)**: This component is required to perform incremental backups. This component will be installed by default if you have selected to register the server as a physical server. You must reboot the server after installing this component. If you are not rebooting the server after installation or not installing this component, then only full backups will be performed. • **File System CBT (Change Blocks Tracker)**: This component is required for the incremental backup of individual MS SQL databases hosted on a server which is registered as a physical server. This component is not installed by default. To install this file system CBT, click the edit icon and enable the **File System CBT (Change Blocks Tracker)** option.	Not applicable

10. Click **Deploy**.

Cohesity will initiate the Cohesity agent deployment on the physical servers. You can view the status by clicking the notification icon on the top-right corner of the Source page.

Deploy Cohesity Agent by Uploading CSV

If the physical servers on which you deploy the Cohesity agent have different credentials for server authentication, then you can perform the following steps:

> **Note:** If the physical servers have the same credentials, then you can deploy the Cohesity agent using the **Enter Hostname/IP** option. For more information, see Deploy Cohesity agent by Entering Hostname or IP Address.

To deploy the Cohesity agent on multiple physical servers having different credentials:

1. Navigate to **Data Protection** > **Sources**.
2. Click the plus icon on the top-right of the page and then select **Deploy Cohesity Agent**.

   The Deploy Cohesity agent page appears.
3. From the Deploy Cohesity agent page, select **Upload CSV** as the option to deploy Cohesity agent.
4. Click **Download sample** file and download the CSV sample file to know the information and format in which the input must be provided in the CSV file. The following is the format in which the input must be provided in the CSV file:

   ```
   #IP/Hostname,OS Type,Server Username,Server Password,Install
   Location,Volume CBT,File CBT,Service Account Username,Service Account
   Password,SSH Key,
   ```

   Where,

   - `IP/Hostname`: The IP address or a valid hostname on which the Cohesity agent needs to be deployed.
   - OS type: The operating system of the server.
   - `Server Username` and `Server Password`: Credentials of the server on which the Cohesity agent needs to be deployed.
   - `Install Location`: (Optional) The path where the Cohesity agent must be deployed. If left blank, then the agent will be installed in the default location.
   - `Volume CBT` : (Optional) Applicable only for Windows OS types. If set to TRUE, the volume CBT driver will be installed. This field is ignored for non-Windows OS types.
   - `File CBT`: (Optional) Applicable only for Windows OS types. If set to TRUE, the file CBT driver will be installed. This field is ignored for non-Windows OS types.
   - `Service Account Username` and `Service Account Password`: (Optional) Credentials to register Cohesity agent as a service account.
   - `SSH Key`: (Optional) Use the SSH key to authenticate the server to deploy the Cohesity agent.

   For example:

- `#10.0.0.1,linux,admin,test_password,/var/agent_location/,,,,,,`
- `#10.0.0.2,windows,admin,test_password,C:\\Program Files\,,,service_admin,service_password,,`

> **Note:**
> - Each entry should end with a comma.
> - If no value is to be given for an optional field, it should be left blank between separating commas.

5. Click **Browse to upload a CSV file** and upload the CSV file in the format provided in the sample file.
6. Click **Select**.

Cohesity will initiate the Cohesity agent deployment on the physical servers. You can view the status by clicking the notification icon on the top-right corner of the Source page.

Deploy Cohesity Agent on Virtual Servers

By deploying the Cohesity agent on a virtual machine, you can:

- Perform efficient file-level recovery.
- Protect VMs as physical servers.
- Protect the applications running on the VMs.

This topic provides information on how to deploy the Cohesity agent on virtual machines from the Cohesity UI.

Plan and Prepare

Before you deploy the Cohesity agent on a virtual server, ensure the following prerequisites:

- The required firewall ports are open to enable communication between the Cohesity cluster and the physical server.
- Minimum permission required to deploy the Cohesity agent.
- Disable the Windows UAC.
- Understand the considerations.
- VMware tool is installed and running on the VMs of the virtual server.

Ports Used for Communication

For deploying the Cohesity agent on a virtual server, port 50051 must be open.

Minimum Permissions

- The user account that is used for auto-deploying agents in a Windows VMware environment must have administrator privileges on the VM where the agent is deployed. The account must have the "sysadmin" Server Role if the virtual server has SQL Server installed.
- If Windows firewall is used, add an inbound rule to accept the Cohesity agent and TCP connections on local port 50051.
- The user account that is used for file recovery to a Windows VM must have administrator privileges on the target VM. The account must have the "sysadmin" Server Role if the virtual server has SQL Server installed.

Deploy Cohesity Agent on VMs for file-level recovery

To perform efficient file-level recovery of the VMs of a virtual server, you must deploy the Cohesity agent on VMs.

To deploy the Cohesity agent on a virtual server from the Cohesity UI for efficient file-level recovery

1. Navigate to **Data Protection** > **Sources**.
2. Navigate the hierarchy to the VMware vCenter server to which you want to deploy the Cohesity agent.
3. Click the server's actions menu, and select **Deploy Cohesity Agent**.

   The Deploy Cohesity agent page appears.
4. Select the VMs onto which you want to deploy the Cohesity agent, and click **Select**. You can filter the VMs based on the operating system.

   > **Note:** You cannot select VMs of different operating systems. For example, if you have selected Windows VMs then you cannot select Linux VMs and vice-versa.
5. For server authentication, enter the guest username and password.
6. By default, the **Register as a Physical Server** option is disabled and you must not enable this option.

   If you enable this option, then the virtual server will be registered as a physical server and you cannot perform file-level recovery of the VMs.
7. Optional. Click the down-arrow icon next to the **More Options** setting and click the edit icon to change the default settings if required:

Option	Description	
	Windows OS	**Linux OS**

Deployed As	By default, the Cohesity agent will be deployed using the **Local System account**.
	
	To change the default account, click the **edit** icon, select **User Account**, and then provide the credentials of a user account having local administrator privileges on the server with "Log on as a service" permission.
		By default, the Cohesity agent will be deployed using the `cohesityagent` user and group. During the agent deployment, the installer updates the **/etc/sudoers** file of the Linux server to allow `cohesityagent` sudo and no-tty sudo access.
		
		To change the default service user, click the **edit** icon, and then provide the user name and group name.
		
		For a new user type:
		
		If you have specified a new user, , then select the **Create the user if it does not exists** checkbox. By selecting this option, the installer updates the **/etc/sudoers** file of the Linux server to allow the specified user sudo and no-tty sudo access.
		
		For an existing user type:
		
		If the user you specified already exists, then you must add the user to the sudoers list by making the following changes in the **/etc/sudoers** file:
		
		`<user_name> ALL=(ALL) NOPASSWD:ALL`
		`Defaults:<user_name> !requiretty`
		
		An example of the sudoers file is as given below:
		
		`#includedir`

Option	Description	
	Windows OS	Linux OS
		`/etc/sudoers.d dgoble ALL=(ALL) NOPASSWD:ALL cohbackup ALL=(ALL) NOPASSWD:ALL Defaults:cohbackup !requiretty`
Deployment Path	By default, the Cohesity agent is deployed in the **C:\Program Files\Cohesity** directory. To change the default path, click the **edit** icon and specify the path.	By default, the Cohesity agent is deployed in the **/opt/cohesity/agent/** directory. To change the default path, click the **edit** icon and specify the path.
Components	• **Volume CBT (Change Blocks Tracker)**: This component is required to perform incremental backups. This component will be installed by default if you have selected to register the server as a physical server. You must reboot the server after installing this component. If you are not rebooting the server after installation or not installing this component, then only full backups will be performed. • **File System CBT (Change Blocks Tracker)**: This component is required for the incremental backup of individual MS SQL databases hosted on a server which is registered as a physical server. This component is not installed by default. To install this file system CBT, click the edit icon and enable the **File System CBT (Change Blocks Tracker)** option.	Not applicable

8. Click **Deploy**.

Cohesity will initiate the Cohesity agent deployment. You can view the status by clicking the notification icon on the top-right corner of the Source page.

Deploy Cohesity Agent to Protect VMs as physical servers

From the Cohesity UI, you can deploy the Cohesity agent on VMs to protect them as physical servers.

To deploy Cohesity agent on VMs to protect the VMs as physical servers:

1. Navigate to **Data Protection** > **Sources**.
2. Click the plus icon on the top-right of the page and then select **Deploy Cohesity Agent**.

   The Deploy Cohesity agent page appears.
3. Select the **Browse vCenter** option to deploy the Cohesity agent on servers.
4. From the **Data Source** drop-down menu, select the virtual server that is already registered with the Cohesity cluster.
5. Select the VMs onto which you want to deploy the Cohesity agent, and click **Select**. You can filter the VMs based on the operating system.

   > **Note:** You cannot select VMs of different operating systems. For example, if you have selected Windows VMs then you cannot select Linux VMs and vice-versa.
6. Provide the guest username and password for authentication. For Linux servers, you can optionally select the **SSH Key** tab and enter the user name and SSH key.
7. By default, the **Register as a Physical Server** option is enabled to register the VMs as physical servers. If you disable this option, then the selected VMs will not be registered as physical servers and you cannot protect the VMs as physical servers.
8. Optional. Click the down-arrow icon next to the **More Options** setting and click the **edit** icon to change the default settings if required:

Option	Description	
	Windows OS	**Linux OS**

Deployed As	By default, the Cohesity agent will be deployed using the **Local System account**.
	
	To change the default account, click the **edit** icon, select **User Account**, and then provide the credentials of a user account having local administrator privileges on the server with "Log on as a service" permission.
		By default, the Cohesity agent will be deployed using the `cohesityagent` user and group. During the agent deployment, the installer updates the **/etc/sudoers** file of the Linux server to allow `cohesityagent` sudo and no-tty sudo access.
		
		To change the default service user, click the **edit** icon, and then provide the user name and group name.
		
		For a new user type:
		
		If you have specified a new user, , then select the **Create the user if it does not exists** checkbox. By selecting this option, the installer updates the **/etc/sudoers** file of the Linux server to allow the specified user sudo and no-tty sudo access.
		
		For an existing user type:
		
		If the user you specified already exists, then you must add the user to the sudoers list by making the following changes in the **/etc/sudoers** file:
		
		`<user_name> ALL=(ALL) NOPASSWD:ALL`
		`Defaults:<user_name> !requiretty`
		
		An example of the sudoers file is as given below:
		
		`#includedir`

Option	Description	
	Windows OS	Linux OS
		`/etc/sudoers.d dgoble ALL=(ALL) NOPASSWD:ALL cohbackup ALL=(ALL) NOPASSWD:ALL Defaults:cohbackup !requiretty`
Deployment Path	By default, the Cohesity agent is deployed in the **C:\Program Files\Cohesity** directory. To change the default path, click the **edit** icon and specify the path.	By default, the Cohesity agent is deployed in the **/opt/cohesity/agent/** directory. To change the default path, click the **edit** icon and specify the path.
Components	• **Volume CBT (Change Blocks Tracker)**: This component is required to perform incremental backups. This component will be installed by default if you have selected to register the server as a physical server. You must reboot the server after installing this component. If you are not rebooting the server after installation or not installing this component, then only full backups will be performed. • **File System CBT (Change Blocks Tracker)**: This component is required for the incremental backup of individual MS SQL databases hosted on a server which is registered as a physical server. This component is not installed by default. To install this file system CBT, click the edit icon and enable the **File System CBT (Change Blocks Tracker)** option.	Not applicable

9. Click **Deploy**.

Cohesity will initiate the Cohesity agent deployment. You can view the status by clicking the notification icon on the top-right corner of the Source page.

Deploy Cohesity Agent to register the Applications Running on the VMs

By deploying the Cohesity agent on a VM, you can register and protect applications such as Oracle database, MS SQL database, or a physical server running on a VM. While registering

the application with the Cohesity cluster, the Cohesity agent is also deployed on the VMs.

Register Oracle Database with Agents Deployed

Currently, from the Cohesity UI you can only deploy Linux Agent on the Oracle database.

To register Oracle database:

1. Navigate to **Data Protection** > **Sources**.
2. Navigate the hierarchy to the VMWare vCenter server of the VM that is running the Oracle database.
3. Mouse over the server's actions menu, and select **More Options** > **Register Oracle**.

   The Register Oracle page appears.
4. Optionally, from the **Data Source** drop-down menu, you can select a different vCenter server that is running Oracle database.
5. Select the VMs onto which you want to deploy the Cohesity agent, and click **Select**.
6. Enter the user name and password for guest authentication.
7. Select the authentication type to connect to the Oracle database:
   1. **Use Server Authentication**: If you want to run Oracle SQL commands as an OS authenticated user, then the installation should be performed as an Oracle OS user. By default, this option is enabled.
   2. **Use Database authentication**: Enter the database user name and password.

   For more information, see Credentials and Privileges for Oracle Database.

   > **Note:** For registering the Oracle database, as it is mandatory to register the virtual server as a physical server, the **Register as a Physical Server** option is enabled by default. You cannot change this setting.
8. Optional. Click the down-arrow icon next to the **More Options** setting and click the **edit** icon to change the default settings if required:
   1. **Deployment Path**: By default, the Cohesity agent is deployed in the **/opt/cohesity/agent/** directory. To change the default path, click the **edit** icon and specify the path.
   2. **Deploy As**: By default, the Cohesity agent will be deployed using the `cohesityagent` user and group. During the agent deployment, the installer updates the **/etc/sudoers** file of the Linux server to allow cohesityagent sudo and no-tty sudo access.

      To change the default user type, click the **edit** icon, and then provide the user name and group name for the agent.

If you have specified a new user, , then select the **Create the user if it does not exists** checkbox. By selecting this option, the installer updates the **/etc/sudoers file** of the Linux server to allow the specified user sudo and no-tty sudo access.

If the user you specified already exists, then you must add the user to the sudoers list by making the following changes in the **/etc/sudoers** file:

```
<user_name> ALL=(ALL) NOPASSWD:ALL
Defaults:<user_name> !requiretty
```

An example of the sudoers file is as given below:

```
#includedir /etc/sudoers.d
dgoble ALL=(ALL) NOPASSWD:ALL
cohbackup ALL=(ALL) NOPASSWD:ALL
Defaults:cohbackup !requiretty
```

9. Click **Register**.

   The oracle database running on the VM will be registered along with the agent deployed.

Cohesity will initiate the Cohesity agent deployment. You can view the status by clicking the notification icon on the top-right corner of the Source page.

Register MS SQL Database with Agents Deployed

To register MS SQL Database:

1. Navigate to **Data Protection** > **Sources**.
2. Navigate the hierarchy to the server that is running the MS SQL database.
3. Mouse over the server's actions menu, and select **More Options** > **Register MS SQL**.
4. Optionally, from the **Data Source** drop-down menu, you can select a different server that is running the MS SQL database.
5. Select the VMs onto which you want to deploy the Cohesity agent, and click **Select**. Since MS SQL is supported only on Windows operating systems, only the VMs running Windows OS are displayed.
6. Provide the MS SQL database username and password for authentication.
7. Enable the **Register as a Physical Server** option if you want the virtual server to be registered as a physical server. By default, this option is disabled.
8. Optional. Click the down-arrow icon next to the **More Options** setting and click the

edit icon to change the default settings if required:

Option	Description
Deployed As	Deploy Cohesity agent using any of the following account: • **Local System**: By default the agent will be deployed using the Local System account. • **User Account**: Use the user credentials of a user account having local administrator privileges on the server with "Log on as a service" permission. For more information, see Requirements for Microsoft SQL Server Protection.
Deployment Path	By default, the Cohesity agent is deployed in the **C:\Program Files\Cohesity** directory. To change the default path, click the **edit** icon and specify the path.
Components	• **Volume CBT (Change Blocks Tracker)**: This component is required to perform incremental backups. You must reboot the server after installing this component. If you are not rebooting the server after installation or not installing this component, then only full backups will be performed. This component is not installed by default. To install volume CBT, click the edit icon and enable the File System CBT (Change Blocks Tracker) option. • **File System CBT (Change Blocks Tracker)**: This component is required for the incremental backup of individual MS SQL databases hosted on a server which is registered as a physical server. This component will be installed by default if you have selected to register the virtual server as a physical server.

9. Click **Register**.

Cohesity will initiate the Cohesity agent deployment. You can view the status by clicking the notification icon on the top-right corner of the Source page.

Register Physical Servers with Agents Deployed

To register physical server:

1. Navigate to **Data Protection** > **Sources**.
2. Navigate the hierarchy to the server where you want to register the physical server.
3. Mouse over the server's actions menu, and select **More Options** > **Register Physical**.

   The Register Physical Server page appears.
4. Optionally, from the **Data Source** drop-down menu, you can select a different server where you want to register the physical server.

5. Select the VMs onto which you want to deploy the Cohesity agent, and click **Select**. You can filter the VM based on the operating system.

   > **Note:** You cannot select VMs of different operating systems. For example, if you have selected Windows VMs then you cannot select Linux VMs and vice-versa.

6. Provide the username and password for authentication.
7. Optional. Click the down-arrow icon next to the **More Options** setting and click the edit icon to change the default settings if required:

Option	Description	
	Windows OS	**Linux OS**

Deployed As	By default, the Cohesity agent will be deployed using the **Local System account**.
	
	To change the default account, click the **edit** icon, select **User Account**, and then provide the credentials of a user account having local administrator privileges on the server with "Log on as a service" permission.
		By default, the Cohesity agent will be deployed using the `cohesityagent` user and group. During the agent deployment, the installer updates the **/etc/sudoers** file of the Linux server to allow `cohesityagent` sudo and no-tty sudo access.
		
		To change the default service user, click the **edit** icon, and then provide the user name and group name.
		
		For a new user type:
		
		If you have specified a new user, then select the **Create the user if it does not exists** checkbox. By selecting this option, the installer updates the **/etc/sudoers** file of the Linux server to allow the specified user sudo and no-tty sudo access.
		
		For an existing user type:
		
		If the user you specified already exists, then you must add the user to the sudoers list by making the following changes in the **/etc/sudoers** file:
		
		`<user_name> ALL=(ALL) NOPASSWD:ALL`
		`Defaults:<user_name> !requiretty`
		
		An example of the sudoers file is as given below:
		
		`#includedir`

Option	Description	
	Windows OS	Linux OS
		`/etc/sudoers.d dgoble ALL=(ALL) NOPASSWD:ALL cohbackup ALL=(ALL) NOPASSWD:ALL Defaults:cohbackup !requiretty`
Deployment Path	By default, the Cohesity agent is deployed in the **C:\Program Files\Cohesity** directory. To change the default path, click the **edit** icon and specify the path.	By default, the Cohesity agent is deployed in the **/opt/cohesity/agent/** directory. To change the default path, click the **edit** icon and specify the path.
Components	• **Volume CBT (Change Blocks Tracker)**: This component is required to perform incremental backups. This component will be installed by default if you have selected to register the server as a physical server. You must reboot the server after installing this component. If you are not rebooting the server after installation or not installing this component, then only full backups will be performed. • **File System CBT (Change Blocks Tracker)**: This component is required for the incremental backup of individual MS SQL databases hosted on a server which is registered as a physical server. This component is not installed by default. To install this file system CBT, click the edit icon and enable the **File System CBT (Change Blocks Tracker)** option.	Not applicable

8. Click **Register**.

Cohesity will initiate the Cohesity agent deployment. You can view the status by clicking the notification icon on the top-right corner of the Source page.

Troubleshoot Cohesity Agent

This topic provides the troubleshooting information for Cohesity Agents.

Collect Diagnostic Information for Cohesity Agents

For Microsoft Windows servers, you can find the logs for Cohesity Agents at `C:\ProgramData\Cohesity\`.

If the **ProgramData** folder is hidden or not visible, then from the top-menu of the **C** directory, click **View**, and then check the **Hidden items** check box.

The hidden folders and files will be displayed.

Diagnostic data is subject to the following default settings. For more information, refer to the table below.

Default Settings - Linux (x64)	Value
Maximum size of a log file before a new file is created	30MB
Log file cleanup interval (frequency at which older logs are cleaned up)	1 Hour
Maximum retention time for a log file	30 days
Maximum space allowed to store log files	50MB
Maximum number of core archives to retain	5
Minimum batch size for log files before cleanup kicks in (at least this many log files should be present for cleanup based on time or size to occur)	8

Default Settings - Windows	Value
Max log retention time for a log file	7 days
Log file cleanup interval (frequency at which older logs are cleaned up)	1 Hour
The maximum amount of space allowed for storing logs (in MB)	10MB
The maximum number of core archives to retain	5
The maximum number of Cristie log archives to retain	2
The maximum number of Windows log archives to retain	500
The maximum number of days for storing diagnostics file	1 day
The maximum amount of space allowed for storing diagnostics file (in MB)	100MB

Default Settings - JAVA agents (AIX, Solaris, HP-UX, Linux PowerPC LE)	Value
Maximum size of a log file before a new file is created	30MB
Max number of agent log files to retain	20
Max log retention time for a log file	7 days
Log file cleanup interval (frequency at which older logs are cleaned up)	1 Hour

> **Note:** Contact Cohesity Support to modify the default diagnostic settings.

Find the Cohesity Agent Version

To find the version of the Cohesity Agent installed on Windows, Linux, and AIX servers, perform the following steps:

1. Navigate to **Data Protection > Sources**
2. Click **Register > Physical Server**.
3. Select a server. If the installed Agent's version is lower than the Cohesity cluster version, it will display **Upgrade available**.

Prerequisites

Ports 80 and 443 are open from the client to the cluster so that the Cohesity agent upgrade from UI can occur.

Troubleshooting Agent Issues

The following table provides details about Agent issues that you might encounter:

Issue	Cause	Workaround	

Registering a Cohesity Agent on a new Cohesity cluster fails with the following error: `Host is already registered with another cluster: <old cluster-id>, <new cluster-id>`	Agent is already registered to a different Cohesity cluster ID.	1. Navigate to **Data Protection > Sources > Register > Physical Server**. 2. cluster_ fqdn/protection/sources/new/physical `?forceRegister=true`" to the end of the URL and press the **Enter** key. You will be redirected to a new registration page. 3. Enter the Agent information and ensure that the Force Agent Registration check box is selected.	
Installing or upgrading the Cohesity Agent either manually or automatically fails with the following error: `WinHttpSendRequest() failed : 0x2ee7`	This error indicates a DNS issue in Windows. While installing the Cohesity Agent, the Agent confirms that it can resolve the host name of the Cohesity cluster. If this check fails, this error is returned.	Ensure DNS forward and reverse lookups are working on the server or VM.	

Login to the Cohesity Support site to see more Knowledge Base Articles.

Upgrading the Cohesity Agent on a Windows Physical Server may Become Stuck

Under specific conditions, upgrading the Cohesity agent on a Windows physical server may become stuck. To identify if a server is affected by this issue, read the following:

Check if the agent logs (under %programdata%\Cohesity) contain "Cannot start the agent because the port 50051 is in use," indicating that the agent is in a crash loop.

The upgrade issue can occur if all of the following are true:

- The Cohesity agent is running under a specific user account (not the default Local System account).
- The Cohesity agent service is the only service in the running state at the time of upgrade using the specified account.
    - The specified user account has not been logged into through other means (such as RDP) at the time of the upgrade.
- The "Do not forcefully unload the user registry at user logoff" policy is "Not Configured" (the default) or set to "No."

To get the agent out of this state:

1. Open Windows Task Manager and click the Details tab.
2. Locate the "installer.exe" and "installer.tmp" processes (with the Cohesity icon).
3. Right-click "installer.tmp" and select "End Task". This stops both processes ("installer.exe" and "installer.tmp").

To avoid future occurrences:

Use the Group Policy Editor (gpedit.msc) to enable the "Do not forcefully unload the user registry at user logoff" policy. The policy is located under Computer Configuration > Administrative Templates > System > User Profiles.

Chapter 28: NoSQL and Hadoop Service

NoSQL and Hadoop Service is an enterprise data management solution to protect Hadoop clusters and NoSQL distributed databases on a single web-scale platform. The NoSQL and Hadoop Service expands Cohesity's DataProtect coverage to support protection for Couchbase, MongoDB, Cassandra, Hbase, Hive, HDFS, all managed through a single policy framework and global user interface. See the following topics for details:

- Supported Software 4147
- Features 4148
- Prerequisites 4149
- Process Overview 4149
- Install NoSQL and Hadoop Service 4150
- Run the NoSQL and Hadoop Service 4152
- Verify the Status of NoSQL and Hadoop Service 4153
- Using NoSQL and Hadoop Data sources 4153
- Post Installation Procedures 4153
- Managing NoSQL and Hadoop Services 4169
- Additional Configuration for NoSQL and Hadoop Services 4176
- Monitor the NoSQL and Hadoop Service Health 4182
- FAQs on NoSQL and Hadoop Services 4189

Supported Software

Cohesity cluster Version: 6.5.1 or higher

For details on the supported versions for Cassandra, Couchbase, MongoDB and Hadoop:

Application	Details
Cassandra	See Supported Versions for Cassandra DataProtect Solution.
Couchbase	See Supported Versions for Couchbase DataProtect Solution.
MongoDB	See Supported Versions for MongoDB DataProtect Solution.
Hadoop	See Supported Versions for Hadoop DataProtect Solution.

Features

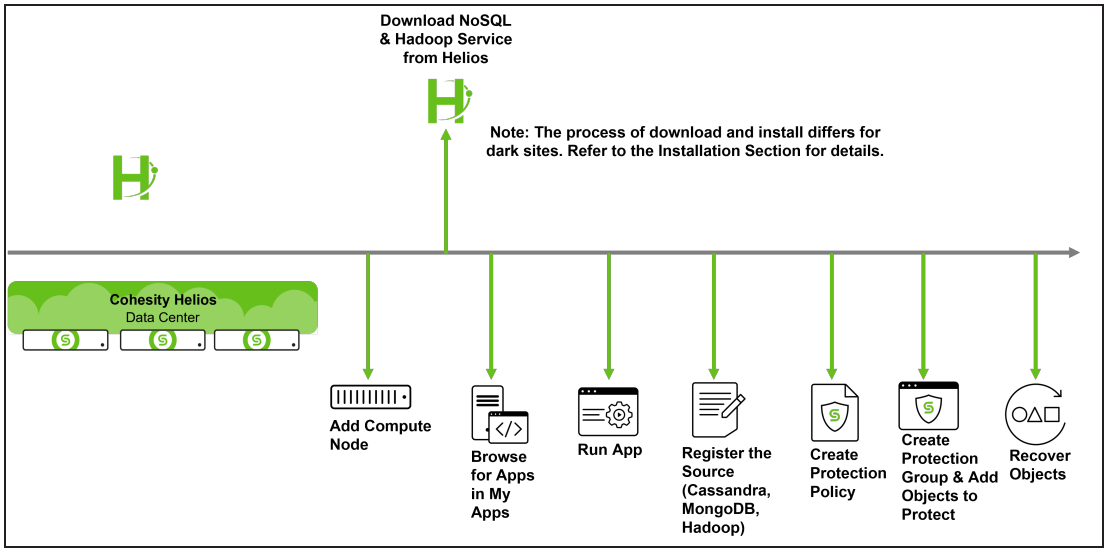
- Supports protection of NoSQL databases such as Couchbase, MongoDB, Cassandra, and Hadoop (HDFS, Hive, and Hbase).
- Scalable backup and recovery architecture supporting petabytes of data.
- Meet business RPOs/RTOs with parallel architecture to support rapid backup and recovery.
- Supports a simple agentless deployment.
- Offers a unified and automated policy-driven model involving no manual steps.
- Supports a flexible backup and recovery method from a database to a table or a collection level.
- Offers incremental forever backup.
- Recovery is topology-independent.
- Improved data resiliency with erasure coding.
- Reduced data footprint with global variable-length deduplication, compression.
- Native cloud integrations for simplified archival to the public cloud for long-term retention.
- One-click archival to public cloud for long term retention using native cloud integrations.
- An API-first architecture approach with RESTful API support.
- Integration with Active Directory, LDAP, and Kerberos.
- Encryption of data in-flight and at rest.
- Customizable role-based access control.
- Supports protection of NoSQL databases such as Cassandra and Couchbase configured using IPv6 addresses.

Prerequisites

- The NoSQL and Hadoop service is designed to handle petabytes of data efficiently by scaling out to perform parallel backups and restores. As a result, the services require a higher amount of CPU and memory depending on the RPO & RTO needs. Compute Nodes in the Cohesity cluster provide CPU and memory resources to run resource-intensive apps and services. In order to install the NoSQL and Hadoop service, the Cohesity cluster must have compute nodes added. See Manage Compute Nodes for details.
- Data and Compute nodes on the Cohesity cluster must have connectivity to all the primary cluster nodes of your data source (Hadoop cluster nodes or Cassandra cluster nodes or MongoDB cluster nodes) for successful discovery, backup and recovery.
- For more information on managing apps and the prerequisites for apps management, see Manage Apps .

Process Overview

A quick overview of the process is as follows:



1. To use NoSQL and Hadoop service, you must first add a compute node.
2. Download the NoSQL and Hadoop Service from Helios, and Run App.
3. Configure the **QoS Policy** and **Instant Size** based on the business requirement and run the application.
4. Ensure that the advanced configuration settings are enabled for NoSQL and Hadoop solutions. Contact Cohesity Support to enable this capability.

> **Note:** Note: You can perform this step even before you initiate the app installation process. However, to be able to perform any operations, you must have the advanced configuration settings enabled.

5. Perform various operations such as register, back up and recover Cassandra, Couchbase, Hadoop and MongoDB solutions.

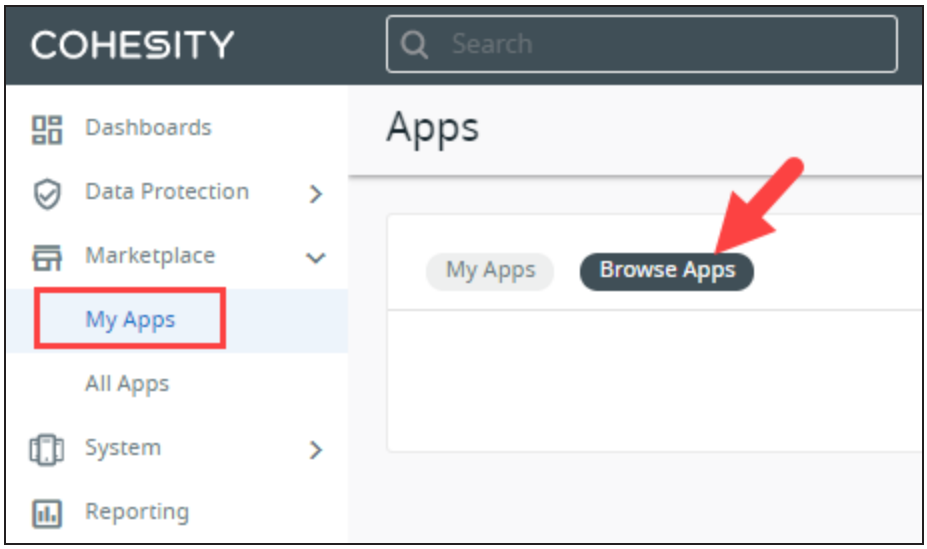
Install NoSQL and Hadoop Service

> **Important:** Ensure you have an understanding of the Cohesity Apps and met the prerequisites required to install an App. For more information, refer to Manage Apps Manage Apps.

> **Note:**
> - The NoSQL and Hadoop Service must be installed and run as a local admin. Using an SSO or AD user to install the app might cause issues while trying to launch the container instances.
> - Upgrading the NoSQL app from version 5.4.11 to version 7.0.1 is not supported. Install the NoSQL app version 7.0.1 when you upgrade Cohesity from version 6.8.1 to version 7.0.1.
> - All the workflows and policies configured in version 5.4.11 will be preserved when you install the NoSQL app version 7.0.1.
> - To preserve the SSL/Kerberos settings done in version 5.4.11, perform the following step on any node, before stopping the NoSQL app in version in 5.4.11:
>
> ```
> imanis_cli.sh -c config save
> ```

To download the NoSQL and Hadoop Service from Helios and install it on your cluster:

1. Log in to Helios with valid credentials.
2. Navigate to **Marketplace** > **My Apps** > **Browse Apps**.



3. Search for the **NoSQL and Hadoop Service** app, and click **Install App**.
4. Select the Cohesity cluster from the list of registered clusters on which you wish to run the app, and click **Install**.

   The service is installed successfully.

To download the NoSQL and Hadoop Service from Helios and install it on a dark site:

1. Log in to Helios with valid credentials.
2. Navigate to **Marketplace** > **My Apps** > **Browse Apps**.
3. Search for the **NoSQL and Hadoop Service** app, and click the title of **NoSQL and Hadoop Service**.
4. Select the **Download** tab (at the end).
5. Select the cluster version and click **Get App versions**.
6. Click on the latest version of the app displayed, and click **Download** to initiate downloading of the app package.
7. Transfer the app package to the dark site where the NoSQL and Hadoop service needs to run from.
8. You can then log in to the Cohesity cluster, navigate to **Marketplace** > **My Apps**, click **Upload App** and select the downloaded app package.
9. Click **Upload and Install**.

   The service is installed successfully.

> **Note:** To use MongoDB CDP, you need to ensure that the set of prerequisites under Configuring Continuous Data Protection (CDP) for MongoDB is satisfied. This should be done before running the NoSQL and Hadoop Services app.

Run the NoSQL and Hadoop Service

1. Log in to the Cohesity cluster, and navigate to **Marketplace** > **My Apps** > **My Apps** tab.
2. If the app upload is successful, the NoSQL & Hadoop Service App is listed and the **Run App** button appears.
3. Click **Run App** to start running the app instance on your cluster.

   > **Note:** You can run only one instance of the app per cluster.

4. Based on the requirement, select **QoS Policy**, **Views**, and **Instant Size**. Enter a brief description (optional) and click **Run App**.

   An instance of the app will be initiated.

Parameters	Description
QoS Policy	This decides how much % of resources of compute nodes are allocated to the NoSQL and Hadoop service. **Note:** • You can set this value as Max if this is the only app instance running on your cluster. However, if you wish to use other apps at the same time, you can set a lower QoS policy. • Max QoS allows 80% of total allocatable resources for NoSQL App. • High QoS allows 50% of total allocatable resources for NoSQL App. • It is recommended that you allow maximum QoS for NoSQL app for better performance.

Parameters	Description
Instance Size	This indicates the size of the container. It is recommended to use a large instance size. Each instance of nodemanager container will be of size • 16GB/4core (small) • 32GB/8core (medium) • 40GB/10core (large) App nodes (compute only nodes) should have enough resources to fit at least 3 small instances of nodemanagers. **Note:** Minimum of 3 instances of nodemanagers are required for NoSQL and Hadoop services to run.

Verify the Status of NoSQL and Hadoop Service

1. Navigate to **Marketplace** > **My Apps** and then click the **All Instances** tab.
2. Make sure the instance status for **NoSQL and Hadoop Service** is **Running**.

> **Note:** If the app status is displayed as Unhealthy, then confirm if the compute node is up and running. Otherwise, Contact Cohesity Support.

Using NoSQL and Hadoop Data sources

To work with the NoSQL and Hadoop data sources, see:

- Working with Cassandra DataProtect Solution
- Working with Couchbase DataProtect Solution
- Working with MongoDB DataProtect Solution
- Working with Hadoop DataProtect Solution

Post Installation Procedures

After the successful installation of NoSQL and Hadoop Service, you must run some of the post installation scripts to ensure that you can seamlessly work with the NoSQL and Hadoop solutions. Some of the post installation procedures to be followed are:

- To Verify Installation
  - Verify Services
  - Verify UI
- To Manage the NoSQL and Hadoop Services
  - Retrieve NoSQL and Hadoop Services Version
  - Work with Kerberos Security enabled primaries for data protection
- Manage SSL enabled NoSQL primary clusters
  - Certificate file formats supported
  - Work with NoSQLandHadoop Services using SSL tool

> **Note:**
> - In the examples below, you can run the `kubectl.sh` and the `imanis_cli` commands from the Cohesity cluster node. Once you execute the `kubectl.sh exec` command, you get logged into the Imanis pod. Subsequently, all the `talena` based commands can be run from that Imanis pod.
> - `imanis_cli.sh` tool must be executed from the Cohesity cluster node where Imanis pods are hosted or running.

To Verify Installation

Before using NoSQL and Hadoop services, you must verify if the installation has been successful. You can either verify the installation on the NoSQL and Hadoop services as well as verify if the GUI is functioning correctly.

Verify Services

Log in to any one Cohesity cluster node and if the installation is successful, the following will be displayed:

```
$ kubectl.sh get pods -A | grep imanis
athena-34                imanis-api-server-0
 1/1     Running             0               13h
athena-34                imanis-historyserver-0
 1/1     Running             0               13h
athena-34                imanis-nodemanager-0
 1/1     Running             0               13h
athena-34                imanis-nodemanager-1
 1/1     Running             0               13h
athena-34                imanis-nodemanager-2
 1/1     Running             0               13h
```

```
athena-34                imanis-nodemanager-3
 1/1     Running             0               13h
athena-34                imanis-nodemanager-4
 1/1     Running             0               13h
athena-34                imanis-nodemanager-5
 1/1     Running             0               13h
athena-34                imanis-nodemanager-6
 1/1     Running             0               13h
athena-34                imanis-resourcemanager-0
 1/1     Running             0               13h
athena-34                imanis-zookeeper-0
 1/1     Running             0               13h
athena-34                imanis-zookeeper-1
 1/1     Running             0               13h
athena-34                imanis-zookeeper-2
 1/1     Running             0               13h
```

In the above example, NoSQL and Hadoop Service is running in 12 kubernetes pods. The namespace name is **athena-104**. You can log in to any of the pod (usually, imanis-nodemanager-0 is used as it has more memory and cpu to run additional load).

```
$ kubectl.sh exec -it imanis-nodemanager-0   -n athena-104 /bin/bash
```

```
[hdfs@imanis-nodemanager-0 /]$ talena-services.sh status all
```

Running Smoke Tests

If all services are running, then you can run the following smoke tests for verification:

```
$ talena-services.sh smoke all
```

If any smoke test fails, then it needs attention before proceeding to use the app.

Verify UI

To verify if the NoSQL and Hadoop data sources are enabled in Cohesity for the first time:

1. Navigate to **Data Protection** > **Sources**.
2. Click the plus icon (+) on the top-right of the page and then verify if the Couchbase, Hadoop, Cassandra and Mongo DB options are displayed in the menu.

To Manage the NoSQL and Hadoop Services

This section provides basic command line options that you can use to manage the NoSQL and Hadoop services.

```
$ imanis_cli.sh
INFO : Checking reachability of pod imanis-nodemanager-0
--------------------------------------------------------------------
```

```
Usage: imanis_cli_main.sh  -c command_name [ command_args ]

-c command_name : valid command_name is one of con-
fig,explorer,hosts,joblog,kerberos,patch,ssl,vip
command_args : "options_string_enclosed_in_double_quotes"
-----------------------------------------------------------------------
```

Retrieve NoSQL and Hadoop Services Version

The following section discusses the procedure to determine the version or release number of NoSQL and Hadoop Services.

1. Navigate to **Marketplace** > **My Apps**.
2. Select the **My Apps** tab to verify the version of NoSQL and Hadoop service.

Work with Kerberos Security enabled primaries for data protection

If your primary cluster to be protected is not Kerberos security enabled, then you can ignore this section. Otherwise, please go through this section before attempting to register a data source in Cohesity. Typical flow of this process is:

a. Obtain Kerberos principal name(s), the corresponding keytab file(s) and Kerberos configuration file (krb5.conf) for your kerberos realm.
b. Ensuring the Kerberos KDC server hostname is resolvable from NoSQL and Hadoop Service pods.
c. Adding the keytab and the kerberos realm to NoSQL and Hadoop Service using a command line tool called imanis_cli.sh.
d. Register the data source in Cohesity.

Obtain Kerberos Principal(s), keytab file(s) and krb5.conf

Verify with your primary cluster administrators about one or more kerberos principals to be used by NoSQL and Hadoop service for connecting to their cluster.

> **Note:**
> NoSQL and Hadoop service recommends using a single principal exclusively for NoSQL and Hadoop service access. This is to ensure better control over what access permissions are granted to this principal and can also be useful for auditing purposes. For example, one can create a principal such as imanis@REALMNAME in the KDC server for exclusive use by NoSQL and Hadoop Service software.
>
> However, in some cases, while protecting Hadoop clusters like CDH or HDP, some deployments may prefer to create 3 separate kerberos principals for allowing access to hdfs, hbase and hive respectively as follows:
>
> - imanis_hdfs@REALMNAME - Kerberos principal used for HDFS workflows
> - imanis_hbase@REALMNAME - Kerberos principal used for HBase workflows
> - imanis_hive@REALMNAME - Kerberos principal used for Hive workflows
>
> In such cases, you may end up with 3 different keytab files corresponding to these 3 principals as opposed to a single keytab file in case of using a single principal.

The key thing to ensure is that the principal(s) given to NoSQL and Hadoop Service have full access permissions granted on the primary cluster, for listing, reading files, tables, keyspaces, databases, collections and write access while restoring a backup from NoSQL and Hadoop Service.

> **Note:** Replace REALMNAME with the actual realm name used in your kerberos cluster. You can use any other existing principal name such as hdfs@REALMNAME , instead of imanis. New principles are created in KDC servers by Kerberos admin.

Ensure Kerberos KDC server hostname is resolvable from NoSQL and Hadoop Service pods

We must ensure that the Kerberos KDC server hostname is resolvable from the NoSQL and Hadoop Service kubernetes pods. This is generally not a problem if the DNS is setup properly and we use FQDN for the Kerberos KDC server. However, if this is not the case, then one can also add this hostname and IP address to /etc/hosts on the pods running NoSQL and Hadoop Service.

Use imanis_cli.sh -c hosts add option to perform this step:

```
$ pwd /home_cohesity_data/athena/mounts/_internal_view_mount/imanis
$ cat $PWD/hosts
10.14.20.237 im39-vm1.cohesity.com
$ imanis_cli.sh -c hosts add $PWD/hosts
```

Add a keytab and Kerberos realm to NoSQL and Hadoop Service

You need to perform this step every time you want to register a new kerberos enabled data source with NoSQL and Hadoop Service. However, if the principal that you plan to use is the same as other data sources that have already been registered, then you can skip this step.

Run a command line tool called imanis_cli.sh on any one Cohesity cluster node. The following options are supported by imanis_cli.sh for the kerberos operations:

```
$ imanis_cli.sh -c kerberos usage:
 imanis_cli.sh -c kerberos addrealm
 imanis_cli.sh -c kerberos deleterealm realm_name
 imanis_cli.sh -c kerberos validatekeytab [local keytabpath]
 imanis_cli.sh -c kerberos import krb5_keytab_dirpath
```

For adding a new kerberos principal, we use the add realm option. There are two ways in which the information about the new Kerberos realm to be added is given as input to this script.

- By pointing the script to an existing krb5.conf file. The conf file will be read and parsed to extract the relevant information. Download the krb5.conf file from your primary node to the node on NoSQL and Hadoop Services
- In case you do not have access to krb5.conf file, you can type the required information manually by confirming the prompts. Download the keytab file(s) and krb5.conf (if you have one) to one of the Cohesity cluster nodes under the directory as follows:

```
cd /home_cohesity_data/athena/mounts/_internal_view_mount/imanis/
mkdir kerb
cd kerb
scp ip_or_hostname:/path/to/keytab_and_krb5_conf_files .
```

Here, replace the ip_or_hostname with the IP address or hostname of the server where the keytab and krb5.conf files are present. This is usually your primary cluster itself or any other server where administrators have generated these files and saved.

> **Note:** It is important to download and keep these files under this specific mount point only. This cannot be changed, however you can create any sub directory.
>
> `/home_cohesity_data/athena/mounts/_internal_view_mount/imanis/`

You must have one or more keytabs and/or krb5.conf file in the present working directory as follows:

```
$ pwd
/home_cohesity_data/athena/mounts/_internal_view_mount/imanis/kerberos
$ ls
```

```
imanis.keytab  krb5.conf
```

If **krb5.conf** file is available:

```
$ imanis_cli.sh -c kerberos addrealm
INFO : Checking reachability of pod imanis-nodemanager-0

INFO: Checking nodes reachability

WARN : All values from [libdefaults] section in krb5.conf on NoSQL will not
be changed

API server is running on [imanis-api-server-0]

INFO: addrealm completed for im39-vm1.realm
```

> **Note:** Primary Domain Realm list from domain_realm section (separated by |) :This is the list of hosts that you would like to be translated to the given kerberos realm. Typically, these are the FQDNs of your primary cluster nodes.

This script can also be used to make changes to the keytab for an existing data repository, without having to modify the realm information. If the Kerberos realm information is already present with the NoSQL and Hadoop Services, then only keytab is processed by the script and changes are incorporated.

Register the data source in Cohesity

Optionally, you can verify the kerberos configuration as follows before proceeding to the registration step.

```
$ imanis_cli.sh -c kerberos validatekeytab

Fetching ImanisData cluster config from athena-6:imanis-nodemanager-0
Keytab validation completed successfully
```

Manage SSL enabled NoSQL primary clusters

In general, two entities (client, server programs in our case) that are communicating with one another must ensure the following:

1. Client to ensure that it is talking to an authentic server.
2. Server to ensure that it is talking to an authentic client.
3. The data client-server exchange must not be seen by anyone else in the middle.

See FAQs on NoSQL and Hadoop Services for details on the most frequently asked questions about SSL enabled NoSQL primary clusters.

Certificate file formats supported

NoSQLandHadoop uses PEM format for certificates and keys for importing.

PEM or Privacy Enhanced Mail is a Base64 encoded DER certificate. So you can open it in your favorite editor to check. Generally when a PEM encoded file is opened in a text editor, it contains very distinct headers and footers as below:

A private key in PEM format is as shown below:

```
-----BEGIN RSA PRIVATE KEY-----
Proc-Type: 4,ENCRYPTED
DEK-Info: DES-EDE3-CBC,E1537934256F0AAE
aNLbkgsTZLESaRTPvpgh3lMRm4ltJ9rOZaZCn3msw22iVUec5u+dpr9FM8jY6y7J
m4MB203AfRexnFwmL3FrIki4vylRmVp7HWMxQLLYBxBPPPEi7QVB6EE6GNKEf973
...
...
...
cy3sLxHa7+IGD/c4pnETQ+9Zna/wrHEyt8WDtFzJ4sL9f1u3peh2ip9OG+Gh6F6Y
SDK129oSj5FF/uY///zkzAneHZwDSuAbNJfJfrKMUDZEWA292DqGJI03MFaHlq2f
-----END RSA PRIVATE KEY-----
```

A certificate file in PEM format is as shown below:

```
-----BEGIN CERTIFICATE-----
MIIGATCCA+mgAwIBAgIJAL0seBEmD2e7MA0GCSqGSIb3DQEBCwUAMIGWMQswCQYD
VQQGEwJJTjELMAkGA1UECAwCTUgxDTALBgNVBAcMBFBVTkUxFTATBgNVBAoMDENv
...
...
...
 dklbn4GF8PmGiNJ5u2WEecfQi2QMOfPl1GcMlhx8aVeRVC3jEDC5W0VEe+4mqwNh
0ULBsWbOLwlTFt3LhEKMh30Duiw0utxaPDoT0Pu5H+L5+/qt50QqVIdHwgSw31ZM
DLnNGkDq670rSjatNncpSAc0VElO/TdhBxhpZxZgMSi40x5IN++dAjKnPbha5Tcz
eEuBSUs=
-----END CERTIFICATE-----
```

> **Note:** One pem file can contain multiple certificates and key. You can copy the certificate and key part into two separate files or concatenate key.pem and certificates.pm into s single file as may be needed, using text editors.

Work with NoSQLandHadoop Services using SSL tool

NoSQL and Hadoop services provide a CLI tool called imanis_cli.sh which can be found on the Cohesity nodes where NoSQL and Hadoop Service is installed. This tool is used to set up keystore and truststore on the NoSQL and Hadoop Service app. Following are the options to imanis_cli.sh -c ssl command.

Log in to one of the Cohesity cluster nodes where NoSQL and Hadoop Service is installed and run the following:

```
$ imanis_cli.sh -c ssl

Fetching ImanisData cluster config from athena-1:imanis-nodemanager-0

Usage :
imanis_cli.sh -c ssl import port hostname1 [ hostname2 hostname3 ...]
download certificate(s) from remote server(s) and
import them into Imanis Truststore automatically
arguments:
port   : SSL port where server is listening
hostname : list of hostnames of the servers to download SSL certificates

imanis_cli.sh -c ssl import-manual alias1 /path/to/certificate/file1 alias2
/path/to/certificate/file2 ...
Import SSL certificates manually into Imanis truststore
NOTE: You need to copy the certificates to one of the Imanis nodes manually
Use this only if the automatic import fails
arguments:
alias : short hostname from where the certificate is importedfile  : path to
certificate file
```

```
imanis_cli.sh -c ssl generate-keystore
Generate self-signed SSL certificates and use it for Imanis keystore
```

```
imanis_cli.sh -c ssl import-keystore /path/to/key/file /path/to/cert/file
Import CA signed SSL certificate+key into Imanis keystore,
Use this when self-signed certificate is not good enough
arguments:
/path/to/key/file : path to file containing private key in PEM format
/path/to/cert/file: path to corresponding certificate file in PEM format
NOTE: If you have a single file containing both key and certificate,
```

```
then repeat the same file path for both arguments
```

```
imanis_cli.sh -c ssl list [truststore|keystore]
List the certificates from Imanis Truststore/Keystore

imanis_cli.sh -c ssl delete alias
Delete the certificate for given alias from Imanis Truststore

imanis_cli.sh -c ssl delete [truststore|keystore]Delete the trust-
store/keystore, if it exists
```

Setting up truststore:

The truststore contains certificates from the SSL enabled servers to which we want to connect to. There are a couple of ways in which you can build the truststore:

a. **Importing certificates from servers automatically**:

   In this case, you run the imanis_cli.sh tool by specifying the port and the list of server hostnames or IP addresses. The tool will connect to the specified port on each server and download the SSL certificate presented by the server.

   IPv4 Example: you have three servers in your MongoDB cluster with IP address

   10.14.20.87, 10.14.20.88 10.14.20.89 and they are listening on port 27221

```
$ imanis_cli.sh -c ssl import  27221 10.14.20.87 10.14.20.88
10.14.20.89

Fetching ImanisData cluster config from athena-1:imanis-nodemanager-0
Downloading certificate from 10.14.20.87:27221 to
/tmp/10.14.20.87.crt.970
Downloading certificate from 10.14.20.88:27221 to
/tmp/10.14.20.88.crt.970
Downloading certificate from 10.14.20.89:27221 to
/tmp/10.14.20.89.crt.970
Importing SSL certificate into Imanis...
 truststore does not exist. A new truststore will be created.
you will be prompted for a password. Please ensure that
you remember this password as it will be required later
for importing more certificates to this Truststore.

Enter the Truststore password : ********

Re-Enter the Truststore password : ********
```

```
Importing /tmp/10.14.20.87.crt.970 to Imanis Truststore
Successfully imported /tmp/10.14.20.87.crt.970

Importing /tmp/10.14.20.88.crt.970 to Imanis Truststore
Successfully imported /tmp/10.14.20.88.crt.970

Importing /tmp/10.14.20.89.crt.970 to Imanis Truststore
Successfully imported /tmp/10.14.20.89.crt.970

Copying truststore to /opt/talena/conf/talena.truststore
```

IPv6 Example:

```
[support@cb146-00505684fff6-node-1 ~]$ imanis_cli.sh -c ssl import
18091 2400::3000:0:0:100:1025 2400::3000:0:0:100:1026
2400::3000:0:0:100:1027
INFO : Checking reachability of pod imanis-nodemanager-0

Generating /tmp/certs.39833/2400::3000:0:0:100:1027.crt.39833-1 ..
Copying truststore to /opt/talena/conf/talena.truststore
Certificates imported successfully
[support@cb146-00505684fff6-node-1 ~]$
```

> **Note:**
> - The port should be same on all nodes.
> - The port number may be different on your setup. Consult with your administrators for your primary cluster.
> - For Hadoop, it may be necessary to use different ports for different hosts (Namenode port and Datanode port, for example). In that case, you need to run this tool multiple times.

b. **Importing certificates manually**:

Although automatic import is the preferred option as it reduces the chances of errors in manual download/import steps, in some cases, you may want to manually download the certificates from a remote location and import them into NoSQL and Hadoop Service truststore. In such cases, use the below option:

```
$ imanis_cli.sh -c ssl import-manual im2-vm4 $PWD/im20-
vm4.cohesity.com.cer im2-vm5 $PWD/im20-vm5.cohesity.com.cer im2-vm6
$PWD/im20-vm6.cohesity.com.cer
Fetching ImanisData cluster config from athena-1:imanis-nodemanager-0
Importing SSL certificate into Imanis...

Enter the Truststore password : ********

Re-Enter the Truststore password : ********

Importing /home_cohesity_data/athena/mounts/_internal_view_
mount/imanis/certs/im20-vm4.cohesity.com.cer to Imanis Truststore
Successfully imported /home_cohesity_data/athena/mounts/_internal_view_
mount/imanis/certs/im20-vm4.cohesity.com.cer

Importing /home_cohesity_data/athena/mounts/_internal_view_
mount/imanis/certs/im20-vm5.cohesity.com.cer to Imanis Truststore
Successfully imported /home_cohesity_data/athena/mounts/_internal_view_
mount/imanis/certs/im20-vm5.cohesity.com.cer

Importing /home_cohesity_data/athena/mounts/_internal_view_
mount/imanis/certs/im20-vm6.cohesity.com.cer to Imanis Truststore
Successfully imported /home_cohesity_data/athena/mounts/_internal_view_
mount/imanis/certs/im20-vm6.cohesity.com.cer
```

```
Copying truststore to /opt/talena/conf/talena.truststore
```

> **Note:** In most cases, you do not have to do this step, as a self-signed certificate is automatically generated, when you try to import any certificate into NoSQL and Hadoop Service truststore for the very first time.

Setting up keystore

A keystore must have a private key and a corresponding certificate. To set up the keystore:

a. **Generate a self-signed key+certificate pair**: This is the default setup. When you import a truststore for the very first time, the script will automatically generate a self-signed keystore, if it does not exist. A self signed certificate will also be generated and can be found at `$INSTALL_DIR/conf/talena.crt` on any of the NoSQL and Hadoop pod.

```
$ imanis_cli.sh -c ssl generate-keystore
Fetching ImanisData cluster config from athena-1:imanis-nodemanager-0
Generating random keystore password
Generating a keystore and self-signed SSL certificate for Imanis
Successfully configured keystore
```

b. **Import a key+CA signed certificate**

In some environments, the company security policy may mandate you to use the CA signed certificate instead of self-signed. In such a case, you need to use the import-keystore option to import a pair of key and CA signed certificate.

```
$ imanis_cli.sh -c ssl import-keystore $PWD/Imanis.key $PWD/Imanis.crt

Fetching ImanisData cluster config from athena-1:imanis-nodemanager-0
Verifying private key and certificate
Keystore already exists on Imanis nodes
Saving it as  /opt/talena/conf/talena.keystore.062220-050744 and /op-
t/talena/conf/talena.crt.062220-050744
Importing SSL KeyStore into Imanis...
You will be prompted to enter a password for the keystore
Please enter the password that was used for generating the key

Enter the Keystore password : *********

Re-Enter the Keystore password : *********
You will be prompted to enter a passphrase for the private key if there is
no passphrase, then just hit enter
Enter the Keystore passphrase : ******
```

```
Re-Enter the Keystore passphrase : ******

private key and certificate look good. Going ahead with import
Converting  /cohesity/mount/sharedview/imanis/certs-root/Imanis.key into

Entry for alias 1 successfully imported.
Import command completed:  1 entries successfully imported, 0 entries failed
or cancelled

Warning:
The JKS keystore uses a proprietary format. It is recommended to migrate to
PKCS12 which is an industry standard format using "keytool -importkeystore -
srckeystore /opt/talena/conf/talena.keystore -destkeystore /op-
t/talena/conf/talena.keystore -deststoretype pkcs12".
Successfully imported .

Restart Imanis ap-server, after importing the appropriate SSL certificates.

Would you like to restart now ? (yes/no) yes ? yes
Stopping API server...
API server  stopped successfully
Starting API server...
API server is running on [imanis-api-server-0]
```

Note:

- The key and certificate files should be placed under directory starting from path /home_cohesity_data/athena/mounts/_internal_view_mount/imanis/ (see the usage for this tool).
- Keystore passphrase is the private key passphrase that was set when the private key was generated. If it was not set, then just hit enter for the pass phrase.
- Restarting the api-server is mandatory for the changes to become effective.
- Ignore the warning about PKCS12 format.

Managing NoSQL and Hadoop Services

Upgrade NoSQL and Hadoop Services

After upgrading Cohesity to the latest version, to continue using the features provided by the NoSQL and Hadoop Service, you must upgrade to the latest version of the NoSQL & Hadoop Service.

To upgrade NoSQL and Hadoop services from an earlier release to the latest one:

Note: It is recommended that all scheduled "NoSQL and Hadoop Service" protection runs are paused before the upgrade. Also verify that no recovery is in progress.

> **Note:**
> NoSQL and Hadoop app upgrade from older versions to 5.2.1 is not supported. The app should be reinstalled.
>
> To reinstall app version 5.2.1, do the following:
>
> 1. Run the following command to save the configurations from the existing version:
>
>   # imanis_cli.sh -c config save
>
> 2. Uninstall existing app version
> 3. Install NoSQL and Hadoop Services 5.2.1
> 4. Launch NoSQL and Hadoop Services5.2.1

1. Download the App package that you want to upgrade.
2. Navigate to **Marketplace** > **My Apps**.
3. Select **My Apps** tab, and click **Upload App** on the top right corner.
4. Click **Select File** and browse the location for the **NoSQL and Hadoop Services App** and select it.
5. Click **Upload and Install**.

   The progress of the upload is displayed and once the upload is completed, the app is installed automatically.

   > **Note:** Please wait for the installation to complete and the version to be shown as the desired upgraded version.

6. Once the installation is complete, click **All Instances** and click **Pause** to pause the current active instance that is running.

   Wait for the Status to be shown as **paused**.

   > **Note:** To continue using data protection for MongoDB, you need to configure the MongoDB CDP service. For more information, see Managing NoSQL and Hadoop Services.

7. Click **Resume** to launch services using the latest upgraded version of NoSQL and Hadoop Services App.

> **Note:** Please wait for around 10-15 minutes for the status to be shown as running. Click on the drop down to see the upgraded version of NoSQL and Hadoop Services App.

8. Make sure that all NoSQL and Hadoop services are up and running.

Perform the following steps to upgrade the NoSQL app:

1. Save the current configuration:

   ```
   imanis_cli.sh -c config save
   ```

2. Pause the current active instance of the app.
3. Upload and install the new NoSQL app.
4. Resume the app after a successful installation.

   The new app instance displays.

5. When the new app is resumed, by default, it restores ssl and krb5 configurations from the config backup. But in case it fails, restore the config using:

   ```
   imanis_cli.sh -c config restore
   ```

   For more information, see Config Save and Restore.

6. To verify whether the app is in running state, use the following:

   ```
   kubectl.sh get pods -A | grep "imanis"
   ```

   Ensure all pods are in running state.

7. Perform a smoke test before running any jobs.
   1. Log in to any one of the imanis pods.
   2. Run the following and make sure all tests PASS.

      ```
      talena-services.sh smoke all
      ```

Install a Patch for NoSQL and Hadoop Service

This section describes the procedure of installing a patch for NoSQL and Hadoop Services.

1. Download the patch, example PATCH-00.tar.gz.
2. Copy the file at location `/home_cohesity_data/athena/mounts/_internal_view_mount/imanis`.
3. Run the patch application utility from a Cohesity node as a *cohesity* user.

   ```
   # imanis_cli.sh -c patch -f /home_cohesity_data/athena/mounts/_
   internal_view_mount/imanis/PATCH-159.tar.gz
   ```

4. Verify if the patch is applied to the system once the patch is successfully applied:

```
# imanis_cli.sh -c patch -i
```

Scale Nodemanager Pods

Sometimes, you may want to increase (scale up) the number of nodemanager replicas to use the additional resources available after adding a new compute node. In such cases, you can utilize the additional resources by launching more nodemanager replicas using the command given below:

```
$ imanis_cli.sh -c scale --help
INFO : Checking reachability of pod imanis-nodemanager-0
-------------------------------------------------------------------------
Performing scale operation of node manager pods.
-------------------------------------------------------------------------
Usage:
To scale up number of nodemanager pods,
imanis_cli.sh -c scale up --nmcount
To scale down number of nodemanager pods,
imanis_cli.sh -c scale down --nmcount
--nmcount: Number of expected node manager pods.
-------------------------------------------------------------------------

$ imanis_cli.sh -c scale up 4
INFO : Checking reachability of pod imanis-nodemanager-0
-------------------------------------------------------------------------
Performing scale operation of node manager pods.
-------------------------------------------------------------------------
NM pods scaled up to 4 successfully.
INFO: Scale up performed successfully
-------------------------------------------------------------------------
```

You can also reduce the number of running nodemanager pods by reducing the replica count using the following command.

```
$ imanis_cli.sh -c scale down 2
INFO : Checking reachability of pod imanis-nodemanager-0
-------------------------------------------------------------------------
Performing scale operation of node manager pods.
-------------------------------------------------------------------------
NM pods scaled down to 2 successfully.
INFO: Scaled down performed successfully
-------------------------------------------------------------------------
```

Configuring Continuous Data Protection (CDP) for MongoDB

Ensure that the NoSQL and Hadoop Service app is installed and running.

To enable MongoDB CDP service, use the following command:

```
$ imanis_cli.sh -c mongocdp enable --cpu <cpu-cores> --memory <memory-GB> --
replica <num-replicas>
```

- **cpu-cores**: Number of CPU cores allocated to each MongoCDP service instance
- **memory-GB**: Amount of memory allocated to each MongoCDP service instance
- **num-replicas**: Number of MongoCDP service instances. Depending on the load on MongoDB primary and the recovery point objective, one or more MongoDB CDP services can be provisioned. The use of multiple smaller CDP services can help RPO in case of nodes going down.

For example, the below command enables MongoDB CDP with single replicas of 1core/2GB memory.

```
$ imanis_cli.sh -c mongocdp enable --cpu 1 --memory 2 --replica 1
INFO : Checking reachability of pod imanis-nodemanager-0
INFO : Log File : /tmp/imanis-cli-workdir.10686/cli/imanis-mongo-cdp.log
INFO : Enabling MongoCDP pods deployment
INFO : Reading allocatable cluster resources
INFO : Total allocatable Memory(GB) : 239
INFO : Total allocatable CPUs : 47
INFO : Number of MongoCDP replicas : 1
INFO : CPUs per MongoCDP replica : 1
INFO : Memory per MongoCDP replica(GB) : 2
INFO : Total CPUs for MongoCDP replicas : 1
INFO : Total Memory for MongoCDP replicas(GB): 2
INFO : Total Memory for Other Services(GB) : 15
INFO : Total CPUs for Other Services : 10
INFO : Small-Nodemanager instance config : 16GB/4 CPUs
INFO : Medium-Nodemanage instance config : 32GB/8 CPUs
INFO : Large-Nodemanager instance config : 40GB/10 CPUs
Please confirm above configurations for 'NoSQL & Hadoop Service' app
deployment with MongoCDP Pods
Do you want to continue (yes/no) yes ? yes
```

```
--------------------------------------------------------------------------------
----
mongocdp : service(s) will be stopped (if running)
--------------------------------------------------------------------------------
----
service : mongocdp is being stopped
Stopping MongoCDP services on imanis-mongocdp-0
MongoCDP services stopped successfully
Setting up MongoCDP services...
Configuring MongoCDP services...
MongoCDP services configured successfully
Deleting stale pod directory:
/cohesity/mount/sharedview/imanis/cdp/mongo/v1/pods/imanis-mongocdp-1
Starting MongoCDP service on imanis-mongocdp-0
MongoCDP service is running on [imanis-mongocdp-0]
MongoCDP service is running
Setting up MongoCDP service successfull
Requested number of pods with given memory and cpu cores is updated
successfully
```

To verify, once the app is Running, run the following command to check the pod status:

```
$ kubectl.sh  get pods  -A
```

Example:

```
$ kubectl.sh get pods -A
NAMESPACE                NAME
 READY   STATUS    RESTARTS   AGE

 1/1     Running   0          12d
cohesity-magnus           magnus-server-0
 1/1     Running   0          12d
```

To disable MongoDB CDP:

1. Run the following command:

   $ imanis_cli.sh -c mongocdp disable

2. Check the pod status from Cohesity node with command "kubectl.sh get pods -A" and verify that no mongocdp pods are running.

> **Note:** Once MongoCDP service is disabled, MongoDB data protection would no longer work.

Uninstall NoSQL and Hadoop Services

To terminate and uninstall the NoSQL and Hadoop services, see Cohesity Helios documentation > MarketPlace Apps > Uninstall an App for details.

Additional Configuration for NoSQL and Hadoop Services

This topic describes some of the additional configuration that can be done to NoSQL and Hadoop Service.

Configure NoSQL and Hadoop Services to Use Updated VIPs

Use the following commands to list and configure the latest VIPs.

Commands	Description
`imanis_cli.sh -c vip`	Provides VIP option to update required config files with latest VIPs.
`imanis_cli.sh -c vip list`	Lists existing VIPs used by NoSQL and Hadoop Services.
`imanis_cli.sh -c vip update`	Configure NoSQL and Hadoop Services to use the latest list of VIPs. **Note:** You need to restart the service for the VIP changes.

Megafile Support for Cassandra

Megafile allows fast backup and recovery for large files, helping reduce backup times as well as downtime when recovering from a disaster. Megafile distributes files across all nodes in a cluster. Megafile breaks large files into smaller chunks for parallel backup and recovery across nodes. The minimum size of these chunks is optimized to maximize performance.

Cassandra backup and recovery of size tiered tables generally contains data files which are in tens or hundreds of GBs. These data files are backed up or recovered as Megafiles. Cassandra uses different approaches for backup and recovery. The Megafile approach is used only if `scp` is being used for backup and recovery.

By default, Megafile support for Cassandra backup and recovery is disabled.

Enable or Disable Megafile for Cassandra Backup

Run the following command to enable Megafile for Cassandra backup:

```
imanis_cli.sh -c megafile --connector cassandra-backup --workdir /tmp/imanis
--enable true
```

where, `-workdir` specifies the directory on the primary cluster nodes where Cassandra can copy the binaries.

Run the following command to disable Megafile for Cassandra backup:

```
imanis_cli.sh -c megafile  --connector cassandra-backup  --enable false
```

Enable or Disable Megafile for Cassandra Recovery

A file is restored as a Megafile only if it is backed up as a Megafile. Otherwise, Cassandra uses the normal recovery workflow to recover Cassandra objects.

Run the following command to enable Megafile for Cassandra recovery:

```
imanis_cli.sh -c megafile --connector cassandra-restore --workdir /tm-
p/imanis --enable true
```

where, `-workdir` specifies the directory on the primary cluster nodes where Cassandra can copy the binaries.

Run the following command to disable Megafile for Cassandra recovery:

```
imanis_cli.sh -c megafile --connector cassandra-restore --enable false
```

Megafile Status

The pulse log shows the following when Megafile is enabled for backup and recovery:

```
- Megafile support is enabled
```

The pulse log shows the following after a protection run or recovery:

```
CASSANDRA_MEGAFILES_COPIED=2 CASSANDRA_MEGAFILES_FAILED=2 CASSANDRA_
MEGAFILES_DATA_COPIED=4931999383
```

where

- `CASSANDRA_MEGAFILES_COPIE`D - Number of Megafiles successfully copied.
- `CASSANDRA_MEGAFILES_FAILED` - Number of Megafiles for which copy failed.
- `CASSANDRA_MEGAFILES_DATA_COPIED` - Total data copied as Megafile.

Job Log Collection Tool

The Job Log Collection tool is used to collect logs for a specific protection run for a specific duration.

Note:

- You must log in to the Cohesity cluster as the Support User
- The Support User must have write permission to `outdir`.
- Ensure the `outdir` has enough space to collect the protection run logs.

Perform the following steps to collect the protection run logs:

1. Log in to the Cohesity cluster where NoSQL and Hadoop Service app is running.
2. Run the following command to check if the NoSQL and Hadoop Service is running:

```
$ kubectl.sh get pods -o wide -A | grep imanis
```

3. Run the following command to collect the protection run logs for a specific duration:

```
imanis_cli.sh -c joblog --jobname <jobname> --outdir <dirname> [--
fromdate <fromdate>] [--todate <todate>]
```

Example:

```
$imanis_cli.sh -c joblog --jobname Hdfs-backup1 --outdir /XYZ --fromdate
2021_09_01
```

Add or Delete Host Entries to /etc/hosts on all Pods

You can add or delete host entries in the `/etc/hosts` file on all pods.

Important:

- Do not manually edit the `/etc/hosts` file. You must use `imanis_cli.sh` command to add or delete host entries in the `/etc/hosts` file.
- Any manual edits made into the `/etc/hosts` file are lost after pod restart or app upgrade.

Add Host Entries

Perform the following steps to add host entries to the `/etc/hosts` file:

1. Log in to the Cohesity cluster as the Support User. The cluster must have the NoSQL & Hadoop Service app running.
2. Prepare a file with the host entries at the location `/home_cohesity_data/athena/mounts/_internal_view_mount`.

> **Note:**
> - The host files must have new line separated entries for hosts in <IP><Hostname> format. For example, 10.14.25.101 server1
> - The host files path must always begin with `/home_cohesity_data/athena/mounts/_internal_view_mount`.

Example:

```
$ cat /home_cohesity_data/athena/mounts/_internal_view_mount/newhosts
10.14.25.101 server1
10.14.25.102 server2
10.14.25.103 server3
```

3. Run the following command to add the host entries:

```
$ imanis_cli.sh -c hosts add <hosts-file-path>
```

Example:

```
$ imanis_cli.sh -c hosts add /home_cohesity_data/athena/mounts/_
internal_view_mount/newhosts
```

Delete Host Entries

Perform the following steps to delete host entries in the `/etc/hosts` file:

1. Log in to the Cohesity cluster as the Support User. The cluster must have the NoSQL & Hadoop Service app running.
2. Prepare a file with the host entries at the location `/home_cohesity_data/athena/mounts/_internal_view_mount`.

> **Note:**
> - The host files must have new line separated entries for hosts in <IP><Hostname> format. For example, 10.14.25.101 server1
> - The host files path must always begin with `/home_cohesity_data/athena/mounts/_internal_view_mount`.

Example:

```
$ cat /home_cohesity_data/athena/mounts/_internal_view_mount/newhosts
10.14.25.101 server1
```

```
10.14.25.102 server2

10.14.25.103 server3
```

3. Run the following command to delete the host entries:

   ```
   $ imanis_cli.sh -c hosts delete <hosts-file-path>
   ```

   Example:

   ```
   $ imanis_cli.sh -c hosts delete /home_cohesity_data/athena/mounts/_
   internal_view_mount/newhosts
   ```

List Host Entries

You can also list the host entries available in the `/etc/hosts` file.

To list the host entries, run the following command:

```
imanis_cli.sh -c hosts list
```

Explorer Log Collection

Explorer tool is used to collect the NoSQL & Hadoop Service app specific logs from pods, CHDFS and Cohesity nodes.

> **Important:**
> - The Support User must have write permission to `dest_dir`.
> - Ensure the `dest_dir` has enough space to collect the logs.

Perform the following steps to collect the logs:

1. Log in to the Cohesity cluster as the Support User. The cluster must have the NoSQL & Hadoop Service app running.
2. Run the following command:

   ```
   imanis_cli.sh -c explorer [-n days] [-p string] [-f] [-s list] dest_dir
   ```

   where

   - `-n`: collect log files which are <= n days old. Applicable only for logs, system.

     > **Note:** Mutually exclusive with either full or incremental backup.

   - `-f`: full backup of logs and hdfs:/system files (incremental by default).
   - `-s list`: subset of explorers to run (comma separated). Valid values are:

    - devops
    - chdfs
    - logs
    - machinfo
    - system
    - config
- `-p string`: prefix string to the output tar ball name.
- `dest_dir`: destination path where explorer output is written.

Example:

```
$ imanis_cli.sh -c explorer -n 10 /home/cohesity/data/timecapsules/
```

Config Save and Restore

After terminating the app, any modification made to any of the config files is lost. This tool allows you to restore configs from previous instances of an app if it is saved with the save option.

- config save is used to save config and patches from the running imanis instance.
- config restore is used to restore config/patches from the previous instance to the current running instance.

Save Config and Patches

Perform the following steps to save config and patches from the running instance:

1. Log in to the Cohesity cluster where the NoSQL & Hadoop Service app is running.
2. Run the following command:

   ```
   $ imanis_cli.sh  -c config
   ```

3. Run the following command to save config and patches:

   ```
   $ imanis_cli.sh  -c config save
   ```

Restore Config and Patches

Perform the following steps to restore config and patches to the running instance:

1. Log in to the Cohesity cluster where the NoSQL & Hadoop Service app is running.
2. Run the following command:

   ```
   $ imanis_cli.sh  -c config
   ```

3. Run the following command to restore config and patches:

   ```
   $ imanis_cli.sh  -c config restore
   ```

Optionally you can also restore specific saved config or configs. Run the following command to restore specific saved config or configs to the running instance:

```
$  imanis_cli.sh -c config restore conf hadoop conf agents
```

Monitor the NoSQL and Hadoop Service Health

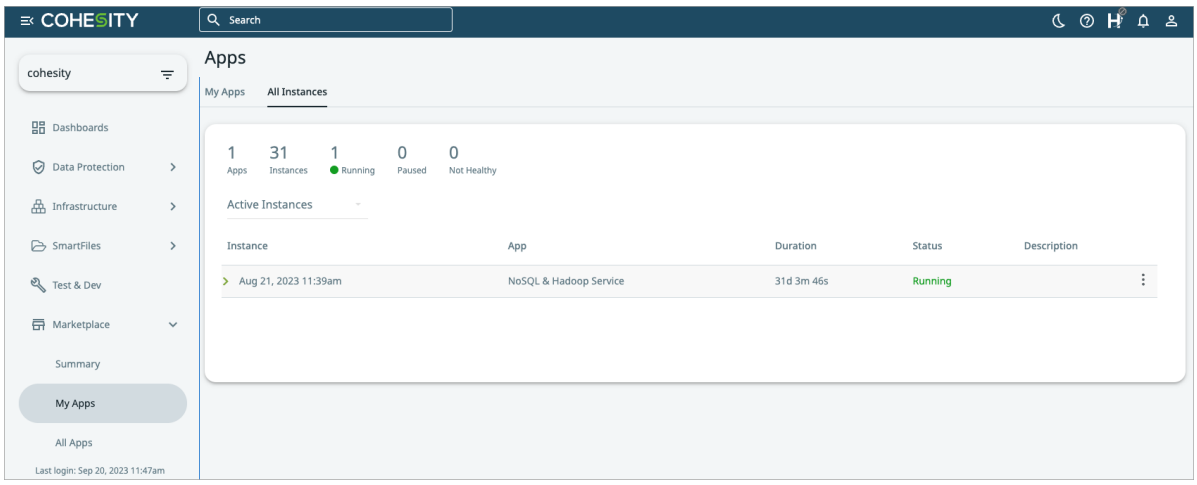
To ensure that the NoSQL and Hadoop Service is healthy, Cohesity constantly monitors the following services running on the Kubernetes pods: `zookeeper`, `YARN`, `api-server`, and `mongocdp` (if enabled for MongoDB protection). These services are required to enable and perform the backup and restore operations.

If any of these services encounter issues, an error message with an error code appears on the Cohesity UI, which can be used for troubleshooting. The status of the NoSQL and Hadoop Service is displayed as either **Running** or **Not Healthy** depending on the status of these services. The status of the NoSQL and Hadoop Service specifies the following:

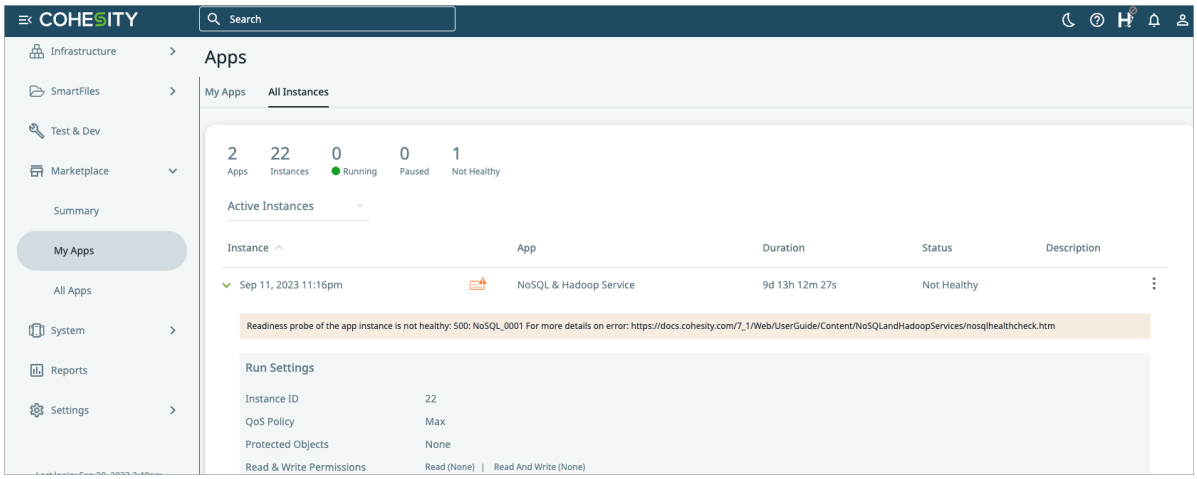
- **Running** - The NoSQL and Hadoop Service is healthy and running.
- **Not Healthy** - The NoSQL and Hadoop Service is not healthy and have some issues.

To view the health of the NoSQL and Hadoop service from the Coheity UI, navigate to **Marketplace** > **My Apps** and then click the **All Instances** tab.

Running State:



Not Healthy State:



NoSQL and Hadoop Service Error Codes

This section covers the NoSQL and Hadoop Service error codes and the troubleshooting steps.

> **Important:** Ensure that you have Host Shell access on the Cohesity cluster to perform the troubleshooting steps.

NoSQL_0000

Issue:

The NoSQL and Hadoop service health check feature cannot report the health of the service. The NoSQL and Hadoop service might be in a **Running** or **Not Healthy** state, and the health check feature cannot detect the service's current status.

Troubleshooting:

Contact Cohesity Support if the issue persists.

NoSQL_0001

Issue:

The NoSQL and Hadoop service, `zookeeper`, is down on one or more of the pods: `imanis-zookeeper-0`, `imanis-zookeeper-1`, and `imanis-zookeeper-2`.

Troubleshooting:

1. Login to the pod using the following command:

   ```
   kubectl.sh exec -it -n <athena-namespace> imanis-zookeeper-0 --
   /bin/bash
   ```

2. Run the following command to find the pod on which the `zookeeper` service is down:

```
talena-services.sh status zookeeper
```

3. Log in to the pod on which the `zookeeper` service is down and verify `zookeeper` log files in `$LOG_DIR` to determine the reason for the issue.

   For example: The log files to look for, if `zookeeper` is down on `imanis-zookeeper-0` pod:

   ```
   $LOG_DIR/zookeeper-hdfs-server-imanis-zookeeper-0.log
   $LOG_DIR/zookeeper-hdfs-server-imanis-zookeeper-0.out
   ```

4. Also, you can collect the logs from the Cohesity cluster for further debugging by running the following command using the `cohesity` user on the cluster:

   ```
   imanis_cli.sh -c explorer -n 1 -s logs -l zookeeper /home/cohesity
   ```

5. Try restarting the `zookeeper` service to fix the issue. Run the following command on any of the pods to restart the `zookeeper` service:

   ```
   talena-services.sh restart zookeeper
   ```

6. Check the status of the `zookeeper` service to verify if the issue is resolved using the following command:

   ```
   talena-services.sh smoke zookeeper
   ```

Contact Cohesity Support if the issue persists.

NoSQL_0002

Issue:

The NoSQL and Hadoop group of services `YARN`, is down on one or more of the mentioned pods: `imanis-resourcemanager-0`, `imanis-resourcemanager-1`, `imanis-nodemanager-*`, and `imanis-historyserver-0`.

Troubleshooting:

1. Login to the pod using the following command:

   ```
   kubectl.sh exec -it -n <athena-namespace> imanis-nodemanager-0 --
   /bin/bash
   ```

   > **Note:** You can use `imanis-resourcemanager-0` instead of `imanis-nodemanager-0`.

2. Run the following command to find the pod on which the `YARN` service is down:

   ```
   talena-services.sh status yarn
   ```

3. Login to the pod on which the `YARN` service is down and verify the log files specific to yarn (`*nodemanager*`, `*resourcemanager*`, `*historyserver*`) in `$LOG_DIR` to

determine the reason for the issue.

For example: The log files to look for, if `resourcemanager` is down on `imanis-resourcemanager-0`:

```
$LOG_DIR/hadoop-hdfs-resourcemanager-imanis-resourcemanager-0.log
$LOG_DIR/hadoop-hdfs-resourcemanager-imanis-resourcemanager-0.out
```

Also, you can collect the logs from the Cohesity cluster for further debugging by running the following command using the `cohesity` user on the cluster:

```
imanis_cli.sh -c explorer -n 1 -s logs -l yarn /home/cohesity
```

4. Try restarting the `YARN` service to fix the issue. Run the following command on any of the pods to restart the `YARN` service:

```
talena-services.sh restart yarn
```

5. Check the status of the `YARN` service to verify if the issue is resolved using the following command:

```
talena-services.sh smoke yarn
```

Contact Cohesity Support if the issue persists.

NoSQL_0003

Issue:

The NoSQL and Hadoop group of services `api-server`, is down on one or more of the mentioned pods: `imanis-api-server-0` and `imanis-api-server-1`.

Troubleshooting:

1. Login to the pod using the following command:

```
kubectl.sh exec -it -n <athena-namespace> imanis-api-server-0 --
/bin/bash
```

> **Note:** You can use `imanis-api-server-1` instead of `imanis-api-server-0`.

2. Run the following command to find the pod on which the `api-server` service is down:

```
talena-services.sh status api-server
```

3. Login to the pod on which the `api-server` service is down and verify the `api-server` log files in `$LOG_DIR` to determine the reason for the issue.

   For example: The log files to look for, if `api-server` is down on `imanis-api-server-0`:

```
$LOG_DIR/api-server-imanis-api-server-0.log
$LOG_DIR/api-server-imanis-api-server-0.log
```

Also, you can collect the logs from the Cohesity cluster for further debugging by running the following command using the `cohesity` user on the cluster:

```
imanis_cli.sh -c explorer -n 1 -s logs -l api-server /home/cohesity
```

4. Try restarting the `api-server` service to fix the issue. Run the following command on any of the pods to restart the `api-server` service:

```
talena-services.sh restart api-server
```

5. Check the status of the `api-server` service to verify if the issue is resolved using the following command:

```
talena-services.sh smoke api-server
```

Contact Cohesity Support if the issue persists.

NoSQL_0004

Issue:

The NoSQL and Hadoop group of services `mongocdp`, is down on one or more mongocdp pods. For example `imanis-mongodp-0`, `imanis-mongodp-1` etc.

Troubleshooting:

1. Login to the pod using the following command:

```
kubectl.sh exec -it -n <athena-namespace> imanis-mongocdp-0 --
/bin/bash
```

2. Run the following command to find the pod on which the `mongocdp` service is down:

```
talena-services.sh status mongocdp
```

3. Log in to the pod on which the `mongocdp` service is down and verify the `mongo*` log files in `$LOG_DIR` to determine the reason for the issue.

   For example: The log files to look for, if `mongocdp` is down on `imanis-mongocdp-0`:

```
$LOG_DIR/mongodb-cdp-imanis-mongocdp-0.log
$LOG_DIR/mongodb-cdp-imanis-mongocdp-0.out
```

   Also, you can collect the logs from the Cohesity cluster for further debugging by running the following command using the `cohesity` user on the cluster:

```
imanis_cli.sh -c explorer -n 1 -s logs -l mongocdp /home/cohesity
```

4. Try restarting the `mongocdp` service to fix the issue. Run the following command on any of the pods to restart the `mongocdp` service:

```
talena-services.sh restart mongocdp
```

5. Check the status of the `mongocdp` service to verify if the issue is resolved using the following command:

```
talena-services.sh smoke mongocdp
```

Contact Cohesity Support if the issue persists.

NoSQL_0011

Issue:

The NoSQL and Hadoop service `zookeeper` smoke test has failed.

Troubleshooting:

1. Log in to the pod using the following command:

```
kubectl.sh exec -it -n <athena-namespace> imanis-zookeeper-0 --
/bin/bash
```

2. Verify `zookeeper` log files in `$LOG_DIR` to determine the reason for the issue.

   For example: The log files to look for:

```
$LOG_DIR/zookeeper-hdfs-server-imanis-zookeeper-0.log
$LOG_DIR/zookeeper-hdfs-server-imanis-zookeeper-0.out
```

   Also, you can collect the logs from the Cohesity cluster for further debugging by running the following command using the `cohesity` user on the cluster:

```
imanis_cli.sh -c explorer -n 1 -s logs -l zookeeper /home/cohesity
```

3. Try restarting the `zookeeper` service to fix the issue. Run the following command on any of the pods to restart the `zookeeper` service:

```
talena-services.sh restart zookeeper
```

4. Check the status of the `zookeeper` service to verify if the issue is resolved using the following command:

```
talena-services.sh smoke zookeeper
```

Contact Cohesity Support if the issue persists.

NoSQL_0012

Issue:

The NoSQL and Hadoop service `chdfs` smoke test has failed.

Troubleshooting:

1. Collect the logs from the Cohesity cluster for debugging by running the following command using the `cohesity` user on the cluster:

```
imanis_cli.sh -c explorer -n 1 -s logs -l yarn /home/cohesity
```

2. Try restarting the `YARN` service to fix the issue. Run the following command on any of the pods to restart the `YARN` service:

   ```
   talena-services.sh restart yarn
   ```

3. Check the status of the `YARN` service to verify if the issue is resolved using the following command:

   ```
   talena-services.sh smoke chdfs
   ```

Contact Cohesity Support if the issue persists.

NoSQL_0013

Issue:

The NoSQL and Hadoop service `mongocdp` smoke test has failed. The `mongocdp` service runs on pods `imanis-mongocdp-*`.

Troubleshooting:

1. Log in to the pod using the following command:

   ```
   kubectl.sh exec -it -n <athena-namespace> imanis-mongocdp-0 --
   /bin/bash
   ```

2. Verify the `mongo*` log files in `$LOG_DIR` to determine the reason for the issue.

   For example: The log files to look for, if `mongocdp` is down on `imanis-mongocdp-0`:

   ```
   $LOG_DIR/hadoop-hdfs-resourcemanager-imanis-resourcemanager-0.log
   $LOG_DIR/hadoop-hdfs-resourcemanager-imanis-resourcemanager-0.out
   ```

   Also, you can collect the logs from the Cohesity cluster for further debugging by running the following command using the `cohesity` user on the cluster:

   ```
   imanis_cli.sh -c explorer -n 1 -s logs -l mongocdp /home/cohesity
   ```

3. Try restarting the `mongocdp` service to fix the issue. Run the following command on any of the pods to restart the `mongocdp` service:

   ```
   talena-services.sh restart mongocdp
   ```

4. Check the status of the `mongocdp` service to verify if the issue is resolved using the following command:

   ```
   talena-services.sh smoke mongocdp
   ```

Contact Cohesity Support if the issue persists.

NoSQL_0020

Issue:

The NoSQL and Hadoop service's health check fails if the disk usage goes above 95% of the disk space.

Troubleshooting

Contact Cohesity Support if the issue persists.

NoSQL_0022

Issue:

There is a problem while fetching and applying configuration parameters. Refer to the `talena_getGflags.log-<date-time>` log file in the NoSQL App logs for failure details.

The api-server may be running or may not be healthy. The health check feature has some issues determining the current status.

Troubleshooting

1. Log in to the pod using the following command:

   ```
   kubectl.sh exec -it -n <athena-namespace> imanis-api-server-0--
   /bin/bash
   ```

2. Check the configuration fetch log files in $LOG_DIR to identify the cause of the issue:

   ```
   $LOG_DIR/talena_config_fetch<date-time>.log
   ```

3. Try restarting the api-server to re-fetch and apply the configuration. Run the following command on any of the pods to restart the api-server service:

   ```
   talena-services.sh restart api-server
   ```

FAQs on NoSQL and Hadoop Services

The following are some of the frequently asked questions about managing SSL enabled NoSQL primary clusters:

1. What is alias which is used while importing the certificates ? Does it have to match the hostname ?

   Alias is just a name or a tag for the entry in the truststore. It is used only by users to identify the certificate they are looking for. It could be any unique string for a given certificate entry. Usually the hostname of the machine to which the certificate belongs is preferred as it makes it easy to identify the same.

2. Can I import the certificates into NoSQL and Hadoop Service in PKCS12 format ?

   No, the certificates should be in PEM format for importing into NoSQL and Hadoop service.

3. My primary server certificate is signed by an intermediate CA and the intermediate CA certificate is signed by another root CA. So do I need to import these two certificates as well into NoSQL and Hadoop service?

   Yes, root CA, intermediate CA certificates should also be imported into NoSQL and Hadoop service truststore. If you import using an automatic method, then usually all

the certificates in the chain are downloaded from the server and imported into NoSQL and Hadoop service truststore.

4. How do I know what format my certificate is in ?

   If you cat the file and find text wrapped in headers such as `-----BEGIN CERTIFICATE----- or -----BEGIN RSA PRIVATE KEY-----`, then the certificate is in PEM format.

5. How do I verify if my private key and certificate match each other ?

   ```
   openssl x509 -noout -modulus -in /path/to/cert | openssl md5
   ```

   ```
   openssl rsa -noout -modulus -in /path/to/key   | openssl md5
   ```

   If both the sums match, then they match each other.

   > **Note:** When importing a keystore into NoSQL and Hadoop service, this check is done by the script.

6. How do I check if I have already imported a certificate into NoSQL and Hadoop Service truststore ?

   ```
   # imanis_cli.sh -c ssl list truststore
   ```

   and check if the entry exists.

7. I am importing a CA signed certificate and the corresponding private key into NoSQL and Hadoop service as keystore. What should be the hostname (CN) ?

   The hostname for NoSQL and Hadoop Service app usually start with `imanis-*.imanis-cluster.*.svc.cluster.local`. But these hostnames are not resolvable outside the Athena app. So for hostname, you can use the Cohesity hostnames on which NoSQL and Hadoop Service app has been deployed.

8. My server certificates have expired. How do I remove the old certificates and re import new ones ?

   Using imanis_cli.sh -c ssl list command, you can list the entries and delete the ones which you want using the specific alias as follows:

   ```
    # imanis_cli.sh -c ssl delete alias
   ```

9. If I delete keystore or truststore while the protection runs are in progress, what happens ?

   Protection runs may fail. This should be done only when you are sure that there are no protection runs connecting to SSL enabled primaries on your NoSQL and Hadoop cluster.

10. What is the difference between password and passphrase for the private key I am importing ? How do I verify if my password and passphrase are correct before importing ?

    Password is set for the keystore or truststore that you import into NoSQL and Hadoop service. Please set a good password and remember it.

    Passphrase is always associated with a private key. It is usually set when you generate a private key. The passphrase you enter should match with the passphrase that was set for the given key. You can not change this afterwards.

11. When do I need to import certificates into NoSQL and Hadoop Service?

    You need to do it before you register your data source into Cohesity UI.

12. Can I only import certificates from my server into NoSQL and Hadoop service? Is importing or generating keystore mandatory ?

    In some environments, there is no requirement for the client to present its certificate to server and server having to carry out the validation. In such environments, you do not need to import NoSQL and Hadoop service certificate into your primary cluster.

    However, in some cases, like in cassandra, the setting required_client_auth=true in yaml configuration file mandates that validation be done both ways. In this case, you have to copy the certificate from NoSQL and Hadoop node into your primary nodes and import it using the methods prescribed by your respective primary setup.

13. Which one should I use ? A self-signed certificate or a CA signed certificate for NoSQL and Hadoop Service?

    This depends on the security requirements of your organization. Self-signed certificate is good enough, if the requirement is to encrypt the data transferred between the NoSQL and Hadoop running cluster and your primary cluster being protected. But if the requirement is not only encrypted data transmission on the wire but also to validate that the server and client are authentic, then you need CA signed certificates.

Chapter 29: Test & Dev (Cloning)

This chapter includes the following topics:

- Test & Dev Overview 4194
- Clone Views 4195
- Clone VMs 4197
- Clone Databases 4213
- Test & Dev Using CloudSpin 4219
- Clone vCloud Director (vCD) VMs 4219

Test & Dev Overview

Cohesity empowers developers to instantiate the latest backup of their production application stack and run it directly off Cohesity, providing a unified foundation for copy data management. Instant, zero-space clones enable businesses to quickly spin up test/dev environments from a backup or existing file share, enabling rapid test and development from actual data without any capacity overhead. Because clones are designed with performance in mind, access time is identical regardless of the number of snapshots or clones that are made.

Cohesity provides the ability to clone objects from snapshots created by a Protection Group. The cloned objects are copied to a new location, rehydrated and restored to a running state. For example when a VMware object is cloned in an on-premises Cohesity cluster, new VM files (such as VMDKs) are created from snapshots and stored in a view on the Cohesity cluster. This view becomes the datastore for these VM files. The Cohesity cluster creates new VMs in the selected resource pool by mounting the view containing the new VMDKs as the datastore on the ESXi hosts. During cloning, VMware is responsible to select the ESXi hosts that have access to the required Datastore based on load balancing.

Note the following about Cohesity Cloning:

- When cloning in an on-premises Cohesity cluster, in a single Clone task you can only clone Protection Groups and VMs that belong to the same Storage Domain and Source.
- You can select only one Snapshot of a VM to clone. While configuring a Clone task, you cannot select two Snapshots that were created from the same VM.

For instructions on how to use Cohesity to Clone VMs, see Clone VMs.

The following example depicts cloning Snapshots of VMware VMs. You want to clone a set of Engineering VMs for use by the QA department for testing. You can select a mix of individual Snapshots and Job Snapshots to clone. In the figure below, the following Snapshots are cloned:

- The individual Snapshot created of VM1 on 03/21/2025 03:00AM
- The individual Snapshot created of VM3 on 03/21/2025 05:10AM

After the testing is complete, you may want to tear down the cloned VMs. For more information, see About Tearing Down Cloned VMs.

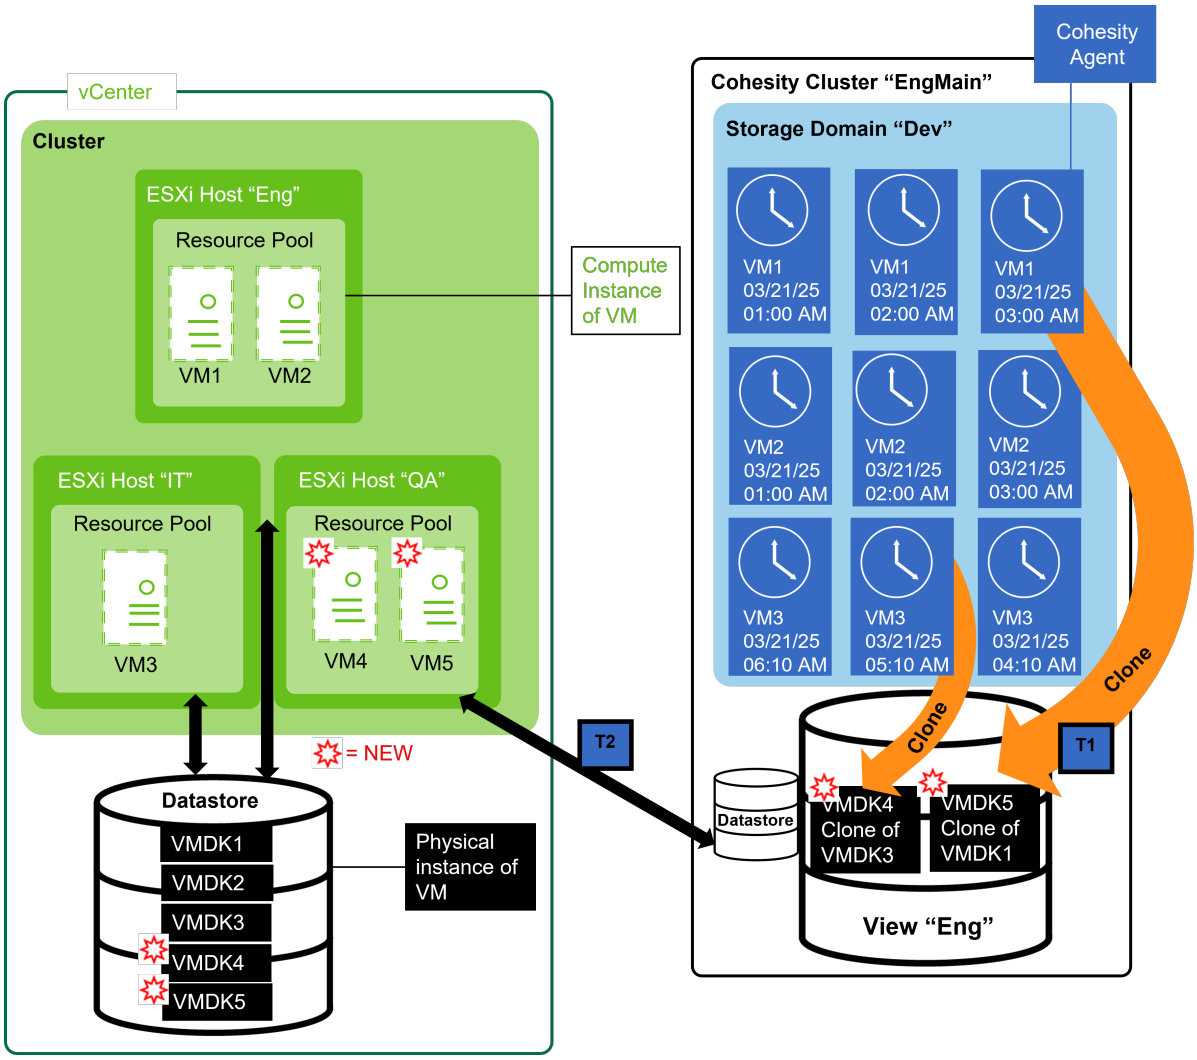
The action steps in the following procedure are represented in the figure below with blue numbered squares:

.

T1) From Snapshots, the Cluster creates new VMDKs in the selected View as shown by VMDK4 and VMDK5. This View becomes the Datastore for these VM files.

T2) The Cohesity cluster creates new VMs by mounting the View containing the new VMDKs from the Datastore onto ESXi Hosts in the selected Resource Pool. In this

example, VM4 and VM5 are created from mounting VMDK4 and VMDK5 onto the ESXi Host QA.



Clone Views

You can make a clone of an existing view. After cloning, the two versions of the data are unique. Changes made to the data in the new view are not replicated in the original view and changes made to the original view are not replicated in the new view. Data within a DataLock view is immutable. You can also clone a view from a view Snapshot. For more information, see Clone a View From a Snapshot.

Before you can clone Protected Objects (Views), Snapshots must exist. To create Snapshots, create and run a Protection Group.

To clone a view:

1. Navigate to **Test & Dev**.
2. Click **Clone** located at the top right of the page.
3. Click **Views**.
4. Select Views to Clone.
5. Set Clone Options.

Select Views to Clone

In this section you select Views to clone.

Before you can clone Protected Objects (Views), Snapshots must exist. To create Snapshots, create and run a Protection Group.

To select Views to clone:

1. Search for Views to clone. Enter characters of the View name and a list of items displays. (You can optionally specify the wildcard character * in the search.) Select an item from the list. You can also optionally narrow the search results by specifying filter criteria. For example, you can filter the search results by a specific Protection Group. Click **Change Filters**, specify Filter by criteria and click **Add**.
2. Click a View.

Set Clone Options

In this section you select the options for the clone task.

To set clone options:

1. Select the clone's **Purpose**.

   Select **Clone as DataLock View** if you want to clone a view as write once read many. Data within a DataLock view is immutable, and most view properties cannot be edited. (Note that view-level DataLock is different than file-level DataLock, as described in File-level DataLock for NFS and SMB Views.)
2. In the **Task Name** field, you can optionally change the default name for the clone task.
3. **View Name:** If you are creating or cloning a new view, specify a name for the view. Forward slashes (/) are not allowed in the view name.

   > **Important:** Renaming a view changes its default share name. Clients won't be able to mount the view unless they use the new share name. Clients using a share alias are not affected by the rename.

For a DataLock view, select a date for lock expiration. During the lock period, data within the view cannot be edited by any user.

During the lock period, users with Data Security privileges can delete the view (unless File DataLock is enabled for the view, in which case the view cannot be deleted), extend the lock period (it cannot be reduced) , add IPs in the allowlist and change the description. After the lock period expires, the view can be deleted by any user that has permission to delete it.

4.
5. The Storage Domain is already set. The new view is always created in the same storage domain as the original view.
6. **QoS Policy:** A QoS Policy determines to which storage media data is written and the priority of I/O when contention occurs. Select an appropriate QoS policy for the view. By specifying a priority and the type of workload you expect, the Cohesity cluster can optimize how it processes data in regard to latency, throughput, and priority.

   For details and recommendations, see QoS Policies for Cohesity Views.
7. To have privileges to mount and access a view, a system must be specified in the allowlist subnet. For more information, see Add Subnets to Allowlists.
8. Select the Snapshot to clone. At the bottom of the page, the View that will be cloned is listed. By default, the latest Snapshot of the View is cloned. You can optionally click Edit ( ) for the Selected Object and choose the exact Snapshot to clone.

After cloning, the two versions of the data are unique. Changes made to the data in the new view are not replicated in the original view and changes made to the original view are not replicated in the new view. Data within a DataLock view is immutable.

> **Tip:** The cluster provides notifications when clone and recover tasks that you initiated complete. To view them, click the notifications icon in the top right corner of the Cohesity UI. You can drill down on tasks for additional details and clear notifications as needed.

Clone VMs

Cohesity provides the ability to clone objects from snapshots created by a Protection Group. The cloned objects are copied to a new location, rehydrated and restored to a running state. For example when a VMware object is cloned in an on-premises Cohesity cluster, new VM files (such as VMDKs) are created from snapshots and stored in a view on the Cohesity cluster. This view becomes the datastore for these VM files. The Cohesity cluster creates new VMs in the selected resource pool by mounting the view containing the new VMDKs as the datastore on the ESXi hosts. During cloning, VMware is responsible to select the ESXi hosts that have access to the required Datastore based on load balancing.

To learn more, see Test & Dev Overview and About Tearing Down Cloned VMs.

> **Tip:** You can also watch the VMware VM Test & Dev (Cloning) video to learn how to clone VMware objects.

You can clone or migrate any DataProtect VM to any Cohesity supported cloud.

Note the following about Cloning VMs:

Prerequisite

Prepare the VM that is ready for cloning by running the Sysprep (System Preparation by Microsoft) tool. This is known as generalizing the virtual disk. Sysprep generates a new machine SID.

Considerations:

- Attached CDROM or floppy drives are not recovered or cloned. When recovering or cloning a Snapshot of a VM that had an attached CDROM or floppy drive with data (such as an ISO file), when the VM is recovered or cloned the attached drives are not created and the data is not available.
- Cloning or recovering VMs may fail if the maximum number of mounted NFS Datastores on a VMware ESXi Host is exceeded. Till 6.7, the default value is 8 and from 7.0, the default value is 32. If an ESXi Host already has the maximum number of NFS datastores mounted, the Cohesity View (datastore) does not mount on the ESXi Host during the Cloning or Recovery process. For more information including instructions on increasing the limit, see Increasing the default value that defines the maximum number of NFS mounts on an ESXi/ESX host (2239).
- During VM Recovery or the Cloning of VMs, the Cohesity cluster stores the VMDK and VMX files in different directories on the Cohesity datastore (View), due to a VMware vSphere issue. The VMDK files are placed in the *taskname*/*vmname* directory and the VMX files are placed in the *vmname* directory, where *taskname* is the Task Name you specify for the Recover task and the *vmname* is the name of the VM. For example, if a Clone is created with the Task Name of `QA` that creates clones of the VMs called `Build` and `Test`, the VMDK and VMX files are stored in the following directories in the Cohesity datastore (View): `QA/Build/Build.vmdk`, `QA/Test/Test.vmdk`, `Build/Build.vmx` and `Test/Test.vmx`. However, when recovering a VM, after bringing up the VM on the Cohesity datastore (View), the Cohesity cluster does a Storage vMotion migration of the VM back to its original primary datastore. After the Storage vMotion migration completes, both the VMX and VMDK files end up in the *vmname* directory and the VMDK files are no longer stored in the *taskname* directory. This VM recovery example assumes that the VMDK files were originally located in the default directory (and not in some special directory) when the backup was performed.

- For some conditions, the VMware vSphere reports an error that there is a mismatch between the actual Content ID of Parent VM and the Parent Content ID stored by the Child VM. If you see this error, follow the instructions to fix this issue provided in the following VMware Knowledge Base article: Resolving the CID mismatch error: The parent virtual disk has been modified since the child was created (1007969).
- During the recovery of a single VM that has multiple networks or datastores, VMware does not check if the VM and the ESXi Host's network and datastore are compatible when assigning the VM to the ESXi Host. This can cause the recovery to fail.
- Due to a VMware issue, specific VM recovery scenarios can cause storage migration (and recovery) to fail.
    - Using default settings to recover a VM to the same datastore. If the recovered VM belongs to a local datastore, migration may fail because VMware does not register the local datastore to all ESX Hosts within the Resource Pool.
    - Using custom settings to recover a VM to a selected Resource Pool and datastore. If the recovered VM belongs to a datastore that is not mounted on all ESX Hosts in the Resource Pool, migration may fail because VMware does not check the compatibility of the ESX Host (within the Resource Pool) with the given datastore while registering the VM.
- When the Cohesity cluster clones a VM, the Cluster makes a request to the vCenter Server to create the new VM. The vCenter Server selects an ESXi host from the specified resource pool to host the new VM. However, the VMware vSphere version of the ESXi host, which was selected by the vCenter Sever, may be incompatible with the VMware vSphere version of the original VM. When this happens, the clone of the VM fails with the following error: `A component of the virtual machine is not accessible on the host.`
- If VMs with the same VM name (but different relative VMDK paths) are cloned, the Cohesity cluster retains the original VM name for one VM and renames the rest by adding *_X* to the end of the VM names, where *X* is an increasing number such as 1, 2, or 3. For example if you clone three VMs called QA, the Cluster names the VMs as QA, QA_1 and QA_2. However, cloning VMs with the same relative path is not supported.
- Cloning not supported with the same relative path and VMDK file name. You cannot clone VMs that have the same relative path and the same VMDK name from two different primary datastores. For example, Protection Groups create Snapshots of `test.vmdk` stored in `qa/testing` on `datastore1` and `test.vmdk` stored in `qa/testing` on `datastore2`. If you attempt to Clone these two Snapshots, the Clone fails with an error message. The Clone fails because relative path and VMDK names are used to store both VMDKs in the Cohesity datastore and the Cluster cannot store them in same location. In addition, if two VMs have reference the same Hard disk, the Clone also fails. For example if VM1 included a Hard Disk that was then removed (not deleted) from VM1 and added to VM2. These two VMs cannot be Cloned because the relative path and reference to the Hard Disk is the same.

- Linked clones of VMware Virtual Machines can be backed up, recovered and cloned by the Cohesity cluster but the linking between the VMs is not preserved. The Cohesity cluster supports the Backup, Recovery and Cloning of linked clones of VMware Virtual Machines. However, the linking between the VMs is not preserved and full Snapshots of the VMs are created. In a single Recover task, you can recover a single linked clone VM but not multiple linked clone VMs.
- Cloning VMs within a vApp is not currently supported; they will be cloned under a specified Resource Pool similar to regular VMs.
- vApp VMs can be recovered to their original location (under the same vApp where the original VM that was backed up was present). When vApp VMs are recovered to an alternate location, they can be recovered to the specified Resource Pool only and the user must then move the VMs to the desired vApp.
- Currently, when a VM with multiple NICs is cloned or recovered to an alternate location, Cohesity creates the VM with only one NIC. This will be fixed in a future release.
- For VMware VMs, Virtual RDM disks are recovered as flat disks.
- Cohesity supports recovery only from VM to VM. Recovering VM to physical server and vice-versa is not supported.
- A workaround is needed for Hyper-V VM recovery in SCVMM configurations using test and development (cloning) scenarios, since the initial recovery may report issues with unsupported configurations. To avoid this, the Cohesity file share needs to be added to the recognized file shares for the host/cluster on SCVMM. Once the file share is successfully configured and a VM refresh is completed, the unsupported configuration issue of the VM is resolved. If a clone view is already added to known file shares and is used to perform subsequent clones, this workaround is not necessary.

  > **Note:** The file share must adhere strictly to the following format:
  > \\<clustervip>\<storageDomain>.<cloneViewName>.fs
  > Example file share path: \\dp-test.domain.com\DefaultStorageDomain.new.fs

Before you can clone Protected Objects (VMs), Snapshots must exist. To create Snapshots, create and run a Protection Group.

To learn more, see Replicate and Clone VMs in AWS Cloud Edition and Clone VMs from On-Premises to AWS Cloud Service (On Demand CloudSpin) .

Best Practice for Cloning VMs

Cohesity recommends the following best practice for cloning a VM:

Do not delete the existing VM source while cloning.

To Clone VMs:

1. Verify the following requirements prior to cloning:

   Cloning Snapshots to an Azure Cloud is supported for VMware and Hyper-V VMs with the following operating systems:

   - Linux CentOS 7 on LVM
     - You can clone as many disks as the selected VM supports. For example, if you select a Standard_DS1_v2 VM, four disks can be cloned.
     - When converting and cloning or copying Snapshots of a Linux VM with multiple disks, the disks must be mounted by UUID prior to being backed up by the Protection Group, as shown by the following example entry in a `/etc/fstab`:

       ```
       UUID=e12e623a-c6ee-4718-9b1a-802456e72258 /userdata ext4 defaults,nofail 0 0
       ```

       For detailed instructions, see Edit /etc/fstab to use UUID.
   - Windows
     - You can clone as many disks as the selected VM supports. For example, if you select a Standard_DS1_v2 VM, four disks can be cloned.
     - For a Windows VM, if you want to access the newly created VM in the Cloud service using Remote Desktop, enable the Windows Remote Desktop on the VM prior to capturing the Snapshots of a Windows VM.
     - When backing up Windows VMs with multiple disks, before a Protection Group captures the Snapshot, the Cohesity agent and VMware tools must be installed on the VM and the VM must be running. The Cohesity agents installed must be of the same version as the Cohesity Cluster version. For more information, see Install and Manage the Agent on Windows Servers. In addition, port 50051 must be open in your Firewall. For more information, see Manage Firewall Ports.
     - Due to a Windows issue in builds 14393 and build 15063, a deployed Windows 10 or Windows 2016 VM may not be connected to the network. Resolve this by installing fix KB4073562 for build 14393 or KB4016240 for build 15063 or by updating Windows. For more information, see Cannot connect remotely to a Windows 10 or Windows Server 2016 VM in Azure because of netvsc.sys.
     - Make the disks online by default using the following SAN policy commands:
       - `diskpart`
       - `san policy=OnlineAll`

       For more information, see the SAN Policy documentation.
   - Red Hat Enterprise Linux

- You can clone as many disks as the selected VM supports. For example, if you select a Standard_DS1_v2 VM, four disks can be cloned.
- For the list of supported RHEL versions, see Supported Software.
- When converting and cloning or copying Snapshots of a Linux VM with multiple disks, the disks must be mounted by UUID prior to being backed up by the Protection Group, as shown by the following example entry in a `/etc/fstab`:

  ```
  UUID=e12e623a-c6ee-4718-9b1a-802456e72258 /userdata ext4
  defaults,nofail 0 0
  ```

  For detailed instructions, see Edit /etc/fstab to use UUID.

- The disk size of the VMware VMs must be a multiple of 1 GB.
- Cohesity does not support the CloudSpin of VMs whose OS Disk is formatted with XFS version 5 to Azure. This limitation applies to both Hyper-V and VMware VMs, regardless of their operating system type.
- Cohesity does not support CloudSpin of VMware VMs from VMware Cloud (VMC) to Azure.

Cloning Hyper-V VMs to Azure

- VMs that have one to five disks can be cloned. Each disk must be smaller than 2 TB.
- SUSE Linux VMs are *not* supported.
- All the Hyper-V versions supported by Cohesity for backup is supported for cloning to Azure. For the list of supported Hyper-V versions, see Supported Software.
- Generation 2 VMs are not supported by all VM sizes in Azure. For information on Generation 2 supported VM series, see Microsoft document.
- Cloning of Hyper-V VMs to Azure Stack Hub is not supported.

Cloning VMware VMs to an AWS Cloud has the following requirements:

- Cloning snapshots to an AWS Cloud is supported for VMware VMs with specific Linux operating systems. For information on supported operating systems, see Supported Software
- Cloning Snapshots to an AWS Cloud is supported for VMware VMs with the Windows operating system.
- The disk size of the VMware VMs must be a multiple of 1 MB.
- VMs that have one to ten disks can be cloned.
- When converting and cloning or copying Snapshots of a Linux VM with multiple disks, the disks must be mounted by UUID prior to being backed up by the

Protection Group, as shown by the following example entry in a `/etc/fstab`:

```
UUID=e12e623a-c6ee-4718-9b1a-802456e72258 /userdata ext4
defaults,nofail 0 0
```

For detailed instructions, see Edit /etc/fstab to use UUID.

For AWS, be aware of the following requirements:

- In addition, the fstab entry for **CentOS 7.4**, **RHEL 7.4**, **RHEL 6.7**, **SUSE 11** and **Ubuntu 16** operating systems must specify the `nofail` option as shown in the following example:

  ```
  UUID=e12e623a-c6ee-4718-9b1a-802456e72258 /userdata ext4
  defaults,nofail 0 0
  ```

- In addition, the fstab entry for the **Ubuntu 14** operating system must specify the `nobootwait` option as shown in the following example:

  ```
  UUID=2b262696-41a6-47c9-b173-d02717ee0e10 /mnt/expvol ext4
  defaults,nobootwait 0 0
  ```

- When backing up Windows VMs with multiple disks, before a Protection Group captures the Snapshot, the Cohesity agent and VMware tools must be installed on the VM and the VM must be running. For more information, see Install and Manage the Agent on Windows Servers. In addition, port 50051 must be open in your Firewall. For more information, see Manage Firewall Ports.

  > **Note:**
  > **For Convert and Deploy**: It is mandatory to install the Cohesity agent on the VMs. Windows does not show the data disks if the Cohesity agent is not installed, irrespective of the SAN/Disk Policy.
  >
  > **For Disaster Recovery**: It is mandatory to install the Cohesity agent on multi-disk Windows VMs. Windows does not show the data disks if the Cohesity agent is not installed, irrespective of the SAN/Disk Policy. In addition, the Protection Group capturing the Snapshot must have **Cloud Migration** enabled. For detailed instructions, see Add or Edit a Protection Group for Virtual Servers.

- For a Windows VM, if you want to access the newly created VM in the Cloud service using Remote Desktop, enable the Windows Remote Desktop on the VM prior to capturing the Snapshots of a Windows VM.

2. Navigate to **Test & Dev**.
3. Click **Clone** located at the top right of the page.
4. Click **VMs**.

5. Select VMs to Clone.
6. Set Clone Options.

Select VMs to Clone

In this section you select VMs to clone.

Before you can clone Protected Objects, Snapshots must exist. To create Snapshots, create and run a Protection Group.

To select VMs to clone:

1. Search for VMs or Protection Groups that contain the Snapshots to clone. Enter characters of the VM name or Protection Group name and a list of items displays. (You can optionally specify the wildcard character * in the search.) Select an item from the list. You can also optionally narrow the search results by specifying filter criteria. For example, you can filter the search results by a specific Protection Group. Click **Change Filters**, specify Filter by criteria and click **Add**.
2. Select a Protection Group or a VM.

   After selecting a VM or protection run, only protection runs and VMs with Snapshots stored in the same Storage Domain are enabled for selection and an automatic locked filter for the Storage Domain appears. Select a Protection Group or a VM.
3. You can optionally select more protection runs or VMs and click **Add to Cart**.
4. You can also optionally edit the cart and remove selected items by clicking the **Cart Icon** ( ).
5. Click **Continue**.

Set Clone Options

In this section you select the options for the clone task.

1. In the **Task Name** field, you can optionally change the default name for the clone task.
2. Select snapshots to clone. The set of VMs that will be cloned are listed. By default, the latest snapshots of the VMs are cloned. You can optionally click Edit ( ) for each selected object and choose the exact snapshot to clone for each VM. To view a VM's consistency information, click Edit. If one type displays, this means all VMs in the snapshot are that type. If the Mixed type displays, this means the snapshot contains VMs of different types, such as crash-consistent and not powered on. You can display individual VMs to see each VM's type.

3. **Preserve Tags**: Toggle this option to preserve the tags in the cloned VMs from the source.
4. **Preserve Custom Attributes**: Toggle this option to preserve the custom attributes in the cloned VMs from the source.
5. Under **Clone Location**, in the **Source** drop-down, select a registered source to clone the VMs to. The options displayed depend on the selected source type.
   vCenter Source—Select a vCenter server to clone VMs to.
   a. In the **Resource Pool** drop-down, select a resource pool to store the cloned VMs.
   b. Optionally, in the **VM Folder** drop-down, select a VM folder in the datacenter in which to create the cloned VMs.

      > **Note:** Not applicable when cloning to a standalone ESX host.

   c. In the **View** drop-down, create a new view by entering a new name or select an existing view. Only views in the same storage domain as the selected objects to clone are listed in the drop-down. A Cohesity view provides a storage location with NFS, SMB, and S3 mount paths in a storage domain on the Cohesity cluster. You can use the NFS protocol to mount the NFS mount path onto systems. You can mount the SMB mount path onto systems as an SMB share. You can use the view to store data such as files, backup snapshots, and cloned VMs. Views can only be mounted on any machines specified in the allowlist subnets. A view can also act as a datastore during the VM cloning process and during VM recovery. You can select the SWIFT protocol and a create SWIFT-only view for OpenStack environments. You can create a view for the following three categories:File Shares Backup Target Object Services You can select the **Read/Write** protocol and, optionally, select the **Read-only** protocol. You can create a Cohesity view only by using a template. The template can be a predefined template or a custom template. For more information, see:Create Views Using a Predefined TemplateCreate Views Using a Custom TemplateIf you are using Kerberos (AD or MIT), you must create a view using the same storage domain that is mapped to AD/MIT-Kerberos + LDAP.

      > **Note:** If the VMware VM is cloned to a new View, by default, the new View is created with Restore High QoS policy. The priority of this QoS policy is the same as TestAndDev High.

   vCloud Director Source—Select a vCloud Director source to the VMs to.
   a. In the **Source** drop-down, select a resource pool in vCloud Director to store the cloned VMs.

b. In the **Organization VDC** drop-down, select an organization VDC for the cloned VMs.

c. In the **vApp** drop-down, select the vApp for the cloned VMs.

d. In the View drop-down, create a new view by entering a new name or select an existing view.

Hyper-V Source—Select a Hyper-V source to clone VMs to.

a. In the **Compute** drop-down, select a Hyper-V host to store the cloned VMs.

> **Note:** Not applicable when cloning to a standalone Hyper-V host.

b. In the **View** drop-down, create a new view by entering a new name or select an existing view. Only views in the same storage domain as the selected objects to clone are listed in the drop-down. A Cohesity view provides a storage location with NFS, SMB, and S3 mount paths in a storage domain on the Cohesity cluster. You can use the NFS protocol to mount the NFS mount path onto systems. You can mount the SMB mount path onto systems as an SMB share. You can use the view to store data such as files, backup snapshots, and cloned VMs. Views can only be mounted on any machines specified in the allowlist subnets. A view can also act as a datastore during the VM cloning process and during VM recovery. You can select the SWIFT protocol and a create SWIFT-only view for OpenStack environments. You can create a view for the following three categories:File Shares Backup Target Object Services You can select the **Read/Write** protocol and, optionally, select the **Read-only** protocol. You can create a Cohesity view only by using a template. The template can be a predefined template or a custom template. For more information, see:Create Views Using a Predefined TemplateCreate Views Using a Custom TemplateIf you are using Kerberos (AD or MIT), you must create a view using the same storage domain that is mapped to AD/MIT-Kerberos + LDAP.

Azure Subscription Source—Select a Subscription ID in Microsoft Azure to clone the VMs to.

a. **Resource Group**—Select a resource pool in Microsoft Azure to store the cloned VMs.

b. **Compute**—Select the Microsoft Azure VM Size Type such as **Standard_D1** to use when creating the cloned VMs.

c. **Availability Set**—Optionally, select the availability set to which the VM has to be cloned. For more information, see Azure Availability Sets.

d. **Storage Account**—Select the Microsoft Azure VM Size to use when creating the cloned VMs.

e. **Storage Container**—Select the Microsoft Azure storage container to store the cloned VMs.

AWS Source—Select an AWS Source to clone the VMs to.

a. In the **Region** drop-down, select an Amazon region where the new cloned VM will run, for example: `us-west-1`. For a list of supported AWS Regions, see Regions and Availability Zones.

b. In the **Instance Types** drop-down, select instance type (such as `m4.2xlarge`) of the new cloned VMs. The instance type defines the CPU, memory, storage and network capacity of the new VMs. For more information, see Amazon EC2 Instance Types.

6. Specify the networking options. The options displayed depend on the selected source type.

vCenter Source

- **Detach network**—For each cloned VM, detach the virtual network interface cards (NICs) from the VM. For each cloned VM, keep the virtual network interface cards (vNIC) disconnected from the network
- **Attach to a new network**—For each cloned VM, attach the vNIC to a new network. The new network can be a standard port group or a distributed port group.

> **Note:** The network options displayed depend on the clone location options that were selected.

vCloud Director Source

- **Detach network**—For each cloned VM, detach the virtual network interface cards (NICs) from the VM. For each cloned VM, keep the virtual network interface cards (vNIC) disconnected from the network
- **Attach to a new network**—For each cloned VM, attach the vNIC to a new network. The new network can be a standard port group or a distributed port group.

> **Note:** The network options displayed depend on the clone location options that were selected.

Auto Select: When enabled, the recovery task automatically selects the correct VLAN.

Azure Subscription Source

a. In the **Virtual Network** drop-down, select the Microsoft Azure Virtual Network for the cloned VMs.

b. In the **Subnet** drop-down, select the Microsoft Azure Virtual subnet for the cloned VMs.

AWS Source

a. In the **VPC** drop-down, select the AWS Virtual Private Cloud that will contain the cloned VMs.

b. In the **Subnets** drop-down, select the subnet for the cloned VMs.

c. In the **Network Security Group** drop-down, select the security group to apply to the instances of the new cloned VM.

d. When cloning a VMware VM that has 1 TB or greater disks, Cohesity launches a temporary EC2 instance and copies data from the Cohesity cluster to the instance. The instance can use the same VPC and subnet that's used for the clone, or you can provide a different VPC and subnet, but they must be reachable from the cluster.

e. You can optionally add **Tags** to the resources. These tags are key-value pairs that will be assigned to all the temporary and permanent resources created during Cloudspin.

7. Toggle **Rename Cloned VMs** on if you want to add Prefix and/or Suffix strings to the VM names of the new VMs created by this task. For example, you could specify Prefix `Test_` and Suffix `_QA` to the VM name `WinOS` and when the VM is cloned, the new VM that is created is called `Test_WinOS_QA`.
8. Deselect **Leave cloned VMs powered off** if you want the cloned VMs to be powered on after they are created.
9. Select **Continue clone even if errors occur when cloning VMs** if you want the clone task to continue even if errors occur when cloning the VMs.
10. **Auto Select**: When enabled, the cloning task automatically selects the correct VLAN.
11. **Interface Group**: Select a configured interface group from the Interface Group drop-down.
12. **Exclude Disk Handling**: This option is under Recovery Options, and when selected, the following two options are displayed:
    - **Create Excluded Disk as an Empty Disk**: Enable this option if you want Cohesity to create blank disks for every disk you excluded from the backup. The metadata of the excluded disks will be used to create the blank disks. These blank disks are available post-recovery and only contain the metadata of the original disk, but no data. You can configure and run databases and applications on these disks, saving you from the effort of creating new disks. This feature is especially helpful if you have many VMs with excluded disks.
    - **Create Independent Disk as an Empty Disk**: By default, independent disks are not backed up. Enable this option if you want Cohesity to create blank disks for such independent disks. These blank disks are available post-recovery and only contain the metadata of the original disk, but no data.

> **Note:** Excluded physical RDM disks cannot be created as blank disks, even when disk exclusion handling is enabled.

When cloning to a cloud service such as AWS or Azure, the cloning process detaches the network before the clone and reattaches the network after the clone completes. After the VM is running in the cloud, you may need to reapply settings to the network.

> **Tip:** The cluster provides notifications when clone and recover tasks that you initiated complete. To view them, click the notifications icon in the top right corner of the Cohesity UI. You can drill down on tasks for additional details and clear notifications as needed.

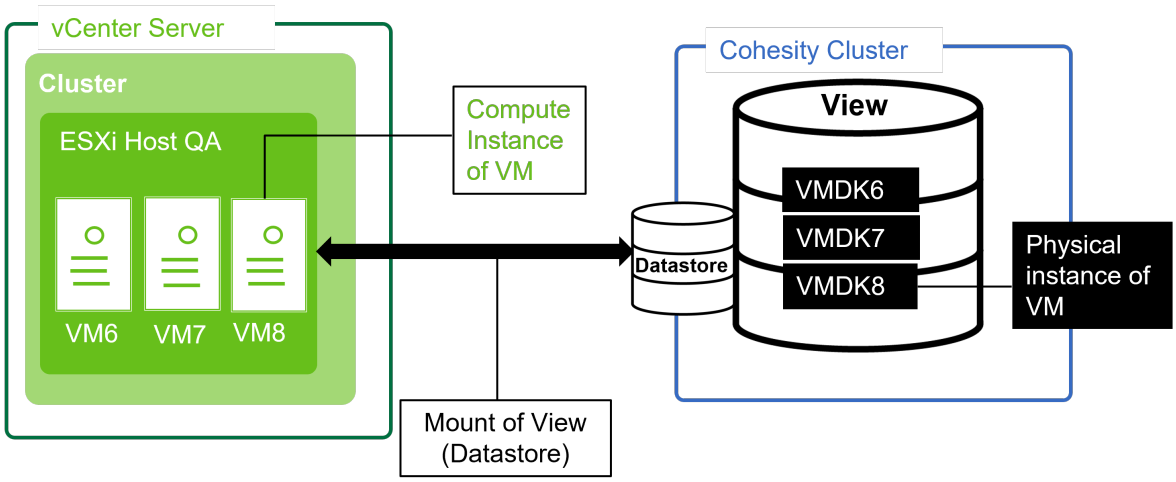
About Tearing Down Cloned VMs

Cohesity provides the ability to clone objects from snapshots created by a Protection Group. The cloned objects are copied to a new location, rehydrated and restored to a running state. For example when a VMware object is cloned in an on-premises Cohesity cluster, new VM files (such as VMDKs) are created from snapshots and stored in a view on the Cohesity cluster. This view becomes the datastore for these VM files. The Cohesity cluster creates new VMs in the selected resource pool by mounting the view containing the new VMDKs as the datastore on the ESXi hosts. During cloning, VMware is responsible to select the ESXi hosts that have access to the required Datastore based on load balancing.

Cohesity also provides the ability to tear down (delete) the set of VMs created by a clone task. The teardown procedure of a VMware VM clone is described below.

You create Clones of VMs by creating a clone task. For example, you might clone a set of development VMs for QA to use for testing as shown in the following figure.

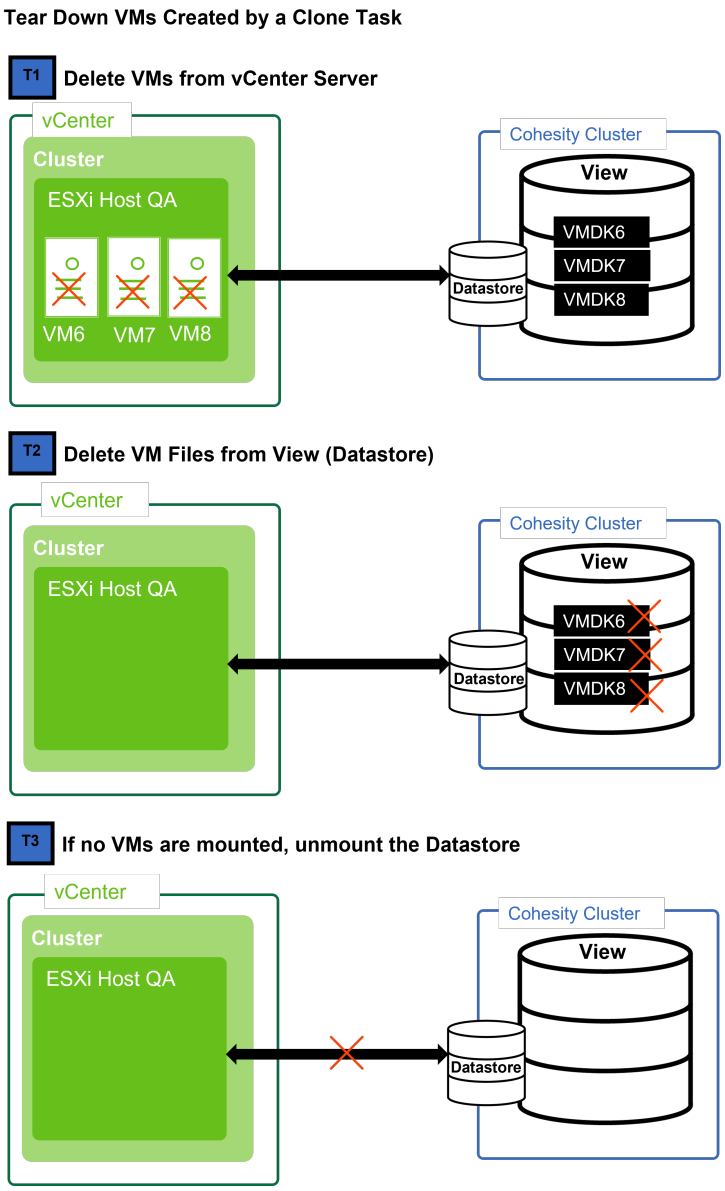
VMs Created by a Clone Task



After the testing is completed, you may want to tear down the cloned VMs created by the clone task. You can initiate a clone teardown as described in Tear Down Clones.
The actions that occur during a teardown are described in the following procedure:

1. The Cohesity cluster deletes the compute instances of the cloned VMs in the ESXi host.
2. The VM files (such as VMDK and VMX) are deleted on the view acting as a datastore.
3. If no VMs are using the view (datastore), the view is umounted from all ESXi hosts.

The steps in the preceding procedure are represented in the following figure with blue numbered squares: T1 .



If a cloned VM has been altered after being created by a clone task, the VM may not be automatically cleaned up during a clone teardown. For more information, see VM Not Deleted if Cloned VM is Altered.

Tear Down Clones

Cohesity provides the ability to clone objects from snapshots created by a Protection Group. The cloned objects are copied to a new location, rehydrated and restored to a running state. For example when a VMware object is cloned in an on-premises Cohesity cluster, new VM files (such as VMDKs) are created from snapshots and stored in a view on the Cohesity cluster. This view becomes the datastore for these VM files. The Cohesity cluster creates new VMs in the selected resource pool by mounting the view containing the new VMDKs as the datastore on the ESXi hosts. During cloning, VMware is responsible to select the ESXi hosts that have access to the required Datastore based on load balancing.

Cohesity also provides the ability to tear down (delete) the set of VMs created by a clone task. To learn more, see About Tearing Down Cloned VMs.

> **Note:** The teardown of an MS SQL clone database removes it from the SQL server; the user does not have to do this beforehand. However, in the rare instance you created other additional databases with files on the mounted drive that the cloned database is on, those additional databases should be deleted first through the SQL Server Management Studio.

Tear Down a Clone

1. Navigate to **Test & Dev**.
2. Click a Task Name link in the table.
3. Click **Tear Down Clone** located at the top right of the page.

The clone teardown process of a VMware VM clone completes the following steps:

1. The Cohesity cluster deletes the compute instances of the cloned VMs in the ESXi host.
2. The VM files (such as VMDK and VMX) are deleted on the view acting as a datastore.
3. If no VMs are using the view (datastore), the view is umounted from all ESXi hosts.

After the teardown, the clone task remains visible in the Cohesity UI. If a clone teardown fails and does not delete all the VMs or VM files, you can restart the clone teardown by repeating the procedure above. For example, if the ESXi host that contains the cloned VMs is not available on the network when the clone teardown first runs, you can run the clone teardown again when the ESXi host becomes available and the VMs will be deleted.

The Test & Dev workflow for VMware VMs provides two options when objects are cloned:

1. Use an existing view
2. Create a new view

If an existing view is used, it may contain other data. If a new view is created, it may be used for other purposes, or for future Test & Dev clones. So in either case, the views are not deleted on clone teardown. Further, it does not hinder any other process or action. The user can still clean up the view manually.

VM Not Deleted if Cloned VM is Altered

If a cloned VMware VM has been altered after being created by a clone task, the VM may not be automatically cleaned up during a clone teardown. These special cases are described below:

1. The VM is using files found in an additional external datastore besides the original datastore (view) that is storing the cloned VM. Here are some examples:

- A directory has been NFS mounted onto the VM and the VM is using files in that directory.
- The original VM files were moved to an additional external datastore using Storage vMotion.

2. The VM was converted to a VMware template.
3. The Fault Tolerant (FT) setting was enabled for the VM.

To delete the altered VMs, you can either manually delete the VMs or revert the changes made to the VMs and run the clone teardown again.

Clone Databases

This chapter includes the following topics:

Clone Microsoft SQL Server Databases

Cohesity now provides the ability to clone an MS SQL database to a Standalone SQL Server, FCI, and AG. A major advantage is that the cloned MS SQL database files reside on the Storage Domain and require no additional storage from the MS SQL host. Multiple clones from a single source of MS SQL Database backup require little or no additional storage space in the Cohesity cluster.

> **Note:** Cloning an MS SQL database is supported with Volume-based and file-based backup methods.

Clone an MS SQL Database

1. Navigate to **Test & Dev** > **Clone** > **Databases**.
2. Search and select the MS SQL database. You can optionally perform a search by specifying the wildcard character *. You can also optionally narrow the search results by specifying filter criteria.
3. Provide the following information listed in the table, and then click **Clone**.

Options	Description
Task Name	(*Optional*) Change the default name for the Clone task.
Objects Being Cloned	By default, the database you selected for cloning is displayed. You can click the change icon to select a different database.

Options	Description
Clone Point	By default, the latest snapshot is cloned. Optionally click the Change icon to select a different snapshot to clone. The selected Restore Point is listed
SQL Host	Select the host to which you want to clone the database. By default, you can select only the physical servers as the host. If you want to select MS SQL FCI as the SQL host, Contact Cohesity Support. Cloning the MS SQL database to an MS SQL FCI is supported only if the following criteria are met: • Microsoft SQL Server version must be 2012 and above, supported on SMB file server. • The MS SQL database to be cloned is backed up with a file-based protection group.
SQL Instance	Select the instance for the cloned database.
Rename Database?	Enable this option if you want to rename the cloned database created by this task.
Cohesity Network interface	Select one of the following options: • **Auto Select**: By default, the **Auto Select** option is enabled and the clone task automatically selects the correct VLAN. • **Interface Group**: select a configured interface group from the **Interface Group** drop-down.

Cancel a Database Clone

You can cancel a running clone task for an individual database. Canceling the task may leave the database in an unusable state. You can delete the database manually and then start another clone task as needed.

1. Navigate to **Test & Dev**.
2. Click a Task Name link in the table to display the details page.
3. Click the **Cancel** button. (The Cancel button is available only if the task is running.)
4. Respond to the confirmation prompt.

Tear Down a Database Clone

To delete an MS SQL database clone from the Cohesity Storage Domain, perform the following steps:

1. Navigate to **Test & Dev**.
2. Click the cloned task or hover your mouse over the actions menu located next to the cloned task you want to delete.
3. Click **Tear Down Clone** > **Yes, Tear Down**.

The MS SQL database clone will be deleted from the Cohesity cluster Storage Domain.

> **Note:** The teardown of an MS SQL clone database removes it from the SQL server; the user does not have to do this beforehand. However, in the rare instance you created other additional databases with files on the mounted drive that the cloned database is on, those additional databases should be deleted first through the SQL Server Management Studio.

Clone Oracle Database

Cohesity provides the ability to clone Oracle databases (Standalone, RAC, Multi-container Database (CDB), and VCS). The Oracle database is cloned at Cohesity Storage Domains and requires no additional storage from the Oracle Host. Multiple clones from a single source of Oracle Database backup may require little to no additional storage space

in the Cohesity cluster.

Supported Oracle Release for TDM Cloning

Cohesity supports TDM cloning in the following Oracle releases:

Oracle Release	Clone Support for Oracle Database
11gR2	Supported
12cR1	Supported
12cR2	Supported
18c	Supported
19c	Supported

Prerequisites

- Install the latest Cohesity Agent on the system running the Oracle Database.
- Capture Snapshots of the Oracle database to be cloned. To create Snapshots, see create and run a Protection Group.

Clone an Oracle Database

1. Navigate to **Test & Dev** > **Clone** > **Databases**.
2. Search and select the Oracle database. (You can optionally specify the wildcard character *in the search.) You can also optionally narrow the search results by specifying filter criteria.
3. Provide the following information listed in the table, and then click **Clone**.

CLI Option	Description
Task Name	(Optional) Change the default name for the Clone task.
Objects Being Cloned	The Oracle database is being cloned. You can click the change icon to select a different database.
Clone Point	The latest clone point. You click the change icon and select a different clone point. Select the Snapshot to clone. By default, the latest Snapshot is cloned and the selected Restore Point is listed. You can optionally click **Edit** and choose the previous Snapshot to clone.
Oracle Host	The host to which you clone the database.
Oracle Home	The home directory for the cloned database.
Base Directory	The base directory for the cloned database.
Database Name	The name for the cloned database. The maximum number of characters for the database name is eight. The database name should be unique for the given Oracle Host.

CLI Option	Description

Pfile Parameters	The Pfile parameters option allows you to see the target database parameters before the clone job is initiated. The Pfile inherits some source database parameters to the target database and allows you to edit the target database parameters based on your requirement by specifying the additional parameters as a `key=value` pair.
	
	The Pfile lists the following parameters:
	
	• **Default Parameters**: Default parameters of the target database and you can edit the default
	• **Inherited Parameters**: Parameters from the source database and you can edit the inherited parameters, if required.
	• **Restricted Parameters**: You cannot edit the restricted parameters in the Pfile. The following are the restricted parameters:
	  • INSTANCE_NAME
	  • DB_NAME
	  • DB_UNIQUE_NAME
	  • DB_BLOCK_SIZE
	  • MAX_STRING_SIZE
	  • COMPATIBLE
	
	If you edit the following values in the Clone Oracle GUI, You must click the Reset button on the top-right corner to reset the Pfile and get the updated parameter values in the Pfile box.
	  • Oracle Home
	  • Oracle Base
	  • Database Name
	
	Target database will be created with the specified parameters in the Pfile. For example, if `SGA_TARGET` is specified as a part of the pfile parameters, the clone operation will use the value specified in the pfile during the cloning of the source database.

SGA (System Global Area)	The SGA is an area of memory (RAM) allocated to an Oracle Instance when it starts up. Ideally, SGA's value varies from 1024M to 102400M.

CLI Option	Description
Shell Environment	User can configure their shell environment that executes the Cohesity clone workflow using this setting. An example would be, define your TNS_ADMIN shell variable here to point to a different sqlnet.ora file to be used for your clone target database. For TDE support, the wallet location for your clone target database may depend on a shell variable. Use this to specify your wallet location for cloning a backup taken from a TDE database. For more information, see Clone Oracle TDE Database.
NFS Protocol	Select the NFS protocol version for the clone job. Options include NFSv3 and NFSv4.1. **Note:** NFS protocol is not supported for Windows and AIX databases.
Change DBID	If this option is disabled, the cloned database UUID will be the same as the source database and it will not be displayed on the Source page. Later, If the cloned databases are required to be discovered by Cohesity, then follow the steps below: 1. Start the database in MOUNT mode. 2. Run the following query to get the DBID: “select DBID from GV$database”. 3. Change the database DBID using the NID command. 4. Run the following query “select DBID from GV$database” and confirm that the DBID is different from the one we obtained in step 2. 5. Once confirmed, start the database in OPEN mode. 6. Add the database entry in the oratab file. 7. Do a source refresh. 8. The database should be listed there now. If none of the other databases on the Oracle host have DBID the same as that of the cloned database then, skip steps 1 to 5.

You will be redirected to the status details page. Once the clone task that you initiated completes, the status will be displayed as “Success”.

You can cancel a clone task for an individual database. Canceling the clone task leaves the database in an unusable state. You can delete this database manually at the Oracle host and then restart the clone task as needed.

Cancel an Oracle Database Clone Task

You can cancel a clone task for an individual database. Canceling the clone task leaves the database in an unusable state. You can delete this database manually at the Oracle host and

then restart the clone task as needed.

1. Navigate to **Test & Dev**.
2. Click a Task Name link in the table to display the details page.
3. Click the **Cancel** button. (The Cancel button is available only if the task is running.)
4. Respond to the confirmation prompt.

Test & Dev Using CloudSpin

You can use Cohesity's CloudSpin for Test & Dev. For more information, see Clone VMs to AWS Cloud Using CloudSpin.

Clone vCloud Director (vCD) VMs

Cloning vCloud Director (vCD) VMs using Cohesity involves integrating Cohesity's data protection platform with your vCD environment. Cohesity allows users to clone vCD VMs and vApps from backups for Test & Dev use cases.

Considerations

- Clone vCD VMs should only use the "Detach network" option for all users, tenants, and administrators.

  > **Note:** Administrators can use attach options until they select a network that is part of the vApp being cloned.

- Cloning templates as templates is not supported for all tenants and administrators.
- The option "Detach Network" will prevent the original VM NIC cards from being reattached after cloning.
- If you cannot attach NICs/Org vDC networks during the cloning workflow, please contact Cohesity support for assistance.
- While cloning VMs to the target, the original IP address and IP mode are not recovered to the NIC cards. By default, the IP mode is set to "none" and the IP address remains empty. Contact Cohesity support to recover the original IP addresses for the clone operation.

Chapter 30: Monitoring

This chapter includes the following topics:

- Performance 4222
- Monitor Performance of Workloads 4225
- Configure and Test SNMP 4232
- Storage Statistics 4238
- Health Dashboard 4250
- Reports 4442
- Audit Logs 4490
- Advanced Diagnostics 4514

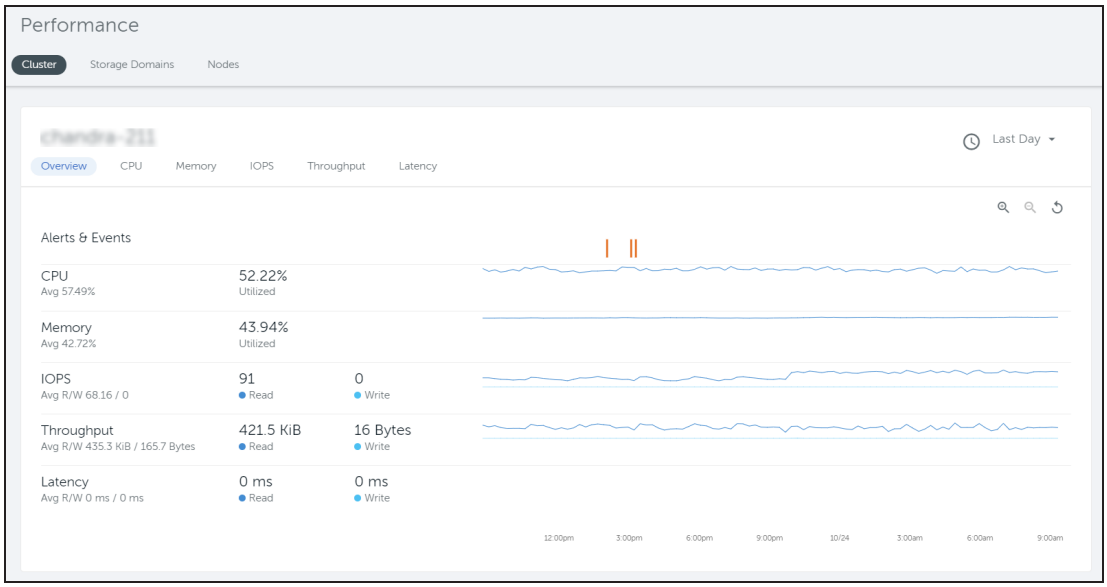
Performance

The performance statistics page helps you to view the performance of the Cohesity cluster, Storage Domains, and Nodes with respect to the attributes such as CPU, memory, IOPS, throughput, and latency. By default, the page provides performance statistics for the entire cluster.

You can view performance statistics by selecting **System** > **Performance**.

Cluster Performance Statistics

To view Cluster performance statistics, select **Cluster** from the top navigation pane of the performance page.



The **overview** tab of the Cluster performance screen shows the performance graph of the following attributes:

- CPU—The total CPU utilization of the Cluster.
- Memory— The total memory utilization of the Cluster.
- IOPS—The read and write I/O operations of the Cluster.
- Throughput—The throughput of the Cluster.
- Latency—The average response time for read and write operations for Views configured with **TestAndDev High** QoS policy.

Following are the characteristics of the performance statistics screen of a cluster:

- You can customize the time frame of each statistic by selecting **Last Day**, **Last Week**, or **Last Month**.
- You can click each attribute to view the activities or jobs that are running in the cluster during the specified time frame. For example, you can click the **CPU** tab to view the jobs that are running on the cluster during the specified time frame.
- You can zoom in on part of the graph by dragging the mouse across a section of the graph or by clicking the **Zoom** icon.
- From each attribute performance page, you can use the **Adapters** and **Tasks** drop-down lists or use the search option and filter the jobs or activities that are displayed.

Storage Domain Performance Statistics

To view performance statistics at the Storage Domain level, select **Storage Domain** from the top navigation pane of the performance page.

By default, the performance statistics of the default Storage Domain are displayed. You can select a Storage Domain from the drop-down menu to view the performance statistics of the selected Storage Domain.

The **overview** tab of the Storage Domain performance screen shows the performance graph of the following attributes:

- IOPS—The IO read and write operations of the selected Storage Domain.
- Throughput—The throughput of the selected Storage Domain.
- Latency—The average response time for read and write operations for Views configured with **TestAndDev High** QoS policy.

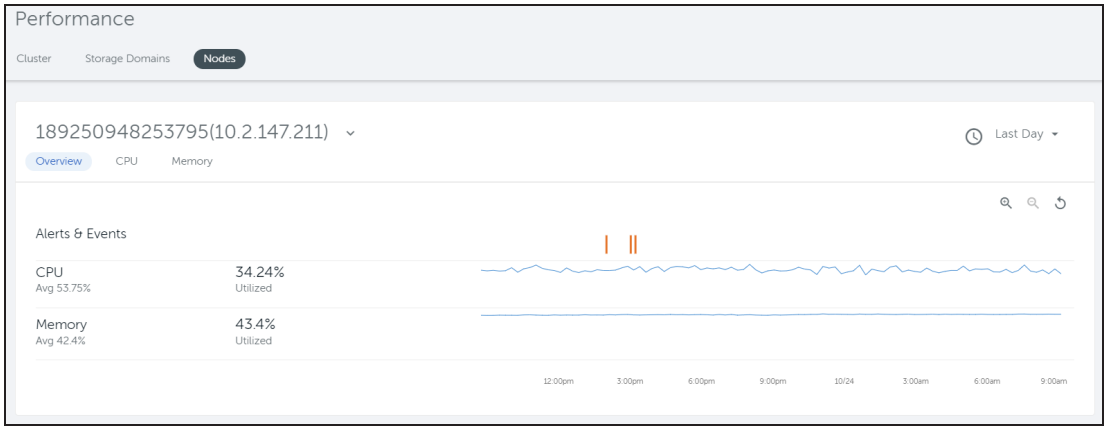
Following are characteristics of the performance statistics screen of a Storage Domain :

- You can customize the time frame of each statistic by selecting **Last Day**, **Last Week**, or **Last Month**.

- You can click each attribute to view the activities or jobs that are running in the cluster for that storage domain during the specified time frame. For example, you can click the **IOPS** tab to view the jobs that are running on the cluster during the specified time frame.
- You can zoom in on part of the graph by dragging the mouse across a section of the graph or by clicking the **Zoom** icon.
- From each attribute performance page, you can use the **Adapters** and **Tasks** drop-down lists or use the search option and filter the jobs or activities that are displayed.

Nodes performance Statistics

To view performance statistics per node, select **Nodes** from the top navigation pane of the performance page.



You can select a node from the drop-down menu to view the performance statistics of the selected node.

The overview tab of the Nodes performance screen shows the performance graph of the following attributes:

- CPU—The performance graph of the total CPU utilization of the services that are running on the selected Node.
- Memory—The performance graph of the total memory utilization of the services that are running on the selected Node.

Following are the characteristics of the performance statistics screen of a Node:

- You can customize the time frame of each statistic by selecting **Last Day**, **Last Week**, or **Last Month**.
- You can click each attribute to view the performance graph of the following Cohesity services that are running on the cluster during the specified time frame.
    - Background System Activity—Collects garbage and fixes replication and deduplication.

- File System—Stores and retrieves data.
- Data Protection—Backs up data.
- Metadata—Stores and maintain metadata.
- Indexing—Indexes the backed-up data.

For example, you can click the **CPU** tab to view the performance graph of the services that are running on the node during the specified time frame. The tab displays the percentage of the total CPU utilized by all the services and the percentage of the CPU utilized by each service.

- You can zoom in on part of the graph by dragging the mouse across a section of the graph or by clicking the Zoom icon.

Monitor Performance of Workloads

Cohesity now provides component-level logical statistics and granular-level statistics that enable you to inspect resource usage and workload distribution across the I/O Operations service. Statistics available on the **System > Performance > Workloads** tab help you:

- Check the overall performance of the Cohesity cluster
- Inspect the resource usage across various components
- Detect whether the cluster is overloaded
- Debug workload-level performance issues
- Debug replication performance issues
- Debug intermittent performance issues

Historical data is available for up to 30 days. This enables you to go back in time and debug issues. For example, if the SmartFiles workload was experiencing high latency at a certain time, you can go back to that particular point in time and view the granular statistics to identify the root cause. You can select one of the following time ranges:

- Past hour
- Past 12 hours
- Past 24 hours
- Past 7 days
- Past 30 days

Add Data to the Charts

You can add or update the data displayed on the charts.

To add or update data displayed on the charts:

1. Navigate to **System > Performance** and click the **Workloads** tab.
2. Select a performance metric:
   - Throughput
   - IOPS
   - Latency
3. Click **Add Data**.
4. Add or update data.

   > **Important:** Depending on the chart, data can be one of the following—workloads, adapters, protection groups, or sources and you can add only up to five workloads, adapters, protection groups, or sources.

5. Click **Apply**.

   The following image illustrates how you can add or update workloads. If five workloads are already added, clear the check box corresponding to the workload that you want to remove and select a new workload:

View Tooltips

You can view tooltips by hovering your mouse over the chart. Hover over a specific date and time to view tooltip data that is automatically generated based on the underlying read and write data. For example, the following image illustrates the tooltip data for the selected workloads on December 6, 2022 at 3:27 PM:

Zoom In and Zoom Out of Charts

You can zoom in on the charts to increase the visible time range. To zoom in, click and drag the mouse pointer over the chart. To zoom out, click **Reset zoom**.

The following image illustrates how you can zoom in and zoom out of the charts:

Components and Supported Filtering Options

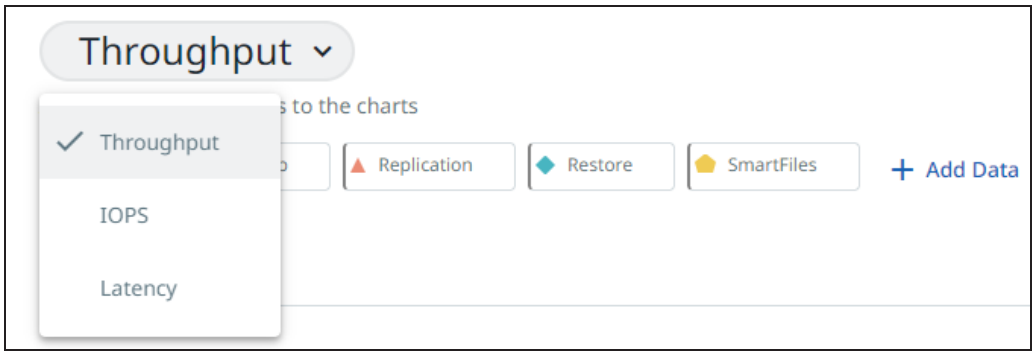
The following table lists the components and the available filtering options for each component. You can select a filter to drill down and view granular details. As an example, for the **Replication** component, you can filter based on adapters or protection groups and get granular-level statistics.

Component	Filtering Options (Granular-level statistics)
Replication	• Adapters • Protection Groups
Indexing	• Adapters • Protection Groups
Apps	Not applicable
SmartFiles	• Protocol
Archive	• Adapters • Protection Groups
Background	Not applicable
Backup	• Adapters • Protection Groups • Sources
Restore	• Adapters • Recoveries
Other	Not applicable

Monitor Throughput of Workloads

To monitor the throughput of the workloads:

1. Navigate to **System > Performance** and click the **Workloads** tab.
2. Select **Throughput** from the drop-down menu:



3. Select the workloads.

   The read and write throughput of the workloads are displayed. The following image illustrates the throughput of the selected workloads for the past 7 days:

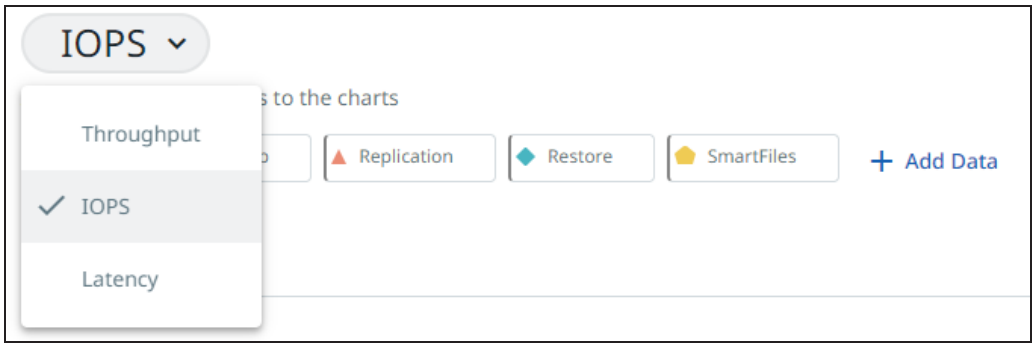
4. After the charts load, you can click on a workload to drill down further. For example, click **Backup** to view the backup details:

5. You can further slice and dice the metrics based on additional filters. For more information about the available filters, see Components and Supported Filtering Options.

Monitor IOPS of Workloads

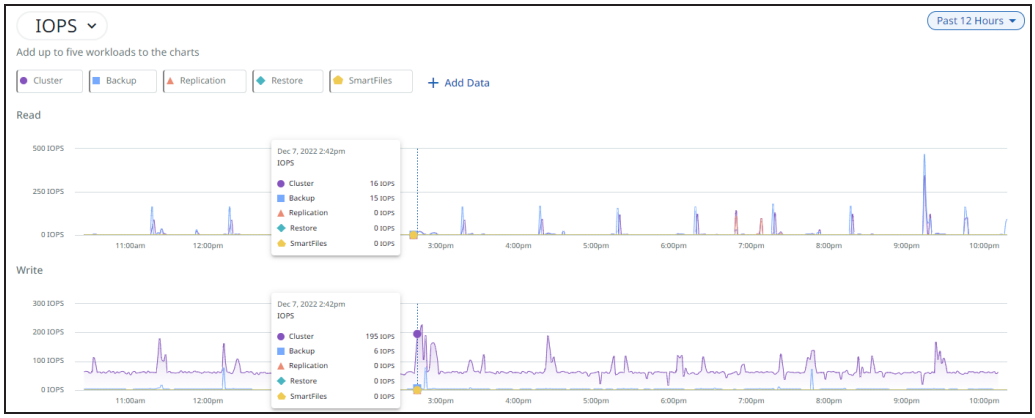
To monitor the IOPS of the workloads:

1. Navigate to **System > Performance** and click the **Workloads** tab.
2. Select **IOPS** from the drop-down menu:



3. Select the workloads.

   The read and write IOPS of the workloads are displayed. The following image illustrates the IOPS of the selected workloads for the past 12 hours:



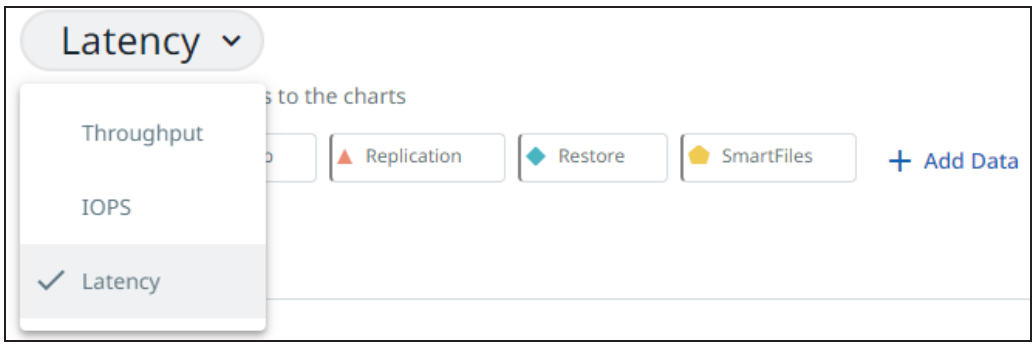
4. After the charts load, you can click on a workload to drill down further. For example, click **Backup** to view the backup details:

5. You can further slice and dice the metrics based on additional filters. For more information about the available filters, see Components and Supported Filtering Options.

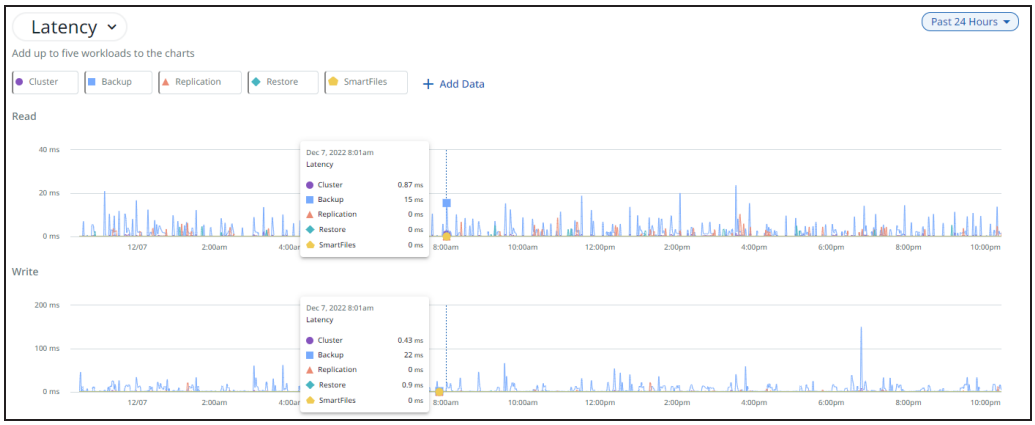
Monitor Latency of Workloads

To monitor the latency of the workloads:

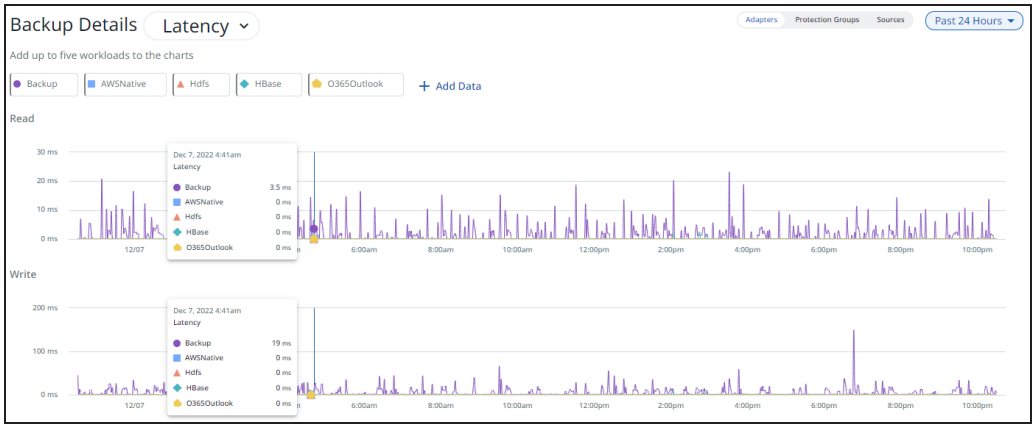
1. Navigate to **System > Performance** and click the **Workloads** tab.
2. Select **Latency** from the drop-down menu:



3. Select the workloads.
4. The read and write latency of the workloads are displayed. The following image illustrates the latency of the selected workloads for the past 24 hours:



5. After the charts load, you can click on a workload to drill down further. For example, click **Backup** to view the backup details:



6. You can further slice and dice the metrics based on additional filters. For more information about the available filters, see Components and Supported Filtering Options.

Configure and Test SNMP

You can enable Simple Network Management Protocol (SNMP) on the Cohesity cluster to further integrate Cohesity into your data center and enterprise management solutions. Whenever events occur on the Cohesity cluster, SNMP notifications are sent to your network management system.

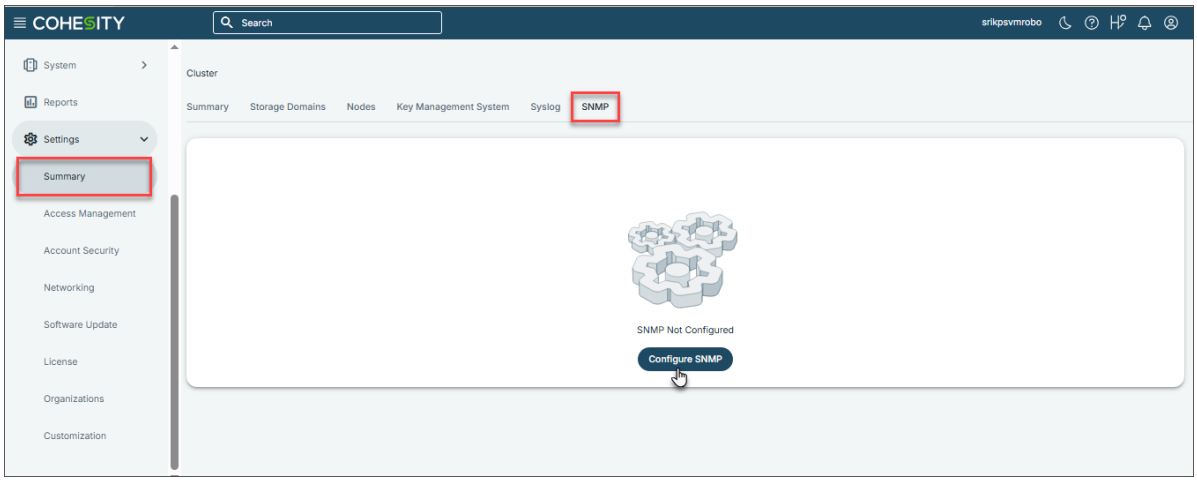
Prerequisites and Considerations

- Cohesity supports SNMP versions 2 and 3.
- The Cohesity cluster supports SNMP polling and notifications.
- Ports 161 (UDP, incoming) and 162 (UDP, outgoing) must be open.

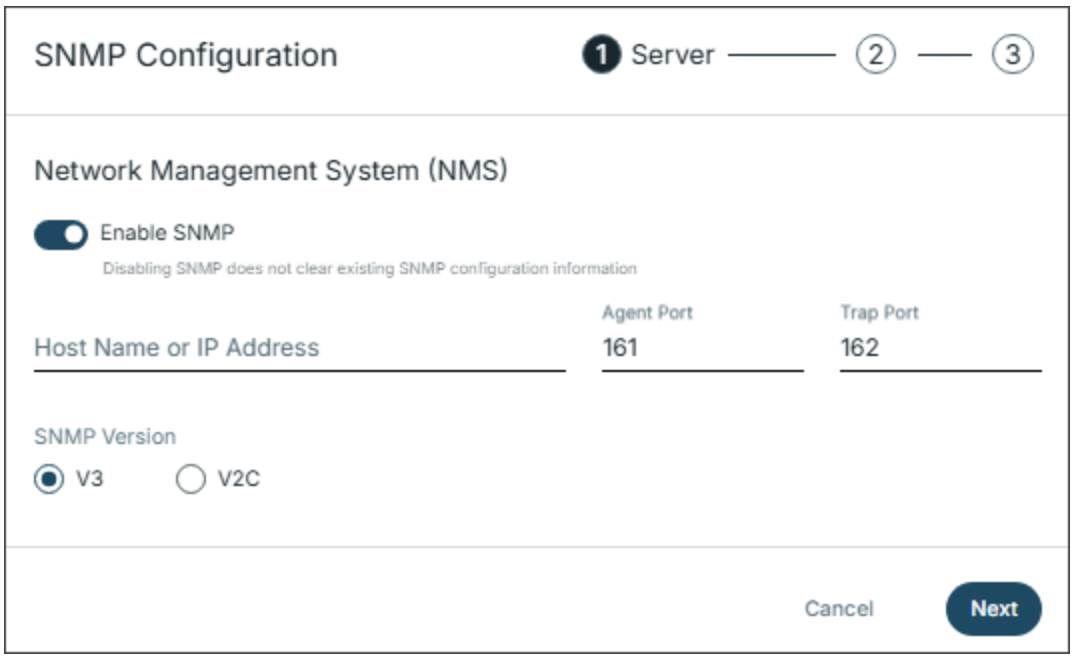
- The SNMP network management system must be accessible from the Cohesity cluster.
- Disabling SNMP stops the notification broadcasts but does not clear the existing SNMP configuration information.
- For a list of SNMP Object Identifiers (OIDs), see Alerts Reference.

Configure SNMP

1. In the Cohesity Dashboard, select **Settings** > **Summary** and click **SNMP** > **Configure SNMP**.



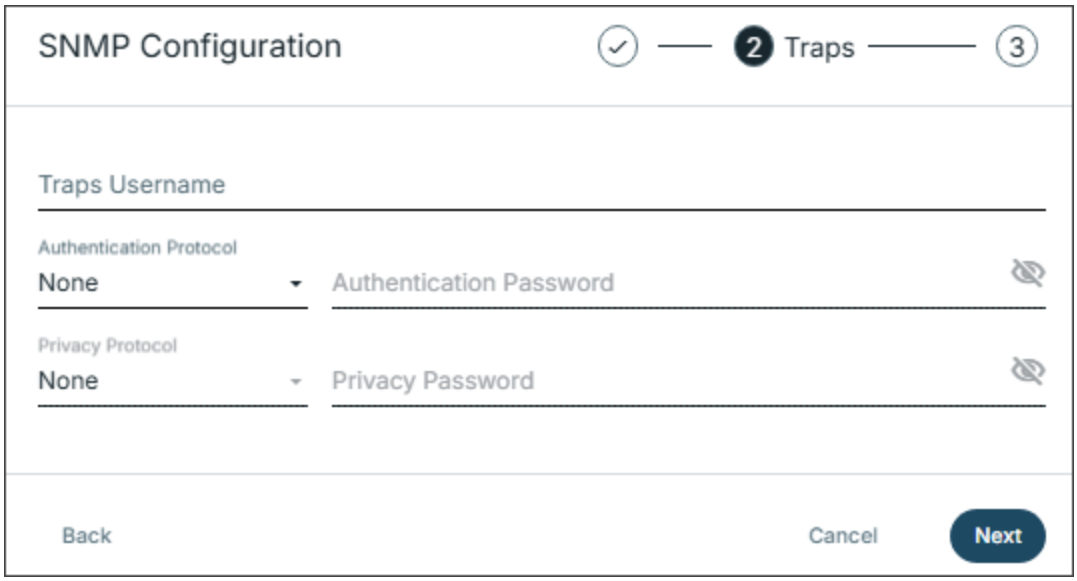
The **SNMP Configuration** dialog appears.



2. Provide the necessary information in the following fields and click **Next**.

Field	Description
Enable SNMP	Use the toggle to enable or disable SNMP. It is enabled by default.
Host Name or IP Address	Enter the IP address or host name of the SNMP trap destination to which you want to send SNMP notifications.
Agent Port	This is the port the SNMP agent listens on. The default is 161.
Trap Port	This is the SNMP trap destination port. The default is 162.
SNMP Version	• V3 - More secure (supports encryption and authentication) • V2C - Basic security with community strings.

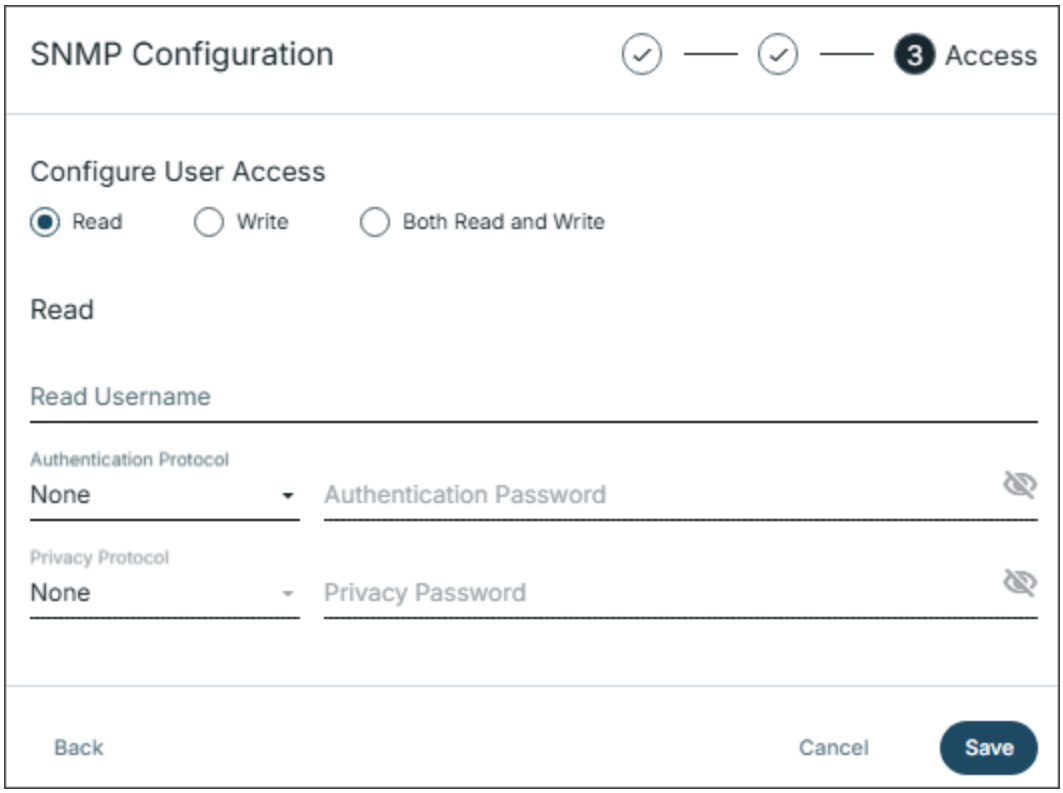
3. If you select V3, provide the necessary information in the following fields and click **Next**:



Field	Description
Traps Username	The default SNMP V3 username for the Cohesity cluster is **cohesityV3Trap**. You can change this string.

Field	Description
Authentication Protocol	• **None** - No security • **MD5** - Uses HMAC-MD5-96 for authentication • **SHA** - Uses HMAC-SHA-96 for authentication
Authentication Password	Required only if MD5 or SHA is selected.
Privacy Protocol	• **None** - No encryption • **DES** - DES-CBC encryption • **AES** - AES-128 (CFB mode) encryption
Privacy Password	Required only if DES or AES is selected.

The **Configure User Access** dialog appears.

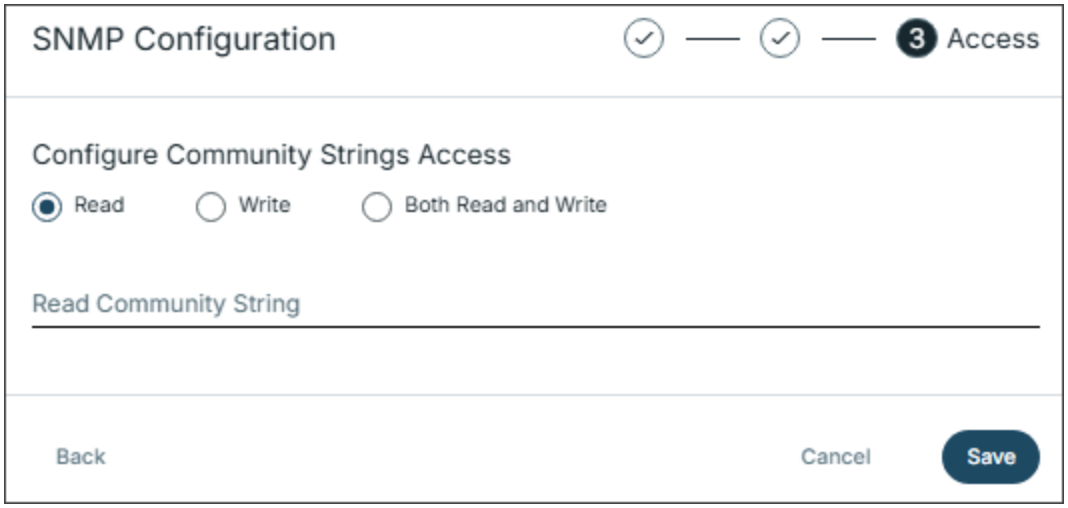


Field	Description
Configure User Access	• **Read** • **Write** • **Both Read and Write**
Read Username	The default read username is **cohesityV3Public**.
Write Username	The default write username is **cohesityV3Private**.
Authentication Protocol	• **None** - No security • **MD5** - Uses HMAC-MD5-96 for authentication • **SHA** - Uses HMAC-SHA-96 for authentication
Authentication Password	Required only if MD5 or SHA is selected.
Privacy Protocol	• **None** - No encryption • **DES** - DES-CBC encryption • **AES** - AES-128 (CFB mode) encryption
Privacy Password	Required only if DES or AES is selected.

4. If you select V2C, provide the necessary information in the following field and click **Next**:

   - **Traps Community String**: The default traps community string for the Cohesity cluster is **cohesityV2Trap**. You can change this string.

The **Configure Community String Access** dialog appears.



Field	Description
Configure Community Strings Access	• **Read** • **Write** • **Both Read and Write**
Read Community String	The default read community string is **cohesityV2Public**.
Write Community String	The default write community string is **cohesityV2Private**.

5. Click **Save** to save the SNMP configuration.

The page shows the updated SNMP configuration.

To edit the SNMP configuration, go to the SNMP Configuration page, click **Edit Configuration**, and update the necessary fields.

Verify SNMP Transmission to Network Management Systems

1. Locate the Network Management System hostname or IP address by accessing the Cohesity Dashboard and selecting **Settings > SNMP**.
2. Run the following command to find the alerts master node:

```
iris_cli cluster ls-masters
```

3. Run the following `tcpdump` command from alerts master node:

```
sudo tcpdump -ni any port 161 or 162 -vv
```

> **Note:** Port 161 is used for SNMP packets and port 162 is used for SNMP traps.

4. Use the following object ID to generate a non-impacting event:

   LogsDiskSpaceLow 1.3.6.1.4.1.47421.0.6

   This event is triggered when the logs partition reaches over 95% full. Use the following steps to determine available space in the logs partition.

```
df -h /home/cohesity/logs
logs=/home/cohesity/logs ; df -h $logs ; fallocate -l 38g $logs/foo
df -h $logs ; sleep 300 ; rm $logs/foo ; df -h $logs
```

5. Observe the SNMP trap confirmation displayed on the wire with `tcpdump` running on alerts' master node.

```
16:06:30.212028 IP (tos 0x0, ttl 64, id 41099, offset 0, flags [DF],
proto UDP (17), length 210) <source_host_hostname> > <NMS_server_host_
hostname>.snmptrap: { SNMPv2c C=YLX0 { V2Trap(167) R=1766176774
system.sysUpTime.0=198748646 S:1.1.4.1.0=E:47421.0.6
E:47421.1.6="<source_host_hostname> : INFO | CE00401007 -
LogsDiskSpaceLow | Logs partition disk space is low" } } E.....@.@...
..* ....r......0.......YLX0.....iE........0..0...+.......C.....0..
+.......... +......=..0j. +......=...\<source_host_hostname> : INFO |
CE00401007 - LogsDiskSpaceLow | Logs partition disk space is low 6.
ctrl-c out tcpdump
```

> **Note:** The example contents of tcpdump given above are not encrypted. The actual contents may be encrypted based on the SNMP configuration.

Test SNMP Reporting for Cohesity Alerts

Run the following command to test SNMP reporting:

```
iris_cli snmp send-test-trap
```

Storage Statistics

You can view storage statistics by selecting **System > Storage**.

Cluster Level Data Statistics

In the **Cluster** tab:

- You can view the storage statistics for the entire cluster. The details are provided under two panes, namely **Consumption** and **Trend**. Click ⛶ on each pane for a more detailed view.
- You can customize the timeframe by selecting **Last Day**, **Last Week** or **Last Month** in the **Trend** pane.
- You can also customize the data presented in the chart. To remove or add chart data, click ⛶ in the **Trend** pane and toggle any combination of the following fields: **Storage Saved** or **Resiliency Impact**. The selected data type is added to or removed from the chart.

This page reports on the following Cohesity cluster data statistics:

Metrics	Description
Logical Data	**Data Protection**: The combined total of data in the objects that are protected by Cohesity. These metrics are different depending on workload type. • **VMs**: The data size reported by VMware is the provisioned amount, not the actual data residing in the VM. For examples, if a VM is provisioned for 1TB but contains only 100GB of data, VMware reports it as 1TB. • **All Other Workloads**: The data size reported is the actual front end data residing on the server. If a server with 1TB capacity contains 100GB of data, the server reports 100GB. **Note:** • These metrics do not include unprotected objects. • Currently, the logical data value shown on the UI is a sum of the logical data values captured across all the protection runs. For instance, if the source has 100GB of logical data, and assuming it remains at 100GB for the first 10 protection runs, Cohesity would report, after 10 runs, the Logical Data to be 1000GB (1TB). **SmartFiles**: Size of total unique logical data of active filesystem as residing on Cohesity. This does not count the space consumed by the Data Protection runs (i.e. snapshots) that may be protecting the active filesystem.
Data Read	Data Read is the size of the set of protected objects as read by Cohesity for a single backup run. This number is a per protection run statistic and is not additive across backup runs.

Metrics	Description
Data In	Total unique logical data residing on the Cohesity cluster. For Data Protection, this is the sum of your first full backup and subsequent change data captured by Cohesity. For SmartFiles, some customers, such as SPs and enterprise customers with multiple tenants, may want to use this as the Logical Data so that snapshot capacity is included in the chargeback.
Data Written	Data written on the Cohesity cluster after the unique logical data has been reduced by data deduplication and data compression. For SmartFiles, this metric value carries the name of Physical Data. > **Note:** This number reflects unique data written, before resiliency operations.
Resiliency Impact	The space required to honor resiliency settings (Erasure Coding / Replication Factor) in addition to the data written. For example, if the Data Written is 100GB and resiliency setting is RF3, the **Resiliency Impact** is 200GB. That is, to honor the resiliency setting, you will need an additional 200GB on top of the 100GB for the **Data Written**.
Storage Consumed	The total size of data stored on the Cohesity file system after all operations on the data (data deduplication, data compression, and data resiliency) have been accounted for. This data can be stored either all locally or as a combination of local storage and in the Cloud Tier (if Cloud Tier is enabled). For example, if the **Data Written** is 100GB and resiliency is set to RF3, leading to the need for an additional 200GB of space, the resulting **Storage Consumed** is 300GB. If the **Data Written** is 100GB and resiliency is set to EC4:2, leading to the need for an additional 50GB (as for every 4 data fragments, 2 parity fragments are added), the resulting **Storage Consumed** is 150GB. > **Note:** If you have enabled Cloud Tiering, then **Storage Consumed** is the sum of space consumed on local storage and space consumed on the cloud tier. In such cases, the sum of **Storage Consumed** value and **Capacity Available** value for the cluster can exceed the cluster capacity.

Metrics	Description
Storage Reduction	The ratio of **Logical Data** to **Storage Consumed**. For Data Protection, this reflects all operations performed by Cohesity on source data, which include snapshotting, change tracking and ingest, data deduplication, data compression, and data resiliency. For SmartFiles, this reflects all operations performed on the Cohesity hosted active filesystem, which include logical data writes, change tracking, data deduplication, data compression, and data resiliency.
Storage Consumed Local and Cloud	If you have enabled Cloud Tiering, then this metric is the sum of space consumed on local storage and space consumed on the cloud tier.
Storage Saved	The space owing to data deduplication and data compression. For example, if **Data In** is 100GB, deduplication ratio is 4x, compression is 2x, then **Data Written** is 12.5GB. Therefore, the **Storage Saved** is 100GB - 12.5GB = 87.5GB.
Total Capacity	The total physical capacity of all storage devices after subtracting the space reserved for Cohesity software operations.
Available	The amount of space still available on the Cohesity cluster, calculated by subtracting the **Storage Consumed** (Locally and not on Cloud Tier) from the **Total Capacity**.

Storage Domain Level Data Statistics

In the **Storage Domains** tab:

- You can view the storage statistics of the storage domains. To view the storage statistics for a single storage domain, from the **Storage Domain** drop-down, select a storage domain.
- You can view the storage domain assigned to Organizations. From the **Organizations** drop-down, select the organization.
- You can view the data growth rate for the **Past 24 Hours**, **Past 7 Days**, **Past 30 Days** or **Past 90 Days**. From the **Growth** drop-down, select the required option.

Click a storage domain to view more details. The **Consumption** tab shows the current data consumed and the space saved owing to data deduplication and data compression. The **Trend** tab shows the data growth trend. The data is presented in a chart. You can customize the timeframe by selecting **Last Day**, **Last Week** or **Last Month**. Turn on or off the **Storage Saved** or **Resiliency Impact** toggle to add or remove data from the chart.

To sort the list in the table by a Column type, click the Column header. To reverse the sorting, click the Column header again.

The page reports on the following Storage Domain data statistics.

> **Note:** All the statistics that are displayed are specific to the selected Storage Domain. If there is more than one Storage Domain, the Storage Domain statistics will be different from the Cluster level statistics.

Metrics	Description
Quota	The total amount of data that can be written to the Storage Domain (value set for **Storage Domain Physical Quota**). After it has been reduced by deduplication and compression, including the space required for honoring the resiliency settings (EC/RF). **Note:** This field is displayed as **None** if **Storage Domain Physical Quota** is not set.
Storage Consumed	The total size of data stored on the Cohesity file system after all operations on the data (data deduplication, data compression, and data resiliency) have been accounted for. This data can be stored either all locally or as a combination of local storage and in the Cloud Tier (if Cloud Tier is enabled). For example, if the **Data Written** is 100GB and resiliency is set to RF3, leading to the need for an additional 200GB of space, the resulting **Storage Consumed** is 300GB. If the **Data Written** is 100GB and resiliency is set to EC4:2, leading to the need for an additional 50GB (as for every 4 data fragments, 2 parity fragments are added), the resulting **Storage Consumed** is 150GB. **Note:** If you have enabled Cloud Tiering, then **Storage Consumed** is the sum of space consumed on local storage and space consumed on the cloud tier. In such cases, the sum of **Storage Consumed** value and **Capacity Available** value for the cluster can exceed the cluster capacity.
Storage Consumed (Local)	Data stored locally including the space required for honoring the resiliency settings (EC/RF).
Storage Consumed (Cloud Tier)	Data stored on the Cloud Tier including the space required for honoring the resiliency settings (EC/RF).

Metrics	Description
Storage Reduction	The ratio of **Logical Data** to **Storage Consumed**. For Data Protection, this reflects all operations performed by Cohesity on source data, which include snapshotting, change tracking and ingest, data deduplication, data compression, and data resiliency. For SmartFiles, this reflects all operations performed on the Cohesity hosted active filesystem, which include logical data writes, change tracking, data deduplication, data compression, and data resiliency.
Storage Saved	The space owing to data deduplication and data compression. For example, if **Data In** is 100GB, deduplication ratio is 4x, compression is 2x, then **Data Written** is 12.5GB. Therefore, the **Storage Saved** is 100GB - 12.5GB = 87.5GB.
Logical Data	**Data Protection**: The combined total of data in the objects that are protected by Cohesity. These metrics are different depending on workload type. • **VMs**: The data size reported by VMware is the provisioned amount, not the actual data residing in the VM. For examples, if a VM is provisioned for 1TB but contains only 100GB of data, VMware reports it as 1TB. • **All Other Workloads**: The data size reported is the actual front end data residing on the server. If a server with 1TB capacity contains 100GB of data, the server reports 100GB. **Note:** • These metrics do not include unprotected objects. • Currently, the logical data value shown on the UI is a sum of the logical data values captured across all the protection runs. For instance, if the source has 100GB of logical data, and assuming it remains at 100GB for the first 10 protection runs, Cohesity would report, after 10 runs, the Logical Data to be 1000GB (1TB). **SmartFiles**: Size of total unique logical data of active filesystem as residing on Cohesity. This does not count the space consumed by the Data Protection runs (i.e. snapshots) that may be protecting the active filesystem.
Data In	Total unique logical data residing on the Cohesity cluster. For Data Protection, this is the sum of your first full backup and subsequent change data captured by Cohesity. For SmartFiles, some customers, such as SPs and enterprise customers with multiple tenants, may want to use this as the Logical Data so that snapshot capacity is included in the chargeback.

Metrics	Description
Data Written	Data written on the Cohesity cluster after the unique logical data has been reduced by data deduplication and data compression. For SmartFiles, this metric value carries the name of Physical Data. > **Note:** This number reflects unique data written, before resiliency operations.
Resiliency Impact	The space required to honor resiliency settings (Erasure Coding / Replication Factor) in addition to the data written. For example, if the Data Written is 100GB and resiliency setting is RF3, the **Resiliency Impact** is 200GB. That is, to honor the resiliency setting, you will need an additional 200GB on top of the 100GB for the **Data Written**.
Storage Consumed Local and Cloud	If you have enabled Cloud Tiering, then this metric is the sum of space consumed on local storage and space consumed on the cloud tier.
Available	The amount of space still available on the Cohesity cluster, calculated by subtracting the **Storage Consumed** (Locally and not on Cloud Tier) from the **Total Capacity**.
Target	Name of the **External Target** used for Cloud Tier.

Organizations Level Statistics

In the **Organizations** tab:

- You can view the storage statistics of organizations.
- You can view the storage domain assigned to Organizations. From the **Storage Domain** drop-down, select the storage domain.
- You can view the data growth rate for **Past 24 Hours**, **Past 7 Days**, **Past 30 Days** or **Past 90 Days**. From the **Growth** drop-down, select the required option.

Click an organization to view more details. The **Consumption** tab shows the current data consumed and the space saved owing to data deduplication and data compression. The **Trend** tab shows the data growth trend. The data is presented in a chart. You can customize the timeframe by selecting **Last Day**, **Last Week** or **Last Month**. Turn on or off the **Storage Saved** or **Resiliency Impact** toggle to add or remove data from the chart.

To sort the list in the table by a Column type, click the Column header. To reverse the sorting, click the Column header again.

The page reports on the following organization data statistics.

Metrics	Description
Organization	The name specified for the organization when added to the cluster.
Storage Consumed	The total size of data stored on the Cohesity file system after all operations on the data (data deduplication, data compression, and data resiliency) have been accounted for. This data can be stored either all locally or as a combination of local storage and in the Cloud Tier (if Cloud Tier is enabled). For example, if the **Data Written** is 100GB and resiliency is set to RF3, leading to the need for an additional 200GB of space, the resulting **Storage Consumed** is 300GB. If the **Data Written** is 100GB and resiliency is set to EC4:2, leading to the need for an additional 50GB (as for every 4 data fragments, 2 parity fragments are added), the resulting **Storage Consumed** is 150GB.
Unique Data	Data that is unique to the objects across the system.
Data Written	Data written on the Cohesity cluster after the unique logical data has been reduced by data deduplication and data compression. For SmartFiles, this metric value carries the name of Physical Data. > **Note:** This number reflects unique data written, before resiliency operations.
Resiliency Impact	The space required to honor resiliency settings (Erasure Coding / Replication Factor) in addition to the data written. For example, if the Data Written is 100GB and resiliency setting is RF3, the **Resiliency Impact** is 200GB. That is, to honor the resiliency setting, you will need an additional 200GB on top of the 100GB for the **Data Written**.
Storage Reduction	The ratio of **Logical Data** to **Storage Consumed**. For Data Protection, this reflects all operations performed by Cohesity on source data, which include snapshotting, change tracking and ingest, data deduplication, data compression, and data resiliency. For SmartFiles, this reflects all operations performed on the Cohesity hosted active filesystem, which include logical data writes, change tracking, data deduplication, data compression, and data resiliency.
Storage Saved	The space owing to data deduplication and data compression. For example, if **Data In** is 100GB, deduplication ratio is 4x, compression is 2x, then **Data Written** is 12.5GB. Therefore, the **Storage Saved** is 100GB - 12.5GB = 87.5GB.

Metrics	Description
Logical Data	**Data Protection**: The combined total of data in the objects that are protected by Cohesity. These metrics are different depending on workload type. • **VMs**: The data size reported by VMware is the provisioned amount, not the actual data residing in the VM. For example, if a VM is provisioned for 1TB but contains only 100GB of data, VMware reports it as 1TB. • **All Other Workloads**: The data size reported is the actual front end data residing on the server. If a server with 1TB capacity contains 100GB of data, the server reports 100GB. **Note:** • These metrics do not include unprotected objects. • Currently, the logical data value shown on the UI is a sum of the logical data values captured across all the protection runs. For instance, if the source has 100GB of logical data, and assuming it remains at 100GB for the first 10 protection runs, Cohesity would report, after 10 runs, the Logical Data to be 1000GB (1TB). **SmartFiles**: Size of total unique logical data of active filesystem as residing on Cohesity. This does not count the space consumed by the Data Protection runs (i.e. snapshots) that may be protecting the active filesystem.
Data In	Total unique logical data residing on the Cohesity cluster. For Data Protection, this is the sum of your first full backup and subsequent change data captured by Cohesity. For SmartFiles, some customers, such as SPs and enterprise customers with multiple tenants, may want to use this as the Logical Data so that snapshot capacity is included in the chargeback.
Data Reduction	The ratio of **Data In** to **Data Written**. This ratio reflects the data deduplication and data compression operations.
Storage Consumed Local and Cloud	If you have enabled Cloud Tiering, then this metric is the sum of space consumed on local storage and space consumed on the cloud tier.
Growth	The physical data written to the storage domain over the number of days specified in the **Growth** field.

Metrics	Description
Growth Rate	The percentage of physical data growth on the storage domain over the number of days specified in the **Growth** field.

Consumers Level Statistics

In the **Consumers** tab:

- You can view the storage statistics of **Views**, **Backups**, **View Backups** and **Replication In**. From the drop-down, select the required option.
- You can view the storage domain assigned to Organizations. From the **Storage Domain** drop-down, select the storage domain.
- You can view the storage domain assigned to Organizations. From the **Organizations** drop-down, select the organization.
- You can view the data growth rate for **Past 24 Hours**, **Past 7 Days**, **Past 30 Days** or **Past 90 Days**. From the **Growth** drop-down, select the required option.

Click a consumer name to view more details. The **Consumption** tab shows the current data consumed and the space saved owing to data deduplication and data compression. The **Trend** tab shows the data growth trend. The data is presented in a chart. You can customize the timeframe by selecting **Last Day, Last Week** or **Last Month**. Turn on or off the **Storage Saved** or **Resiliency Impact** toggle to add or remove data from the chart.

To sort the list in the table by a Column type, click the Column header. To reverse the sorting, click the Column header again.

The page reports on the following consumer data statistics.

Metrics	Description
Consumer	The name of the consumer.
Storage Consumed	The total size of data stored on the Cohesity file system after all operations on the data (data deduplication, data compression, and data resiliency) have been accounted for. This data can be stored either all locally or as a combination of local storage and in the Cloud Tier (if Cloud Tier is enabled). For example, if the **Data Written** is 100GB and resiliency is set to RF3, leading to the need for an additional 200GB of space, the resulting **Storage Consumed** is 300GB. If the **Data Written** is 100GB and resiliency is set to EC4:2, leading to the need for an additional 50GB (as for every 4 data fragments, 2 parity fragments are added), the resulting **Storage Consumed** is 150GB.
Physical	Data written on the Cohesity cluster after the unique logical data has been reduced by data deduplication and data compression.

Metrics	Description
Resiliency Impact	The space required to honor resiliency settings (Erasure Coding / Replication Factor) in addition to the data written. For example, if the Data Written is 100GB and resiliency setting is RF3, the Resiliency Impact is 200GB. That is, to honor the resiliency setting, you will need an additional 200GB on top of the 100GB for the Data Written.
Logical Data	**Data Protection**: The combined total of data in the objects that are protected by Cohesity. These metrics are different depending on workload type. • **VMs**: The data size reported by VMware is the provisioned amount, not the actual data residing in the VM. For example, if a VM is provisioned for 1TB but contains only 100GB of data, VMware reports it as 1TB. • **All Other Workloads**: The data size reported is the actual front end data residing on the server. If a server with 1TB capacity contains 100GB of data, the server reports 100GB. **Note:** • These metrics do not include unprotected objects. • Currently, the logical data value shown on the UI is a sum of the logical data values captured across all the protection runs. For instance, if the source has 100GB of logical data, and assuming it remains at 100GB for the first 10 protection runs, Cohesity would report, after 10 runs, the Logical Data to be 1000GB (1TB). **SmartFiles**: Size of total unique logical data of active filesystem as residing on Cohesity. This does not count the space consumed by the Data Protection runs (i.e. snapshots) that may be protecting the active filesystem.
Quota	The total amount of data that can be written to the Storage Domain (value set for **Storage Domain Physical Quota**). After it has been reduced by deduplication and compression, including the space required for honoring the resiliency settings (EC/RF). **Note:** This field is displayed as **None** if **Storage Domain Physical Quota** is not set.

Metrics	Description
Data In	Total unique logical data residing on the Cohesity cluster. For Data Protection, this is the sum of your first full backup and subsequent change data captured by Cohesity. For SmartFiles, some customers, such as SPs and enterprise customers with multiple tenants, may want to use this as the Logical Data so that snapshot capacity is included in the chargeback.
Data Written	Data written on the Cohesity cluster after the unique logical data has been reduced by data deduplication and data compression. For SmartFiles, this metric value carries the name of Physical Data. **Note:** This number reflects unique data written, before resiliency operations.
Unique Data	Data that is unique to the objects across the system.
Data Reduction	The ratio of Data In to Data Written. This ratio reflects the data deduplication and data compression operations.
Storage Reduction	The ratio of **Logical Data** to **Storage Consumed**. For Data Protection, this reflects all operations performed by Cohesity on source data, which include snapshotting, change tracking and ingest, data deduplication, data compression, and data resiliency. For SmartFiles, this reflects all operations performed on the Cohesity hosted active filesystem, which include logical data writes, change tracking, data deduplication, data compression, and data resiliency.
Storage Saved	The space owing to data deduplication and data compression. For example, if **Data In** is 100GB, deduplication ratio is 4x, compression is 2x, then **Data Written** is 12.5GB. Therefore, the **Storage Saved** is 100GB - 12.5GB = 87.5GB.
Storage Consumed Local and Cloud	If you have enabled Cloud Tiering, then this metric is the sum of space consumed on local storage and space consumed on the cloud tier.
Growth	The physical data written to the storage domain over the number of days specified in the **Growth** field.
Growth Rate	The percentage of physical data growth on the storage domain over the number of days specified in the **Growth** field.

Health Dashboard

The Health dashboard provides detailed information about the health of your Cohesity cluster. You can use this information to identify your Cohesity cluster's potential problems and address them before becoming severe.

The dashboard provides an overview of the number of Critical, Warning, and Healthy (Info) alerts triggered by the Cohesity cluster. It collates all the alerts triggered by your cluster, categorizes them based on the alert category, and then displays them as the following components:

- Hardware
- Software
- Maintenance
- Data Service

In each of these components, the alert categories are displayed as individual cards and contain the number of alerts triggered for the category. The alert categories are color-coded based on the severity of the alerts:

- **Red** - Critical
- **Yellow** - Warning
- **Green** - Informational (Info)

Hardware

In the **Hardware** section, the dashboard provides an overview of the alert categories triggered by the Cohesity hardware. You can click the alert category to view the associated alerts in the **Alerts** tab and take action, respectively.

The following are the alert categories triggered by the Cohesity hardware:

- Memory
- CPU
- NIC
- Firmware
- Disk
- Power Supply
- Fan
- Temperature
- Chassis
- Node
- Cluster

For more information on the alert categories, see Alerts Reference.

Software

In the **Software** section, the dashboard provides an overview of the alert categories triggered by the Cohesity software component. You can click the alert category to view the associated alerts in the **Alerts** tab and take action, respectively.

The following are the alert categories triggered by the Cohesity software component:

- Operating System
- App MarketPlace
- Node Health
- Metadata
- Indexing
- Data Path

For more information on the alert categories, see Alerts Reference.

Maintenance

In the **Maintenance** section, the dashboard provides an overview of the alert categories triggered by other components apart from the Cohesity hardware, software, and the data services running on the Cohesity cluster.

You can click the alert category to view the associated alerts in the **Alerts** tab and take action, respectively.

The following are the alert categories triggered by other components apart from the Cohesity hardware, software, and the data services running on the Cohesity cluster:

- Cluster Management
- Networking
- Configuration
- Fault Tolerance
- License
- Storage Usage
- Upgrade
- Security

For more information on the alert categories, see Alerts Reference.

Data Service

In the **Data Service** section, the dashboard provides an overview of the alert categories triggered by the data services running on the Cohesity cluster. You can click the alert category to view the associated alerts in the **Alerts** tab and take action, respectively.

The following are the alert categories triggered by the services running on the Cohesity cluster:

- Remote Replication
- Quota
- Archival & Restore
- Backup & Restore

For more information on the alert categories, see Alerts Reference.

Alerts

The Cohesity cluster creates an alert when:

- It finds a potential problem or when it exceeds the defined threshold.
- A Protection Group is configured to trigger an alert indicating the success or failure of the job.

You can configure general alert email notifications in the **System > Health** > **Settings** tab and job-specific email notifications in a Protection Group.

Each alert has a severity rating that indicates the seriousness of the problem:

- **Critical**—Immediate action is required because it detects a severe problem that might be imminent or major functionality is not working, such as a disk failure.
- **Warning**—Action is required, but the affected functionality is still working, such as the disk space on the Cohesity cluster is 80% to 90% full.
- **Informational**—Immediate action is not required, and the alert provides an informational message.

The **Alerts** tab displays all the alerts that are generated by the Cohesity cluster. Alerts are grouped into one alert (with multiple occurrences) if the alerts are of the same type, and they are reporting the same Object and occur within the specified time-frame of the alert.

Analyze the Alert

From the **Alerts** tab, you can click on an alert and view the alert details on the **Details for <Alert_Name>** page.

The **Details for <Alert_Name>** page includes a timeline view that shows the date and time when the alert was triggered. The page also provides the following details of the alert:

Details	Description
Alert Code	The alert code. You can click on the alert code for detailed information about the alert.

Details	Description
Severity	The severity rating of the alert.
Type	The alert type. It defines the Cohesity component that triggered the alert.
Category	The alert category.
Status	The status of the alert. It can be Open, Resolved, or Note.
Description	A brief description of the problem that triggered the alert.
Cause	A brief description of the cause of the problem.

Alert Notification

You can configure general alert email notifications in the **System** > **Health** > **Settings** tab and job-specific email notifications in a Protection Group. For more information, see Configure Alert Notification Settings.

Alert Dedup

The **Alerts** tab displays all the alerts generated by the Cohesity cluster. Alerts are grouped into one alert (with multiple occurrences) if the alerts are of the same type, reporting the same Object, and occur within the specified time frame of the alert. For information on the deduplication interval, see Alerts Reference.

Resolve Alerts

In case you are aware of the problem and confirm that the issue has been resolved or if the issue does not require further attention, from the **Alerts** tab, you can manually resolve those alert(s).

You can either create a new resolution of the alert(s) or attach an existing resolution to the alert(s).

> **Note:** If you want to view the details of an alert and resolve it, see Resolve an alert in the Details for <Alert_Name> page.

Create a new Resolution

To create a new resolution:

1. In the **Alerts** tab, select an alert or multiple alerts that you plan to resolve and click **Resolve Selected Alerts**.

2. On the **Resolution** page, do the following:
    1. Select Create new resolution.
    2. In the Resolution Summary field, add a resolution summary for the alert.
    3. In the Resolution Description field, add a brief description of the resolution.
    4. Click Resolve.

The resolution is added to the selected alerts, and the status of the alert(s) is marked as **Resolved**.

Attach an Existing Resolution

To attach an existing resolution to the alert(s):

1. In the **Alerts** tab, select an alert or multiple alerts that you plan to resolve and click **Resolve Selected Alerts**.
2. On the **Resolution** page, do the following:
    1. Select **Associate with existing resolution**.
    2. From the **Resolution Summary** drop-down, you can search and select the resolution that you plan to attach to the alert.
    3. Click **Resolve**.

The existing resolution is attached to the selected alerts, and the status of the alert(s) are marked as **Resolved**.

Resolve an alert in the Details for <Alert_Name> page

Once you have reviewed the alert, you can resolve the alert using the page's **Resolution** section. In the **Resolution** section, you can either create a new resolution for the alert or attach an existing resolution.

To create a new resolution:

1. In the **Resolution** section, select **Create new resolution**.
2. In the **Resolution Summary** field, add a resolution summary for the alert.
3. In the **Resolution Description** field, add a brief description of the resolution.
4. Click **Resolve**.

To attach an existing resolution:

1. In the **Resolution** section, select **Associate with existing resolution**.
2. From the **Resolution Summary** drop-down, you can search and select the resolution that you plan to attach to the alert.
3. Click **Resolve**.

Auto-Resolve an Alert

Some alerts are automatically resolved when the dependent success alert is triggered. For example, `CreateSnapshotFailedAlert` is auto-resolved when the `CreateSnapshotSucceededAlert` is triggered. The complete list of such dependencies is available in the Alerts Reference.

Alert Retention

For **Critical** and **Warning** alerts, the retention period is six months. On the other hand, informational alerts are stored only for 14 days; after that, the alerts are not accessible.

> **Note:** You cannot customize the retention period for alerts.

View Alert Resolution Summary

From the **Resolution Summary** tab on the Health dashboard, you can summarize the resolutions added to the alerts.

View the Resolution Summary

To view the resolution summary:

1. Navigate to **System > Health** and click the **Resolution Summary** tab.
2. In the **Resolution Summary** page, you can click on the Resolution summary to view the alerts that are resolved using the resolution. Also, you can click on the alert to view the alert details.

Configure Alert Notification Settings

From the **Health** dashboard, you can configure general alert notification rules in the **Settings** tab. You can configure email, Syslog, SNMP, and webhook as the notification output for the alert notification.

> **Important:**
> In multi-tenant deployments, the rules for alert notifications work as follows:
>
> - If the notification rules are set up at the organization level, only alerts raised at that level will trigger notifications.
> - If the notification rules are set up at the cluster level, and alerts are raised at the organization level, all organizations' alerts will trigger notifications.
>
> Additionally, notifications will be sent if the alert's category, severity, and name match the specified filters.

> **Note:** Alert notifications are sent once per active alert within the dedup interval.

Add Alert Notification Rule

You can add different alert notification rules that send emails, SNMP, Syslog, and/or cURL HTTP POST requests to a webhook URL based on the alert categories, severities, and names. Rules can be configured at both the service provider and the tenancy level.

Prerequisites

Before you add an alert notification rule, make sure that you:

- Configure an SMTP Server on the Cohesity cluster, if you plan to send email notifications when an alert is triggered. For details on configuring the SMTP server, see Configure Settings.
- Configure the SNMP setting on the Cohesity cluster, if you plan to send SNMP notifications to your network management system when an alert is triggered. For details on configuring SNMP settings, see Configure and Test SNMP.
- Add a Syslog server to the Cohesity cluster, if you plan to send Syslog notifications to the server when an alert is triggered. For details on configuring the Syslog server, see Add a Syslog Server.

To add an alert notification rule:

1. Navigate to **System > Health** and click the **Settings** tab.
2. Click **Add Alert Notification Rule**.
3. On the **Add Alert Notification Rule** page, do the following:
    1. **Rule Name**: Type a descriptive name for the rule, for example, Cluster Disk Offline or Backup Job Failure.
    2. **Alert Category**: Optional. Select one or more categories from the drop-down. Otherwise, all alerts in any category will trigger the rule.
    3. **Alert Severities**: Optional. Select one or more severities from the drop-down. Otherwise, all alerts with any severity will trigger the rule.
    4. **Alert Name**: Optional. Select one or more names from the drop-down. Otherwise, any Alert name will trigger the rule. If you selected any categories, the list includes only alerts in those categories.
    5. **Email**: Optional. Click **Add** and from the drop-down menu, perform the following:
        1. Select **To** and type an email address or distribution list of the recipients to whom you plan to send the email notification.
        2. Select **CC** and type an email address or distribution list of the recipients to whom you plan to send a copy of the email notification.

6. **SNMP**: Optional. Toggle on if you want the rule to send SNMP notifications when the alert is triggered.
7. **Syslog**: Optional. Toggle on if you want the rule to send Syslog notifications when the alert is triggered.
8. **Webhook**: Optional. Toggle on and provide the URL and cURL details if you want the rule to send a web callback to a server. Type the URL for the server and type any cURL options you want to use. When an alert is triggered, the Cohesity cluster sends an HTTP request to the server. Your application can then interpret the request. For example, the webhook might notify the server about a critical disk alert, and your application might open a trouble ticket to track the problem. For more information, see Configuring Webhooks.

4. Click **Save**.

Edit Alert Notification Rule

You can edit an existing alert notification rule and update the following:

Change the rule name.

- Select or discard alert categories from the **Alert Categories** list.
- Select or discard alert severities from the **Alert Severities** list.
- Select or discard alert names from the **Alert Name** list.
- Add or remove email addresses
- Enable or disable SNMP notification
- Enable or disable Syslog notification
- Enable or disable Webhook.

The updated alert notification rule is applied from the next alert that is triggered.

To edit an existing alert notification rule:

1. Navigate to **System** > **Health** and click the **Settings** tab.
2. Click the edit icon next to the rule.
3. On the **Edit Alert Notification Rule** page, update the settings as per your requirement.
4. Click **Save**.

Delete Alert Notification Rule

You can delete the alert notification rules that you do not want to use for alert notifications.

To delete alert notification rule:

1. Navigate to **System** > **Health** and click the **Settings** tab.
2. Click the delete icon next to the rule.
3. In the **Delete Alert Notification Rule** dialog box, click **Delete**.

Configuring Webhooks

Webhooks are HTTP callbacks which are usually triggered by some event. Webhooks are configured on one website and when an event occurs on this website, an HTTP request is made to the configured URL which invokes action on the other website.

You can enable webhooks for Cohesity alerts by creating an alert notification rule. When the alert is triggered and meets the criteria in the rule, the cluster sends an HTTP request to the specified website. Your application can then interpret the request. For example, the webhook might notify the website about a critical disk alert and your application might open a trouble ticket to track the problem.

To create an alert notification rule and enable a webhook:

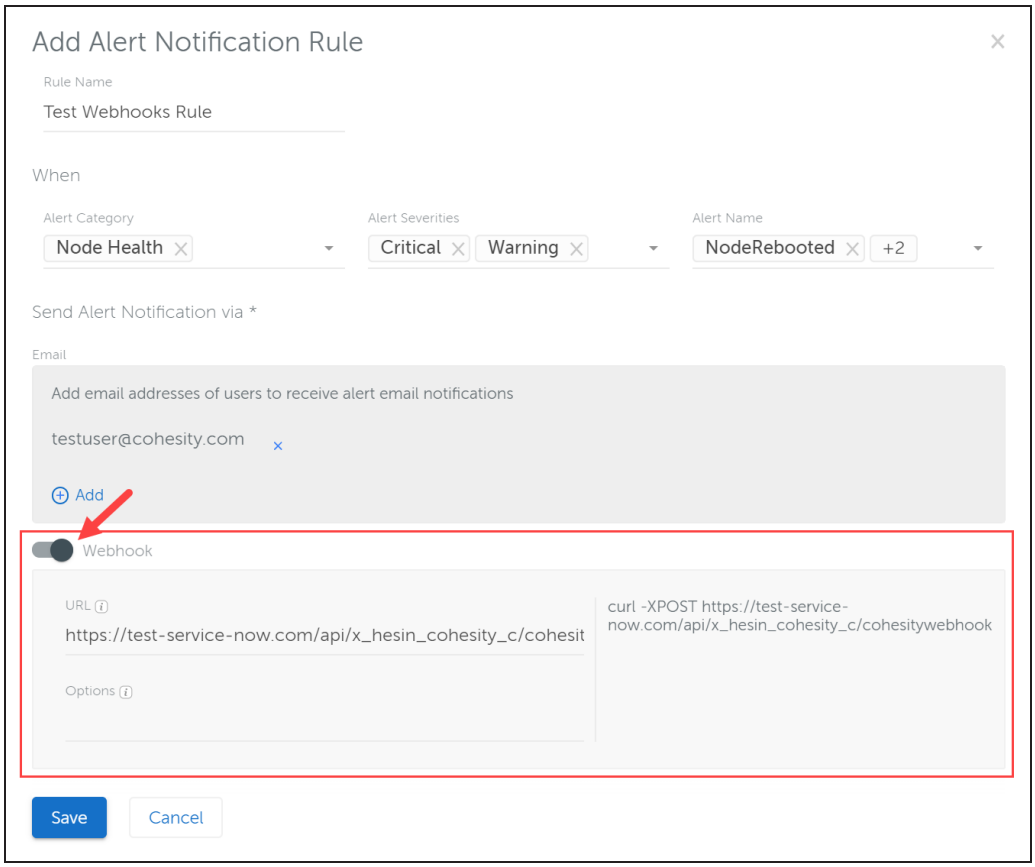
1. Navigate to **System > Health** and select the **Alerts** tab.

   The **Alerts** summary page is displayed.
2. Select the **Settings** tab, and click **Add Alert Notification Rule**.
3. Configure the following details:

Parameter	Description
Rule Name	Alert rule name.
Alert Category/Severity/Name	Choose the alert category/severity and name from the list. You can specify one or multiple values.
Send Alert Notification Via Email	The configured email addresses will receive alert email notifications.
Send Alert Notification via Webhook	The URL to which the system will connect when the above alert notification rule is matched. That is the alerts will be notified to the configured URL.

4. Toggle on **Webhook** and provide the URL and cURL options.

> **Note:** Ensure that the Webhook configuration follows the rfc3986 standards.



5. Click **Save**.

Alert Request

When an alert is triggered, a sample payload as shown below will be available at the configured URL:

CURL Request:

```
Curl -XPOST https://test-service-now.com/api/x_hesin_cohesity_c/co-
hesitywebhook
```

The Payload sent to the above URL:

```
{
       "alertType": "1060",
       "alertId": "437441:1665640208440874",
       "alertName": "DnsServerUnReachable",
       "alertDescription": "DNS server is not reachable.",
       "alertSeverity": "WARNING",
       "alertCategory": "Networking",
       "alertCause": "DNS servers [10.2.0.1] unreachable. Please update DNS
Server.",
       "alertHelpText": "Check and provide alternate DNS server.",
```

```
       "languageCode": "en-us",
       "alertUrl": "https://cluster-ip/health/alert-info/437441:1665640208440874",
       "clusterName": "cohesity",
       "clusterId": "4398906079065976",
       "alertCode": "CE03601060",
       "alertProperties":
       {
              "cluster_id": "4398906079065976",
              "alert_message": "DNS servers [10.2.0.1] unreachable. Please update DNS
Server."
       },
       "firstOccurrenceUsecs": "1665640208440874",
       "lastOccurrenceUsecs": "1665640208440874"
}
```

> **Note:** *prod-cluster.eng.cohesity.com* refers to the IP address of the cluster.

Customized Template for URL Request and Data Payload

Webhook also supports template options for both URL requests and data payload.

Data payload can be sent in any customized format as a template with placeholders. These placeholders are replaced with the actual values of the generated alert.

The placeholders can be any of the following:

```
"$alertType", "$alertId", "$alertName", "$alertDescription", "$aler-
tSeverity", "$alertCategory", "$alertCause", "$alertHelpText", "$lan-
guageCode", "$alertUrl", "$clusterName", "$clusterId", "$alertCode",
"$alertProperties", "$firstOccurrenceUsecs", "$lastOccurranceUsecs”
```

The following is an example of a template for a Slack channel:

```
--template {"blocks": [{ "type": "section", "fields": [{"type": "plain_
text", "text": "alert name" }, {"type": "mrkdwn", "text": "*$alertName*"},
{"type": "plain_text", "text": "alertSeverity"}, {"type": "mrkdwn", "text":
"*$alertSeverity*"}, {"type": "plain_text", "text": "alertCategory"},
{"type": "mrkdwn", "text": "*$alertCategory*"}, {"type": "plain_text",
"text": "alertDescription" }, {"type": "mrkdwn", "text": "*$aler-
tDescription*" }, {"type": "plain_text", "text": "alertCause" }, {"type":
"mrkdwn", "text":"*$alertCause*"}]}]}
```

Webhook URL path can also be customized with placeholders.

Example:

`"http://example.webhooksite.com?alertName=$alertName"`, where `alertName=$alertName` is the placeholder.

[content type]

If the content-type is not specified, by default, it is application/json. If a content-type is specified it must be acceptable by the webhook server.

Example:

```
-H content-type:text/html
```

[curl options]

For security reasons, valid webhook options can only be `-H( or --header)`, `-d(or --data)` and `--template`. If `--template` is provided then `-d(or --data)` is ignored. If `--template` is not provided then the payload in `--data` is merged with the default alert JSON content. Ensure that you provide a valid JSON entry for the `-d(or --data)` option.

Example:

```
-d {"accountId": 12345, "accountName": "test" }
```

Resolving Alerts

When an alert is triggered at the Cohesity cluster side, the above data as shown in the sample payload must be notified to the configured URL. Using the above payload, the alerts can be resolved at the target based on the **alertID**. This eliminates the need to switch back to the Cohesity cluster to manage and resolve alerts.

To resolve alerts, the alertURL from the sample payload must be extracted and used in the API request as shown below:

URL Request:

```
https://prod-cluster-
.eng.cohesity.com/irisservices/api/v1/public/alertResolutions
```

Method : POST

Payload :

```
{"resolutionDetails":{"resolutionSummary":"Resolved at 11/1, high pri-
ority"},"alertIdList":["157373326:1577990357283489"]}
```

> **Note:** *alertIdList* refers to the alertID in the payload. *Resolved at 11/1, high priority* is a user defined string.

CE00101009 MissingDisk

Alert Description: The node is missing disks.

Reason: This alert is generated when the number of disks assigned to a node does not match the number of disks supported by the hardware model of the node. The alert is triggered once per hour as long as a disk is missing. This alert can be caused by one of the following conditions.

- The Cohesity cluster was created with fewer disks than supported by the hardware model of the node.
- A node with fewer disks than supported by the hardware model of the node, is added to the Cohesity cluster. The disk(s) may be pulled out or not completely inserted.

Action: Find the node with the issue and add enough disks as supported by the hardware model of the node. This may involve pushing in a partially pulled-out disk or inserting a new disk if a slot in the node is empty and following the instructions in the hardware replacement procedure.

Severity: Warning

Related Error Code: Not Applicable

Dedup Interval: 86400 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.8

Platform: All

CE00101034 BootDiskHealth

Alert Description: The boot disk may be unhealthy on the node.

Reason: This alert is triggered when a boot disk might be unhealthy.

Action: Contact Cohesity Support.

Related Error Code: Not Applicable

Severity: Critical

Dedup Interval: 86400 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.168

Platform: All

CE00101071 DiskAddedToBlacklist

Alert Description: A disk is added to the denylist on the node.

Reason: This alert is triggered when a disk is added to the denylist on a node, either manually or through auto-detection of a bad disk.

Action: Contact Cohesity Support.

Related Error Code:

Error Codes	Description
kMissingStaticRoutes	The alert with the error code is raised when there are missing routes in the routing table than what is configured in the Cohesity cluster configuration.

Severity: Warning

CE00113014 DriveFault

Reason: This alert is triggered when a Hard Disk Drive (HDD) fault is detected by monitoring the IPMI SEL log.

Action: Contact Cohesity Support to investigate the problem with the HDD and determine if the HDD needs to be replaced.

Severity: Critical

Dedup Interval: 3600 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.19

Platform: C2000 Series Only

CE00101001 MarkDiskForRemoval

Alert Description: The disk is marked for removal.

Reason: This alert is triggered when a disk previously removed from the Cohesity cluster is inserted back in the node. The alert is triggered for both types of disk removals:

- A graceful removal of a disk where the disk is marked offline before being pulled as described in hardware replacement.
- An ungraceful removal of a disk. The disk is not marked offline before it is pulled.

Action: If you unintentionally removed a disk, just reinsert the disk back into the slot. If you intentionally removed the disk but did not follow the graceful removal process, reinsert the disk. For more information, see hardware replacement. You can ignore this alert if you intentionally removed the disk and followed the hardware replacement procedure.

CE00113036 DiskNeedFirmwareUpgrade

Alert Description: The disk needs a firmware upgrade on the node.

Reason: This alert is triggered if the SSD firmware version has a known issue related to an SSD media error. When there is no media error, the alert is info. When there is any media error, the alert is critical.

Action: Update the SSD firmware.

Related Error Code: Not Applicable

Severity: Critical

Dedup Interval: 86400 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.315

Platform: All

CE00113036 DiskNeedFirmwareUpgrade

Alert Description: The disk needs a firmware upgrade on the node.

Reason: This alert is triggered if the SSD firmware version has a known issue unrelated to an SSD media error.

Action: Update the SSD firmware.

Related Error Code: Not Applicable

Severity: Informational

Dedup Interval: 3600 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.315

Platform: All

CE00101115 DiskOkToRemove

Alert Description: A disk on the node is ready to be removed.

Reason: This alert is triggered when a disk is ready to be physically removed from the node in the Cohesity cluster. The alert indicates that data healing is completed on the disk.

Action: You can physically remove the disk from the node for replacement.

Related Error Code: Not Applicable

Severity: Informational

Dedup Interval: 3600 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.293

Platform: All

CE00113001 DiskIsBad

Alert Description: Disk is bad.

Reason: This alert is triggered if uncorrected errors are detected on the disk or if the disk temperature exceeds the set threshold.

Action: Contact Cohesity Support to investigate the problem with the disk and determine if the disk needs to be replaced.

Related Error Code: Not Applicable

Severity: Warning

Dedup Interval: 3600 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.66

Platform: All

CE00113013 DrivePresent

Reason: This alert is triggered when the upgrade or link has issues after the node rebooted due to the upgrade.

Action: Verify if the link issue is caused by the system reboot or upgrade.

Severity: Warning

Dedup Interval: 3600 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.214

Platform: All

CE00101029 DiskNotHealthy

Alert Description: A disk on the node is not healthy.

Reason: The disk is detecting read/write errors. This alert is triggered when one of the following conditions occur:

- When uncorrectable errors are detected on a disk.
- When the disk temperature exceeds the threshold set by the disk vendor.

Action: Contact Cohesity Support to investigate the disk problem and determine if the disk needs to be replaced.

Related Error Code: Not Applicable

Severity: Critical

Dedup Interval: 3600 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.1

Platform: All

CE00109034 DiskMarkedForRemoval

Alert Description: Disk marked for removal.

Reason: This alert is triggered when the disk initialization process fails.

Action: Contact Cohesity Support

Cluster Alerts

CE00301039 RemoveNodeSuccess

Alert Description: Removal of the node is successful

Reason: This alert is triggered daily.

Action: If a node is intentionally being removed from the cluster, no action is required. Otherwise, contact Cohesity Support.

Related Error Code: Not Applicable

Severity: Informational

SNMP OID: Not Applicable

Platform: All

CE00301040 ForcefulRemoveNodeWarning

Alert Description: The node is forcefully being removed from the Custer.

Reason: This alert is triggered daily.

Action: If a node is intentionally being removed from the cluster, no action is required. Otherwise, contact Cohesity Support.

Related Error Code: Not Applicable

Severity: Warning

SNMP OID: Not Applicable

Platform: All

CE00301041 AddNodeSuccess

Alert Description: The node has successfully joined the cluster.

Reason: This alert is triggered every hour.

Action: No action required.

Related Error Code: Not Applicable

Severity: Informational

SNMP OID: Not Applicable

Platform: All

CE00301053 VerifyRemoteClusterConnection

Alert Description: The cluster needs to confirm a connection to a remote Cluster. This alert is triggered yearly until resolved.

Action: Do one or more of the following:

- Verify the remote cluster connection on both Clusters: Log in to the Cohesity Dashboard, select **Infrastructure > Remote Clusters** and verify the remote cluster connection and details.
- Verify the remote cluster connection by using the CLI on both Clusters. Run the command: `iris_cli remote-cluster ls`.
- Verify the static routes on both Clusters by using the CLI. Run the command: `iris_cli route ls`.
- Verify the static route file, for example:

```
[cohesity@node-1 ~]$ cat /etc/sysconfig/network-scripts/route-
bond1198.16.0.0/20 via 10.2.32.1 dev bond1198.16.10.179/32 via
10.2.32.1 dev bond1198.16.10.180/32 via 10.2.32.1 dev
bond1198.16.10.181/32 via 10.2.32.1 dev bond1
```

Severity: Warning

CE00302123 NodeFailureIsNotTolerated

Alert Description: Effective usage space in the cluster is high, the cluster may not have enough space to heal if a node failure happens.

Reason: This alert is triggered when the Cohesity cluster detects that a *potential* node failure could result in an effective Cohesity cluster disk usage of 95% or greater. This alert Cause field indicates the current *actual* disk usage, which is typically less than 95%. If a node in the Cohesity cluster fails, its contents need to be copied to the other nodes. If the Cohesity cluster detects that the contents of a potentially failed node cannot be copied to the remaining nodes due a lack of disk space, this alert is triggered to indicate that node failures cannot be tolerated.

Action: Do one or more of the following:

- Add more nodes to your Cohesity cluster.
- Clean up Snapshots that are no longer required.
- Archive Snapshots to an External Target.
- Configure Cloud Tier to hold rarely used data.
- Consider changing Storage Domains to use Erasure Coding. Capacity utilization will be reduced over time in the background.

CPU Alerts

CE02113028 CpuThrottled

Alert Description: The CPU throttled.

Reason: The alert is triggered when a node's CPU is throttled.

Description: The alert might be caused by lower than expected CPU frequency because of a possible BIOS issue. You can power cycle the node to recover the CPU throttle; if the CPU throttle issue is persistent or reoccurring, then the possible causes might be:

- Firmware issue.
- Thermal issues in the node.
- Power supply issues.

Action: Perform the following:

- Verify that the node is running the latest firmware version.
- Thermal issues in the node might cause the CPU to overheat. Check the node environment for issues such as whether the data center is too hot or issues with air circulation in the server rack.
- Power supply issue might cause the CPU to throttle to reduce the power consumption. Verify if there are power supply failures in the IPMI SEL logs and replace the insufficient power supply.

  If the issue still persists, contact Cohesity Support.

Chassis Alerts

CE01901010 NodeChassisChanged

Alert Description: A node is detected on a different chassis.

Reason: This alert is triggered when the Cohesity cluster detects that a node has been moved to a different chassis than the chassis registered in the Cohesity cluster configuration. This alert may be triggered whenever the cluster services start on a node, which is typically when a node first boots up.

Action: Verify if the node was deliberately moved from one chassis to another.

Related Error Code:

Error Codes	Description
`kChassisChangedError`	The alert with the error code is raised when the node in a Cohesity cluster is moved from one chassis to another.

Severity: Warning

Dedup Interval: 3600 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.4

CE00401108 DuplicateIpDetected

Alert Description: A duplicate IP address is detected in the node.

Reason: This alert is triggered when duplicate node IP addresses are detected in the Cohesity cluster. Duplicate node IP addresses in the Cohesity cluster cause network issues.

Action: Verify if the same IP address is assigned to multiple nodes in the Cohesity cluster or malicious actors are trying to steal the IP address on the nodes in the Cohesity cluster.

Related Error Code: Not Applicable

Severity: Critical

Dedup Interval: 3600 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.266

Platform: All

CE00401107 NodeTcpOrphanConnectionsExceeded

Alert Description: The number of TCP Orphan connections exceeds the limit.

Reason: This alert is triggered when TCP FIN WAIT connections exceed the maximum threshold (100). It is typically triggered if there are unclosed TCP connections due to the following reasons:

- The TCP connections are closed due to a network issue.
- The end-user removes the network connection without closing the application.
- The Cohesity applications are closing the connections without waiting for the ACK from the server. If there are many such open connections, the new connections are denied. The Cohesity cluster detects this condition and proactively closes the connections.

Action: No action is required if you are using a physical cluster. If you are using Cohesity Cloud Edition for AWS and the network usage exceeds the AWS allowed limit (for M4X limit is 2Gbps/100kpkts/sec), then Cohesity recommends upgrading the EC2 instance to M5N.

SNMP OID: 1.3.6.1.4.1.47421.1.441

Platform: All

CE00401149 NetworkInterfaceFlaky

Alert Description: The number of network interface flaps is exceeding the limit.

Reason: This alert is triggered when a network interface exhibits "flaky" behavior. A physical interface is considered flaky when it repeatedly transitions between an up and down state within a specific time period, exceeding a defined threshold.
Definition of Flaky Behavior
The network interface transitions up or down more than n times within a t-second window.
These thresholds are defined by default as, n = 10 transitions and t = 60 seconds. Both values are configurable using a GFLAG.
Example of Flaky Behavior
If the interface undergoes transitions like this: [U D U D U D U D U D U]. This results in 11 counts (each up and down counts individually) within 60 seconds, which exceeds the default threshold of 10. Consequently, the alert is raised to signal potential instability or hardware issues.

Action: If you encounter this alert, follow these steps to identify and address the issue:
- **Inspect the Physical Link**: Verify the physical connection of the network interface.

- **Examine the Network Interface Card (NIC)**: Confirm that the NIC is functioning correctly.
- **Check the Peer Router or Switch**: Investigate the device connected to the interface (peer router or switch).
If the issue persists after the initial checks, contact Cohesity Support for assistance.

CE02809003 ActiveDirectoryNotReachable

Alert Description: The active directory domain is not reachable.

Reason: This alert is triggered when the registered Active Directory server is not reachable. The alert can be caused by one of the following conditions:

- The Active Directory server is down.
- Incorrect network settings on the Cohesity cluster.
- Incorrect DNS settings on the Cohesity cluster.

Action: Check the following:

- If the Active Directory server is online.
- The Cohesity cluster can establish a network connection to the Active Directory server

(ping test is successful).

- The network settings on the Cohesity cluster.

CE02820013 ArchiveObjectGCFailedAlert

Alert Description: Archive object garbage collection in external target failed.

Reason: This alert is triggered when the icebox tries to GC archive objects in the external target but fails.

Action: Assess if the objects are protected by data lock on purpose. If yes, ignore it. Check if the required permissions are provided. If not, contact Cohesity Support

Related Error Code: Not Applicable

Severity: Warning

Dedup Interval: 86400 seconds

SNMP OID: N/A

Platform: All

CE02809046 EntityWithTooManyOpenHandles

Alert Description: There are too many open handles for the same entity.

Reason: The SMB protocol triggers the alert when the open handle (file descriptor) number for a specific file exceeds the configured threshold. By default, this alert is disabled. The alert can be caused when some rogue applications create file handles and never close these handles. These open file handles cause the metadata bloat and cause the File Server to be in the crash loop.

Action: You can list the open file handles for the file for which the File server has raised the alert with the `iris_cli` command: `iris_cli view ls-sfo`.
The command provides a list that details the client IP address, user name, and so on that created an open handle on the file. In addition, this list provides the application details that create these many open handles on the file. You must contact the application vendor to check whether the application is leaking these open handles.

Platform: All

CE02806028 ImbalanceThresholdExceededAlert

Alert Description: Imbalance threshold exceeded for chunkfiles. This can cause increase in the cluster usage.

Reason: There is sub-optimal erasure coding overhead of greater than 100GB in an erasure coding enabled view box. When the minimum data stripe size and maximum data stripe size of the erasure coded chunk files differ a lot, the erasure coding involves space overhead when compared to an ideal case where all data stripes are of the same size. Such EC imbalance space overheads are automatically reclaimed in the background by the MapReduce and Space Reclamation service. This alert is caused when the overheads are not reclaimed in a timely manner.

Action: Contact Cohesity Support for assistance.

Related Error Code: Not Applicable

Severity: Warning

SNMP OID: 1.3.6.1.4.1.47421.0.387

Platform: All

CE02806029 MorphedGarbageThresholdExceededAlert

Alert Description: Morphed garbage threshold exceeded for chunkfiles in cluster.

Reason: Some view boxes contain more than 100GB of garbage that are not reclaimed from the disks. This accounts for greater than 20% of the view box utilization. This alert is caused when the garbage is not reclaimed in a timely manner. Cohesity software optimally reclaims garbage from the disks by holding off until a threshold value is reached. After that, the MapReduce and Space Reclamation service reclaims the garbage periodically.

Action: Contact Cohesity Support for assistance.

CE02915002 MetadataServerUnreachable

Alert Description: Metadata server on disk has been unreachable for a long time.

Reason: This alert is triggered when a metadata server in the Cohesity cluster is unreachable for one hour. After the initial alert is triggered, if the metadata server continues to be unreachable, the alert is triggered every 24 hours. The alert can be caused by one of the following conditions:

- A node is powered off.
- A network connectivity issue due to a node or software/hardware issue is causing a metadata server to fail.

Action: Power on any nodes that are powered off. Resolve any network issues between nodes. Contact Cohesity Support if the problem persists.

Related Error Code: Not Applicable

Severity: Critical

Dedup Interval: 86400 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.110

Platform: All

CE02915003 MetadataUnavailable

Alert Description: Metadata server failures have exceeded the fault tolerance level.

Reason: This alert is triggered when multiple replicas of a metadata server in the Cohesity cluster are unreachable for 1 hour. Metadata cannot be read or updated due to this condition, so the cluster will be unusable. After the initial alert is triggered, if the majority of the metadata servers continue to be unreachable, the alert is triggered every 24 hours. This alert can be caused by one of the following conditions:

- A node is powered off.
- A network connectivity issue due to a node or software/hardware issue is causing a metadata server in multiple nodes to fail.

Action: Power on any nodes that are powered off. Resolve any network issues between nodes. Contact Cohesity Support if the problem persists.

CE03008010 IndexingPaused

Alert Description: Indexing of the object contents is paused.

Reason: This alert is triggered when the Cohesity cluster detects that the indexing component has less than 10 MB of disk space available on the cluster. The alert is triggered when the Cohesity cluster pauses the indexing of the contents of objects because the cluster detects that available disk space is too low.

Action: Do the following:

- Add more nodes to your Cohesity cluster.
- Clean up Snapshots that are no longer required.
- Archive Snapshots to an External Target.
- Configure Cloud Tier to hold rarely used data.
- Consider changing Storage Domains to use Erasure Coding. Capacity utilization will be reduced over time in the background.
- See the Alert: CE03802121/CE03802122 Cluster Space Usage High KB article.

CE00610002 ProtectionGroupFailed

Alert Description: The backup run of the protection group failed.

Reason: This alert is triggered if a Protection Group Run fails. A protection run can fail for any of the following reasons:

- There is an issue with primary environment such as a removed VM or a Snapshot failure.
- The primary storage is full. (The primary storage contains the Objects that are backed up by the Cohesity cluster.)
- The Cohesity Agent is unreachable while attempting to back up physical servers.
- The storage on the Cohesity cluster is full.

Action: In the Cohesity Dashboard, drill-down on a protection run to get details about the failure including the objects (such as VMs, databases, physical servers etc) that were not backed up. Read the Cohesity and VMware documentation for a resolution. If the resolution is not found, see the Alert: CE00610002 BackupJobFailed KB article.

Related Error Code:

Job Type	Error Codes	Description
All	`kNonExistent`	If the parent entity cannot be found in the registered sources or there are no eligible sources for the protection run, an alert with the error code is raised.
	`kInvalid`	The alert with this error code is raised in the following scenarios: • When the parameters for the host entity's connector cannot be retrieved. • When the retention policy is missing from the protection policy. • When the backup parameters for the Sfdc environment are not configured.
	`kInternalError`	Failed due to error injection. Should not happen in release builds.
	`kDisabled`	The alert with this error code is raised when the Storage Array Snapshots are disabled.
	`kSchedulingError`	The alert with this error code was raised when the scheduled protection run was supposed to start earlier, but it couldn't get scheduled.
	`kRetry`	For Universal Data Adapter jobs that require an AWS S3 view backup, the Iris user config needed to fetch the S3 details was not found.
	`kRejected`	The alert with this error code is raised when a job exceeds its object limit and needs to be split across multiple jobs.

CE00610003 ProtectionGroupSlaViolated

Alert Description: The SLA of the protection run is violated.

Reason: This alert is triggered if the amount of time that a protection run takes to complete exceeds the amount of time specified in the SLA. This alert can also be triggered due to a failed protection run. A protection run may take longer than the specified SLA for the following reasons:

- If the primary storage is slow.
- The network is slow.
- The Cohesity cluster is overloaded.
- You specified an SLA that is too short.

Action: Investigate why the protection run took longer than the specified SLA. If appropriate, adjust the time period specified in the SLA. If the alert is triggered due to a failed protection run, you can override the default behavior and disable the alert when there is a protection run failure. For more information, see the ProtectionGroupSlaViolated alert triggered for backup jobs which has failed runs KB article.

CE00610004 ProtectionGroupCancelledBlackoutWindow

Reason: This alert is triggered if a protection run aborts because the protection run started executing during a blackout period specified for the job and the Abort Running Jobs during Blackouts toggle is set on for this Protection Group.

Description: By default this toggle is set off which means after a protection run starts, it continues to execute even when a black period specified for this job starts. However, a new protection run will not start during a blackout period.

Action: No action required.

CE00610005 ProtectedObjectFailed

Alert Description: The backup failed .

Reason: This alert is raised when the Cohesity cluster detects that an object (such as a VM) failed to be backed up during a Protection Group Run. One alert is raised for each object (such as a VM) that failed to be backed up. For instructions on how to enable this alert, contact Cohesity Support. A protection run can fail to back up an object for any of the following reasons:

- There is an issue with primary environment such as a removed VM or a Snapshot failure.

- The primary storage is full. (The primary storage contains the Objects that are backed up by the Cohesity cluster.)
- The Cohesity Agent is unreachable while attempting to back up physical servers.
- The storage on the Cohesity cluster is full.

Action: See the CE00610005 | BackupRestore - BackupObjectFailed KB article for a resolution.

Related Error Code:

Job Type	Error Codes	Description
kVMware	kNonExistent	The alert with the error code is raised in the following scenarios: • When the virtual machines protected by a VM protection group are not found in the VM hierarchy. • Due to decommissioned or repaved VM.
	kVSphereError	The alert with this error code is raised in the following scenarios: • When a timeout occurs while connecting to the vCenter from the Cohesity cluster. • Pings to the vCenter server fail due to IP connectivity issues. • The account used to register the source doesn't have proper permissions.
	kVixError	The alert with the error code is raised in the following scenarios: • The Cohesity node cannot resolve the DNS name of the ESX host. • The Cohesity node cannot connect to the ESX host over port 902. • When the Cohesity node connecting to the VMDK to read the changed blocks through the ESX host failed.
	kTransportError	The alert with the error code is raised when there is a communication issue between the Cohesity cluster and the Cohesity Agent on the Host.

Job Type	Error Codes	Description
	`kInvalidRequest`	The alert with the error code is raised in the following scenarios: • The source file system inclusion list contains duplicate paths. • The metadata or input file for the File Directive backup or User-based backup has the same file or folder path listed as duplicate. • The exclude path is not a child path of the include path. • The File Directive backup or User-based backup does not specify the metadata or input file when running the backup scripts or specifies an invalid or non-existent file name. • When the inclusion path is not found, the protection run fails. • During a protection run, the Cohesity cluster requests the source server to retrieve a list of available volumes. The protection run fails when a path that has been explicitly included is missing.

Job Type	Error Codes	Description
kPhysicalFiles	kTransportError	The alert with the error code is raised when there is a communication issue between the Cohesity cluster and the Cohesity Agent on the Host.
	kInvalidRequest	The alert with the error code is raised in the following scenarios: • The source file system inclusion list contains duplicate paths. • The metadata or input file for the File Directive backup or User-based backup has the same file or folder path listed as duplicate. • The exclude path is not a child path of the include path. • The File Directive backup or User-based backup does not specify the metadata or input file when running the backup scripts or specifies an invalid or non-existent file name. • When the inclusion path is not found, the protection run fails. • During a protection run, the Cohesity cluster requests the source server to retrieve a list of available volumes. The protection run fails when a path that has been explicitly included is missing.
	kNonExistent	The alert with the error code is raised when metadata or input file part of the File Directive backup or User-based Backup is nonexistent on the source server.

Job Type	Error Codes	Description
	`kFsError`	The alert with the error code is raised in the following scenarios: • Microsoft Windows permissions issue. • The credentials were changed recently. • The domain account used to register the host with the Cohesity cluster is not in the domain(s) to which the cluster has been joined. • The domain account used to register the host with the Cohesity cluster is not in a domain that is trusted by the domain(s) to which the cluster has been joined. • The domain account used to register the host with the Cohesity cluster is in a domain that is denied in the cluster's Active Directory configuration or trusted.
`kCassandra`	`kTransportError`	The alert with the error code is raised when there is a communication issue between the Cohesity cluster and the Cohesity Agent on the Host.
	`kImanisError`	The alert with the error code is raised in the following scenarios: • Source connectivity issue. • The keyspace being backed up is not present in the data center configuration on the Cassandra cluster. • In a Cassandra cluster, keyspaces and tables are spread across nodes; and are created such that data would be spread across nodes based on the configured replication factor. • If for instance RF is 3, and snapshot creation activity fails more than three times, backup would be expected to fail. • Review yarn application log to determine why snapshot creation failed.

Job Type	Error Codes	Description
kNetapp	kInvalidRequest	The alert with the error code is raised in the following scenarios: • The source file system inclusion list contains duplicate paths. • The metadata or input file for the File Directive backup or User-based backup has the same file or folder path listed as duplicate. • The exclude path is not a child path of the include path. • The File Directive backup or User-based backup does not specify the metadata or input file when running the backup scripts or specifies an invalid or non-existent file name. • When the inclusion path is not found, the protection run fails. • During a protection run, the Cohesity cluster requests the source server to retrieve a list of available volumes. The protection run fails when a path that has been explicitly included is missing.

CE00610009 ProtectedObjectSlaViolated

Alert Description: SLA in backup run violated.

Reason: This alert is triggered when the service level agreement violation (SLA) occurs for an individual object in a Protection Group run. A Protection Group run may take longer than the specified SLA for the following reasons:

- If the primary storage is slow.
- The network is slow.
- The Cohesity cluster is overloaded.
- You specified an SLA that is too short.

Action: Investigate why the Protection Group run took longer than the specified SLA. If appropriate, adjust the time period specified in the SLA.

CE00610024 SourceConnectivityFailure

Alert Description: The source cannot be reached.

Reason: This alert is triggered when the Cohesity cluster detects that it is no longer connected with the vCenter. The Cohesity cluster failed to connect with the vCenter due to one of the following conditions:

- The user credentials of the vCenter have been updated recently but are not in sync with the Cohesity cluster's vCenter configuration.
- The vCenter is not reachable.

Action: Do one of the following:

- If you get an "incorrect username and password" alert, update the current vCenter credentials in the Cohesity cluster.
- If you get a "timeout" or "not reachable" alert, try the following to ensure the vCenter is accessible by the Cohesity cluster:
  - Validate network connectivity between the Cohesity cluster and the vCenter.
  - Ensure the vCenter Server is running.
  - Diagnose the error using the vCenter logs.

CE02809069 ClockSkewBetweenClusterAndDC

Alert Description: A big clock skew between the Cohesity cluster and Domain Controller, causing the authentication to fail.

Reason: The clock skew between the Cohesity cluster (or Hyx node if existent) and the DC controller is more significant than a threshold.

> **Important:** Time synchronization is crucial for Kerberos authentication. Kerberos tickets use timestamps to prevent replay attacks by rejecting old or expired tickets. If system clocks are out of sync, attackers can exploit the gap to gain unauthorized access. Keeping all systems synchronized ensures security and prevents authentication vulnerabilities.

Action: Perform the following:
- Verify the NTP server configuration on both the Cohesity cluster and the Domain Controller to ensure they are using the same NTP server.
- Use the `iris_cli cluster sync-ntp` command to synchronize the NTP servers on the Cohesity cluster.
- Check the network connectivity between the Cohesity cluster and the NTP server to ensure there are no issues.

Related Error Code:

Error Codes	Description
`kDomainController`	If the clock skew between the Cohesity cluster (or Hyx node if existent) and the DC controller is more significant than a threshold, authentication will fail through this DC. Thus, the time skew is periodically monitored. If it gets close to the threshold, The alert is raised as a reminder to sync up the clock on the DC.

CE00820001 MediaErrorDuringArchival

Alert Description: The archival job is waiting to correct the error.

Reason: This alert is triggered when there are no more tapes available for archiving data.

Action: Add new tapes.

Related Error Code: Not Applicable

Severity: Critical

Dedup Interval: 43200 seconds

SNMP OID: Not Applicable

Platform: All

CE00820002 MediaErrorDuringRestore

Alert Description: The restore task is waiting to correct the error.

Reason: This alert is triggered when the tape required to restore data is not available in the tape drive. One or more tapes that are required to restore data are not available.

Action: Insert the required tapes to continue with the restore. The required tapes are listed in the alert.

Related Error Code: Not Applicable

Severity: Critical

Dedup Interval: 43200 seconds

SNMP OID: Not Applicable

Platform: All

CE00820003 kIntegralVolumeReachingMaxCapacity

Alert Description: The current integral volume on the QStar host is reaching its max capacity limit.

Reason: A QStar Integral Volume can handle about 1PB (Petabyte) of data. This alert is triggered when an integral volume is close to this capacity and there are no integral volumes available which have not already reached this threshold.

Action: Add a new QStar Integral Volume.

Related Error Code: Not Applicable

Severity: Warning

Dedup Interval: 21600 seconds

SNMP OID: Not Applicable

Platform: All

CE00820004 ArchiveJobFailed

Alert Description: The crchive task for the job failed.

Reason: This alert is triggered when the archive task of a job fails. This alert is triggered only once per archive task. This alert can be caused by one of the following conditions:

- When an archive task fails due to some external target connectivity and/or credentials issues.
- When an archive task fails due to an internal Cohesity issue.

Action: Check and fix external target connectivity or credential issues. If the archive task is still failing after fixing these issues, contact Cohesity Support.

Related Error Code: Not Applicable

Severity: Warning

Dedup Interval: 604800 seconds

SNMP OID: Not Applicable

Platform: All

CE00820005 ArchiveJobStuck

Alert Description: The archive task for the job is stuck.

Reason: This alert is triggered when the archive task of a job is stuck and does not make any progress for more than 3 hours. If the archive task continues to be stuck/queued, this alert is triggered once a week per archive task. This alert can be caused by one of the following conditions:

- When an archive task doesn't make progress due to some external target connectivity and/or credential issues.
- When an archive task doesn't make progress due to an internal Cohesity issue.

Action: Check and fix external target connectivity or credential issues.

Related Error Code: Not Applicable

Remote Replication Alerts

CE00910010 ProtectionGroupReplicationBacklog

Alert Description: Protection group has replication tasks with high queue wait time.

Reason: This alert is triggered when a backup job has replication tasks with a high wait time for the specified remote clusters.

Action: Contact Cohesity Support to help resolve this issue.

Related Error Code: Not Applicable

Severity: Warning

Dedup Interval: 86400 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.131

Platform: All

CE00910012 ProtectionGroupReplicationFailed

Alert Description: Replication to remote cluster failed.

Reason: This alert is triggered when a replication task fails. The alert is caused due to network connectivity issues between the clusters involved in the replication

Action: If you notice error messages related to connectivity, verify the connectivity between the clusters involved in the replication. If not, Cohesity Support.

Related Error Code:

Job Type	Error Codes	Description
All	`kInvalid`	The alert with the error code is raised when the snapshot on the primary Cohesity cluster is deleted before the Cohesity cluster can replicate the snapshot to the remote cluster.
	`kUnsupported`	The alert with the error code is raised when: • An older version of the Cohesity software is running on the remote cluster. • The remote cluster does not support the workload that is being replicated. • The remote cluster does not support cascaded replication, and you attempt to perform cascaded replication.
	`kDisabled`	The alert with the error code is raised for Azure or AWS native workloads if their disaster recovery failback support is disabled
	`kIneligible`	The alert with the error code is raised when no objects are copied to the remote cluster.
	`kCancelled`	The alert with the error code is raised when replication is canceled on the source Cohesity cluster.
	`kPending`	The alert with the error code is raised when an attempt to perform replication fails. After a backoff, the replication is retried.
	`kTransportError`	The alert with the error code is raised when the RPC to the remote cluster to initiate replication fails.
	`kTimeout`	The alert with the error code is raised when the RPC to the remote cluster to initiate replication timed out.
	`kRejected`	The alert with the error code is raised when the remote cluster rejects the replication request. This scenario can happen if the remote cluster has been rebuilt recently.

CE01509026 AVServerLicenseError

Alert Description: The license of the Antivirus server with ICAP service is expired.

Reason: This alert is raised when Antivirus server licensing fails.

Action: Update the license of the service.

Related Error Code: Not Applicable

Severity: Critical

Dedup Interval: 3600 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.56

Platform: All

CE01509027 AVThreatFound

Alert Description: A threat is found in the view.

Reason: This alert is triggered when a virus file is detected by the Antivirus ICAP server.

Action: Review the threats in the Antivirus Threats page in the Cohesity Dashboard by selecting **SmartFiles > Antivirus**.

Related Error Code: Not Applicable

Severity: Critical

Dedup Interval: 300 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.50

Platform: All

CE01512001 EncryptionKeyCreated

Alert Description: A new encryption key has been created.

Reason: This alert is triggered when a new encryption key is generated because a Storage Domain is created and the Storage Domain has either Encryption or Cloud Tier enabled. This alert is triggered for auditing.

Action: No action required.

Related Error Code: Not Applicable

Severity: Informational

Dedup Interval: 3600 seconds

SNMP OID: Not Applicable

Platform: All

CE01512002 EncryptionKeyRotated

Alert Description: Encryption key has been rotated.

Reason: This alert is triggered when an encryption key is rotated.

Action: No action. This alert is logged for auditing.

Related Error Code: Not Applicable

Severity: Informational

Dedup Interval: 3600 seconds

SNMP OID: Not Applicable

Platform: All

CE01512101 KeyRotationPolicyChanged

Alert Description: Key rotation policy has been changed.

Reason: This alert is triggered when the key rotation period is changed. This alert is triggered for auditing purposes.

Action: No action required.

Related Error Code: Not Applicable

Severity: Informational

Dedup Interval: 3600 seconds

SNMP OID: Not Applicable

Platform: All

CE01512201 KeyObjectCreated

Alert Description: A key object has been created.

Reason: This alert is triggered when a new key manager is attached to the Cohesity cluster, which can be used to get new encryption keys. This alert is triggered for auditing.

Action: No action required.

Related Error Code: Not Applicable

Severity: Informational

Dedup Interval: 3600 seconds

SNMP OID: Not Applicable

Platform: All

CE01512202 KeyObjectDestroyed

Alert Description: A key object has been destroyed.

Reason: This alert is triggered when a new key manager is removed from the Cohesity cluster. This alert is triggered for auditing.

Action: No action required.

Related Error Code: Not Applicable

Severity: Informational

Dedup Interval: 3600 seconds

SNMP OID: Not Applicable

Platform: All

CE01512206 KMSError

Alert Description: Error occurred while communicating to KMS server.

Reason: A communication failure or request was rejected by the KMS Server. This alert may be triggered hourly. This alert can be caused by errors in communication, authentication, insufficient privileges, KMS setup, etc.

Action: Review the KMS Server settings.

Related Error Code: Not Applicable

Severity: Informational

Dedup Interval: 3600 seconds

SNMP OID: Not Applicable

Platform: All

CE01501102 UserDefaultPassword

Alert Description: The cluster is using the default password on the node.

Reason: This alert is triggered when the Cohesity UI or Cohesity CLI '**admin**' user or the shell '**cohesity**' user uses the default password to log in to the node(s) in the cluster.

Action: For added security, ensure that you change the default password of the user accounts. For detailed instructions, see the *Update Default User Passwords* topic in the Cohesity Platform: Security Hardening Guide.

Related Error Code: Not Applicable

Severity: Critical

Dedup Interval: 86400 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.254

Platform: All

CE01516011 DataIngestAnomalyAlert

Reason: This alert is triggered when an anomalous change in the data ingest rate for a protected Source is detected, and is only generated if the cluster is registered with Helios. The change might be a symptom of a ransomware attack on your primary environment.

Action: Consider restoring the Source from a Snapshot. This alert provides a link to begin an Instant Recovery using the latest clean Snapshot. For more information on how to detect anomalies and ransomware attacks, see Detect Anomalies and Detect Ransomware Attacks.

Severity: Critical

SNMP OID: Not Applicable

Platform: All

CE01501090 AuditLogFailure

Alert Description: The cluster is at risk of failing to process audit logs as required.

Reason: This alert is triggered when the Cohesity cluster fails to generate audit logs for an operation. Issues in writing of the audit log record might cause the alert.

Action: Contact Cohesity Support.

Related Error Code: Not Applicable

Severity: Critical

Dedup Interval: 3600 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.237

Platform: All

CE01512203 KMSUnreachable

Alert Description: The KMS server is unreachable.

Reason: This alert is triggered if the Cohesity cluster is unable to reach the KMS server. The alert can be caused due to a networking issue, or the KMS server is down.

Action: Fix any networking issue or verify the KMS server status.

Related Error Code: Not Applicable

Severity: Warning

Dedup Interval: 3600 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.218

Platform: All

CE01512204 KMSCertificateWillExpire

Alert Description: A KMS server certificate will expire soon in the cluster.

Reason: This alert is triggered when the certificates related to the KMS server are about to expire.

Action: Update the certificates related to the KMS server.

Severity: Warning

Dedup Interval: 3600 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.213

Platform: All

CE01512205 KMSCertificateExpiration

Alert Description: A KMS server certificate will expire soon in the cluster.

Reason: This alert is triggered when the certificates related to the KMS server have expired.

Action: Replace the certificates related to the KMS server immediately.

Related Error Code: Not Applicable

Severity: Warning

Dedup Interval: 3600 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.214

Platform: All

CE01501104 WormChangeForPolicyAlert

Alert Description: The cluster is at potential security risk due to changes in the policy settings.

Reason: This alert is triggered when a WORM-enabled policy is modified to reduce WORM retention. The alert signifies that the Cohesity cluster is at potential security risk due to the reduction in WORM retention. If WORM retention is reduced and expires before the data lock (WORM) is removed, the snapshots are immediately deleted after WORM gets disabled.

Action: Ensure that you have configured WORM retention appropriately in your policy settings.

Related Error Code: Not Applicable

Severity: Critical

Dedup Interval: 3600 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.257

Platform: All

CE01501127 PrincipalWithNonViewerRole

Alert Description: The cluster has one or more IRIS principals with roles other than viewer.

Reason: This alert is triggered whenever an AD group, SSO user/group with a non-viewer role is created or updated.

Action: For security reasons, it is recommended that the third-party users do not have any non-viewer role.

Related Error Code: Not Applicable

Severity: Warning

Dedup Interval: 86400 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.337

Platform: All

CE01501103 WormChangeForGroupAlert

Alert Description: The cluster is at potential security risk due to changes in the protection group settings.

Reason: This alert is triggered when a Protection Group configured with a WORM-enabled policy is updated to associate a Protection Policy without WORM settings. The alert signifies that the Cohesity Cluster is at potential security risk due to the removal of WORM (data lock) settings from the policy associated with an existing Protection Group. It might lead to data loss if the snapshots are deleted after the Protection Group is updated with a Protection Policy without WORM settings.

Action: Ensure that you do not remove WORM (data lock) settings from the policy associated with an existing Protection Group.

Related Error Code: Not Applicable

Severity: Critical

Dedup Interval: 3600 seconds

Upgrade Alerts

CE03301003 UpgradeFailed

Alert Description: Upgrade failure.

Reason: This alert is triggered when an upgrade fails and is aborted. This is triggered once per failed upgrade. After the Cohesity cluster upgrade is initiated, if the first node is unable to download the upgrade package and install, then the upgrade is marked as failed and aborted. Downloading the upgrade package may fail for a number of reasons such as network failures, download checksum mismatch, or mismatched versions.

Action: Investigate why the upgrade failed. After correcting any invalid input, initiate the upgrade again using the Cohesity UI or Cohesity CLI.

Related Error Code:

Error Codes	Description
`KUpgradeSoftwareDownloadError`	The alert with the error code is raised when the Cohesity cluster cannot download the upgrade package.
`KUpgradeHealthCheckError`	The alert with the error code is raised when the Cohesity cluster state is not healthy.
`KUpgradeDiskMarkedForRemoval`	The alert with the error code is raised when a disk in the Cohesity cluster is marked for removal and the upgrade fails.

Error Codes	Description
`KUpgradeFeatureCompatabilityError`	The alert with this error code is raised when the existing version's features matrix is incompatible with the upgrade version.
`KUpgradeManagedBaseOSMissingPackages`	The alert with the error code is raised when the customer-managed OS is missing the required packages and the upgrade fails.

Severity: Warning

Dedup Interval: 600 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.4

Platform: All

CE03301006 NewUpgradePackagesAvailable

Alert Description: New upgrade packages are available on the node.

Reason: This alert is triggered when new compatible upgrade packages are available on the Cohesity cloud upgrade package server. If your Cohesity cluster has automatic polling enabled, the cluster raises this alert whenever Cohesity releases a new upgrade package and publishes it to the Cohesity cloud upgrade server.

Action: If desired, upgrade the Cohesity cluster. For more information, see Upgrade Cluster.

CE03601053 VerifyRemoteClusterConnection

Alert Description: The cluster requires a connection confirmation from another remote cluster.

Reason: The cluster needs to confirm a connection to a remote cluster. This alert is triggered yearly until resolved.

Action: Do one or more of the following:

- Verify the remote cluster connection on both Clusters: Log in to the Cohesity Dashboard, select **Infrastructure > Remote Clusters** and verify the remote cluster connection and details.
- Verify the remote cluster connection by using the CLI on both clusters. Run the command: `iris_cli remote-cluster ls`.
- Verify the static routes on both clusters by using the CLI. Run the command: `iris_cli route ls`.
- Verify the static route file, for example:

```
[cohesity@node-1 ~]$ cat /etc/sysconfig/network-scripts/route-
bond1198.16.0.0/20 via 10.2.32.1 dev bond1198.16.10.179/32 via
10.2.32.1 dev bond1198.16.10.180/32 via 10.2.32.1 dev
bond1198.16.10.181/32 via 10.2.32.1 dev bond1
```

CE03601030 ConfigureVipFailed

Alert Description: Failed to configure VIP on the node.

Reason: This alert is triggered when the Cohesity cluster is unable to configure a virtual IP (VIP) address on a node.

Action: Contact Cohesity Support.

Related Error Code:

Error Codes	Description
`kVipConfigurationError`	The alert with the error code is raised when the VIP configuration has failed.

Severity: Critical

Dedup Interval: 3600 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.164

Platform: All

CE03613037 NodeConnectivityFailed

Alert Description: Node connection failure.

Reason: The alert is triggered when the TCP connections on any of the following ports fail for the node-to-node communication:

- 2049
- 11111
- 12222
- 23456
- 23457
- 20000
- 22222

The alert is triggered after three retry attempts. This alert can be caused by one of the following conditions:

- There is a network issue that prevents connection on any of the ports.
- The applications listening on either one of the ports are down, so the TCP connection failed.

Action: Perform the following:

- Verify the networking configuration to check the ping connectivity between the nodes is working.
- Verify if the Gateway ping is working.
- Verify if any of the Cohesity services are failing.

Related Error Code: Not Applicable

Severity: Warning

Dedup Interval: 3600 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.323

Platform: All

CE03613038 NetworkStatsIsNotNormal

Alert Description: Node netstats is not normal.

Reason: The alert is triggered when TCP/UDP/IP checksum error counters are more than 10% of the actual TCP/UDP/IP packets received in a node. This alert can be caused by one of the following conditions.

- There is an issue with the network cable.
- There is an issue with the SFP Hardware.

- The link speed is not negotiated accurately with the peer switch.
- The packet gets corrupted in the network if there is an error in any of the intermediate switches or routes.

Action: Perform the following:

- Check the network cable.
- Verify the SFP re-seat
- Verify if the peer switch has auto-neg turned on.
- Check if there are any network issues.
- Check the peer node or switch to find any particular hardware issues.

Related Error Code: Not Applicable

Severity: Warning

Dedup Interval: 86400 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.320

Platform: All

CE03619004 KubernetesObjectsCleanupAlert

Alert Description: Failed to clean up Kubernetes objects on stale incarnation id.

Reason: When the Marketplace Apps Services subnet is updated, all the Kubernetes objects are deleted automatically. The Kubernetes objects are stuck in a terminating state in certain scenarios, triggering the alert.

Action: Manually delete all the Kubernetes namespaces.

Related Error Code: Not Applicable

Severity: Critical

Dedup Interval: 2592000 seconds

SNMP OID: 1.3.6.1.4.1.47421.0.327

Platform: All

CE03601129 AppsModeDisabledDueToSubnetClash

Alert Description: Apps mode and Marketplace apps mode are disabled due to a subnet clash.

Reason: This alert is triggered if the configured Apps Subnet clashes with any other subnets configured in the cluster.

Action: In the Cohesity Dashboard:

1. Go to **Settings > Summary** and click **Configure**.
2. In the **Configure Apps management network**field, set a non clashing subnet for apps management.

Related Error Code: Not Applicable

Severity: Critical

Fault Tolerance Alerts

CE03915005 MetadataCannotTolerateAnymoreFailures

Alert Description: Metadata fault tolerance level has been reached. Autohealing from an additional failure will not be possible.

Reason: This alert is triggered when automatic healing of failed Nodes is stalled and any more failures would result in unavailability and possible data loss. This alert is triggered daily. The metadata server cannot tolerate any more failures because the

automatic healing of failed nodes has stalled. Possible causes include an insufficient number of nodes online or a failed metadata server on available nodes.

Action: Bring any failed nodes back online. Look for any metadata server failed Alerts and resolve them. If the problem persists, contact Cohesity Support.

Related Error Code: Not Applicable

Severity: Warning

CE03902123 NodeFailureIsNotTolerated

Alert Description: The effective usage space in the cluster is high. The cluster may not have enough space to heal if a node failure happens.

Reason: This alert is triggered when the Cohesity cluster detects that a potential node failure could result in an effective Cohesity cluster disk usage of 99% or greater. This alert Cause field indicates the current actual disk usage, which is typically less than 99%. If a node in the Cohesity cluster fails, its contents need to be copied to the other nodes. If the Cohesity cluster detects that the contents of a potentially failed node cannot be copied to the remaining nodes due a lack of disk space, this alert is triggered to indicate that node failures cannot be tolerated.

Action: Do one or more of the following:

- Add more nodes to your Cohesity cluster.
- Clean up Snapshots that are no longer required.
- Archive Snapshots to an External Target.

- Configure Cloud Tier to hold rarely used data.
- Consider changing Storage Domains to use Erasure Coding. Capacity utilization will be reduced over time in the background.
- See the Alert: CE03902123 Cluster Space Usage High KB article.

Storage Usage Alerts

CE03815001 MetadataSizeExceedsThreshold

Alert Description: Metadata size on disk exceeding threshold.

Reason: This alert is triggered when the Cohesity cluster detects that the metadata usage on an SSD disk exceeds 95% of the total capacity of the disk. After the alert is triggered, if the metadata size continues to exceed 95% of disk capacity, this alert is triggered every 24 hours.

Action: See the ALERT: CE03815001 METADATASIZEEXCEEDSTHRESHOLD KB article.

- Review the Protection Policy and reduce the frequency of any full backups or reduce the Snapshot retention period.
- Delete old Snapshots or add more nodes to expand the cluster.
- If you are performing data dumps on Views (Oracle RMAN, Robocopy, SQL Dumps, Remote Adapter) and view backups, review how long such dumps are being retained.

Reports

> **Important:** Helios Reporting supports global reporting and has an enhanced library of built-in reports. You can find equivalent reports in the new and improved Helios Reporting. Please create new schedules with the equivalent reports in Helios Reporting to start using these new features.

In today's data-driven business environment, it is more important than ever to analyze your data and identify patterns and trends that help organizations make better decisions. With reporting, Cohesity extends its built-in reporting features to give you the flexibility to produce several reports to understand cluster capacity, usage metrics and help you address your organization's specific needs most effectively.

For information about how long the cluster keeps audit data, see Data Retention for Audits.

Run Reports

1. Navigate to **Reporting** and click **Proceed to cluster Reporting**.
2. Select a report from the **Select Report** drop-down.
3. If the **Filters** panel is provided for the report, you can optionally filter your results by the options listed. Select the options and click **Apply Filters**.

Email Reports

You can email most reports as needed or on a recurring basis.

> **Note:** To email reports, an email address must be specified for the local System Admin account (admin) of the Cohesity cluster. Select **Settings > Access Management** and if necessary, edit the local admin user to provide an email address.

1. Navigate to **Reporting** and click **Proceed to cluster Reporting**.
2. Select a report from the **Select Report** drop-down.
3. If the **Filters** panel is provided for the report, you can optionally filter your results by the options listed. Select the options and click **Apply Filters**.
4. Click the **Email** icon ( ) and type one or more email addresses in the **Email Recipients** field. (Not all reports can be emailed.)
5. Select a format for the report in the **Format** drop-down. A CSV format report is sent as an email attachment. An HTML format report is sent in the body of the email.
6. To email the report one time, toggle **Schedule Recurring Email** off.

   To send recurring emails, select one or more days in **Email Every** and set the time the emails should be sent.
7. Optionally, select the **Time Zone** that matches your mailing schedule.
8. The current report filters are displayed. You can use them as is or modify them.
9. Click **Save Schedule**.

If you scheduled emails, click the **Scheduled Emails** tab to display all scheduled emails.

If you did not provide schedule information, the report is emailed immediately.

Delete a Scheduled Email

1. Navigate to **Reporting** and click **Proceed to cluster Reporting**.
2. Click the **Scheduled Emails** tab.

   This tab lists the scheduled emails for all reports.
3. To edit a scheduled email, click the edit icon ( ) and edit the recipients, format, filters and scheduling information and then click **Save Schedule**.
4. To permanently delete a scheduled email, click its delete icon ( ).

Download a Report as a CSV File

For most reports, you can download the data generated for the currently displayed report as described below. (You can also schedule an email that includes the report as a CSV attachment as described previously in this topic.)

1. Navigate to **Reporting** and click **Proceed to cluster Reporting**.
2. Select a report from the **Select Report** drop-down.
3. If the **Filters** panel is provided for the report, you can optionally filter your results by the options listed. Select the options and click **Apply Filters**.
4. Click the **CSV** icon (↓). The file is downloaded immediately to your device.

Cohesity Reports

Cohesity provides the following reports:

Report Name	Description
Available Local Snapshots Per Job	This report provides Snapshot summary statistics for a leaf Protection Source Object (such as a VM) for all Protection Groups or a specific Protection Group. For detailed information about this report, see Available Local Snapshots.
Agent Status Summary	This report provides information about the Cohesity Agents installed on servers registered as Sources on the Cluster. For detailed information about this report, see Agent Status.
Backup Summary	This report shows an overview of the Protection Groups run on the Cohesity cluster for the specified filter criteria. For each Protection Group, this report shows how many times the Job has run, total bytes read and statistics about the last time the Job ran. For detailed information about this report, see Backup Summary.
Clone and Recover VM Tasks Summary	This report shows an overview of Clone and Recover tasks for the specified date range. For detailed information about this report, see Clone and Recover VM Tasks Summary.
Cluster Wide Storage	This report provides Cluster storage statistics that are useful for administrators to plan out disk space utilization. For detailed information about this report, see Cluster Wide Storage.

Report Name	Description
Data Transferred to External Targets	This report provides statistics about the data transferred to External Targets for archiving Snapshots created by Protection Groups, and moving cold data from the Cohesity cluster to Cloud Tier. For detailed information about this report, see Data Transferred to External Targets.
Failed Objects	This report lists all the Objects for which an error occurred during the last protection runs and prevented the Objects from being backed up. For detailed information about this report, see Failed Objects.
GDPR Object Summary	This report provides information about whether an Object is protected, who has access to it, where Object Snapshots are stored and how long they are retained, and any actions performed on the Object. For detailed information about this report, see GDPR Objects Summary.
Objects Protected by Multiple Protection Groups	This report lists all the Objects that have been backed up (protected) by more than one Protection Group. For detailed information about this report, see Objects Protected by Multiple Protection Groups.
Protected Objects Heatmap	This report provides an interactive grid of cells that indicate whether the Backup Tasks associated with Protection Group runs were successful (green cells) or encountered errors (red cells). For detailed information about this report, see Protected Objects Heatmap.
Protection Details Per Object	This report provides Protection Run (Snapshot) details for a leaf Protection Source Object (such as a VM). For detailed information about this report, see Protection Details Per Object.
Protection Groups Inventory and Schedule	This report lists all the Protection Groups on the Cohesity cluster matching the specified filter criteria. For each Protection Group, this report lists all the Objects that will be backed up by this group and the schedule for when the Objects will be backed up. For detailed information about this report, see Protection Groups Inventory and Schedule.
Protection Runs Summary	This report provides information about Protection Group runs and related replication and archival tasks. For detailed information about this report, see Protection Runs Summary.

Report Name	Description
Protection Summary by Object Type	This report shows the protection status of Objects as of the last protection runs that occurred in the specified Date Range. For detailed information about this report, see Protection Summary By Object Type.
Source Growth and Variance	This report shows how the size of protected Servers per registered Source are changing over time. For detailed information about this report, see Source Growth & Variance.
Sources Protected	This report provides overview statistics about the number of Servers protected or unprotected for registered Sources on the Cohesity cluster. For detailed information about this report, see Sources Protected.
Storage Consumed by Backups	This report provides statistics about the Protection Groups that are consuming the most disk space on the Cohesity cluster. For detailed information about this report, see Storage Consumed by Protection Groups.
Storage Consumed by File Categories	This report provides data statistics about File Categories in the latest Snapshots for all Servers stored on the Cohesity cluster. Statistics are only reported for files indexed by the Cohesity cluster. For detailed information about this report, see Storage Consumed by File Categories.
Storage Consumed by Servers	This report provides statistics about the Servers that are using the most disk space on the Cohesity cluster and Primary Storage. For detailed information about this report, see Storage Consumed by Servers.
Storage Consumed by Storage Domains	This report provides information about the Storage Domains that are storing the most logical data and raw data data on the Cohesity cluster. For detailed information about this report, see Storage Consumed by Storage Domains.
Storage Consumed by Organizations	This report provides information about the organizations consuming the most storage. For detailed information about this report, see Storage Consumed by Organizations.
Top Jobs	This report shows the top Protection Groups by the average amount of data transferred, the length of Protection Group run time, the number of Objects protected and the number of SLA violations. For detailed information about this report, see Top Protection Group.

Report Name	Description
Unprotected VMs	This report provides lists of VMs that are protected and not protected by Cohesity for the registered Sources on the Cohesity cluster. In addition, overview statistics about protected and unprotected VMs are provided. For detailed information about this report, see Unprotected/Protected VMs.
User Quota	This report provides information about the default user quota defined for a View and any overrides defined for individual users. For detailed information about this report, see User Quotas.

Understanding Storage Metrics

The Cohesity UI and reports use the following terminology to describe storage metrics:

Metrics	Description
Logical Data	The combined total of data in the objects that are protected by Cohesity.
Data In	Total unique logical data residing in Cohesity.
Data Written	Data written on the Cohesity after the unique logical data has been reduced by data deduplication and data compression.
Storage Consumed	The total size of data stored on the Cohesity file system after all operations on the data (data deduplication, data compression, and data resiliency). This data can be stored either all locally or as a combination of local storage and in the Cloud Tier (if Cloud Tier is enabled).
Resiliency Impact	The space required to honor resiliency settings (Erasure Coding / Replication Factor) in addition to the data written.
Storage Consumed Local and Cloud	Data stored locally and in the Cloud Tier (if Cloud Tier is configured) including the space required for honoring the resiliency settings (EC/RF).

Custom Reporting

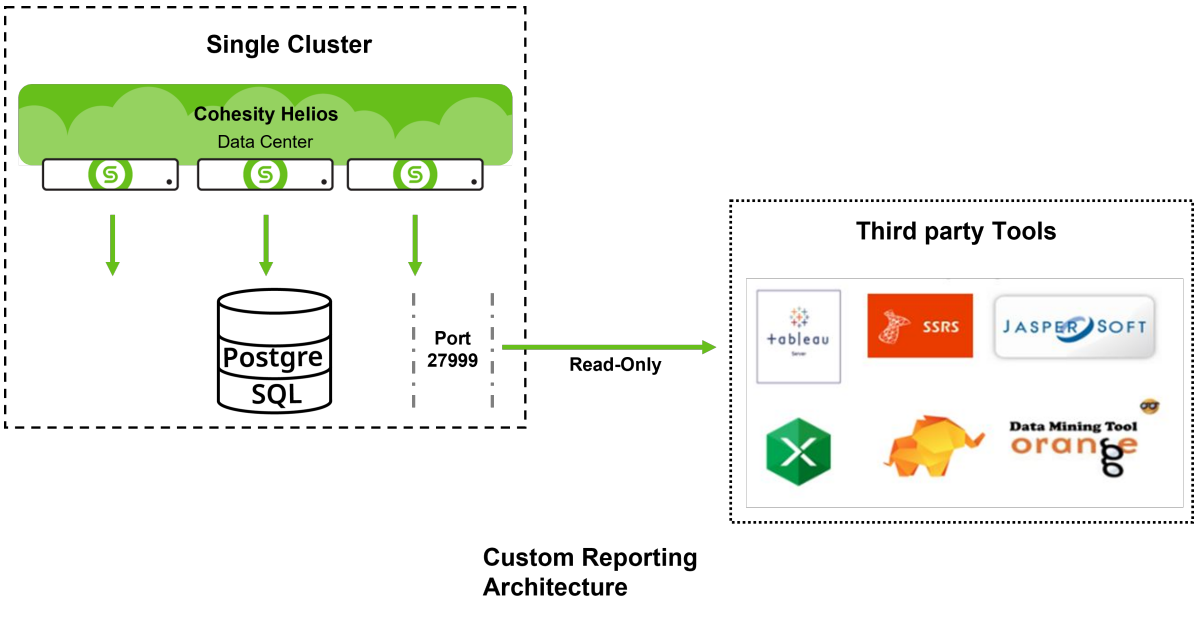
The Custom Reporting feature addresses the limitations of monitoring options for historical data. This feature helps in creating custom reports to capture the information outside of the built-in reports available on the Cohesity cluster.

The Custom Reporting in Cohesity is achieved by reading the data from a Custom Database (Postgres) that stores relevant performance metrics, stats, and information of a (standalone) Cohesity cluster.

Note:

- In earlier releases, there was no firewall rule for custom reporting. After upgrading to the latest version, you may encounter connection failures to the Reporting Database because, starting from version 6.8, the new firewall rule is set to `deny` by default.
- To use custom reporting in a Cohesity cluster, you should edit the firewall rule for Reporting Database and set it to Allow. For more information, refer to the *Configure Firewall Rule* section in Manage Application-Based Firewall Rules.
- The IP address of the Reporting Database may change, as it can fail over to another node in the cluster during service restarts, patching, upgrades, or similar events.
- Contact your Cohesity account team to use the Custom Reporting feature.

The users can use the third-party SQL reporting tools, such as JasperSoft, TablePlus, Orange, DevArt plugin for Excel, Microsoft SSRS / Visual Studio, and Tableau for Desktop to access the Custom Database and build reports tailored to specific business requirements.



Custom Reporting Architecture

For more information, see the Cohesity Custom Reporting Solution Guide.

Limitations

- If you change the fault tolerance values of the Postgres database in the Cohesity Dashboard (**Settings > Summary > Configure**), the changes are not applied to the Postgres database.
- Data archival is not supported for the Postgres database.
- Custom Reporting does not track expired snapshot data for Protection Group runs.

Connecting to the Postgres Database

To avoid a single point of failure, the data is replicated across the nodes in the Cohesity cluster. A service manager manages redundant Postgres databases inside the cluster. This redundancy is set during cluster configuration. The number of replicas depends on the fault tolerance of the cluster.

1. Connect to the Cohesity CLI. For more information, see Using the Cohesity CLI and List of Cohesity CLI Commands.

   > **Note:** The Cohesity Admin user should perform the steps listed in this section.

2. Execute the following command to get the default credentials to connect to the Postgres database.

   ```
   iris_cli custom-reporting database
   ```

   > **Note:** The default credentials returned by the command are those generated on the cluster, not the global default.

3. Connect to the Postgres database using any third-party SQL reporting tools with the following parameters.
   - IP: Node IP running Postgres
   - Port: 27999
   - Database: postgres
   - User: reporting_read
   - Password: default password from the previous step

> **Note:** The default password of the reporting database is changed after you upgrade a Cohesity cluster to the 6.7 release. You should update the password of the reporting database in your database clients. The connection to the reporting database will be broken after the upgrade if the connection is established using the default password provided in the previous releases.

- Schema: reporting

  Cohesity recommends changing the password after connecting to the Postgres database.

4. To change the password, connect to the Postgres database as described below and execute the following query:

   ```
   alter role reporting_read with encrypted password 'new_strong_pass_here';
   ```

   > **Note:** This changes the password for the Postgres instance on the current node.

   Repeat the above 4 steps on all Postgres instances.

This changes the password for the Postgres instance on the current node. Repeat these steps on all Postgres instances.

Understanding the Database

The users can build reports by understanding the underlying database schema. The database schema is intuitive and user-friendly. The table names and the field names in the database are straightforward and self-explanatory. Click the link below to refer to the Entity Relationship diagram and the Data Dictionary for the Custom Reporting database.

- Entity Relationship Diagram and Data Dictionary

If you update your Cohesity version to 6.4 and later, the following changes are made to the Custom Reporting tables:

- `Snapshot_expiry_time_usecs` attribute added in the *protection_job_runs* table.
- `Logical_size_in_bytes` attribute added in the *leaf_entities* table.
- The status' of the job run has been updated and from Cohesity version 6.4 the *job_run_status* table will report more updated status as listed in the table below.

Existing job run status	Updated job run status
1, 'success' 2, 'in_progress' 3, 'error' 4, 'cancelled'	0, 'Accepted' 1, 'Running' 2, 'Canceling' 3, 'Canceled' 4, 'Success' 5, 'Warning 6, 'Failure' 7, 'OnHold' 8, 'Missed' (Not currently used)

- The status' of the *restore_status_types* table from Cohesity version 6.4 will report more updated status types as listed in the table below.

Existing restore status types	Updated restore status types
0, 'kReadyToSchedule' 1, 'kAdmitted' 2, 'kInProgress' 3, 'kFinished' 4, 'kProgressMonitorCreated' 5, 'kFinishingProgressMonitor' 6, 'kRetrievedFromArchive' 7, 'kCancelled' 8, 'kInternalViewCreated' 9, 'kZipFileRequested	0, 'Accepted' 1, 'Running' 2, 'Canceling' 3, 'Canceled' 4, 'Success' 5, 'Warning 6, 'Failure' 7, 'OnHold'

- `is_latest_attempt` attribute added to *protection_job_run_entities* table to track the latest attempt for entities (in case of failures).
- `timezone` attribute added to the *cluster* table.
- `restore_source_type_id` attribute added to *restored_objects* table to identify the source from which the restore task was performed.
- Added support for AD leaf entities and Protection Groups.

Agent Status

This report provides information about the Cohesity Agents installed on servers registered as Sources on the Cluster. An Agent is required to protect physical servers and some hypervisor environments.

You can filter the report results by changing the Agent health status, operating system and software version and then clicking **Apply Filters**. If you do not have the Agent Version, run the report without this filter, copy the desired version from the report results and paste it into this field.

Click the **Email** icon to provide information for scheduling report emails. For more information, see Email Reports. The **Scheduled Emails** tab on the Reports page displays those emails.

Click the **CSV** icon to download the current report as a CSV file to your device.

The report contains the following columns.

Column Name	Description
Host IP	The IP address of the host on which the Agent is installed.
Host OS Type	The operating system running on the host.
Agent Health Status	The status of the Agent: • **Healthy**–The Agent is healthy and is able to contact the Cluster. • **Degraded**–The Agent is running but in a degraded state because of internal issues on the server. • **Unknown**–The Agent is unknown and the Cluster does not attempt to contact the Agent. • **Unreachable**–The Cluster cannot contact the Agent. The server might be powered off. • **Unhealthy**–An attempt to refresh the status of the Agent failed.
Software Version	The software version of the Agent.

Column Name	Description
Upgradability	Indicates the whether the Agent can or should be upgraded to the same software version as the Cluster: • **Upgradable**–The Agent is running a back-level version and can be upgraded. For information about upgrading, see Install and Manage Cohesity Agents. • **Current**–The Agent is running the same software version as of Cluster. No upgrade is needed. • **Unknown**–The Agent is running a non-production version. This is unlikely in a production environment, but possible if the Agent is running a pre-release version for testing purposes. • **NonUpgradableAgentisNewer**–When Agent is running a later version than the Cluster version. • **NonUpgradableInvalidVersion**–The Agent is running an invalid version. This is unlikely in a production environment, but possible if the Agent is running a pre-release version for testing purposes. • **NonUpgradableAgentisOld**–The Agent is running a version that is too old to upgrade to the Cluster version. If possible, install a newer version of the Agent on the server.
Last Upgrade Status	Indicates whether the last upgrade was successful or not. This is the message text from the last upgrade attempt.

Available Local Snapshots

This report provides Snapshot summary statistics for a leaf Protection Source Object (such as a VM) for all Protection Groups or a specific Protection Group.

In the Actions panel, you can also optionally filter your results by Date Range or Job Name. By default, Snapshot summary statistics are reported for all Jobs. In the **Job Name** field, you can optionally specify a Job name to limit the Snapshots summary statistics to a single Job. To apply the filters, click **Apply Filters**.

Click the **Email** icon to provide information for scheduling report emails. For more information, see Email Reports. The **Scheduled Emails** tab on the Reports page displays those emails.

Click the **CSV** icon to download the current report as a CSV file to your device.

If data is found matching the specified filters, a Job table is displayed.

Protection Group Table

The columns for the Protection Group table are described below. To sort the list in the table by Column type, click the Column header. To reverse the sorting, click the Column header again.

Column Name	Description
Object	The leaf Protection Source Object (such as a VM). Drill down on this Object link to get details about the protection runs backing up this Object. (See the Object table below.)
Total Snapshots	The total number of Snapshots that backed up the leaf Protection Source Object based on the specified filter criteria
Last Snapshot	List the last Snapshot that backed up this Protection Source Object based on the specified filter criteria.
First Snapshot	List the first Snapshot that backed up this Protection Source Object based on the specified filter criteria
Error Snapshots	List the number of protection runs that failed when attempting to back up this Protection Source Object based on the specified filter criteria
Last Error Snapshot	List the last protection run that reported an error while attempting to back up this Protection Source Object based on the specified filter criteria

> **Tip:** To view the Snapshots summary statistics for all Reports again after viewing a single Job, clear the Job Name field and click **Apply Filters**.

Object Table

When you drill down on an Object in the Job table, an Object table displays providing details about the Snapshots backing up the Object that match the specified filter criteria. To sort the list in the table by Column type, click the Column header. To reverse the sorting, click the Column header again.

Column Name	Description
Start Time	The time this protection run started.
Protection Group Name	The name of the Protection Group.
End Time	The time this protection run ended.

Column Name	Description
Status	The current status of the protection run: • **Success**–Indicates that the protection run was successful. • **Running**–Indicates that the protection run is currently running. • **Warning**–Indicates that the protection run was successful but warnings were detected. • **Canceled**–Indicates that the protection run was canceled before completing. • **Error**–Indicates the protection run encountered an error and did not run to competition.
Schedule Type	The type of run specified in the Policy for the Job: • **Incremental**–When possible, utilizes Change Block Tracking (CBT) when capturing a Snapshot of this Object. • **Full**–Always captures a Full Snapshot of this Object and does not utilize Change Block Tracking (CBT). • **Log**–Captures database transaction logs to allow rolling back to a specific point in time.
Data Read	The total number of bytes read for this Object during this protection run.
Logical	The total number of logical bytes protected for this Object during this protection run. Indicates the size of the data if the data is fully hydrated or expanded. The actual physical data stored on the Cohesity cluster is reduced by change-block tracking, compression and deduplication.
Copy Task Status	The status of copy tasks for this protection run such as replication and archival tasks. These tasks copy Snapshots to a Remote Cohesity Cluster or External Targets.

Backup Summary

This report shows an overview of the Protection Groups run on the Cohesity cluster for the specified filter criteria. For each Protection Group, this report shows how many times the Job has run, total bytes read and statistics about the last time the Job ran.

For information about how long the cluster keeps audit data, see Data Retention for Audits.

This report contains the following charts:

- **Overview of Last Run Statuses Doughnut Chart**—This chart shows only the last run status for all the Protection Groups in the cluster that meet the specified filter criteria. For example if the first run of a Protection Group fails with an error but then is successful, the chart shows the status of success for this Protection Group.
- **Protection Runs Hourly Bar Chart**—This chart provides a status snapshot of all the Protection Group runs in the last twenty-four hours that meet the specified filter criteria. A single Protection Group can be represented multiple times in this chart. For

example, if one runs four times in the last twenty-four hours, each run is represented by a one-run bar in this chart.

In the Actions panel, you can also optionally filter your results by Data Range, Job Name, Registered Sources or Last Run Status of the Protection Group. You can specify a Date Range, enter part of a Job name, select one or more Sources from the Registered Source drop-down list and only report on Jobs that the last run status is successful. To apply the filters, click **Apply Filters**. You cannot filter on Storage Domain Sources.

Click the **Email** icon to provide information for scheduling report emails. For more information, see Email Reports. The **Scheduled Emails** tab on the Reports page displays those emails.

Click the **CSV** icon to download the current report as a CSV file to your device.

The columns for the table at the bottom of the Protection Groups Summary page are described below.

Column Name	Description / Action
Job	Drill down on this link to get statistics about this Protection Group such as throughput, megabytes read, a list of job runs, job details and a job audit trail.
Source	Drill down on this link to get details and protection statistics about this Source on the Cohesity cluster. If you drill down on a VMware Source, the reported VM statistics reflect all VMs in the Source and is not specific to the current Protection Group.
Runs	For the specified filter criteria, the number of times this Protection Group has run.
Last Run Success/Error	This column lists how many Objects were successfully backed up and how many failed during the last Run of this Protection Group based on the specified filter criteria. Drill down on this link to see Backup Run Details for this Job. A list of protection runs for this Job are listed. If this is a Server Protection Group, you can also drill down on the protection run to get a listing of the Servers that were backed up.
Data Read (total)	This column reports the cumulative number of bytes read from the Source for all the Runs of this Protection Group that meets the specified filter criteria.

Column Name	Description / Action
SLA Violation	For the last Protection Group Run based on the specified filter criteria, this column reports the SLA status. • **Pass**–The last run of this Protection Group completed within the SLA time period specified for this Protection Group. • **Fail**–The last run of this Protection Group did not complete within the SLA time period specified for this Protection Group. • **n/a**–Pass/Fail statistics are not available. The last Run of this Protection Group is still running or did not complete. The service-level agreement (SLA) defines how long the administrator expects protection run to take.
Bandwidth	The average amount of data transferred over the network per second per backup job.
Last Run Status	For the last Protection Group Run based on the specified filter criteria, this column reports the current status: • **Succeeded**–The protection group run completed without error. • **Canceled**–A protection group run started and then was canceled in the Cohesity Dashboard The protection group run did not complete. • **Canceling**–In the Cohesity Dashboard, the cancel option was selected for the protection group run and the cluster is in the process of canceling the run but the run is not yet canceled. • **Failed**–The protection group run did not complete due to an error. •  –The protection group run is currently running but is not completed yet.
Last Run Replication/Archival Status	For the last Protection Group Run based on the specified filter criteria, this column indicates the status of any replication ( ) and archival ( ) tasks. Mouse over the icon to see the replication or archival target, or click the icon to display additional details about the task.

Clone and Recover VM Tasks Summary

This report shows an overview of Clone and Recover tasks for the specified date range.

This report contains the following charts:

- **Recover Operations**—This doughnut chart shows how many VM Recover and Clone tasks have run in the specified date range.

- **Latest Operations**—In the specified date range, this bar chart represents the run time for the five last VM Recover and VM Clone tasks.

In the Actions panel, you can filter the results by Date Range. Select the range and click **Apply Filters**.

In the Search field above the table, you can filter the results by entering part of the Recover Task Name and Return.

The table lists all the cloning VM and recovering VM tasks in the specified date range. In the table, drill-down on the Task Name to find out details about the Task.

Cluster Wide Storage

This report provides Cluster storage statistics that are useful for administrators to plan out disk space utilization.

This page provides the following data use statistics about the entire local Cohesity cluster. The disk space available from External Targets is not included in the reported statistics. For example, the value reported in the Cluster Storage Capacity field does not include the disk space available in the Cloud Tier.

Field	Field Description
Cluster Storage Capacity	The amount of total disk space on the Cohesity cluster available for storage of your data such as Snapshots of Protection Groups, files and directories. **Note:** • Storage Domain settings such as number of failures tolerated and erasure coding affect how much data can be stored on the Cluster. • On All Flash clusters, Cohesity reserves extra space for metadata. This space is automatically made available for data (cluster capacity) if the cluster usage exceeds 90%. Due to this behavior, cluster capacity would vary when the cluster usage is 90% or exceeds 90%.
Cluster Storage Used	The amount of disk space on the Cohesity cluster currently used for storing your data such as Snapshots of Protection Groups, files and directories.
Daily Growth Rate	Daily growth rate for the **Storage Consumed** value. Where ***Storage Consumed*** is the total size of data stored on the Cohesity file system after all operations on the data (data deduplication, data compression, and data resiliency) have been accounted for.

Field	Field Description
Data Reduction Ratio	The data reduction ratio is calculated by dividing the Logical Data Managed by the Physical Data Used. **Logical Data Managed**–Indicates the size of the data if the data is fully hydrated or expanded. The actual physical data stored on the Cohesity cluster is reduced by change-block tracking, compression and deduplication. **Physical Data Used**–The size of the data physically stored on the Cohesity cluster, after the data has been reduced by change block tracking, compression and deduplication, including the disk space used for data resiliency (fault tolerance and erasure coding).
Utilization Ratio	Ratio of **Storage Consumed** to **Raw Cluster Capacity**. Where ***Storage Consumed*** is the total size of data stored on the Cohesity file system after all operations on the data (data deduplication, data compression, and data resiliency) have been accounted for.
Date to Exceed 80% Utilization	Based on the current daily growth rate, what is the projected date that the Cohesity cluster is expected to be 80% full.
Raw Cluster Capacity	The total physical capacity of all storage devices. This is pre-reservation of capacity for Cohesity software operations.
Minimum Usable	The total physical capacity of all storage devices after subtracting the space reserved for Cohesity software operations.

Below the list of statistics is the following chart:

Cluster Storage Used Over 7 Days—This chart graphs the physical growth of the disk space used on the Cohesity cluster over the last seven days.

You can optionally Filter your results by **Date Range**. Specify a date range to check the physical growth of the disk space for the specified dates.

Data Transferred to External Targets

This report provides statistics about the data transferred to External Targets for archiving Snapshots created by Protection Groups, and moving cold data from the Cohesity cluster to Cloud Tier.

You can filter the report by date range, target type and target name.

The report provides the By Target and By Protection Group tabs as described below.

Click the **Email** icon to provide information for scheduling report emails. For more information, see Email Reports. The **Scheduled Emails** tab on the Reports page displays those emails.

Click the **CSV** icon to download the current report as a CSV file to your device.

By Target

This tab provides a table of statistics for each External Target.

Column Name	Description
Target Name	The name of the External Target.
Protection Groups	The number of Protection Groups that transferred data to the External Target.
Logical Data Transferred	**Data Protection**: The combined total of data in the objects that are protected by Cohesity. These metrics are different depending on workload type. • **VMs**: The data size reported by VMware is the provisioned amount, not the actual data residing in the VM. For example, if a VM is provisioned for 1TB but contains only 100GB of data, VMware reports it as 1TB. • **All Other Workloads**: The data size reported is the actual front end data residing on the server. If a server with 1TB capacity contains 100GB of data, the server reports 100GB. **Note:** - These metrics do not include unprotected objects. - Currently, the logical data value shown on the UI is a sum of the logical data values captured across all the protection runs. For instance, if the source has 100GB of logical data, and assuming it remains at 100GB for the first 10 protection runs, Cohesity would report, after 10 runs, the Logical Data to be 1000GB (1TB).
Physical Data Transferred	Data written to the External Target after the unique logical data has been reduced by data deduplication and data compression.
Total Storage Consumed	The total size of data stored on the External Target after all operations on the data (data deduplication, data compression, and data resiliency) have been accounted for. **Note:** The Total Storage Consumed on an external target may vary or be unavailable for collection when using an S3 bucket.

By Protection Group

This tab provides a table of the Projection Job statistics for each External Target.

> **Note:** This tab does not reflect data that has been moved from the Cohesity cluster to theCloud Tier.

Column Name	Description
Protection Group	The name of the Protection Group.
Logical Data Transferred	**Data Protection**: The combined total of data in the objects that are protected by Cohesity. These metrics are different depending on workload type. • **VMs**: The data size reported by VMware is the provisioned amount, not the actual data residing in the VM. For example, if a VM is provisioned for 1TB but contains only 100GB of data, VMware reports it as 1TB. • **All Other Workloads**: The data size reported is the actual front end data residing on the server. If a server with 1TB capacity contains 100GB of data, the server reports 100GB. **Note:** - These metrics do not include unprotected objects. - Currently, the logical data value shown on the UI is a sum of the logical data values captured across all the protection runs. For instance, if the source has 100GB of logical data, and assuming it remains at 100GB for the first 10 protection runs, Cohesity would report, after 10 runs, the Logical Data to be 1000GB (1TB).
Physical Data Transferred	Data written to the External Target after the unique logical data has been reduced by data deduplication and data compression.
Storage Consumed	The total size of data stored on the Cohesity file system after all operations on the data (data deduplication, data compression, and data resiliency) have been accounted for.

Failed Objects

This report lists all the Objects for which an error occurred during the last protection runs and prevented the Objects from being backed up. Objects are entities such as VMs and Views that are protected by Protection Groups.

For information about how long the cluster keeps audit data, see Data Retention for Audits.

In the Actions panel, you can optionally filter the report results. Specify a Date Range, part of a Job Name, Object Type and Registered Source, and click **Apply Filters**.

Click the **Email** icon to provide information for scheduling report emails. For more information, see Email Reports. The **Scheduled Emails** tab on the Reports page displays those emails.

Click the **CSV** icon to download the current report as a CSV file to your device.

The summary table at the top of the report contains the following columns.

Column Name	Description
Type	The Object type.
Sources	The number of registered Sources for the Object type.
Total Objects	The total number of Objects that were selected to be backed up by the last protection runs.
Failed Objects	The number of Objects for which an error occurred during the last protection runs and prevented the Objects from being backed up.

Detailed tables are provided for each Object type and contain the following columns.

Column Name	Description
Object	The name of the Object, such as VM, View or Volume.
Failed Backup	The date and time of the protection run that encountered an error.
Run Type	The type of run specified in the Policy for the Job: • **Incremental**–When possible, utilizes Change Block Tracking (CBT) when capturing a Snapshot of this Object. • **Full**–Always captures a Full Snapshot of this Object and does not utilize Change Block Tracking (CBT). • **Log**–Captures database transaction logs to allow rolling back to a specific point in time.
Message	The message that indicates why the last protection run failed to back up this Object.

GDPR Objects Summary

This report provides information about whether an Object is protected, who has access to it, where Object Snapshots are stored and how long they are retained, and any actions

performed on the Object. Objects are entities such as VMs, physical servers, Views and storage volumes. You would typically run this report for Objects that contain Personally Identifiable Information (PII) as defined in the General Data Protection Regulation (GDPR).

Begin typing an Object name in the **Object Name** field and then select one or more Objects from the list.

You can filter the report results by changing the date range for the audit logs and then click **Apply Filters**.

Click the **Email** icon to provide information for scheduling report emails. For more information, see Email Reports. The **Scheduled Emails** tab on the Reports page displays those emails.

Click the **CSV** icon to download the current report as a CSV file to your device.

The report is organized by Objects and provides the following information. Mouse over the Object's icon to display its description.

Column Name	Description
Source	The name of the Source that hosts the Object.
Accessible By	The local users and Active Directory users or groups who have access to the Object based on their Cohesity role.
Protection Status	The name of the Protection Groups, if any, that back up the Source.
Data Locations	**Location:** Where Snapshots (backups) of the Source are located, including the local Cohesity cluster and any replication, archive and cloud tier targets. **Snapshots:** The number of Snapshots stored at each location. **Retention:** The retention period for the Snapshots as specified by the Policy associated with the Protection Group. **Expiration:** How long the Snapshot is available before it is deleted (based on the retention period). The **Data Locations** section of the report is available only if the Source is protected by a Protection Group.
Audit Logs	Shows the actions performed on the Source during the time period specified in the **Date Range** filter field. **Date:** When the action was performed. **User:** Who performed the action and whether the user is a local or Active Directory user. **Action:** Which action was performed, such as `ran a Protection Group`, `created a view` or `started recover task`.

Objects Protected by Multiple Protection Groups

This report lists all the Objects that have been backed up (protected) by more than one Protection Group. Objects are entities such as VMs and Views that are protected by Protection Groups.

A table is provided for each Object that has been backed up by multiple Protection Groups that match the specified search criteria. In the sub-heading of the table, a link to the protected Source is provided. Drill down on this link to get details and protection statistics about this Source on the Cohesity cluster. If you drill down on a VMware Source, the reported VM statistics reflect all VMs in the Source and is not specific to the current Protection Group.

In the table, a link to each of the Protection Groups is provided. Drill down on this link to get statistics about this Protection Group such as throughput, megabytes read, a list of job runs, job details and a job audit trail.

Using the top right **Sort results by...** drop-down, you can sort by the Object tables by the following criteria:

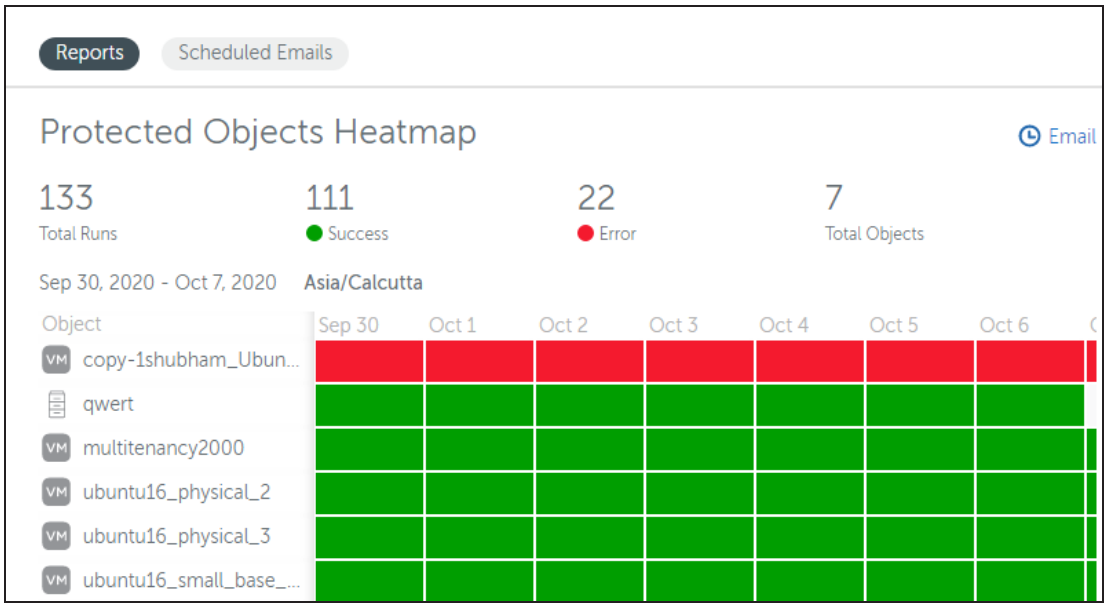
- **Sort by Object Name**
- **Sort by Projection Job Count**
- **Sort by Source**

By default, this page reports on all the Protection Groups for all the Sources in the Cohesity cluster. In the Actions panel, you can limit the results to report on the Protection Groups for specific Sources. In the **Registered Source** drop-down list, select one or more Sources and click **Apply Filters**. You cannot filter on Storage Domain Sources.

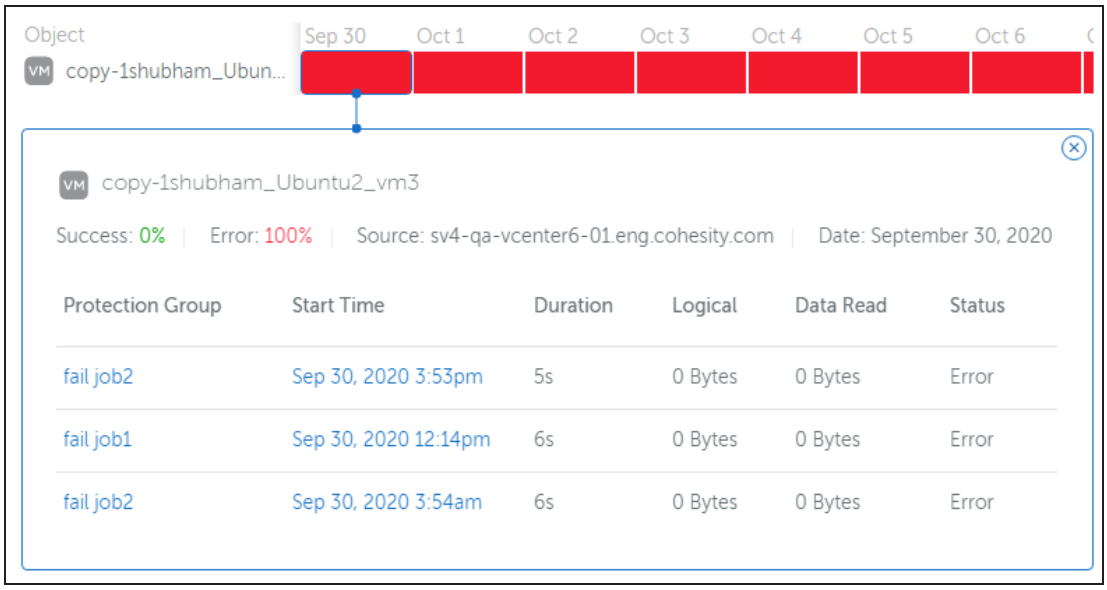
Protected Objects Heatmap

The Protected Objects Heatmap Report displays the status of the backup tasks of Objects that are associated with a Protection Group. This report lists the protected Objects.

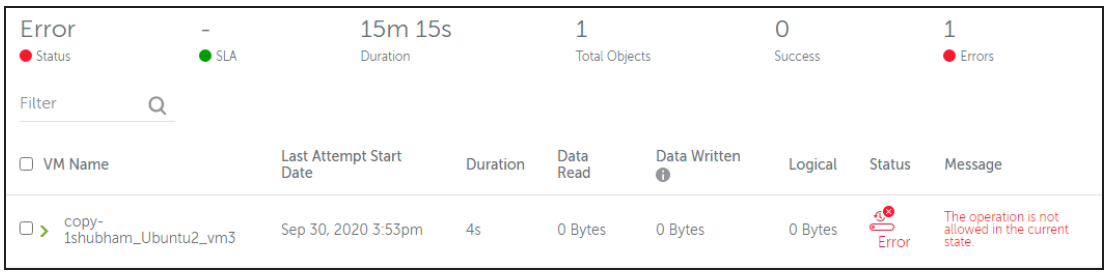
The report provides an interactive grid of cells. By default, the report shows the backup tasks for the last seven days. Each cell indicates whether the backup task runs were successful (green cells) or encountered errors (red cells). The Red cells indicate both the failed and missed job runs. Gray cells indicate a period for which there were no Job runs.



To find the root cause of an error, click a red cell to drill down to a list of Protection Group runs, then click the **Start Date** to drill down to job run details.



The **Message** column displays the error.



The right pane allows you to filter the report results. Use Date Range, Aggregate By, Time Zone, Object Type, Registered Source, Protection Group Name, Object Name, and Organizations to filter the report based on specific criteria. Click **Apply Filters** to view the report based on the specified criteria.

Click the **Email** icon to provide information for scheduling report emails. For more information, see Email Reports. The **Scheduled Emails** tab on the Reports page displays those emails.

> **Note:** The Protected Heatmap Report only allows to send an email in HTML format.

The report does not reflect the status of other Protection Group run tasks, such as replication or archive tasks. The Protection Runs Summary provides some of that information for Protection Groups.

To view another report, in the right-pane, from the **Select Report** drop-down, select the required report.

Protection Details Per Object

This report provides Protection Run (Snapshot) details for a leaf Protection Source Object (such as a VM).

For information about how long the cluster keeps audit data, see Data Retention for Audits.

To filter on Objects (such as VMs), in the **Object Name** field enter one or more leaf Protection Source Object names.

In the Actions panel, you can also optionally filter your results by Date Range or Run Status of the protection run. The **All Jobs** option clears the other run status options.

Click the **Email** icon to provide information for scheduling report emails. For more information, see Email Reports. The **Scheduled Emails** tab on the Reports page displays those emails.

Click the **CSV** icon to download the current report as a CSV file to your device.

The columns for the table of this report are described below. To sort the list in the table by Column type, click the Column header. To reverse the sorting, click the Column header again.

Column Name	Description
Start Time	The time this protection run started.
Protection Group Name	The name of the Protection Group.

Column Name	Description
End Time	The time this protection run ended.
Status	The current status of the protection run: • **Success**–Indicates that the protection run was successful. • **Running**–Indicates that the protection run is currently running. • **Warning**–Indicates that the protection run was successful but warnings were detected. • **Canceled**–Indicates that the protection run was canceled before completing. • **Error**–Indicates the protection run encountered an error and did not run to competition.
Schedule Type	The type of run specified in the Policy for the Job: • **Incremental**–When possible, utilizes Change Block Tracking (CBT) when capturing a Snapshot of this Object. • **Full**–Always captures a Full Snapshot of this Object and does not utilize Change Block Tracking (CBT). • **Log**–Captures database transaction logs to allow rolling back to a specific point in time.
Data Read	The total number of bytes read for this Object during this protection run.
Logical	The total number of logical bytes protected for this Object during this protection run. Indicates the size of the data if the data is fully hydrated or expanded. The actual physical data stored on the Cohesity cluster is reduced by change-block tracking, compression and deduplication.
Copy Task Status	The status of copy tasks for this protection run such as replication and archival tasks. These tasks copy Snapshots to a Remote Cohesity Cluster or External Targets.

Protection Groups Inventory and Schedule

This report lists all the Protection Groups on the Cohesity cluster matching the specified filter criteria. For each Protection Group, this report lists all the Objects that will be backed up by this group and the schedule for when the Objects will be backed up. Objects are entities such as VMs and Views that are protected by Protection Groups.

A table is provided for each Protection Group and all the Objects that will be protected by this Protection Group are listed that match the specified filter criteria. The title for the table is the name of the Protection Group and a link. Drill down on this link to get statistics about this Protection Group such as throughput, megabytes read, a list of job runs, job details and a job audit trail.

In the sub-heading of the table, a link to the Source is provided. Drill-down on the link to get more information about the Source:

- **Source is a hypervisor**Drill-down on this link to get details and protection statistics about this registered Source on the Cohesity cluster. The VM statistics reported in the drill-down page reflect all VMs that use the Source and is not specific to the current Protection Group. In the table, a link to each of the VMs is provided. Drill down on this link to get statistics about the files stored in this Server.
- **Source is a Storage Domain**—Drill down on this link to get storage statistics about the Storage Domain.

Using the top right **Sort results by...** drop-down, you can sort by the Job tables by the following criteria:

- **Sort by Job Name**
- **Sort by Source**

In the Actions panel, you can also optionally filter your results by Job or VM name. You can enter part of a Job name and/or VM name and click **Apply Filters**.

Click the **Email** icon to provide information for scheduling report emails. For more information, see Email Reports. The **Scheduled Emails** tab on the Reports page displays those emails.

Click the **CSV** icon to download the current report as a CSV file to your device.

Protection Runs Summary

This report provides information about Protection Group runs and related replication and archival tasks. If the protection run has multiple replication or archival targets configured, only the first of each is displayed in the report.

You can filter the report results by changing the date range and then clicking **Apply Filters**.

Click the **Email** icon to provide information for scheduling report emails. For more information, see Email Reports. The **Scheduled Emails** tab on the Reports page displays those emails.

Click the **CSV** icon to download the current report as a CSV file to your device.

The report contains the following columns.

Column Name	Description
Protection Group Name	The name of the Protection Group.
Start Time	The date and time the Protection Group started running.

Column Name	Description
Duration	The amount of time the Protection Group run required.
Bytes Read	The size of the set of protected objects as read by Cohesity for a single backup run. This number is a per protection run statistic and is not additive across backup runs.
Status	Whether the protection run was successful or not.
Replication	If snapshots are replicated for this protection run, this column indicates the name of the remote replication cluster. Otherwise, the column is empty. You can drill down on the cluster name for details.
Replication Status	Indicates whether the replication was successful or not.
Replication Duration	The amount of time the replication required.
Bytes Transferred	Total unique logical data received by Cohesity. For Data Protection, this is the sum of your first full backup and subsequent change data captured by Cohesity.
Archival	If snapshots are archived for this Protection Group, this column indicates the name of the archival destination. Otherwise, the column is empty. You can drill down on the archival destination name for details.
Archival Status	Indicates whether the archival was successful or not.
Archival Duration	The amount of time the archival required.
Bytes Transferred	The number of bytes transferred to the archival destination.

Protection Summary By Object Type

This report shows the protection status of Objects as of the last protection runs that occurred in the specified Date Range. Objects are entities such as VMs and Views that are protected by Protection Groups.

For information about how long the cluster keeps audit data, see Data Retention for Audits.

In the Actions panel, you can optionally filter the report results. Specify a Date Range, part of a Job Name, Object Type and Registered Source, and click **Apply Filters**.

Click the **Email** icon to provide information for scheduling report emails. For more information, see Email Reports. The **Scheduled Emails** tab on the Reports page displays those emails.

Click the **CSV** icon to download the current report as a CSV file to your device.

The summary table at the top of the report contains the following columns.

Column Name	Description
Type	The Object types displayed in the report.
Sources	The number of registered Sources for the Object type.
Objects	The number of protected Objects in the source.
Success	The number of Objects that were successfully backed up by the last protection runs that occurred during the specified Date Range.
Error	The number of Objects for which an error occurred (and the Object was not backed up) during the last protection runs that occurred during the specified Date Range.
Running	The number of Protection Groups currently running.
Data Read	The total number of bytes read for this Object by the last protection runs that occurred during the specified Date Range.
Logical	The total number of logical bytes protected for this Object by the last protection runs that occurred during the specified Date Range. Indicates the size of the data if the data is fully hydrated or expanded. The actual physical data stored on the Cohesity cluster is reduced by change-block tracking, compression and deduplication.

The Object type tables contain the following columns.

Column Name	Description
Object	The name of the Object, such as VM, View or Volume.

Column Name	Description
Last Run Status	The status of the last protection run: • **Success**–Indicates that the protection run was successful. • **Running**–Indicates that the protection run is currently running. • **Warning**–Indicates that the protection run was successful but warnings were detected. • **Canceled**–Indicates that the protection run was canceled before completing. • **Error**–Indicates the protection run encountered an error and did not run to completion.
Start Time	The time this protection run started.
End Time	The time this protection run ended.
Run Type	The type of run specified in the Policy for the Job: • **Incremental**–When possible, utilizes Change Block Tracking (CBT) when capturing a Snapshot of this Object. • **Full**–Always captures a Full Snapshot of this Object and does not utilize Change Block Tracking (CBT). • **Log**–Captures database transaction logs to allow rolling back to a specific point in time.
Data Read	The total number of bytes read for this Object during this protection run.
Logical	The total number of logical bytes protected for this Object by protection runs that occurred during the specified Date Range. Indicates the size of the data if the data is fully hydrated or expanded. The actual physical data stored on the Cohesity cluster is reduced by change-block tracking, compression and deduplication.

Source Growth & Variance

This report shows how the size of protected Servers per registered Source are changing over time.

This report provides the following chart:

- **Sources Growth**—This chart shows how the size of the protected Servers per Source is changing over the specified number of days. The size of a Server is reported if the Server has been selected to be backed up (protected).

In the **Calculate Variance Over Specified Days** field of the Actions panel, you can specify the number of days used to calculate the following:

- The number of days to show the growth in the **Source Growth** chart.
- Calculate the **# Objects Backed Up (<Num> days ago)** column in the table
- Calculate the **Unique on Primary (<Num> Days Ago)** column in the table.
- Calculate the **Variance of Unique on Primary** column in the table.

Enter a number of days (from 1 to 180) and click **Apply Filters**.

In the Actions panel, you can also optionally filter your results by Source. In the **Registered Source** drop-down list, select one or more Sources and click **Apply Filters**.

Click the **Email** icon to provide information for scheduling report emails. For more information, see Email Reports. The **Scheduled Emails** tab on the Reports page displays those emails.

Click the **CSV** icon to download the current report as a CSV file to your device.

The columns for the table at the bottom of this report are described below. To sort the list in the table by Column type, click the Column header. To reverse the sorting, click the Column header again. By default, this table is sorted by the **Primary Physical** column.

Column Name	Description / Action
Source	Drill-down on this link to get details and protection statistics about this registered Source on the Cohesity cluster. **Note:** The VM statistics reported in the drill-down page reflect all VMs that use the Source and is not specific to the current Protection Group.
# Objects Backed Up	As of today, the number of Objects that are successfully backed up by the Cohesity cluster for the current Source.
# Objects Backed Up (<Num> Days ago)	As of a past date, the number of VMs that were successfully backed up by the Cohesity cluster for the current Source. The past date is calculated from the current date and time minus the number of days specified in the **Calculate Variance Over Specified Days** field in the Actions panel.
Logical	As of today, the total amount of logical data on the protected Servers per Source. Indicates the size of the data if the data is fully hydrated or expanded.

Column Name	Description / Action
Unique on Primary	As of today, the total amount of physical storage required to store all the protected VMs on the primary storage device. (This is not the secondary storage consumed on the Cohesity cluster.) For VMware VMs, this metric is provided by the VMware API and corresponds to the `uniqueSize` property as defined in the VMware documentation.
Unique on Primary (<Num> Days Ago)	The same as **Unique on Primary**, but as of a past date. The past date is calculated from the current date and time minus the number of days specified in the **Calculate Variance Over Specified Days** field in the Actions panel.
Variance of Unique on Primary	This field shows the percentage difference between the two **Unique on Primary** fields defined above.The past date is calculated from the current date and time minus the number of days specified in the **Calculate Variance Over Specified Days** field in the Actions panel. The Variance is calculated using the following formula: `( (Unique on Primary Data Used Today - Unique on Primary Data Used on a Past Date) / Unique on Primary Data Used on a Past Date) * 100`

Sources Protected

This report provides overview statistics about the number of Servers protected or unprotected for registered Sources on the Cohesity cluster.

This report contains the following chart:

- **Total Protection Across Sources**—This doughnut chart shows the protection level of all Sources registered in the Cohesity cluster.

This report contains the following Table:

- **Protection by Source**—This table provides statistics about all Sources in the Cohesity cluster as described below.

Column Name	Description / Action
Source	Drill-down on this link to get details and protection statistics about this registered Source on the Cohesity cluster. > **Note:** The VM statistics reported in the drill-down page reflect all VMs that use the Source and is not specific to the current Protection Group.

Column Name	Description / Action
Protected Servers	Lists the number of protected Servers in this Source that are backed up by Jobs.
Unprotected Servers	Lists the number of unprotected Servers in this Source that are not backed by Jobs.
Protection Groups	Lists the number of Protection Groups that back up this Source.
Registered	Date and time that the Source was registered on the Cohesity cluster.
Refreshed	Date and time that the Object hierarchy for the Source has been refreshed on the Cohesity cluster. The Cohesity cluster tracks all the objects (for example VMs, resource pools, datacenters, folders, and ESXi hosts) found within a source in an object hierarchy. This object hierarchy is automatically refreshed every four hours. If a new object such as a VM is added to the source, the Cohesity Dashboard does not list the new VM until the object hierarchy is refreshed, either manually or automatically after four hours. To manually force a refresh of the Object hierarchy, select **Data Protection > Sources** , find the Source in the list and click .

Storage Consumed by Protection Groups

This report provides statistics about the Protection Groups that are consuming the most disk space on the Cohesity cluster. This report provides statistics for all types of Objects. Objects are entities such as VMs and Views that are protected by Protection Groups.

This report provides the following charts:

- **Top <Num> Protection Groups by Logical Data Managed**—This chart lists up to ten Protection Groups that match the specified filter criteria and have stored the largest amount of logical data from a Source. Indicates the size of the data if the data is fully hydrated or expanded. The actual physical data stored on the Cohesity cluster is reduced by change-block tracking, compression and deduplication.

In the **Calculate Variance Over Specified Days** field of the Actions panel, you can specify the number of days used to calculate the **Logical Managed (At <Num> Days Ago)** and **Variance of Logical Managed** columns in the table. Enter a value from 1 to 180 and click **Apply Filters**. In the Actions panel, you can also optionally filter your results by Registered Sources or Storage Domains. Select a Storage Domain and Sources to filter by and click **Apply Filters**.

Click the **Email** icon to provide information for scheduling report emails. For more information, see Email Reports. The **Scheduled Emails** tab on the Reports page displays those emails.

Click the **CSV** icon to download the current report as a CSV file to your device.

The columns for the table at the bottom of this report are described below. To sort the list in the table by Column type, click the Column header. To reverse the sorting, click the Column header again. By default, this table is sorted by the **Total Physical Written** column from smallest to largest.

Column Name	Description / Action
Protection Group	Drill down on this link to get statistics about this Protection Group such as throughput, megabytes read, a list of job runs, job details and a job audit trail.
Total Runs	The total number of times this Protection Group has run based on the specified search criteria.
Objects	The total number of Objects backed by all the Runs of this Protection Group based on the specified search criteria. For example if a Protection Group backs up 3 VMs and runs twice, a total of 6 Objects is reported in this column.
Storage Domain	The Storage Domain that is used to store the data backed up by this Job.
Logical (total)	**Data Protection**: The combined total of data in the objects that are protected by Cohesity. These metrics are different depending on workload type. • **VMs**: The data size reported by VMware is the provisioned amount, not the actual data residing in the VM. For example, if a VM is provisioned for 1TB but contains only 100GB of data, VMware reports it as 1TB. • **All Other Workloads**: The data size reported is the actual front end data residing on the server. If a server with 1TB capacity contains 100GB of data, the server reports 100GB. **Note:** - These metrics do not include unprotected objects. - Currently, the logical data value shown on the UI is a sum of the logical data values captured across all the protection runs. For instance, if the source has 100GB of logical data, and assuming it remains at 100GB for the first 10 protection runs, Cohesity would report, after 10 runs, the Logical Data to be 1000GB (1TB).
Logical (total at <Num> days ago)	As of a past date, the total amount of logical data stored on the Cluster by all the Runs of this Protection Group that matches the specified filter criteria. Indicates the size of the data if the data is fully hydrated or expanded. The actual physical data stored on the Cohesity cluster is reduced by change-block tracking, compression and deduplication. The past date is calculated from the current date and time minus the number of days specified in the **Calculate Variance Over Specified Days** field in the Actions panel.

Column Name	Description / Action
Variance of Logical Managed	The percentage difference between the values of Logical (total) today, and Logical (total) x days ago, where x is a user input value.
Data In	Total unique logical data residing on the Cohesity cluster. This is the sum of your first full backup and subsequent change data captured by Cohesity as measured in units of source-side bytes.
Data Written	Data written and retained on the Cohesity cluster, as measured in post-dedupe and post-compression bytes.
Storage Consumed	The total size of data stored on the Cohesity file system, as measured in bytes after all operations on the data (data deduplication, data compression, and data resiliency) have been accounted for. This data can be stored either all locally or as a combination of local storage and in the Cloud Tier (if Cloud Tier is enabled). For example, if the Data Written is 100GB and resiliency is set to RF3, leading to the need for an additional 200GB of space, the resulting Storage Consumed is 300GB. If the Data Written is 100GB and resiliency is set to EC4:2, leading to the need for an additional 50GB (as for every 4 data fragments, 2 parity fragments are added), the resulting Storage Consumed is 150GB. > **Note:** If you have enabled Cloud Tiering, then Storage Consumed is the sum of space consumed on local storage and space consumed on the cloud tier. In such cases, the sum of Storage Consumed value and Capacity Available value for the cluster can exceed the cluster capacity.
Storage Consumed (<Num> days ago)	The total size of data stored on the Cohesity file system, as measured in bytes after all operations on the data (data deduplication, data compression, and data resiliency) have been accounted for over the number of days.
Growth Rate	Shown as a percentage, the increase in “storage consumed” over the time period specified in the report’s filter.
Daily Growth Rate	Daily growth rate for the Storage Consumed value over the time window specified in the report’s filter. Where Storage Consumed is the total size of data as measured in bytes stored on the Cohesity file system after all operations on the data (data deduplication, data compression, and data resiliency) have been accounted for.
Storage Reduction	The ratio of Logical Data to Storage Consumed.

Storage Consumed by File Categories

This report provides data statistics about File Categories in the latest Snapshots for all Servers stored on the Cohesity cluster. Statistics are only reported for files indexed by the Cohesity cluster.

> **Note:** The report only provides data statistics about File Categories in the latest Snapshots for all Servers and not other Objects like Views.

A file in a Snapshot is not indexed due to one of the following reasons:

- In the Protection Group that creates the Snapshot, the directory where the file is located was not selected to be indexed.

To get File Category statistics for a specific Server, go to the Storage Consumed by Servers and drill-down on the Servers in the Protected Object column.

This report provides the following chart:

- **Top Categories by Size in Cluster**—This chart lists the collections of files of similar types that store the largest amount of logical space for the last Snapshots of all the Servers on the Cohesity cluster. For example, the **image** file category reports all the files that end with image file extensions such as `*.png`, `*.tif`, `*.jpg`, `*.gif` etc.

In the **Calculate Variance Over Specified Days** field of the Actions panel, you can specify the number of days used to calculate the **Data Size (total, <Num> Days Ago)** and the **Variance** columns in the table. Enter a value from 1 to 180 and click **Apply Filters**.

Click the **Email** icon to provide information for scheduling report emails. For more information, see Email Reports. The **Scheduled Emails** tab on the Reports page displays those emails.

Click the **CSV** icon to download the current report as a CSV file to your device.

The columns for the table at the bottom of this report are described below. To sort the list in the table by Column type, click the Column header. To reverse the sorting, click the Column header again. By default, this table is sorted by the **Total Logical Data Written** column.

Column Name	Description
File Category	The name of the file category. For example, the **image** file category reports all the files that end with image file extensions such as `*.png`, `*.tif`, `*.jpg`, `*.gif` etc.
Number of Files	The number of files of the current category found in the latest Snapshots for all the Servers in the Cohesity cluster. Statistics are only reported for files indexed by the Cohesity cluster. See notes above.

Column Name	Description
Data Size (total)	As of today, the total size of the data, prior to deduplication and compression, for all the files in this Category found in the latest Snapshots for all the Servers in the Cohesity cluster. Statistics are only reported for files indexed by the Cohesity cluster.
Data Size (total, <Num> Days Ago)	The same as **Data Size (total)**, but as of a past date. The past date is calculated from the current date and time minus the number of days specified in the **Calculate Variance Over Specified Days** field in the Actions panel.
Variance	This field shows the difference between the two **Data Size** fields defined above. Statistics are only reported for files indexed by the Cohesity cluster. The Variance is calculated using the following formula: `( (Data Size as of Today - Data Size on a Past Date)/ Data Size on a Past Date) * 100`

Storage Consumed by Organizations

This report provides information about the organizations consuming the most storage. For more information about organizations, see Manage Organizations (Tenants).

Click the **Email** icon to provide information for scheduling report emails. For more information, see Email Reports. The **Scheduled Emails** tab on the Reports page displays those emails.

Click the **CSV** icon to download the current report as a CSV file to your device.

This report consists of the following two tabs:

- Physical Usage
- Workload

Physical Usage Tab

The **Physical Usage** tab is displayed only in the Service Provider login. You must use the **Storage Consumed by Organizations** report available in the Service Provider login for billing purposes.

> **Note:** The data displayed on the **Physical Usage** tab is refreshed between 2 to 7 days.

By default, the report displays all storage domains and organizations in the cluster, but you can filter the data by:

- Storage domain(s)
- Organization(s)

The **Physical Usage** tab consists of the following two charts:

- Top organizations by Storage Consumed
- Top organizations by Storage Reduction Ratio

The following table describes the fields displayed on the **Physical Usage** tab:

Column Name	Description
Organization Name	The name specified for the organization when added to the cluster.
Storage Domain	The name of the storage domain assigned to the organization.
Logical Data	Data residing on the primary object.
Data In	Data sent from primary objects to Cohesity.
Data Written	Data to be written post-deduplication.
Storage Consumed	Data written with all copies required for honoring the resiliency setting.
Dedupe Ratio	Part of the data-reduction process that eliminates redundant copies of data to reduce storage required on the cluster. The ratio reflects the original size of data versus the size of the data after eliminating redundancy.
Compression Ratio	Part of the data-reduction process that performs a compression operation within a file or a set of files and further reduces the storage requirements. The ratio reflects the size of uncompressed data versus the size of compressed data.
Storage Reduction Ratio	The ratio of Logical Data to Storage Consumed.

Workload Tab

The **Workload** tab displays the following two charts:

- Top Organizations by Backup Data
- Top Organizations by View Data

> **Note:** The data displayed on the **Workload** tab is refreshed in real time.

> **Note:** The **Physical Usage** tab is not displayed in the tenant login. Do not use the **Storage Consumed by Organizations** report in the tenant login for billing purposes.

By default, the report displays all organizations in the cluster, but you can filter the data by organization(s). In the **Calculate Variance Over Specified Days** field, you can specify the number of days used to calculate the **Daily Logical Storage Growth Rate** column in the table. Enter a value and click **Apply Filters**.

The following table describes the fields displayed on the **Workload** tab:

Column Name	Description
Organization Name	The name specified for the organization when added to the cluster.
Storage Domain	The name of the storage domain assigned to the organization.
Data In	Data sent from primary objects to Cohesity.
Logical Used by Backups	Logical storage consumed by backups.
Protected Objects Count	The number of objects protected.
Physical Used by Backups	Physical storage consumed by backups.
Daily Logical Storage Growth Rate	This field shows the percentage daily growth rate of the total logical size of the views for the organization in this Storage Domain. The percentage daily growth rate is calculated using the following formula: `( (Sum of logical size of views Today - Sum of logical size of views of a Past Date) / ( (Number of Days Specified + 1) * Sum of logical size of views of a Past Date ) ) * 100` The past date is calculated from the current date and time minus the number of days specified in the **Calculate Growth Over Specified Days** field in the Actions panel.
Logical Used by Views	Logical storage consumed by views.

Storage Consumed by Servers

This report provides statistics about the Servers that are using the most disk space on the Cohesity cluster and Primary Storage. This report provides statistics about Servers only and not other Objects like Views.

This report provides the following charts

- **Top <Num> Servers by Primary Physical**—This chart lists up to twenty Servers whose Snapshots are using the most disk space on the Cohesity cluster that match the specified filter criteria.

In the **Calculate Variance Over Specified Days** field of the Actions panel, you can specify the number of days (from 1 to 180) used to calculate the **Primary Physical (At <Num> Days Ago)** and **Variance of Primary Physical** columns in the table. In the Actions panel, you can also optionally filter your results by Job Name, Registered Sources or a Storage Domain. You can enter part of a Job name, select one or more Registered Sources or a Storage Domain from the drop-down lists and click **Apply Filters**.

> **Note:** The data displayed in the **Storage Consumed by Servers** report is refreshed every six minutes.

Click the **Email** icon to provide information for scheduling report emails. For more information, see Email Reports. The **Scheduled Emails** tab on the Reports page displays those emails.

Click the **CSV** icon to download the current report as a CSV file to your device.

The columns for the table at the bottom of this report are described below. To sort the list in the table by Column type, click the Column header. To reverse the sorting, click the Column header again. By default, this table is sorted by the **Primary Physical** column from smallest to largest.

Column Name	Description / Action
Protected Object	Drill down on this link to get statistics about the files stored in this Server.
Job Name	Drill down on this link to get statistics about this Protection Group such as throughput, megabytes read, a list of job runs, job details and a job audit trail.
Storage Domain	The Storage Domain that is used to store the Snapshots made by the listed Protection Group of this Protected Object (Server).

Column Name	Description / Action
Snapshots	The total number of Snapshots of this Server created by all the Runs of the listed Protection Group that are currently stored on the Cohesity cluster and match the specified filter criteria. Snapshots that have been deleted because they exceeded the retention policy limit defined by the Protection Group are not counted.
Last Snapshot	The creation time and date of the last Snapshot of this Object (Server) created by the listed Protection Group that matches the specified filter criteria and currently stored on the Cohesity cluster.
Logical	The total capacity of the protected Source object, including free and used space. For more information, see Understanding Storage Metrics
Unique on Primary	Current value of actual data residing on source. Protected data is either equal to or less than this value for this source. The use-case where certain drives are excluded from protection is where this value is greater than the value of data protected from the object / source in the latest run.
Unique on Primary (<Num> Days Ago)	The same as **Unique on Primary**, but as of a past date. The past date is calculated from the current date and time minus the number of days specified in the **Calculate Variance Over Specified Days** field in the Actions panel.
Variance of Unique on Primary	Percentage difference between the values of Unique on Primary today, and Unique on Primary x days ago, where x is a user input value.

Storage Consumed by File Categories for Server: <myServer>

This report provides logical data statistics about File Categories and File Sizes for the last Snapshot of this Server created by the listed Protection Group. Statistics are only reported for files indexed by the Cohesity cluster.

A file in a Snapshot is not indexed due to one of the following reasons:

- In the Protection Group that creates the Snapshot, the directory where the file is located was not selected to be indexed.

This page provides the File Categories and File Size tabs that each contain a chart and table as described below.

File Categories

This tab provides the following chart:

- **Top Categories by Size**—This chart lists the collections of files of similar types that have the largest amount of logical space stored the Cohesity cluster for the last

Snapshot of this Server created by the listed Protection Group. Statistics are only reported for files indexed by the Cohesity cluster. See above for details. For example, the **image** file category reports all the files that end with image file extensions such as `*.png`, `*.tif`, `*.jpg`, `*.gif` etc.

In the **Calculate Daily Variance Over Specified Days** field of the Actions panel, you can specify the number of days used to calculate the **Total Logical Data Written (<Num> Days Ago)** and the **Variance** columns in the table. Enter a value from 1 to 180 and click **Apply Filters**.

This tab also provides the following table that lists statistics about the file categories found in the last Snapshot of this Server created by the listed Protection Group. To sort the list in the table by Column type, click the Column header. To reverse the sorting, click the Column header again. By default, this table is sorted by the **Total Logical Data Written** column.

Column Name	Description
File Category	The name of the file category. For example, the **image** file category reports all the files that end with image file extensions such as `*.png`, `*.tif`, `*.jpg`, `*.gif` etc.
Number of Files	The number of files of this category found in the last Snapshot of this Server created by the listed Protection Group. Statistics are only reported for files indexed by the Cohesity cluster.
Total Logical Data Written	As of today, the total size of the logical data for all the files in this Category is found in the last Snapshot of this Server created by the listed Protection Group. Statistics are only reported for files indexed by the Cohesity cluster. Indicates the size of the data if the data is fully hydrated or expanded. The actual physical data stored on the Cohesity cluster is reduced by change-block tracking, compression and deduplication.
Total Logical Data Written (<Num> Days Ago)	As of a past date, the total size of the logical data for all the files in this Category found in the last Snapshot of this Server created by the listed Protection Group. Indicates the size of the data if the data is fully hydrated or expanded. The actual physical data stored on the Cohesity cluster is reduced by change-block tracking, compression and deduplication. The past date is calculated from the current date and time minus the number of days specified in the **Calculate Variance Over Specified Days** field in the Actions panel.
Variance	This field shows the difference between the total logical data size for all the files in this Category found in the last Snapshot of this Server created by the listed Protection Group as of today compared to the total logical data size for all the files in this Category found in the last Snapshot of this Server created by the listed Protection Group as of a past date. The Variance is calculated using the following formula: `( (Total Logical Data Written as of Today - Total Logical Data Written on a Past Date)/ Total Logical Data Written on a Past Date) * 100`

File Size

This tab provides the following chart:

- **Top 20 Files by Size**—This chart lists the top twenty files with the largest amount of logical space found in the last Snapshot of this Server created by the listed Protection Group.

This tab also provides the following table that lists the top twenty files with the largest amount of logical space found in the last Snapshot of this Server created by the listed Protection Group. To sort the list in the table by Column type, click the Column header. To reverse the sorting, click the Column header again. By default, this table is sorted by the **Latest Logical Data Size** column.

Column Name	Description
File Name	The name of the file containing the logical data.
Latest Logical Data Size	The total size of the logical data for this file is found in the last Snapshot of this Server created by the listed Protection Group. Indicates the size of the data if the data is fully hydrated or expanded. The actual physical data stored on the Cohesity cluster is reduced by change-block tracking, compression and deduplication.

Storage Consumed by Storage Domains

This report provides information about the Storage Domains that are storing the most logical data and raw data data on the Cohesity cluster.

This report provides the following charts:

- **Top <Num> Storage Domains by Storage Used**—This chart lists up to ten Storage Domains that have stored the largest amount of data.
- **Top <Num> Jobs by Logical Data Managed**—This chart lists up to ten Storage Domains that have stored the largest amount of logical data from a Source.

In the **Calculate Variance Over Specified Days** field of the Actions panel, you can specify the number of days used to calculate the **Daily Storage Growth Rate** column in the table. Enter a value and click **Apply Filters**.

> **Note:** The data displayed in the **Storage Consumed by Storage Domains** report is refreshed every six minutes.

Click the **Email** icon to provide information for scheduling report emails. For more information, see Email Reports. The **Scheduled Emails** tab on the Reports page displays those emails.

Click the **CSV** icon to download the current report as a CSV file to your device.

The columns for the table at the bottom of this report are described below. To sort the list in the table by Column type, click the Column header. To reverse the sorting, click the Column header again. By default, this table is sorted by the **Total Physical Data Written** column from smallest to largest.

Column Name	Description
Storage Domain	The name of the Storage Domain.
Logical	The sum of the logical sizes of all the protected Source objects, such as a VM, physical server or NAS share, stored in this Storage Domain. The logical size is the total capacity of the object, including free space and used space. For more information, see Understanding Storage Metrics.
Raw Used	Total space consumption which is the sum of storage consumption and space reserved for Cohesity software operations
Raw Used (<Num> Days Ago)	Same as **Raw Used**, but as of a past date. The past date is calculated from the current date and time minus the number of days specified in the **Calculate Growth Over Specified Days** field in the Actions panel.
Daily Storage Growth Rate	Daily growth rate for the **Storage Consumed** value.

Top Protection Group

This report shows the top Protection Groups by the average amount of data transferred, the length of Protection Group run time, the number of Objects protected and the number of SLA violations. Objects are entities such as VMs and Views that are protected by Protection Groups.

This report provides the following charts:

- **Data Read (average per run)**—This chart shows the top Protection Groups that have the highest average of data transferred. The average is calculated over all the runs of a Protection Group.

- **Average Run Time**—This chart shows the top Protection Groups that have the longest average run time. The average is calculated over all the runs of a Protection Group.
- **Total Objects Backed Up**—This chart shows the top Protection Groups that have the largest number of backed-up Objects. Objects are entities such as VMs and Views that are protected by Protection Groups.
- **Total SLA Violations**—This chart shows the top Protection Groups that have the largest number of SLA violations. An SLA violation occurs when the run time of the Protection Group exceeds the SLA time period specified in the Protection Group.

In the Actions panel, you can also optionally filter your results by Data Range, Job Name or Registered Source. You can specify a Date Range, enter part of a Job name, or select one or more Sources from the Registered Source drop-down list and click **Apply Filters**. You cannot filter on Storage Domain Sources.

In addition, the Top Jobs Report provides the Data Transferred, Run Time and SLA Violations tabs that each contain a table as described below.

Data Transferred Tab

This table lists the top Protection Groups that have the highest average of data transferred. To sort the list in the table by Column type, click the Column header. To reverse the sorting, click the Column header again. By default, this table is sorted by the **Average Transferred** column from largest to smallest.

Column Name	Description / Action
Job Name	Drill down on this link to get statistics about this Protection Group such as throughput, megabytes read, a list of job runs, job details and a job audit trail.
Source	The Source that contains the Objects the Job is protecting. Objects are entities such as VMs and Views that are protected by Protection Groups.
Objects	The number of Objects protected by this Protection Group matches the filter criteria. Objects are entities such as VMs and Views that are protected by Protection Groups.
Data Read (average per run)	The average number of bytes read from Sources over all runs of this Protection Group matching the filter criteria
Data Read (total)	The cumulative number of bytes read from Sources for all the runs of this Protection Group matches the filter criteria. The amount of data actually stored on the Cluster is reduced by compression and deduplication.

Column Name	Description / Action
Data Reduction	The data reduction ratio is calculated by dividing the Logical Data Managed by the Physical Data Used. **Logical Data Written**–Indicates the size of the data if the data is fully hydrated or expanded. The actual physical data stored on the Cohesity cluster is reduced by change-block tracking, compression and deduplication. **Physical Data Written**–The size of the data physically stored on the Cohesity cluster, after the data has been reduced by change block tracking, compression and deduplication, including the disk space used for data resiliency (fault tolerance and erasure coding).

Run Time Tab

This table lists the top Protection Groups that have the longest average run time. The average is calculated over all the runs of a Protection Group. To sort the list in the table by Column type, click the Column header. To reverse the sorting, click the Column header again. By default, this table is sorted by the **Avg Run Time** column from longest to shortest.

Column Name	Description / Action
Job Name	Drill down on this link to get statistics about this Protection Group such as throughput, megabytes read, a list of job runs, job details and a job audit trail.
Source	The Source that contains the Objects the Job is protecting. Objects are entities such as VMs and Views that are protected by Protection Groups.
Protection Runs	The number of times this Protection Group has run within the specified filter criteria.
Avg Run Time	The average amount of run time for all the Runs of this Protection Group that match the specified filter criteria.
Min Run Time	The minimum amount of run time for all the Runs of this Protection Group that match the specified filter criteria.
Max Run Time	The maximum amount of run time from all the Runs of this Protection Group that match the specified filter criteria.

SLA Violations Tab

This table lists the top Protection Groups that have the largest number of SLA Violations. To sort the list in the table by Column type, click the Column header. To reverse the sorting, click the Column header again. By default, this table is sorted by the **SLA Violations** column from smallest to largest.

Column Name	Description / Action
Job Name	Drill down on this link to get statistics about this Protection Group such as throughput, megabytes read, a list of job runs, job details and a job audit trail.
Source	The Source that contains the Objects the Job is protecting. Objects are entities such as VMs and Views that are protected by Protection Groups.
Protection Runs	The number of times this Protection Group has run within the specified filter criteria.
Avg Run Time	This column reports the average amount of time the Protection Group Run takes to complete over all Runs of this Protection Group that match the specified filter criteria.
SLA	The SLA time period specified for this Protection Group when the Job was created or last edited. The service-level agreement (SLA) defines how long the administrator expects protection run to take.
SLA Violations	The number of Runs of this Protection Group that match the specified filter criteria that have taken longer than the SLA time period specified for this Protection Group.

Unprotected/Protected VMs

This report provides lists of VMs that are protected and not protected by Cohesity for the registered Sources on the Cohesity cluster. In addition, overview statistics about protected and unprotected VMs are provided.

This report provides the following tabs:

- **Unprotected VMs**—Lists the VMs that are not protected by Jobs on the Cohesity cluster grouped by registered Source.
- **Protected VMs**—Lists the VMs that are protected by Jobs on the Cohesity cluster grouped by registered Source.

Click the **Email** icon to provide information for scheduling report emails. For more information, see Email Reports. The **Scheduled Emails** tab on the Reports page displays those emails.

Click the **CSV** icon to download the current report as a CSV file to your device.

Each tab provides tables with the columns described below. You can sort by VM Size by clicking the triangle next to the VM Size heading.

Column Name	Description / Action
VM Name	The name of the VM.
VM Size	**Data Protection**: The combined total of data in the objects that are protected by Cohesity. The data size reported by VMware is the provisioned amount, not the actual data residing in the VM. For example, if a VM is provisioned for 1TB but contains only 100GB of data, VMware reports it as 1TB. **Note:** - These metrics do not include unprotected objects. - Currently, the logical data value shown on the UI is a sum of the logical data values captured across all the protection runs. For instance, if the source has 100GB of logical data, and assuming it remains at 100GB for the first 10 protection runs, Cohesity would report, after 10 runs, the **Logical Data** to be 1000GB (1TB).
Indexed	This applies to Protected VMs only. The current state of indexing of the VM: • **Fully-Indexed**–All the files in the VM were successfully indexed. • **Not-Indexed**–No files in the VM were indexed. Maybe indexing was not enabled for the Protection Group protecting this VM. • **Partially-Indexed**–Some files in the VM were indexed and some files were not. Indexing was enabled but not all files were indexed because the Cohesity cluster encountered a problem during indexing such as an unsupported file system. Indexing enables you to search and recover files or VMs.

User Quotas

This report provides information about the default user quota defined for a View and any overrides defined for individual users. For information about adding user quotas, see User and Directory Quotas for Views.

Begin typing a View name in the **View Name** field and then select a View from the drop-down.

In the Actions panel, you can optionally filter the report results by a Unix user ID or an Active Directory domain and user name, and click **Apply Filters**.

Click the **Email** icon to provide information for scheduling report emails. For more information, see Email Reports. The **Scheduled Emails** tab on the Reports page displays those emails.

Click the **CSV** icon to download the current report as a CSV file to your device.

The summary table at the top of the report contains the following columns.

Column Name	Description
Users	The number of users who have a quota that overrides the default quota for the View.
Default Quota per User	The default quota defined for all users of the View.
Users with Quota Exceptions	The number of users who have used 100% of their quota for View capacity.
Users Over Alert Thresholds	The number of users who have used 85% (the default threshold) of their quota.

The table at the bottom of the report contains the following columns.

Column Name	Description
User	The user for which a quota override is defined. Click the user name to drill down to more details.
Alert Threshold	The amount of View capacity the user can use before an Alert is triggered.
Quota	The quota defined for the user.
Usage	The percentage and graphical representation of how much of the quota is used.

Audit Logs

Cohesity records all events and operations occurring on your Cohesity cluster in the form of Audit Logs. An audit log contains details about an event, such as date and time, category, type, and user.

Audit logs help you as a cluster administrator to monitor and analyze the events that occurred if you need to troubleshoot issues and investigate unauthorized or suspicious activities.

> **Note:** Cohesity captures the audit logs at the cluster level and file services-level (NFS and SMB Views).

You can enable or disable the logging of the events in the audit logs and manage the audit logs retention period and access privileges.

For information about Cohesity Audit Logs, see the following topics:

- Cluster Audit Logs
- File Services Audit Logs
- Add a Syslog Server

Cluster Audit Logs

The Cluster audit logs feature records all events that occur at the cluster level. You can view these logs in the Cohesity UI and download the log files for analysis purposes.

You can enable or disable cluster audit logs and set retention periods. For more information, see Settings Cluster Audit Logs

The **Audit Logs** page lists the following actions that are logged by the Cohesity cluster:

- Details
- Time
- User
- Action
- Category
- Entity Name

You can use the filters to narrow the visible logs.

> **Note:** It can take up to 30 minutes for logged actions to appear in the Cohesity UI.

You can also download the audit logs as a CSV file. The CSV file may contain more records than the Cohesity UI can display. For more information, see Download Cluster Audit Logs.

Categories in Cluster Audit Logs

All cluster audit logs are logged under different predefined categories for you to find the relevant audit logs fast and analyze easily.

- API Key
- Access Token
- Active Directory
- Alert
- Alert Notification Rule

- Antivirus Service Group
- App
- Csr
- Chassis
- Clone Refresh Task
- CloudSpin

- Swift Roles
- Tags
- Vault
- View
- Share
- VLAN

Logged Actions

The following table describes the actions that are logged.

Action	Description
Assign	A user assigns a source to a tenant.
Unassign	A user removes a source from a tenant.

Action	Description
Accept	A user accepted the license agreement.
Activate	A user activated a Protection Group.
Cancel	A user canceled an entity such as a running Protection Group or Recover task.
Clone	A user cloned an entity such as a Snapshot, VM, View or SQL Server.
Close	A user closed an SMB file open.
Create	A user created an entity such as a Protection Group.
Deactivate	A user deactivated a Protection Group.
Delete	A user deleted an entity such as a Protection Group, Protection Policy or View.
Disjoin	A user disjoined the Cluster from an AD domain.
Download	A user downloaded a VMX file or a file from a VM Snapshot.
Join	A user joined the Cluster to an AD domain.
Login	A user logged in to the Cohesity cluster.
Logout	A user logged out of the Cohesity cluster.
Mark	A user marked an entity for removal such as a disk.
Modify	A user modified an entity such as a User, Protection Group or Remote Cluster.
Pause	A user paused an entity such as a running Protection Group.
Recover	A user recovered an entity such as a VM, file, or SQL Database.
Refresh	A user refreshed the Object hierarchy in a Source.
Register	A user registered an entity such as an External Target (Vault).
Rename	A user renamed an entity such as a Storage Domain.
Resume	A user performed a resume action on a Protection Group.

Action	Description
Run Now	A user performed a Run Now action on a Protection Group.
Unregister	A user unregistered an entity such as a Source.
Upgrade	A user upgraded the Cohesity cluster.

Settings for Cluster Audit Logs

Enable or Disable Cluster Audit Logs

By default, the Cluster Auditing setting is enabled. You can disable or enable it back from the **Log Settings** tab of the **Audit Logs** page. When you disable the option, the old logs continue to retain until the retention period ends.

To enable or disable cluster auditing, complete the following in the Cohesity UI:

1. Select **System> Audit Logs>Log Settings**.
2. In the **Log Settings** tab, toggle the **ClusterAudit** button to enable or disable.

After enabling the **Cluster Audit**, option the **Log Retention Period** option appears. Using this option you can set the audit logs retention period.

Set Log Retention Period for Cluster Audit Logs

You can set the retention period for cluster audit logs. When you set a retention period, the logs are retained on the cluster until the retention period ends.

> **Note:** The default retention period is 90 days.

To set a retention period for cluster audit logs, complete the following in the Cohesity UI:

1. Select **System> Audit Logs>Log Settings**.
2. In the **Log Settings** tab, click the pencil icon ( ) for the **Log Retention Period** audit information option, type the desired number, and select retention period (Days, Weeks, Months, or Years).
3. The **Log Retention Period** is displayed in days as Cohesity converts weeks, months, or years into days.
4. Click **Save**.

Monitor Cluster Audit Logs

You can view cluster audit logs to know the activities on your cluster.

To monitor cluster audit logs, complete the following in the Cohesity UI:

1. Select **System>Audit Logs>Cluster.**
2. In the **Cluster** tab of the **Audit Logs** page, apply filters on the required fields (**Date Range**, **Users**, **Category**, or **Action**) and monitor logs.

Download Cluster Audit Logs

You can download the cluster audit logs for analyzing the logs outside your cluster. Cohesity cluster allows you to download the logs in a .CSV format.

> **Note:** The download .CSV file has more details than what the Cohesity displays. The file contains details about the IP addresses of the systems from which the cluster is accessed, tenants, impersonation, and so on.

To download a cluster audit log, complete the following in the Cohesity UI:

1. Select **System>Audit Logs>Cluster**.
2. In the **Cluster** tab of the **Audit Logs** page, click the ⬇ icon.

The CSV file automatically downloads to your local system.

File Services Audit Logs

The File Services Audit Logs feature enables you to record and monitor events occurring on your SMB and NFS views.

Unlike the cluster-level audit logs, the logs for views are not displayed in the Cohesity GUI. The file services audit logs are saved in an internal view called ***filesystem_audit***. You can access these views by mounting the path ***COHESITY_AUDIT_VIEW\filesystem_audit***.

The **File Services** tab in the **Audit Log** page provides two mount paths for NFS and SMB. You can mount these paths to access and view the audit logs.

You can set permissions for the view and restrict access only to required subnets or users. Only the subnet's IP addresses in the allowlist can access and view the audit logs.

> **Note:**
>
> By default, when you create a view, the **Audit Log** option is disabled. You must manually enable it when creating the view or after creation.

Events Logged for NFS Views

Event	Description
Mount	To mount a view using NFS.
File Create	To create a file.
Link	To create a hard link to a file.
Folder Create	To create a folder.
Mknod	To create a special file used for resource like a device.
File Remove	To delete a file.
Folder Remove	To delete a folder.
Rename	To rename a file or folder.
Change Mode	To change the Unix mode bits of a file or folder for permission.
Change Ownership	To change the Unix UID or GID of a file or folder.
Modify Content	To modify the file's content.
Symlink	To create a soft link to a file or folder.

The following information is logged for NFS views. The information logged depends on the event type.

- Timestamp
- RecordID
- Protocol
- Client IP
- UserID
- ViewName
- Fsid
- RequestType
- Result
- EntityType

- EntityPath
- EntityInode
- EntityMode
- PrevEntityMode
- EntityUserID
- PrevEntityUserID
- EntityGroupID
- PrevEntityGroupID
- EntityModifyTimestamp
- DestinationEntityPath
- DestinationEntityInode
- InodeSizeBytes
- SourceParentEntityInode

Events Logged for SMB Views

Event	Description
Mount	To mount a view using SMB.
Logon	To establish an SMB session.
Logoff	To disconnect the current SMB session.
Close	To close a file or folder.
Create	To create a file or folder.
File Open	To open a file.
Delete	To delete a file or folder.
Rename	To rename a file or folder.
Modify Content	To modify the content of a file.
Change Ownership	To change the owner of a file or folder.
Change Permission	To add or remove the ACL permission of a file or folder.
File Change Protection	To enable or disable the Windows file protection of a file or folder.

The following information is logged for SMB views. The information logged depends on the event type.

- Timestamp
- RecordID
- Protocol
- Client IP
- Username
- UserID
- DomainName
- UserSID
- ViewName
- ViewAliasName
- Fsid
- RequestType
- Result
- EntityType
- EntityPath
- EntityInode
- EntityMode
- EntityUserID
- EntityGroupID
- SecurityDescriptor
- PrevSecurityDescriptor
- EntityModifyTimestamp
- EntityAccessMask
- DestinationEntityPath
- DestinationEntityInode
- DeleteOnClose
- InodeSizeBytes
- SourceParentEntityInode

Settings for File Services Audit Logs

Enable or Disable File Services Audit Logs

By default, the File Services Audit setting is disabled. You should enable the File Services Audit option for Cohesity to start logging operations on the cluster's views for auditing purposes.

You can disable or enable it back from the **Settings** tab of the **Audit Logs** page. When you disable the option, the old logs are retained until the retention period ends.

To enable or disable File Services Audit, complete the following:

1. Navigate to **System > Audit Logs** > **Log Settings**.
2. In the **Log Settings** tab, turn on/off the **File Services Audit** toggle to enable or disable.

After enabling the **File Services Audit**, the **Log Retention Period** audit information option appears. Use this option to set the audit logs retention period.

Set Log Retention Period for File Services Audit Logs

You can set the retention period for file services audit logs on the Cohesity cluster.

> **Note:** The default retention period is 90 days. You can increase or decrease the renewal period. Once the retention period expires, the audit logs are deleted automatically.

Prerequisite:

- You must enable the File Services Audit option. For more information, see Settings for File Services Audit Logs.

To set a retention period for File Services Audit Logs, complete the following:

1. Navigate to **System > Audit Logs** > **Log Settings**.
2. In the **File Services Audit** section of the **Log Settings** tab, click the icon for the **Log Retention Period** option, type the desired number, and select the retention period (Days, Weeks, Months, or Years).

   The Log Retention Period is displayed in days as Cohesity converts weeks, months, or years into days.
3. Click **Save**

Add IP Allowlist for File Services Audit Logs

By default, every client that is part of the Global Allowlist set at the cluster level can access the File Services audit logs. You can change access permission by the **Override Allowlist**

option to allow or deny access to a subnet. Additionally, access can also be restricted using SMB Permissions on the view for AD or LOCAL principals.

As the file services audit logs are saved in an internal view, you can provide access only to required networks by adding them to the allowlist along with Allow Deny setting for NFS/SMB Clients in the allowlist.

To override the global IP allowlist set at the cluster level and add a subnet to the allowlist for file service audit:

1. Navigate to **System > Audit Logs** > **Log Settings**.
2. In the **IP Allowlist** section of the **Log Settings** page, turn on the **Override Global IP Allowlist** toggle.
3. Click **Add**.
4. In the **Add Allowlist** dialog, complete the following:
    1. Type the Subnet IP address in CIDR format.

       Example: Subnet in CIDR format (IPv4 - 10.0.0.0/24 or IPv6 - FE80:CD00::211E:729C/60).
    2. Select **NFS Permissions**, **SMB Permissions**, or **S3 Permissions**. (**Read/Write**, **Read Only**, or **Disabled**).
    3. Optionally, type a description.
    4. Click **Add**.

    The added allowlist IP subnet details appear in the File Services Audit section of the page.

Edit IP Allowlist for File Services Audit Logs

You can edit the IP allowlist for File Services audit logs if you need to change the subnet or change the permission for access.

To provide access to a network by adding to the IP allowlist for file service audit:

1. Navigate to **System > Audit Logs** > **Log Settings**.
2. In the **IP Allowlist** section of the **Log Settings** page, click the for the required subnet.
3. In the **Edit Allowlist** dialog, complete the following:
    1. Modify the Subnet IP address.

       Example: Subnet in CIDR format (IPv4 - 10.0.0.0/24 or IPv6 - FE80:CD00::211E:729C/60).
    2. Modify **NFS Permissions**, **SMB Permissions**, or **S3 Permissions**. (**Read/Write**, **Read Only**, or **Disabled**).

3. Optionally, type a description.
4. Click **Add**.

The added allowlist IP subnet details appear in the File Services Audit section of the page.

Delete Allowlist for File Services Audit Logs

You can delete the allowlist IP subnet to remove access to a network. After deleting, clients in the deleted subnet cannot access the audit log files.

To delete an allowlist for File Services Audit logs:

1. Navigate to **System> Audit Logs>Log Settings**.
2. In the **IP Allowlist** section of the **Log Settings** page, click the delete icon for the required subnet.
3. In the **Delete Allowlist** dialog, enter **YES** to confirm, and click **Delete**.

The subnet disappears from the list and the audit logs view is restricted for the deleted subnet.

Add SMB Permissions for File Services Audit Logs

You can provide permission for SMB domain users and groups. The access permission is Read-Only and access type can be Allow or Deny.

To add SMB permissions for the File Services audit log:

1. Navigate to **System > Audit Logs** > **Log Settings**.
2. In the **SMB Permissions** section of the **Log Settings** page, click the **Add**.
    1. In the **Add SMB Permission** dialog, complete the following:
    2. Select an **AD Domain** from the list.
    3. Select a **Principal** from the list.
    4. Select Type: **Allow** or **Deny**.
    5. Click **Add**.

    The new permission appears under the SMB Permissions section.

Delete SMB Permissions for File Services Audit Logs

You can delete an SMB permission to remove the set permission (Allow or Deny) for a principal (user or group).

To delete SMB permissions for file services audit log, complete the following:

1. Navigate to **System > Audit Logs** > **Log Settings**.
2. In the **SMB Permissions** section of the **Log Settings** page, click the delete icon for the required SMB permission.

3. In the **Delete SMB Permission** screen, type **Yes** for confirmation.
4. Click **Delete**.

Access NFS Audit Logs using a Mount Path

Prerequisite:

- The subnet you are using should have read-only permission to the File services audit log view.

To access NFS audit logs, complete the following steps:

1. Navigate to **System > Audit Logs** > **File Services**.
2. In the **Log Location** section of the **File Services** tab, click the copy icon for NFS and mount using the following steps:
    1. Mount the path using the syntax given below:

        ```
        mount cluster_name:/COHESITY_AUDIT_VIEW/filesystem_audit /mnt/path
        ```

    2. Connect to a hidden internal view 'COHESITY_AUDIT_VIEW'.
    3. Connect to `mount cluster_name:/COHESITY_AUDIT_VIEW/filesystem_audit /mnt/path`.

Sample NFS Audit Log

```
{"Timestamp" : "2022-03-10T22:12:17.838Z", "RecordID" : "bd65:2afc4", "Pro-
tocol" : "NFS3", "ClientIP" : "10.2.223.127", "UserID" : 1000, "ViewName" :
"test", "Fsid" : 4377, "RequestType" : "Delete", "Result" : "NFS3_OK",
"EntityType" : "File", "EntityPath" : "bbb", "EntityInode" : 9422800,
"SourceParentEntityInode" : 9422329}
```

Access SMB Audit Logs using a Mount Path

Prerequisites:

- The subnet you are using should have read-only permission to the File services audit log View.
- As an SMB user, you must have permission to access the File services audit log View.

To access SMB audit logs, complete the following steps:

1. Navigate to **System > Audit Logs** > **File Services**.
2. In the **Log Location** section of the **File Services** tab, click the copy icon for SMB and mount using the following steps:
    1. Connect to a hidden internal view 'COHESITY_AUDIT_VIEW'.
    2. Access `\\cluster_name\COHESITY_AUDIT_VIEW\filesystem_audit`.

Sample SMB Audit Log

```
{"Timestamp" : "2022-03-04T00:01:40.503Z", "RecordID" : "30fe:216", "Pro-
tocol" : "SMB", "ClientIP" : "10.14.0.41", "UserName" : "Administrator",
"UserID" : 500, "DomainName" : "w2k16-0.qa.local", "UserSID" : "S-1-5-21-
2148495376-676708989-2532157484-500", "ViewName" : "audit_filer_actions",
"Fsid" : 6642, "RequestType" : "SetAttributes", "Result" : "Ok",
"EntityType" : "File", "EntityPath" : "audit-actions/d1/e1/f1.txt",
"EntityInode" : 6214}
```

Check Audit Logs Status for Views

You can enable or disable the status of the Audit Logs option for views.

You can check the audit status for views to know whether audit logs are being logged for required views. The GUI displays all views with the status and it allows you to filter the views to see the audit log enabled or disabled list of views.

To check the audit status for views, complete the following:

1. Navigate to **System > Audit Logs** > **File Services**.
2. In the **Audit Status of Views** section, click the **Audit Logs** drop-down menu and select **Enabled** or **Disabled**, and click **Apply**

Based on your selection, the list of views with **Audit Log enabled** or **disabled** status appears.

Enable or Disable Audit Logs for Views

You can check the audit status of a view to know whether audit logs are being logged for required the view and enable or disable the **Audit Log** option.

You can also enable or disable the Audit Logs option for a view from: **SmartFiles > Views**, click the actions menu (⋮) and select **Edit** > **Audit Logs.**

To enable or disable audit logs status for a view, complete the following:

1. Navigate to **System > Audit Logs** > **File Services**.
2. In the **Audit Status of Views** section, click the **Audit Logs** drop-down menu and select **Enabled** or **Disabled**, and click **Apply**.
3. Based on your selection, the list of views with **Audit Log** enabled or disabled status appears.
4. To enable or disable audit logs, click the toggle corresponding to the view under the **Audit Logs** column.

Add a Syslog Server

You can add a Syslog server to the Cohesity cluster and send cluster audit logs, filer audit logs, alert audit logs, and data protection events entries to that server. These logs are

identified by their respective audit tags as listed below:

- Cluster audit log entries are identified with the tag `cluster_audit`.
- Filer audit log entries are identified with the tag `filesystem_audit`.
- Alert audit log entries are identified by the tag `cohesity_alerts`.
- Data protection events are identified by the tag `dataprotection_events`.

Optionally, you can set custom tags or token IDs for these Syslog messages to aggregate and parse them based on the set tags and tokens.

Add a Syslog server to the Cohesity cluster

There are two ways you can add a Syslog server to the Cohesity cluster.

- Adding a Syslog server using the Cohesity CLI
- Adding a Syslog server using the Cohesity UI

Adding a Syslog server using the Cohesity CLI

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. Add a syslog server to the Cohesity cluster using the `syslog create` CLI command:

   ```
   admin>syslog create address=<IPAddressorHostname> port=<Port>
   ```

CLI Option	Example	Description
`address=`	`198.51.100.1`	Specify the hostname or IP address of the syslog server.
`name=`	`MySyslogServer`	Optional. Specify a name or description for the syslog server.
`port=`	`100`	Specify the port where the syslog server listens.
`protocol=`	`udp`	Optional. Specify the protocol used by the syslog server. The default is TCP, but UDP is also supported.
`program-names`	`cluster_audit`	Optional. The logs of specific programs sent to the syslog server.

CLI Option	Example	Description
`facilities`	`auth,authpriv`	The logs of specific facilities sent to the syslog server.
`permitted-peer`	-	Optional. Specify the syslog server certificate common name.
`message-patterns`	`denied`	The message with the patterns will be sent to the syslog server.
`raw-message-patterns`	`session`	The raw message with the patterns will be sent to the syslog server.
`ca-certificate-path`		Specify the syslog server CA certificate absolute file path.
`enable`	`true`	Enable or disable the syslog server to the Cohesity cluster.
cluster-audit	-	Deprecated. Same as program name “cluster_audit”
filer-audit	-	Deprecated. Same as program name “filesystem_audit”
dataprotection-events	-	Deprecated. Same as program name “dataprotection_events”
ssh-events-log	-	Deprecated. Same as program name “sshd”

> **Tip:** You can also use the CLI Help feature to view the `syslog create` options by entering the following command: `syslog create help`.

Adding a Syslog server using the Cohesity UI

1. Navigate to **Settings** > **Summary** and then select the **Syslog** tab.
2. Click **Add** located at the top-right of the page.
3. **IP Address/Hostname**: Specify the hostname or IP address of the syslog server.
4. **Protocol**: Specify the protocol used by the syslog server. The default is TCP, but UDP is also supported.
5. **Port**: Specify the port where the syslog server listens.
6. **Stream**: Select the logs to be sent to the syslog server from the drop-down list.

7. **Facilities (Optional)**: Enable this option to send the logs of specific facilities to the syslog server.
8. **Secure Connection**: Toggle to configure the authentication method to securely connect to the syslog server.
    1. **Authentication Mode**: Select one of two modes from the drop-down list.
        1. **anon**: This method uses TLS encryption without server identity validation, suitable for trusted networks where authentication is not required.
        2. **x509/name**: This method uses TLS with certificate-based authentication. The server's identity will be verified using a trusted CA certificate and an expected subject name.

           In **Permitted Peer Identity** field, enter the expected subject name of the syslog server's TLS certificate. For example, syslog.example.com.

           > **Important:** The connection will only be established when the server presents a certificate with this identity.
    2. **Trusted CA Certificate**: Paste the PEM-encoded certificate text or click **Select Certificate File** to select the file containing the certificate text.
9. **Enable Syslog Forwarding**: Toggle to forward logs and events to the syslog server.
10. Click **Add**.

Optional. Click **Manage Streams** to set custom tags or token IDs for cluster audit logs, file system audit logs, alert audit logs, and data protection event entries to aggregate and parse them based on the set tags and tokens.

You must set up an alert rule to get the logs for the Alert Audit Logs stream sent to the Syslog server. For more information, see Add Alert Notification Rule.

Enable or Disable Syslog Server

You can enable or disable the syslog server to the Cohesity cluster.

To enable a syslog server:

1. Navigate to **Settings** > **Summary** and then select the **Syslog** tab.
2. Find the syslog server in the list, click the **Edit** button, and toggle on or off the **Syslog Server** button to enable or disable the syslog server to the Cohesity cluster.

Delete a Syslog Server

You can delete a syslog server when you do not want the Cohesity cluster to send logs to the syslog server.

To delete a syslog server:

1. Navigate to **Settings** > **Summary** and then select the **Syslog** tab.
2. Find the syslog server in the list, click the **Delete** button and then click **Confirm** to delete the Syslog server.

Syslog Format and Keys Published to the Syslog Server

This topic provides the actions logged and published to the Syslog server.

Cohesity_Alerts

The following table describes the actions that are logged for the event `cluster_alerts`.

Field	Description
ClusterName	The cluster name on which the alert is triggered.
AlertCode	The alert code.
AlertName	The alert name.
AlertSeverity	The severity rating of the alert.
AlertDescription	A brief description of the problem that triggered the alert.
AlertCause	A brief description of the cause of the problem.

Data Protection_Events

The following table describes the actions that are logged for the event `dataprotection_events`.

Field	Description
EventMessage	A brief description of the event
Timestamp	The time the event occurs
ClusterInfo {ClusterId, ClusterName}	The cluster name and cluster id
EventType	The type of the event
EnvironmentType	Type of the adapter
EntityType	The type of entity

Field	Description
EntityId	The entity Id on which the event is generated.
EntityName	Entity Name on which the event is generated.
RegisteredSource	The source under which the entity is present.
RestoreTarget	The target entity for restore
BackupJobName	The protection run name generated for the event
BackupJobId	The protection run Id generated for the event
Entities	The entities for which the event is generated
Error {ErrorCode, ErrorMessage}	The error code and error message associated with the event
TaskId	The Id of the task
ReplicationTarget	The target cluster for replication
ArchivalTarget {Type, Name}	The archival target type and name
AttributeMap {_key, _value}	The key-value associated with the entity activities

Cluster_Audit

The following table describes the actions that are logged for the event `cluster_audit`.

Field	Description
Time	The time the audit log is generated
User	The username who created the audit log
Entity Name	The entity name
Category	The entity type
Action	The action-type for the audit log
Details	The change details of the audit log

For more information, see Cluster Audit Logs.

File Services_Audit

The following table describes the actions that are logged for the event `filesystem_audit`.

Field	Description
Timestamp	The time the event occurs
Protocol	The protocol for the specific event
Client Ip	The client's IP address
User name/User Id	The user name and the user ID of the user who performed the action
Domain name	The AD domain name
Share name	The name of the share the user is accessing
Entity Name(s)/Entity Id(s)	The name of the share and the share Id.
Entity attributes	The attributes of the entity for NFS

For more information, see File Services Audit Logs.

API_Audit

The following table describes the actions that are logged for the event `api_audit`.

Field	Description
Username	Cohesity login username
Domain	Active Directory or Local
Method	HTTP method
UrlPath	API URL
StatusCode	HTTP status code
ResponseHeader	HTTP response
ResponseTime	HTTP response time stamp
RequestTimestamp	HTTP request time stamp

CLI_Audit

The following table describes the actions that are logged for the event `cli_audit`.

Field	Description
User	Cohesity login username
Domain	Active Directory Domain or Local
Timestamp	The time the event occurs
Command	Iris_cli command

Capture Logs

Use the `timecapsule` command to capture a comprehensive log bundle of Cohesity services across a single or multiple Nodes in a Cohesity cluster for a specified time range.

To capture logs:

Use any of the following `timecapsule` command depending on your requirement:

- To capture logs from the cluster (all Nodes) for all components for a time range:

  ```
  timecapsule --clusterip=<Cluster_Ip_address> -start_time_secs=<Seconds_in_Unix_Time> -end_time_secs=<Seconds_in_Unix_Time>
  ```

  For example, `timecapsule --clusterip=198.51.100.1 -start_time_secs=1549001025 -end_time_secs=1549173873`

  By default, the `timecapsule` command captures logs for all services.

- To capture logs from the cluster (all Nodes) for specific components for a time range:

  ```
  timecapsule --clusterip=<Cluster_Ip_address> -start_time_secs=<Seconds_in_Unix_Time> -end_time_secs=<Seconds_in_Unix_Time> -service_names=<Service_names_list>
  ```

  For example, `timecapsule --clusterip=198.51.100.1 -start_time_secs=1549001025 -end_time_secs=1549173873 -service_names=genie, magneto`

- To capture logs from a single or multiple nodes for all components for a time range:

  ```
  timecapsule --hostips=<Nodes_IP_addresses> -start_time_secs=<Seconds_in_Unix_Time> -end_time_secs=<Seconds_in_Unix_Time>
  ```

For example, `timecapsule --hostips=198.51.100.1,198.51.100.2,198.51.100.3 -start_time_secs=1549001025 -end_time_secs=1549173873`

- To capture logs from a single or multiple nodes for specific components for a time range:

```
timecapsule --hostips=<Nodes_IP_addresses> -start_time_secs=<Seconds_in_Unix_Time> -end_time_secs=<SSeconds_in_Unix_Time> -service_names=<Service_names_list>
```

For example, `timecapsule --hostips=198.51.100.1 -start_time_secs=1549001025 -end_time_secs=1549173873 -service_names=bridge,apollo`

CLI Option	Placeholder Name	Example	Description
`--hostips=`	<Nodes_IP_addresses>	`198.51.100.1, 198.51.100.2, 198.51.100.3`	Specify the IP addresses of Nodes in a comma-separated list, from which you want to capture logs.
`--clusterip=`	<Cluster_Ip_address>	`198.51.100.2`	Specify the IP address of any of the nodes in the cluster from which you want to capture logs.
`-start_time_secs`	<Seconds_in_Unix_Time>	1549001025	Specify the start time in seconds (Unix timestamp).
`-end_time_secs`	<Seconds_in_Unix_Time>	1549001025	Specify the end time in seconds (Unix timestamp).
`-service_names`	<Service_names_list>	all, logwatcher, statscollector, physical_agents, windows_agent, and so on.	Specify the service names in a comma-separated list for which you to want parse logs. If the value provided is 'all', then log files of all services are parsed.
`-msg_type`	<log_file_level>	INFO, WARNING, ERROR, or FATAL	*Optional*. Specify the log file level to parse.

CLI Option	Placeholder Name	Example	Description
`-output_dir`	<output_ directory>		*Optional* Specify the output directory for collected data. This directory should not already exist. The `timecapsule` command will create this directory.
`-skip_cores`		true	*Optional*. If true, skip copying the core files that are generated when a service crashes.
`-tar_gz_node_ dumps`		true	*Optional*. If true, tar gzips the dump directories on each node before aggregating.
`-tar_gz_ timecapsule`		true	*Optional*. If true, tar gzips the final **timecapsule** directory after aggregating the dumps from each node.
`-service_ pages_only`		false	*Optional*. If true, it enables the collection of only Cohesity service pages (varz, flagz, tracez, tec). The default value is false.

Advanced Diagnostics

Cohesity provides common pre-canned statistics in charts and graphs with pre-determined X and Y axes at the following locations in the Cohesity UI:

- **Performance Statistics**—Select **System > Performance**. For more information, see Performance.
- **Storage Statistics**—Select **System > Storage**. For more information, see Storage Statistics.

In addition, Cohesity provides an extensive set of reports. For more information, see Reports.

Cohesity also provides advanced diagnostics that allow you to customize the plotted statistics.

To use Advanced Diagnostics:

1. Navigate to **System > Advanced Diagnostics**.
2. From the **Schema** drop-down, select a Cohesity component that you are interested in viewing statistics about. For example, if you want to learn more about physical disk statistics on the Cohesity cluster, select **Disk Physical Stats** in the **Schema** drop-down. After selecting a Schema, the Metric and Entity drop-downs are populated with options specific to this Schema.

   > **Note:** Entity is equivalent to an Object in the Cohesity Dashboard.

3. Select a Metric to plot. The options available in the Metric drop-down are specific to the chosen Schema. The Metric drop-down provides data that can be plotted on a graph. For example, after selecting the **Node Physical Stats** Schema, you could select the **Bytes Written** Metric.
4. Select an Entity to report on. The options available in the Entity drop-down are specific to the chosen Schema. The Entity drop-down defines the specific Cohesity Object to report on such as a disk, node or storage domain. For example, after selecting the **Node Physical Stats** Schema and the **Bytes Written** Metric, you can select one of the nodes in the cluster from the **Entity** drop-down.
5. Select a Rollup Function to apply to the data points returned by the selected Metric and Entity for the specified time period. For example, you could select the **Node Physical Stats** Schema, the **Bytes Written** Metric, the **Node:1** Entity and the **Average** Rollup Function.

   The available Rollup Functions are listed in the following table.

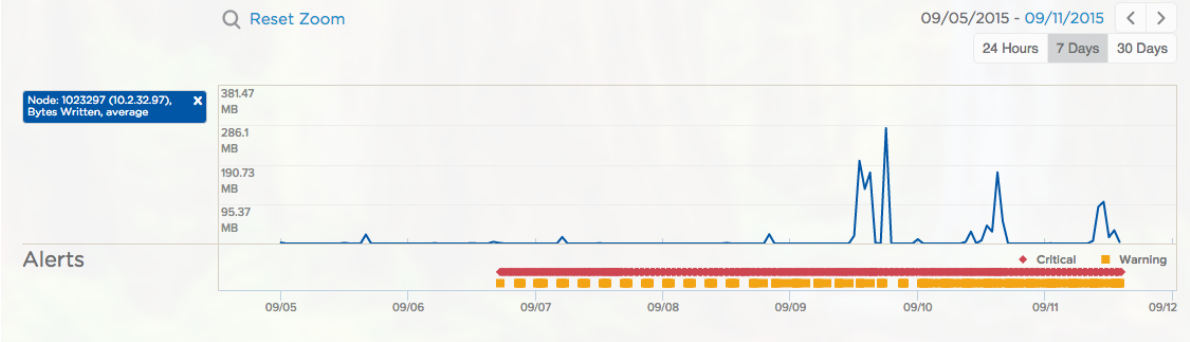
Rollup Function Name	Function Description
Raw	The data is not altered by a Rollup Function. All data points in the specified time interval are reported.
Sum	The sum of all the data points over the specified time interval. Add all the data points together for the specified time period.
Average	The mean of the data points over the specified time period. Sum of the data points divided by the number of data points.

Rollup Function Name	Function Description
Count	The number of data points for the specified time interval.
Max	The largest value of all the data points for the specified time interval.
Min	The smallest value of all the data points for the specified time interval.
Median	The middle value of all the data points if all the data points in the specified time interval are sorted by value. (50 Percentile)
Rate	The sum of the data points divided by the specified time interval in seconds. For example if the **Bytes Read** Metric is specified for the **Cluster Physical** Schema, the **Rate** Rollup Function and an interval of 10 Minutes, the number of bytes per second read by the cluster is reported. This is the throughput of the cluster. In this example, the rate of bytes per second is calculated by dividing the number of bytes read in 600 seconds by 600 seconds (10 Minutes).
95 Percentile	The data point that is 95% greater than all the other data points if all the data points in the specified time interval are sorted by value.
Latest	Is the last data point that was recorded during the specified interval.

> **Warning:** Not all Rollup Functions are appropriate for all metrics. For example, reporting the bytes read every hour on the cluster using the **Latest** Function is probably not very informative. However, reporting cumulative statics about the number of bytes read during a time period on the cluster is more informative. For example, you can report on the average number of bytes read on the cluster in one hour using the **Average** function or you can report on the total number of bytes read on the cluster during one day using the **Sum** function.

6. Select a time interval from the drop-down or choose **Custom** to specify your own time interval in seconds. For example, you could select the **Node Physical Stats** Schema, the **Bytes Written** Metric, the **Node:1** Entity, using the **Average** Rollup Function over a **10 Minutes** Interval.
7. Click **Plot** and either a new graph displays with the plotted data or a line of the plotted data is added to an existing graph. For this example, a new graph showing the

average number of bytes written per ten-minute interval to a node is plotted as shown in the following figure.



Plot lines that have the same Y-axis are plotted on the same graph with different colors. For example, all plot lines that report on bytes are plotted on the same graph. (The X-axis is always time.) A plot line with different Y-axis are plotted in a new graph.

A graph showing Critical (Red) and Warning (Yellow) Alerts can be found along the bottom of the page. You can click an Alert in the graphic to drill down to more information about the Alert. A detail page about the Alert is displayed in a new Browser tab.

8. You can delete a plot line by clicking the X in the top right corner of the colored label.
9. You can optionally further customize the data displayed on the Advanced Diagnostics page:
    - You can customize the data range reported by clicking **24 Hours**, **7 Days** or **30 Days**.
    - You can also change the starting date that is reported by clicking the arrow buttons or on the date.
    - You can zoom in on part of the graph by dragging the mouse across a section of the graph. The graph is zoomed in. To restore the original view, click **Reset Zoom**.
    - **Runs** - Toggle this setting on to view the type of protection run within the specific interval. On the graph, mouse hover on a specific protection run to view the start and end time of the protection run

Related Topic

Schema and Metric.

Schema and Metric

This topic provides details on the different types of schema and its corresponding metrics that helps you to understand the performance of each Cohesity component.

Object Level Backup Performance

The table below lists the metrics for the following schema:

- Backup Job Stats
- Backup Source Stats

> **Note:** The **Backup Job Stats** and **Backup Source Stats** schemas are not supported for Oracle sources.

Metric	Description
Bytes backed up	Based on the Rollup Function and Interval, the graph plots the total bytes backed up on the specified Entity.
Read latency from backup source	Based on the Rollup Function and Interval, the graph plots the read latency from the backup source. Preferred Rollup Function is **Average**.

Cloud Spinned VMs

The table below lists the metrics for the **Cloud Spin Stats** schema.

Metric	Description
Count of cloud spinned VMs	Based on the Rollup Function and Interval, the graph plots the total number of Virtual machines created on the cloud.

Cluster Performance

The table below lists the metrics for the following schema:

- Cluster CPU/MemoryUsage Metrics
- Node CPU/Memory Usage Metrics
- Process CPU/Memory Usage

Metric	Description
CPU Usage	Based on the Rollup Function and Interval, the graph plots the CPU usage of the specified Entity. Preferred Rollup Function is **Average**.

Metric	Description
Memory Usage	Based on the Rollup Function and Interval, the graph plots the memory usage of the specified Entity. Preferred Rollup Function is **Average**.

Cluster Backup Performance

The table below lists the metrics for the **Cluster Backup and Restore Stats** schema.

Metric	Description
Bytes backed up	Based on the Rollup Function and Interval, the graph plots the total bytes backed up in the specified Entity.
Bytes restored	Based on the Rollup Function and Interval, the graph plots the total bytes restored in the specified Entity.
Num active backup tasks	Based on the Rollup Function and Interval, the graph plots the total number of active backup tasks running on the specified Entity.
Num active restore tasks	Based on the Rollup Function and Interval, the graph plots the total number of active restore tasks running on the specified Entity.
Read latency from backup source	Based on the Rollup Function and Interval, the graph plots the read latency from the backup source. Preferred Rollup Function is **Average**.
Write latency to restore target	Based on the Rollup Function and Interval, the graph plots the write latency to restore target. Preferred Rollup Function is **Average**.

External Target Space Utilization

The table below lists the metrics for the following schema:

- Cluster External Target Stats
- External Target Job Stats
- External Target Stats
- Node Physical Stats Storage
- Domain Logical Stats
- Domain Tier Physical Stats

Metric	Description
Cloud Direct Downtier Op Errors	Based on the Rollup Function and Interval, the graph plots the number of errors occurred while downtiering chunkfiles to cloud target. Preferred Rollup Function is either **Rate** or **Sum**.
Cloud Direct Downtier Op Latency	Based on the Rollup Function and Interval, the graph plots the latency of downtiering chunkfiles to cloud targets. Preferred Rollup Function is **Average**.
Cloud Direct Downtier Ops	Based on the Rollup Function and Interval, the graph plots the number of chunkfiles downtier ops triggered.
Cloud Direct Downtiered bytes	Based on the Rollup Function and Interval, the graph plots the number of bytes downtiered from the specified Entity.
Downtier Op Errors	Based on the Rollup Function and Interval, the graph plots the number of errors occurred while executing the downtier ops. Preferred Rollup Function is either **Rate** or **Sum**.
Downtier Op Latency	Based on the Rollup Function and Interval, the graph plots the latency of downtier ops. Preferred Rollup Function is **Average**.
Downtier Ops	Based on the Rollup Function and Interval, the graph plots the number of downtier ops triggered.
Downtiered bytes	Based on the Rollup Function and Interval, the graph plots the number of bytes downtiered.
Journal Bandwidth	Based on the Rollup Function and Interval, the graph plots the write bandwidth of the specified Entity. Preferred Rollup Function is **Rate**.
Journal Flush Bandwidth	Based on the Rollup Function and Interval, the graph plots the flush bandwidth of the specified Entity. Preferred Rollup Function is **Rate**.
Journal Flush Latency	Based on the Rollup Function and Interval, the graph plots the latency of flush operation observed on the specified Entity. Preferred Rollup Function is **Average**.

Metric	Description
Journal IOs	Based on the Rollup Function and Interval, the graph plots the number of write IOs. Preferred Rollup Function is **Rate**.
Random IOs	Based on the Rollup Function and Interval, the graph plots the number of random IOs. Preferred Rollup Function is **Rate**.
Read Bandwidth	Based on the Rollup Function and Interval, the graph plots the read bandwidth of the entity chosen. Preferred Rollup Function is **Rate**.
Read Errors	Based on the Rollup Function and Interval, the graph plots the number of read errors occurred on the specified Entity. Preferred Rollup Function is either **Rate** or **Sum**.
Read IOs	Based on the Rollup Function and Interval, the graph plots the number of Read IOs performed on the specified Entity. Preferred Rollup Function is **Rate**.
Read Latency	Based on the Rollup Function and Interval, the graph plots the latency of read operation observed by the entity chosen. Preferred Rollup Function is **Average**.
Sequential IOs	Based on the Rollup Function and Interval, the graph plots the number of sequential IOs performed on the specified Entity. Preferred Rollup Function is **Rate**.
Total Data Archived (Morphed)	Based on the Rollup Function and Interval, the graph plots the number of bytes archived to the external target after compression and encryption.
Total Data Archived (Unmorphed)	Based on the Rollup Function and Interval, the graph plots the number of bytes archived to the external target after decryption and decompression.
Total Data Restored (Morphed)	Based on the Rollup Function and Interval, the graph plots the number of bytes restored from the external target after compression and encryption.

Metric	Description
Total Data Restored (Unmorphed)	Based on the Rollup Function and Interval, the graph plots the number of bytes restored to the external target after decryption and decompression.
Total Data Uptiered (Unmorphed)	Based on the Rollup Function and Interval, the graph plots the number of bytes uptiered in the external target after decryption and decompression.
Total Garbage Collected (Morphed)	Based on the Rollup Function and Interval, the graph plots the number of garbage bytes collected from the external target after compression and encryption.
Total Garbage Collected (Unmorphed)	Based on the Rollup Function and Interval, the graph plots the number of garbage bytes collected from the external target after decryption and decompression.
Total IOs	Based on the Rollup Function and Interval, the graph plots the total IOs involved during the selected interval. Preferred Rollup Function is **Rate**.
Total Storage Used	Based on the Rollup Function and Interval, the graph plots the total storage used by the specified Entity. Preferred Rollup Function is **Sum**.
Write Bandwidth	Based on the Rollup Function and Interval, the graph plots the write bandwidth of the specified Entity. Preferred Rollup Function is **Rate**.
Write Errors	Based on the Rollup Function and Interval, the graph plots the write errors of the specified Entity. Preferred Rollup Function is either **Rate** or **Sum**.
Write IOs	Based on the Rollup Function and Interval, the graph plots the number of write IOs performed on the specified Entity. Preferred Rollup Function is **Rate**.
Write Latency	Based on the Rollup Function and Interval, the graph plots the write latency of the specified Entity. Preferred Rollup Function is **Average**.

Metric	Description
Dedup Morphed Usage	Based on the Rollup Function and Interval, the graph plots the estimated used bytes count (space utilized) in the specified Entity. This bytes count is post-encryption /post-compression/post-dedup. Preferred Rollup Function is either **Average** or **Latest**.
Dedup Unmorphed Usage	Based on the Rollup Function and Interval, the graph plots the estimated used bytes count (space utilized) in the specified Entity. This bytes count is pre-encryption /pre-compression/post-dedup. Preferred Rollup Function is either **Average** or **Latest**.
Non Dedup Morphed Usage	Based on the Rollup Function and Interval, the graph plots the estimated used bytes count (space utilized) in the specified Entity. This bytes count is post-encryption /post-compression/pre-dedup. Preferred Rollup Function is either **Average**.
Non Dedup Unmorphed Usage	Based on the Rollup Function and Interval, the graph plots the estimated used bytes count (space utilized) in the specified Entity. This bytes count is pre-encryption /pre-compression/post-dedup. Preferred Rollup Function is **Average**.

Space Consumption by Workloads

The table below lists the metrics for the following schema:

- Cluster Logical Stats
- Cluster Logical Stats by Workload
- Cluster Physical Stats
- Cluster Tier Physical Stats
- Disk Physical Stats
- Storage Domain Logical Stats by Workload Storage

Metric	Description
Cloud Direct Downtier Op Errors	Based on the Rollup Function and Interval, the graph plots the number of errors occurred while downtiering chunkfiles to cloud target. Preferred Rollup Function is either **Rate** or **Sum**.
Cloud Direct Downtier Op Latency	Based on the Rollup Function and Interval, the graph plots the latency of downtiering chunkfiles to cloud targets. Preferred Rollup Function is **Average**.

Metric	Description
Cloud Direct Downtier Ops	Based on the Rollup Function and Interval, the graph plots the number of chunkfiles downtier ops triggered.
Cloud Direct Downtiered bytes	Based on the Rollup Function and Interval, the graph plots the number of bytes downtiered from the specified Entity.
Cluster Capacity	Based on the Rollup Function and Interval, the graph plots the cluster capacity of the specified Entity.
Downtier Op Errors	Based on the Rollup Function and Interval, the graph plots the total errors occurred in the downtier op of the specified Entity. Preferred Rollup Function is either **Rate** or **Sum**.
Downtier Op Latency	Based on the Rollup Function and Interval, the graph plots the downtier latency of the specified Entity. Preferred Rollup Function is **Average**.
Downtier Ops	Based on the Rollup Function and Interval, the graph plots the number of downtier ops triggered.
Downtiered bytes	Based on the Rollup Function and Interval, the graph plots the total number of bytes downtiered.
Journal Bandwidth	Based on the Rollup Function and Interval, the graph plots the write bandwidth of the specified Entity. Preferred Rollup Function is **Rate**.
Journal Flush Bandwidth	Based on the Rollup Function and Interval, the graph plots the flush bandwidth of the specified Entity. Preferred Rollup Function is **Rate**.
Journal Flush Latency	Based on the Rollup Function and Interval, the graph plots the latency of flush operation observed on the specified Entity. Preferred Rollup Function is **Average**.
Journal IOs	Based on the Rollup Function and Interval, the graph plots the number of write IOs. Preferred Rollup Function is **Rate**.
Morphed Garbage	Based on the Rollup Function and Interval, the graph plots the estimated garbage bytes count in the specified Entity. This bytes count is post-encryption / post-compression.

Metric	Description
Morphed Usage	Based on the Rollup Function and Interval, the graph plots the estimated used bytes count (space utilized) in the specified Entity. This bytes count is post-encryption / post-compression. Preferred Rollup Function is **Average**.
Read Bandwidth	Based on the Rollup Function and Interval, the graph plots the read bandwidth of the specified Entity. Preferred Rollup Function is **Rate**.
Read Errors	Based on the Rollup Function and Interval, the graph plots the number of read errors performed on the specified Entity. Preferred Rollup Function is either **Rate** or **Sum**.
Read IOs	Based on the Rollup Function and Interval, the graph plots the number of reads IOs performed on the specified Entity. Preferred Rollup Function is **Rate**.
Read Latency	Based on the Rollup Function and Interval, the graph plots the read latency of the specified Entity. Preferred Rollup Function is **Average**.
Sequential IOs	Based on the Rollup Function and Interval, the graph plots the number of sequential IOs performed on the specified Entity. Preferred Rollup Function is **Rate**.
System Capacity	Based on the Rollup Function and Interval, the graph plots the system capacity of the specified Entity.
Total IOs	Based on the Rollup Function and Interval, the graph plots the number of write IOs performed on the specified Entity. Preferred Rollup Function is **Rate**.
Unmorphed Garbage	Based on the Rollup Function and Interval, the graph plots the estimated garbage bytes count in the specified Entity. This bytes count is the logical count that is pre-encryption / pre-compression.
Unmorphed Usage	Based on the Rollup Function and Interval, the graph plots the estimated used bytes count (space utilized) in the specified entity. This bytes count is the logical count pre-encryption / pre-compression. Preferred Rollup Function is **Average**.

Metric	Description
Write Bandwidth	Based on the Rollup Function and Interval, the graph plots the write bandwidth of the specified Entity. Preferred Rollup Function is **Rate**.
Write Errors	Based on the Rollup Function and Interval, the graph plots the write errors of the specified Entity. Preferred Rollup Function is either **Rate** or **Sum**.
Write IOs	Based on the Rollup Function and Interval, the graph plots the number of write IOs performed on the specified Entity. Preferred Rollup Function is **Rate**.
Write Latency	Based on the Rollup Function and Interval, the graph plots the write latency of the specified Entity. Preferred Rollup Function is **Average**.
Brick Referenced Usage	Based on the Rollup Function and Interval, the graph plots the total usage of all bricks in bytes.
Pre Replication Morphed Usage	Based on the Rollup Function and Interval, the graph plots the usage after dedup and compression but before replication or erasure coding.

CPU Performance

The table below lists the metrics for the **CPU Temperature Stats** schema.

Metric	Description
CPU Temperature	Based on the Rollup Function and Interval, the graph plots the CPU temperature of the specified Entity. Preferred Rollup Function is **Max**.

Disk Performance

The table below lists the metrics for the **Disk Health Metrics** schema.

Metric	Description
Disk Health	Based on the Rollup Function and Interval, the graph plots the disk health of the specified Entity. Preferred Rollup Function is **Average**.
Percentage Used (Wearouts)	Based on the Rollup Function and Interval, the graph plots the percentage of ssd disks used, measuring SSD wearout on the specified Entity. Preferred Rollup Function is **Average**.

Node Backup Performance

The table below lists the metrics for the following schema:

- Node Backup Stats
- Node Restore Stats
- Restore Source Stats
- Restore Task Stats

Metric	Description
Bytes restored	Based on the Rollup Function and Interval, the graph plots the total bytes restored on the specified Entity.
Num active backup tasks	Based on the Rollup Function and Interval, the graph plots the total number of active backup tasks running on the specified Entity.
Read Latency from backup source	Based on the Rollup Function and Interval, the graph plots the read latency from the backup source. Preferred Rollup Function is **Average**.
Write latency to restore target	Based on the Rollup Function and Interval, the graph plots the write latency to restore the target. Preferred Rollup Function is **Average**.

Power Supply Performance

The table below lists the metrics for the **Power supply temperature stats** schema.

Metric	Description
Power supply temperature	Based on the Rollup Function and Interval, the graph plots the power supply temperature of the specified Entity. Preferred Rollup Function is **Average**.

Replication Performance

The table below lists the metrics for the following schema:

- BackupJobReplicationStats
- BackupJobTargetNodeReplicationStats
- Target Replication Stats

Metric	Description
Logical bytes received	Based on the Rollup Function and Interval, the graph plots the logical bytes received on the specified Entity.
Logical bytes transmitted	Based on the Rollup Function and Interval, the graph plots the logical bytes transmitted by the specified Entity.
Number of metadata actions transmitted	Based on the Rollup Function and Interval, the graph plots the total number of metadata transmitted by the specified Entity.
Physical bytes received	Based on the Rollup Function and Interval, the graph plots the physical bytes received by the specified Entity.
Physical bytes transmitted	Based on the Rollup Function and Interval, the graph plots the physical bytes transmitted by the specified Entity.
Physical bytes transmitted on wire	Based on the Rollup Function and Interval, the graph plots the physical bytes transmitted on wire by the specified Entity.
Tx RPC round trip latencies	Based on the Rollup Function and Interval, the graph plots the Remote Procedure Call (RPC) round trip latency of the specified Entity. Preferred Rollup Function is **Average**.
Tx WAN Latencies	Based on the Rollup Function and Interval, the graph plots the WAN latency of the specified Entity. Preferred Rollup Function is **Average**.

Chapter 31: Virtual Edition

This chapter includes the following topics:

- Cohesity Virtual Edition 4530
- Initial Virtual Edition Cluster Setup 4531
- Configure vSphere Availability for Virtual Edition for VMware 4531
- Extend the Capacities of a Virtual Edition for VMware 4532

Cohesity Virtual Edition

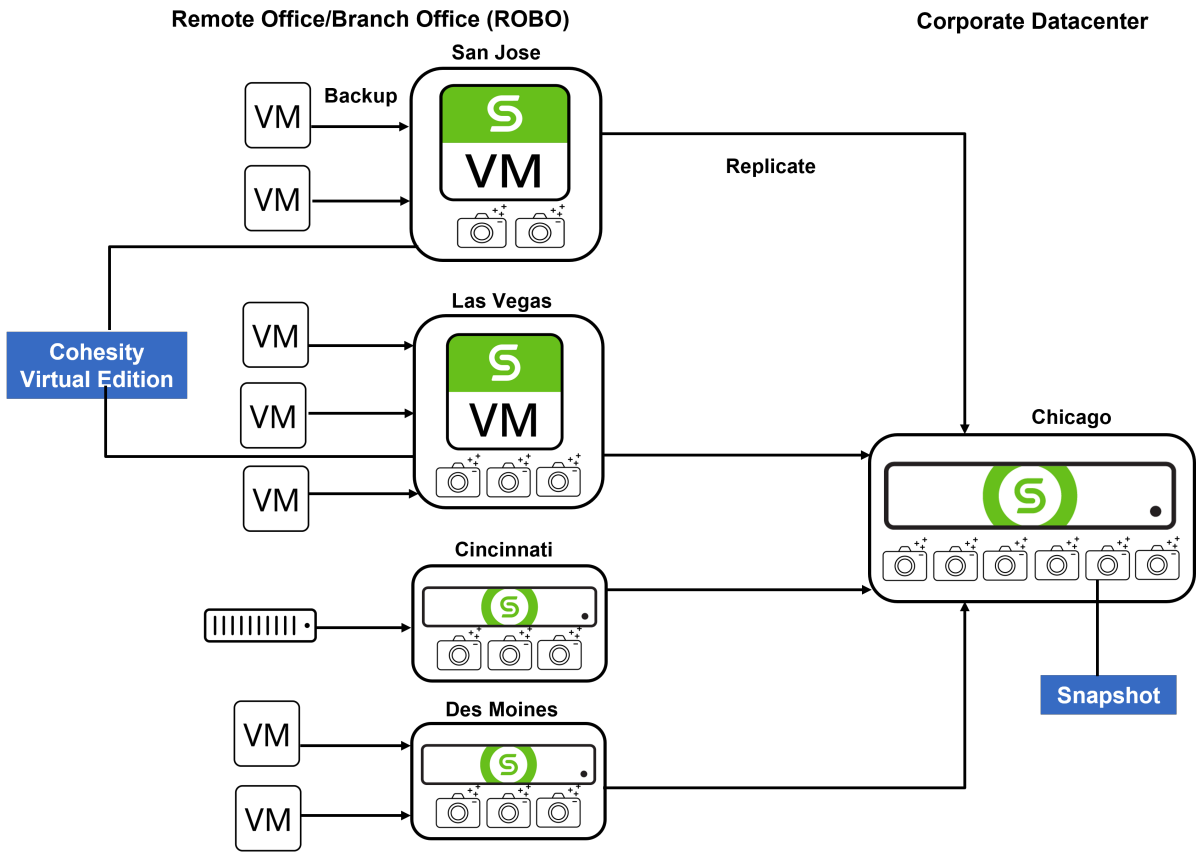
Cohesity Virtual Edition is a single-node Cohesity cluster (ROBO) or multi-node Cohesity cluster that is hosted on a Virtual Machine that is hosted on VMware vCenter Server, Microsoft Hyper-V server, Nutanix AHV, RHEL KVM, AlmaLinux, or OCI Linux KVM. You can use a single-node Virtual Edition if your environment has smaller offices with reduced workloads that do not require the full computing power of a Cohesity cluster running on multiple nodes. In addition, Cohesity Clustered Virtual Edition is a multiple node Cohesity cluster that can support larger workflows and is hosted on multiple Virtual Machines in VMware vCenter Server, Nutanix AHV, RHEL KVM, AlmaLinux, or OCI Linux KVM. For information on the hypervisors and their support for single-node and multi-node clusters, see Virtual Edition.

A single Node Virtual Edition is appropriate for the following reduced workflow example. A company has San Jose and Las Vegas remote offices that require backing up of a small number of VMware Virtual Machines. However, the company wants to centralize the backups on a central Cohesity cluster located in the Datacenter of the Corporate Headquarters. These two smaller remote offices can use Cohesity cluster Virtual Editions to capture Snapshots of the VMs and replicate the Snapshots to the central Cohesity cluster located in the Chicago Corporate Datacenter. This central Cohesity cluster is running directly on hardware supported by Cohesity.

In addition, other remote offices can also replicate Snapshots to the central Cohesity cluster using Cohesity clusters running directly on supported hardware as shown by the following examples:

- At the Cincinnati remote office, a Cohesity cluster captures and then stores Snapshots of a physical server.
- At the Des Moines remote office, a Cohesity cluster captures and then stores Snapshots of Virtual Machines.

These Snapshots are then replicated to the central Cohesity cluster located in Chicago.



Initial Virtual Edition Cluster Setup

The initial Cohesity cluster Virtual Edition setup instructions are available at the Initial Cluster Setup.

Configure vSphere Availability for Virtual Edition for VMware

- Turn On vSphere HA
- Set the Host Failure Response to Restart VMs
- Enable VM Monitoring of the heartbeat

To enable these vSphere Availability Settings, follow the **Configure vSphere Availability for Virtual Edition for VMware** procedure in the Setup Guide (Cohesity Virtual Edition for VMware) and complete the appropriate procedure for your vSphere version.

Extend the Capacities of a Virtual Edition for VMware

Extending the node capacities of a Virtual Edition(VE) for VMware is predefined by the cluster configuration, either SMALL or Large.

> **Note:** For multi-node cluster,
> - you can add or extend the disk for individual nodes or all nodes.
> - you can add multiple disks to a node.
> - you must add or extend the disk on only one node at a time.

This section assumes that the node to be extended is part of the cluster and is healthy with no cluster operation running on the node. To check the cluster operations, run `iris_cli cluster status` and ensure the cluster status is as below:

```
SERVICE STATE SYNC: DONE
```

```
CLUSTER ACTIVE OPERATION: <this field must be empty>
```

```
CLUSTER HEAL STATUS: NORMAL
```

Small Configurations (8TB VE)

Small configurations support a maximum of 8TB data disk space on each node accumulating all data disks on the node. The node to be extended must satisfy the following conditions before and after the capacity extend:

Settings	Value
Minimum size for each Metadata disk	256GB (preferred size is 512GB)
Maximum size for each Metadata disk	1TB
Maximum total number of Metadata disks allowed to be attached to the node	2
Maximum total size of all Metadata disks on a node	1TB
Minimum size for each Data disk	512GB (preferred size is 1TB)
Maximum size for each Data disks	8TB
Maximum total number of data disks allowed to be attached to the node	8
Maximum total size of all Data disks on a node	8TB
Data disk size (x) to Metadata disk size (y) maximum ratio	x/y<=20

Settings	Value
Data disk size (x) to Metadata disk size (y) preferred ratio	x/y<=16
Minimum number of CPUs	12
Minimum memory required	32GB

Large Configuration (16TB VE)

Large configurations support a maximum 16TB data disk space on each node accumulating all data disks on the node. The node to be extended must satisfy the following conditions before and after the capacity extend:

Settings	Value
Minimum size for each Metadata disk	256GB (preferred size is 512GB)
Maximum size for each Metadata disk	1TB
Maximum total number of Metadata disks allowed to be attached to the node	4
Maximum total size of all Metadata disks on a node	2TB
Minimum size for each Data disk	512GB (preferred size is 1TB)
Maximum size for each Data disks	8TB
Maximum total number of data disks allowed to be attached to the node	8
Maximum total size of all Data disks on a node	16TB
Data disk size (x) to Metadata disk size (y) maximum ratio	x/y<=20
Data disk size (x) to Metadata disk size (y) preferred ratio	x/y<=16
Minimum number of CPUs	24
Minimum memory required	64GB

During the initial installation and configuration of the Virtual Edition Virtual Machine, you select one of the predefined configuration deployment types, either SMALL or LARGE.

The initial installation and configuration process of the Virtual Edition VM is described in the Virtual Edition for VMware Setup Guide (PDF).

Review the following prerequisites and warnings before starting the process to extend the capacities of the Virtual Edition VMware VM:

- You must have a vCenter Server account that has been granted administrator privileges for the ESXi host that is hosting the Virtual Edition.
- During this process, the Cohesity cluster services must be stopped and the cluster must be powered off. Therefore, during this process, the cluster is unable to run workflow tasks such as Protection Groups, Recover tasks, Replicating Data tasks, etc. Cohesity recommends stopping all tasks on the cluster before starting this process.
- If the ESXI host reboots, power cycles or powers off during this extension process, data loss may occur. If this occurs, contact Cohesity Support.
- The ESXi Datastores that are hosting the Virtual Edition VM must have enough capacity to support the disk size expansion of the VM. A new Datastore cannot be used to extend the size of the existing disks on the VM. It can be used only to expand the capacities of an existing VM by adding a new disk with a restriction on the total number of disks attached to the VM.
- All disks must be attached to different SCSI controllers.

You can extend the node capacities of a Virtual Edition VMware in two ways:

- Add a new disk to Virtual Edition VMware.
- Extend an existing disk on the Virtual Edition VMware.

> **Note:** Cohesity recommends adding multiple disks each from different datastore to the Virtual Edition VMware as it provides better disk bandwidth.

Add a New Data Disk or Metadata Disk

1. Run the Cohesity CLI locally or remotely on the Virtual Edition. For more information, see Using the Cohesity CLI and List of Cohesity CLI Commands.

   ```
   iris_cli
   admin>
   ```

2. Verify the capacities of the existing Metadata and Disk Tier disks. For a Metadata disk, STORAGE TIER is set to PCIeSSD. For a Data Tier disk, STORAGE TIER is set to SATA-HDD.

   ```
   admin> disk ls
   ```

   Sample Output

   In the following sample output, the capacity of the Data disk is 7.99 TiB and the capacity of the Metadata disk is 500 GiB.

```
DISK ID                    : 7
CURRENT NODE ID            : 1508041826908565
CURRENT NODE IP            : 10.2.43.160
REMOVAL STATE              :
REMOVAL REASON             :
STORAGE TIER               : SATA-HDD
DISK SERIAL                :
LOCATION IN CHASSIS        : N/A
MOUNT PATH                 : /home/cohesity/data/disks/sdc2_b1c65849-
40ad-4e59-86e5-51c0134f73bc
MAXIMUM PHYSICAL CAPACITY : 7.99 TiB
MAXIMUM USABLE CAPACITY    : 7.99 TiB
DISK RESERVATIONS          :
librarian                  : 163.64 GiB
apollo                     : 114.55 GiB
hydra                      : 81.82 GiB
groot                      : 81.82 GiB

DISK ID                    : 6
CURRENT NODE ID            : 1508041826908565
CURRENT NODE IP            : 10.2.43.160
REMOVAL STATE              :
REMOVAL REASON             :
STORAGE TIER               : PCIeSSD
DISK SERIAL                :
LOCATION IN CHASSIS        : N/A
MOUNT PATH                 : /home/cohesity/data/disks/sdb1_5a6ccde4-
4600-4b50-9ae6-ab441c2fe42b
MAXIMUM PHYSICAL CAPACITY : 500.00 GiB
MAXIMUM USABLE CAPACITY    : 500.00 GiB
DISK RESERVATIONS          :
scribe                     : 163.64 GiB
hydra                      : 35.00 GiB
yoda                       : 5.00 GiB
```

3. Using a VMware vSphere Web Client, log in to a vCenter Server that hosts Virtual Edition VM:
    1. Enter the URL of your vCenter Server in the address bar of a web browser in the following format: https://<vcenter_server_ip_address_or_fqdn>.
    2. On the vSphere Welcome page, click **Launch vSphere Client (HTML5)**.
    3. On the vSphere login page, enter the username and password of the vCenter Server and click **Login**.
4. In the left pane, browse for the Virtual Edition VM to extend capacity.

5. If the VM is running, right-click the VM and select **Power Off**.
6. Right-click the VM and select **Edit Settings**.
7. Click the **Add hard disk** tab > **New hard disk**.
8. Update the size of the new hard disk.

   Warning: Do not change the size of existing data disks.

   Note: If the newly added disk is for the data tier, the data tier size after extension must be at most 16 times than the size of the metadata tier. If this is not the case, you need to extend the metadata disk tier capacity either by updating the size of the existing metadata disk or adding one more disk for the metadata tier. For example if the Virtual Edition VM was originally a configuration with a 500GB Metadata disk and a 8000GB Data Tier disk and you increase the disk sizes to a 1000 GB Metadata disk and a 16000 GB Data Tier disk, you must also increase the number of vCPUs to 8 and the memory to 64000. At most, allocate 16 times more disk space to the Data Tier drive than the Metadata drive. The Metadata drive size must be smaller than the Data Tier drive size.

9. Click **OK** to save the changes. Wait until this operation is completed.
10. Right-click the VM and select **Power On**.
11. Run the Cohesity CLI locally or remotely on the Virtual Edition. For more information, see Using the Cohesity CLI and List of Cohesity CLI Commands.

    ```
    iris_cli
    admin>
    ```

12. Stop the cluster services.

    ```
    admin> cluster stop
    ```

    Wait for 2 minutes for the cluster services to stop.

13. Find and copy the node ID of the cluster.

    ```
    admin> node list
    ```

14. Based on the requirement, perform the following:

    Adding a Data Disk to the Node

> **Note:** You must be on the same VM node where the new disk is added. If the data-to-metadata tier ratio is not maintained after adding a new data disk, you must add a new metadata disk or extend the existing one before adding a new data disk to maintain the ratio.

Perform the following steps:

1. Run `lsblk` on bash on the node to see the new disk added and copy its disk path.
2. Run the following command:

```
iris_cli
```

```
admin> disk assimilate disk-paths=<disk_path_of_new_disk_on_node>
node-id=<node ID>
```

Adding a Metadata Disk to the Node

Perform the following steps:

1. Run `lsblk` on bash on the node to see the new disk added and copy its disk path.
2. Run the following command:

```
iris_cli
```

```
admin> disk assimilate disk-paths=<disk_path_of_new_disk_on_node>
node-id=<node ID> is-metadata=true
```

15. View the current disk size

```
admin> disk ls
```

Keep repeating this command until the MAXIMUM PHYSICAL CAPACITY field settings for both the Metadata disk and the Data Tier disk are equal to the new sizes you specified. For a Metadata disk, STORAGE TIER is set to PCIeSSD. For a Data Tier disk, STORAGE TIER is set to SATA-HDD.

> **Note:** It can take up to 10 minutes for the size to be increased.

16. After the sizes are equal to the new sizes you specified, start the cluster services.

```
admin> cluster start
```

Wait for 2 minutes for the cluster services to start.

17. Log in to the Cohesity Dashboard:

a. Start a browser and enter the Cohesity cluster domain name in the browser address bar.

b. Log in to the Cohesity Dashboard. The default System Admin account is `admin` and the default password is `administartor`.

18. Wait for the Cohesity Dashboard to report the updated storage capacity.

    It can take about 10 minutes for the Cohesity Dashboard to report the updated storage capacity.

19. Resume running the workflow tasks on the cluster such as Protection Groups, Recover tasks, Replicating Data tasks, etc.

Extend Existing Data Disk or Metadata Disk

1. Run the Cohesity CLI locally or remotely on the Virtual Edition. For more information, see Using the Cohesity CLI and List of Cohesity CLI Commands.

```
iris_cli
admin>
```

2. Verify the capacities of the existing Metadata and Disk Tier disks. For a Metadata disk, STORAGE TIER is set to PCIeSSD. For a Data Tier disk, STORAGE TIER is set to SATA-HDD.

```
admin> disk ls
```

Sample Output

In the following sample output, the capacity of the Data disk is 7.99 TiB and the capacity of the Metadata disk is 500 GiB.

```
DISK ID                   : 7
CURRENT NODE ID           : 1508041826908565
CURRENT NODE IP           : 10.2.43.160
REMOVAL STATE             :
REMOVAL REASON            :
STORAGE TIER              : SATA-HDD
DISK SERIAL               :
LOCATION IN CHASSIS       : N/A
MOUNT PATH                : /home/cohesity/data/disks/sdc2_b1c65849-
40ad-4e59-86e5-51c0134f73bc

MOUNT PATH                 : /home/cohesity/data/disks/sdb1_5a6ccde4-
4600-4b50-9ae6-ab441c2fe42b
MAXIMUM PHYSICAL CAPACITY : 500.00 GiB
MAXIMUM USABLE CAPACITY    : 500.00 GiB
DISK RESERVATIONS          :
scribe                     : 163.64 GiB
hydra                      : 35.00 GiB
yoda                       : 5.00 GiB
```

3. Using a VMware vSphere Web Client, log in to a vCenter Server that hosts Virtual Edition VM:
    1. Enter the URL of your vCenter Server in the address bar of a web browser in the following format: https://<vcenter_server_ip_address_or_fqdn>.
    2. On the vSphere Welcome page, click **Launch vSphere Client (HTML5)**.
    3. On the vSphere login page, enter the username and password of the vCenter Server and click **Login**.
4. The vSphere Client home page opens. The left panel displays the hosts, clusters, and VMs in the vSphere inventory. From the left pane, find the Virtual EditionVM to extend capacity.
5. If the VM is running, right-click the VM and select **Power Off**.
6. Right-click the VM and select **Edit Settings**.
7. Select the hard disk that you want to extend and update its size.

    > **Note:** If you are extending the Data disk, the disk size must be extended to a size that is at most 16 times the size of the Metadata disk. If this requirement is not met, you need to extend the Data disk capacity by increasing the size of the existing Data disk or by adding an additional Data disk. To add a new disk, see Add a New Data Disk or Metadata Disk.

8. Click **OK** to save the changes. Wait until this operation completes.
9. Right-click the VM and select **Power On**.

10. Run the Cohesity CLI locally or remotely on the Virtual Edition. For more information, see Using the Cohesity CLI and List of Cohesity CLI Commands.

```
iris_cli
admin>
```

11. Stop the cluster services.

```
admin> cluster stop
```

Wait for 2 minutes for the cluster services to stop.

12. Disable Secure Shell

```
admin> cluster secure-shell enable=false
```

> **Note:** After disabling the secure shell, the current session will exit, wait a few minutes and log back in again.

13. Stop the containerd service.

```
[support@virtual-node-1 ~]$ sudo systemctl stop containerd
```

14. Check for any Cohesity services that are still actively using the disk. Ensure the output of this command is empty before you proceed. Update the sdc2 value according to the disk that needs to be extended (refer to the output from Step 2).

```
[support@virtual-node-1 ~]$ sudo lsof | grep /home_cohesity_
data/disks/sdc2
```

15. Find and copy the node ID of the cluster.

```
admin> node list
```

16. Extend the size of the disks

```
admin> disk extend node-id=<node ID of node where disks are extended>
```

> **Note:** If you are extending the Data disk or Metadata disk size by adding a new disk, follow the steps in Add a New Data Disk or Metadata Disk.

17. View the current disk size

```
admin> disk ls
```

Keep repeating this command until the MAXIMUM PHYSICAL CAPACITY field settings for both the Metadata disk and the Data Tier disk are equal to the new sizes you specified. For a Metadata disk, STORAGE TIER is set to PCIeSSD. For a Data Tier disk, STORAGE TIER is set to SATA-HDD.

> **Note:** It can take up to 10 minutes for the size to be increased.

18. Start the containerd service.

```
[support@virtual-node-1 ~]$ sudo systemctl start containerd
```

19. Start Secure Shell

```
admin> cluster secure-shell enable=true
```

> **Note:** Enabling the secure shell will disconnect the current session, wait a few minutes and login again.

20. After the sizes are equal to the new sizes you specified, start the cluster services.

```
admin> cluster start
```

Wait for 2 minutes for the cluster services to start.

21. Log in to the Cohesity Dashboard:
    a. Start a browser and enter the Cohesity cluster domain name in the browser address bar.
    b. Log in to the Cohesity Dashboard. The default System Admin account is `admin` and the default password is `administartor`.
22. Wait for the Cohesity Dashboard to report the updated storage capacity.

    It can take about 10 minutes for the Cohesity Dashboard to report the updated storage capacity.
23. Resume running the workflow tasks on the cluster such as Protection Groups, Recover tasks, Replicating Data tasks, etc.

Chapter 32: DataProtect for Cloud

Cohesity simplifies data management for organizations, allowing them to experience the benefits of the cloud without giving up control over their data. DataProtect for cloud is a Cohesity cluster deployed in a cloud service, designed to offer high performance and greater cluster capacity.

Cohesity supports the following DataProtect for cloud:

DataProtect for Cloud in AWS

DataProtect for Cloud in Azure

DataProtect for Cloud in GCP

For information on the DataProtect for cloud supportability, see DataProtect for Cloud Supportability.

DataProtect for Cloud in AWS

DataProtect for cloud in AWS is a Cohesity cluster deployed in AWS, designed to offer high performance and greater cluster capacity. This solution employs advanced data deduplication and compression techniques to significantly reduce data footprints and storage costs.

This section provides the following information on DataProtect for cloud in AWS:

Supported Regions for Deploying DataProtect for Cloud in AWS

The following table lists the regions you can deploy DataProtect for cloud in AWS using CLI and Helios:

Supported Regions for Deploying DataProtect for cloud in AWS Using CLI	Supported Regions for Deploying DataProtect for cloud in AWS Using Helios
In CLI, you can deploy DataProtect for cloud in AWS in all regions supported by the AWS cloud (including AWS GovCloud). For the list of supported regions, see Regions and zone.	• us-east-1: US East (N. Virginia) • us-east-2: US East (Ohio) • us-west-1: US West (N. California) • us-west-2: US West (Oregon) • ca-central-1: Canada (Central) • eu-central-1: Europe (Frankfurt) • eu-west-1: Europe (Ireland) • eu-west-2: Europe (London) • eu-west-3: Europe (Paris) • eu-north-1: Europe (Stockholm) • ap-east-1: Asia Pacific (Hong Kong) • ap-northeast-1: Asia Pacific (Tokyo) • ap-northeast-2: Asia Pacific (Seoul) • ap-northeast-3: Asia Pacific (Osaka) • ap-southeast-1: Asia Pacific (Singapore) • ap-southeast-2: Asia Pacific (Sydney) • ap-south-1: Asia Pacific (Mumbai)

Supported Regions for Deploying DataProtect for cloud in AWS Using CLI	Supported Regions for Deploying DataProtect for cloud in AWS Using Helios
	• sa-east-1: South America (São Paulo) • us-gov-west-1: US-Gov-West • us-gov-east-1: US-Gov-East

Supported DataProtect for Cloud in AWS Configurations

Based on the performance and cluster capacity per cluster node requirement, Cohesity supports the following cluster configurations:

Cluster Configuration	Instance Type (Intel/AMD)	EBS Volume Type	CPU and Memory	Metadata Tier	Cache Tier	Boot Disk
NGCE AWS Entry - Config 1	m6i.2xlarge /m6a.2xlarge	gp3 for metadata and cache tiers io1 for boot disk	8 vCore 32 GB	2 x 511 GB	2 x 512 GB	81 GB
NGCE AWS Core - Config 11	m6i.4xlarge/m6a.4xlarge		16 vCore 64 GB	2 x 1 TB	2 x 1 TB	
NGCE AWS Archive - Config 21	m6i.4xlarge/m6a.4xlarge		16 vCore 64 GB	2 x 2 TB	2 x 2 TB	
NGCE AWS Performance - Config 31	m6i.8xlarge/m6a.8xlarge		32 vCore 128 GB	2 x 1 TB	2 x 1 TB	

DataProtect for Cloud in AWS Permissions

The following table lists the permission that is required for the deploying DataProtect for cloud in AWS:

For information on backup and recovery permissions, see AWS resources.

> **Note:** For a node being added to an existing cluster. Once the cluster is deployed, the IAM permissions are not required and can be removed.

Open the JSON (or right-click and save as a file).

AWS Resource Type	Permissions	Description
IAM	ListAttachedUserPolicies GetPolicyVersion GetPolicy ListGroupsForUser ListUsers ListPolicies GetUser GetRole CreateRole TagRole AttachRolePolicy DetachRolePolicy CreateInstanceProfile RemoveRoleFromInstanceProfile DeleteInstanceProfile PassRole AddRoleToInstanceProfile GetInstanceProfile DeleteRole	Cohesity uses the access key and the secret access key provided to validate the IAM user. IAM permissions are required to get the user, the policy for the user and to validate the credentials. To create a cluster by using Helios, Cohesity uses System Service Manager (SSM). A role is created for SSM and passed onto the service. These IAM permissions are required to create a policy, create a role for SSM operation, attach the policy to this role and pass the role onto the SSM service for performing operations to create a cluster using Helios. Delete role and delete role policy permissions are required to delete the role and policy created for the SSM operation after the task is complete.

AWS Resource Type	Permissions	Description
CloudFormation	UpdateStack ListStackResources CreateStack GetTemplate DeleteStack DescribeStacks DescribeStackEvents ValidateTemplate	Cohesity creates a CloudFormation template using the information provided on the UI for cluster creation, and creates a CloudFormation stack. The stack is deleted when destroy cluster command is used from the control VM. Validate cluster validates the Cloud Formation template which requires the permission "`cloudformation:ValidateTemplate`". "`cloudformation:DeleteStack`" is required while executing destroy cluster.

AWS Resource Type	Permissions	Description
EC2	AttachNetworkInterface AttachVolume AuthorizeSecurityGroupEgress AuthorizeSecurityGroupIngress CreateLaunchTemplate CreateNetworkInterface CreateSecurityGroup CreateTags CreateVolume DeleteNetworkInterface DeleteSecurityGroup DeleteTags DeleteVolume DescribeAvailabilityZones DescribeIamInstanceProfileAssociations DescribeInstanceStatus DescribeInstances DescribeNetworkInterfaces DescribeRegions DescribeSecurityGroups DescribeSubnets DescribeVolumes DescribeVpcs DetachNetworkInterface DetachVolume ModifyNetworkInterfaceAttribute ModifyVolumeAttribute ReplaceIamInstanceProfileAssociation RevokeSecurityGroupEgress	Creating a cluster requires creating AWS EC2 instances. Network Interface and volumes are created and attached to the instance to create a cluster node in a particular region. Tags are created and added to these EC2 services. Permissions to start/stop these instances are required while executing commands to start/stop cluster from the control VM. Permissions to delete all the EC2 services created while creating cluster are required while executing destroy cluster/delete VMs from the control VM. While creating a cluster using Helios, users can create a new security group and deploy the cluster using that security group instead of using the existing security group. Therefore, Cohesity needs permission to create the security group, delete the security group, authorize the security group ingress and egress, and revoke the security group ingress and egress.

AWS Resource Type	Permissions	Description
	RevokeSecurityGroupIngress RunInstances StartInstances StopInstances TerminateInstances	
SSM	GetCommandInvocation SendCommand	Cohesity uses the SSM agent to communicate with the cluster node VMs when they come up. This communication is required to send commands to create the cluster and also to check the cluster creation status. Therefore, SSM commands are required to create a cluster using Helios.
S3	CreateBucket DeleteBucket DeleteObject GetObject PutBucketPublicAccessBlock PutObject ListBucket GetBucketObjectLockConfiguration GetObjectRetention PutObjectRetention	These permissions are required when the CloudFormation template size exceeds 51200 bytes and Cohesity needs to upload the template to an S3 bucket. `S3:GetBucketObjectLockConfiguration`, `S3:GetObjectRetention`, and `S3:PutObjectRetention` are the permissions required if you are enabling object lock. • `S3:GetBucketObjectLockConfiguration`: Gets the Object Lock configuration for a bucket. • `S3:GetObjectRetention`: Retrieves an object's retention settings. • `S3:PutObjectRetention`: Places an Object Retention configuration on an object.

DataProtect for Cloud in AWS Cluster Setup

The initial setup instructions for DataProtect for cloud in AWS are available at Initial Cluster Setup.

DataProtect for Cloud in AWS Supportability

Supported Sources and Workloads

The following table provides the mapping of the workflows that are supported on the sources DataProtect for cloud in AWS supports, as per the latest release:

Workload	Backup	Recovery	Cloud Archive*	Replication	Recovery Level	Notes
Amazon RDS for MySQL	Yes	Yes	Yes	Yes	Database-level (with ingest-based protection) Instance-level (with snapshot-based protection)	Supports both snapshot-based and ingest-based protection.
Amazon Aurora MySQL	Yes	Yes	Yes	Yes	Database-level (with ingest-based protection) Cluster-level (with snapshot-based protection)	Supports both snapshot-based and ingest-based protection.
Amazon Redshift Cluster	Yes	Yes	Yes	Yes	Database-level	Supports only ingest-based protection.
Amazon DocumentDB	Yes	Yes	Yes	Yes	Database-level	Supports only ingest-based protection.

Workload	Backup	Recovery	Cloud Archive*	Replication	Recovery Level	Notes
Amazon RDS for Oracle	Yes	Yes	Yes	Yes	Instance-based	Supports both ingest based and snapshot-based protection.
Amazon DynamoDB	Yes	Yes	Yes	Yes	Table-level	Supports only ingest-based protection.
Amazon RDS PostgreSQL	Yes	Yes	Yes	Yes	Database-level (with ingest-based protection) Instance-level (with snapshot-based protection)	Supports both ingest based and snapshot-based protection.
Amazon Aurora PostgreSQL	Yes	Yes	Yes	Yes	Database-level (with ingest-based protection) Cluster-level (with snapshot-based protection)	Supports both ingest based and snapshot-based protection.

Workload	Backup	Recovery	Cloud Archive*	Replication	Recovery Level	Notes
Amazon RDS for Microsoft SQL Server (MS SQL)	Yes	Yes	Yes	Yes	Database-level (with ingest-based protection) Instance-level (with snapshot-based protection)	Supports both ingest based and snapshot-based protection.
Amazon RDS for MariaDB	Yes	Yes	Yes	No	Instance-level	Supports only snapshot-based protection
Amazon RDS Custom for Oracle					Database-level (with ingest-based protection) Instance-level (with snapshot-based protection)	Supports both ingest based and snapshot-based protection.
Amazon RDS Custom for SQL Server	Yes	Yes	Yes	No	No	
AWS EC2	Yes	Yes	Yes	Yes	File-level	File-level recovery is not supported for EC2 instances with XFSv5 file system.

Workload	Backup	Recovery	Cloud Archive*	Replication	Recovery Level	Notes
AWS S3	Yes	Yes	Yes	Yes	File-level	Granular recovery of S3 objects with prefixes is supported.
VMware Cloud (VMC)	Yes	Yes	Yes	No	File-level	Multi-tenancy should be enabled and hybrid extender needs to be configured. Supported from 7.2.2_u2 version onwards.
Nutanix AHV Prism Central	Yes	Yes	Yes	Yes	File-level	
Acropolis: Acropolis Standalone Cluster	Yes	Yes	Yes	Yes	File-level	
Physical Server for Windows and Linux	Yes	Yes	Yes	Yes	File-level	Supports both file-based and block-based backups.
MS SQL Server (Standalone,AG, and FCI)	Yes	Yes	Yes	Yes	File-level	Supports MS SQL File-based and VDI-based backups.
Microsoft 365	Yes	Yes	Yes	Yes	File-level	

Workload	Backup	Recovery	Cloud Archive*	Replication	Recovery Level	Notes
NAS (Generic NAS, NetApp, Isilon, Pure Storage FlashBlade)	Yes	Yes	Yes	Yes	File-level	• Supports NAS volumes with NFSv3, NFSv4.1, SMB v1, v2.x, and v3 versions. • NetApp: Supports only File-Runner-based backup. SnapDiff-based backup is not supported. • Isilon: Supports both File-runner and CFT-based backups.
SAP HANA on Linux (x86)	Yes	Yes	Yes	Yes	Not Applicable	
MongoDB	Yes	Yes	Yes	Yes	Not Applicable	
Cassandra	Yes	Yes	Yes	Yes	Not Applicable	

Workload	Backup	Recovery	Cloud Archive*	Replication	Recovery Level	Notes
Hadoop	Yes	Yes	Yes	Yes	File-level (Only Hadoop HDFS)	Supports protection of HDFS, Hive, and HBase objects.
Oracle Database	Yes	Yes	Yes	Yes	Not Applicable	Supports both Oracle Adapter and Oracle SBT Plug-in.
IBM DB2 on Linux	Yes	Yes	Yes	Yes	Not Applicable	
PostgreSQL on Linux	Yes	Yes	Yes	Yes	Not Applicable	Supports instant restore.
SAP on Oracle for Linux	Yes	Yes	Yes	Yes	Not Applicable	
SAP on Oracle for Windows	Yes	Yes	Yes	Yes	Not Applicable	
SAP MaxDB on Linux	Yes	Yes	Yes	Yes	Not Applicable	
SAP MaxDB on Windows	Yes	Yes	Yes	Yes	Not Applicable	
MySQL EE Commercial Edition	Yes	Yes	No	No	Database-level	

*DataProtect for cloud in AWS supports only Cloud Archive with **Incremental Forever** archival format.

- DataProtect for cloud in AWS supports Write Once Read Many (WORM) for Cloud Archive with incremental forever archival format. The WORM model ensures that the objects written to the WORM-supported targets cannot be tampered with (deleted or overwritten). The archives created are immutable for the duration configured. For the list of external targets with WORM support,

For the list of supported external targets for Cloud Archive, see Supported Workflows and External Targets.

For information on registering an external target, see Register an External Target.

SmartFiles Support

DataProtect for cloud in AWS supports SmartFiles for SMB, NFS, and S3 protocols, with functionality limited to View Snapshots and Replication.

For more information, see SmartFiles (File and Object Services).

Marketplace Support

You can install Marketplace Apps on DataProtect for cloud in AWS. For more information on Marketplace App, see Apps.

FortKnox Support

Cohesity FortKnox supports vaulting data from DataProtect for cloud in AWS to a cloud vault. For more information, see Clusters.

Multitenancy

DataProtect for cloud in AWS supports the multitenancy feature. The multitenancy feature enables you to configure the multitenant environment on your Cohesity Platform and securely isolate each tenant in your environment. For more information, see Organizations (Multitenancy) .

Manage DataProtect for Cloud Nodes in AWS

For information on managing nodes of DataProtect for cloud in AWS, see Manage Nodes.

DataProtect for Cloud in AWS Object Lock

For DataProtect for cloud in AWS, you can configure Object Lock to secure the backed-up data. Enabling Object Lock prevents data from being modified, deleted, or overwritten on the object storage. You can configure Object Lock while registering the object storage as an external target to store the data.

Prerequisites for Object Lock

Before registering an object storage as an external target with Object Lock enabled, ensure the following:

- **For AWS external target (AWS S3 Bucket)**: The AWS external target must have versioning and Object Lock enabled. For more information, see Using S3 Object Lock. This property must be set at the time of target creation and cannot be enabled after creation.

> **Note:**
> Avoid setting default retention on AWS target- this is not required as Cohesity locks the objects for the duration required. Large default retentions affect garbage collection and increase costs.

Considerations for Object Lock

- For the AWS target, the objects will be locked in the Governance retention mode by default. To use the Compliance mode, contact Cohesity Support.
- When backing up data to versioned buckets, ensure that you do not edit the storage class of objects directly. Editing the storage class of objects directly will create a new version of the object while the original version remains in the previous storage tier. Object-level locks will not be carried over to the new version.
- The expiry of the object lock will match the retention of the backup snapshots. However, the object lock will not update if you modify the expiry for archived snapshots after the Protection Group has run.
- Once enabled, Object Lock cannot be disabled.
- With Object Lock enabled, the storage utilization of external targets may be higher.
- If Object Lock compliance is not met for a backup, then the backup will fail.

DataProtect for Cloud in AWS Considerations

Review the following considerations for DataProtect for cloud in AWS:

- Cohesity does not support the following features on DataProtect for cloud in AWS:
  - Direct migration from DataProtect for cloud (legacy) in AWS to DataProtect for cloud in AWS. As an alternative, you can deploy a new DataProtect for cloud in AWS cluster and then replicate the data from DataProtect for cloud (legacy) in AWS to the newly deployed DataProtect for cloud in AWS.
  - CloudArchive with periodic full.
  - CloudTier workflow.
  - Data movement policy to move data to archive tiers.
  - Policy-based Cloud Spin.
- DataProtect for cloud in AWS supports Write Once Read Many (WORM) for CloudArchive with incremental forever format. The WORM model ensures that the objects written to the WORM-supported AWS targets cannot be tampered with (deleted or overwritten). The archives created are immutable for the duration configured. For the list of WORM supported AWS external targets, see Supported Workflows and External Targets.

DataProtect for Cloud in Azure

DataProtect for cloud in Azure is a Cohesity cluster deployed in Azure, designed to offer high performance and greater cluster capacity. This solution employs advanced data deduplication and compression techniques to significantly reduce data footprints and storage costs.

This section provides the following information on DataProtect for cloud in Azure:

Supported Regions for Deploying DataProtect for Cloud in Azure

The following table lists the regions you can deploy DataProtect for cloud in Azure using CLI and Helios:

Supported Regions for Deploying DataProtect for cloud in Azure Using CLI	Supported Regions for Deploying DataProtect for cloud in Azure Using Helios
In CLI, you can deploy DataProtect for cloud in Azure in all regions supported by the Azure cloud. For the list of supported regions, see Regions.	• Australia Central (Canberra) • Australia Central 2 (Canberra) • Australia East (New South Wales) • Australia Southeast (Victoria) • Brazil South (Sao Paulo State) • Brazil Southeast (Rio) • Brazil US • Canada Central (Toronto) • Canada East (Quebec) • Central India (Pune) • Central US (Iowa) • East Asia (Hong Kong) • East US (Virginia) • East US 2 (Virginia) • France Central (Paris) • France South (Marseille) • Germany North (Berlin) • Germany West Central (Frankfurt) • Israel Central (Israel) • Italy North (Milan) • Japan East (Tokyo, Saitama) • Japan West (Osaka) • Jio India Central (Nagpur) • Jio India West (Jamnagar) • Korea Central (Seoul) • Korea South (Busan) • Mexico Central (Querétaro State) • North Central US (Illinois) • North Europe (Ireland)

Supported Regions for Deploying DataProtect for cloud in Azure Using CLI	Supported Regions for Deploying DataProtect for cloud in Azure Using Helios
	• Norway East (Norway) • Norway West (Norway) • Poland Central (Warsaw) • Qatar Central (Doha) • South Africa North (Johannesburg) • South Africa West (Cape Town) • South Central US (Texas) • Southeast Asia (Singapore) • South India (Chennai) • Spain Central (Madrid) • Sweden Central (Gävle) • Switzerland North (Zurich) • Switzerland West (Geneva) • UAE Central (Abu Dhabi) • UAE North (Dubai) • UK South (London) • UK West (Cardiff) • West Central US (Wyoming) • West Europe (Netherlands) • West India (Mumbai) • West US (California) • West US 2 (Washington) • West US 3 (Phoenix)

Supported DataProtect for Cloud in Azure Configurations

Based on the performance and cluster capacity per cluster node requirement, Cohesity supports the following cluster configurations:

Supported configurations for 7.2 version:

Cluster Configuration	Managed Disk Type	CPU and Memory	Metadata Tier	Cache Tier	Boot Disk
NGCE Azure Entry - Config 1	Premium_LRS (SSD)	16 Core 64 GB	1 x 1 TB	2 x 1 TB	81 GB (Premium_ LRS (SSD))
NGCE Azure Core - Config 2		16 Core 64 GB	2 x 1 TB	4 x 1TB	
NGCE Azure Archive - Config 3		16 Core 64 GB	2 x 2 TB	4 x 2TB	
NGCE Azure Performance - Config 4		32 Core 128 GB	2 x 1 TB	4 x 1TB	
NGCE Azure Performance - Config 5		32 Core 128 GB	2 x 2 TB	4 x 2TB	
NGCE Azure Core v2 - Config 12	PremiumV2_ LRS (SSDv2) *	16 Core 64 GB	2 x 1 TB	2 x 1TB (ssd v2)	
NGCE Azure Archive v2 - Config 13		16 Core 64 GB	2 x 2 TB	2 x 2TB (ssd v2)	
NGCE Azure Performance v2 - Config 14		32 Core 128 GB	2 x 1 TB	2 x 1TB (ssd v2)	
NGCE Azure Performance v2- Config 15		32 Core 128 GB	2 x 2 TB	2 x 2TB (ssd v2)	

Cohesity supports Standard_DSV5 series instance type

***Considerations for PremiumV2_LRS**

- PremiumV2_LRS is supported only in limited Azure regions.
- PremiumV2_LRS requires deployment into a specific zone.

- PremiumV2_LRS has more restrictive quotas than Premium_LRS. Therefore ensure the quota for PremiumV2_LRS is high enough in the region and zone you want to deploy your DataProtect for cloud in Azure.

Supported configurations for 7.1, 7.1.1, and 7.1.2 versions:

Cluster Configuration	Managed Disk Type	CPU and Memory	MetaData Tier	Cache Tier	Boot Disk
Entry	Premium_LRS (SSD)	16 Core 64 GB	1 x 1023	2x 1024	81 GB (Premium_ LRS (SSD))
Core		16 Core 64 GB	2 x 1023	4 x 1024	
Archive		16 Core 64 GB	2 x 2047	4 x 2048	
Core ssdv2	PremiumV2_ LRS (SSDv2) *	16 CPU 64 GB	2 x 1023	4 x 1024	

Cohesity supports Standard_DSV5 series instance type

***Considerations for PremiumV2_LRS**

- PremiumV2_LRS is supported only in limited Azure regions.
- PremiumV2_LRS requires deployment into a specific zone.
- PremiumV2_LRS has more restrictive quotas than Premium_LRS. Therefore ensure the quota for PremiumV2_LRS is high enough in the region and zone you want to deploy your DataProtect for cloud in Azure.

Quota Requirement

The quotas required for instance types and disk types to deploy DataProtect for cloud in Azure depend on the node configuration and the number of nodes in the cluster. The following table lists the quotas requirement for instance type and disk types to deploy DataProtect for cloud in Azure.

Type	Quota Name	Quota consumed per node
Instance Type	Standard DSv5 Family vCPUs	16 or 32(performance) vCPUs

Type	Quota Name	Quota consumed per node
Premium_LRS Disk Type	Premium Managed Storage	• For 7.1, 7.1.1, and 7.1.2 versions: 1 boot disk, and 3 or 6 data disks • For 7.2 version: 1 boot disk, and 2 or 4 data disks
PremiumV2_LRS Disk Type	PremiumV2StorageDisks	• For 7.1, 7.1.1, and 7.1.2 versions: 3 or 6 data disks • For 7.2 version: 2 or 4 data disks
	PremiumV2TotalDiskSizeGB	• For 7.1, 7.1.1, and 7.1.2 versions: 3072, 6144, or 12288 GiB • For 7.2 version: 2048, 4096, or 8192 GiB

DataProtect for Cloud in Azure Permissions

The following table lists the permission required for deploying DataProtect for cloud in Azure:

For information on backup and recovery permissions, see Azure VM.

Open the JSON (or right-click and save as a file).

Action	Resource Provider	Operation Name
Cluster creation using the setup utility on the Control VM.	Microsoft.Authorization	Microsoft.Authorization/locks/write

Action	Resource Provider	Operation Name

DataProtect for Cloud in Azure Cluster Setup

The initial setup instructions for DataProtect for cloud in Azure are available at Initial Cluster Setup.

DataProtect for Cloud in Azure Supportability

Supported Sources and Workloads

The following table provides the mapping of the workflows that are supported on the sources DataProtect for cloud in Azure supports, as per the latest release:

Workload	Backup	Recovery	Cloud Archival*	Replication	Granular Recovery	Notes
Azure Blob and Azure Data Lake Storage	Yes	Yes	Yes	Yes	File-level	
Azure SQL	Yes	Yes	Yes	Yes	Database-level	
Azure Table Storage	Yes	Yes	Yes	Yes	Table-level	
Azure Cosmos DB - Table	Yes	Yes	Yes	Yes	Table-level	
Azure Cosmos DB - Cassandra	Yes	Yes	Yes	Yes	Keyspace - level	
Azure Cosmos DB - NoSQL	Yes	Yes	Yes	Yes	Database-level	
Azure Cosmos DB - MongoDB	Yes	Yes	Yes	Yes	Database-level	
Azure PostgreSQL	Yes	Yes	Yes	Yes	Database-level	
Azure MySQL	Yes	Yes	Yes	Yes	Database-level	
Azure VMware Solution (AVS)	Yes	Yes	Yes	Yes	File-level	Supported from 7.2.2_u2 version onwards.

Workload	Backup	Recovery	Cloud Archival*	Replication	Granular Recovery	Notes
Azure VM	Yes	Yes	Yes	Yes	No	**Note:** Files and folder recovery of Azure VM is an Early Access feature on Data Protect for cloud in Azure. Contact your Cohesity account team to enable the feature.
Nutanix AHV Prism Central	Yes	Yes	Yes	Yes	File-level	

Workload	Backup	Recovery	Cloud Archival*	Replication	Granular Recovery	Notes
Acropolis: Acropolis Standalone Cluster	Yes	Yes	Yes	Yes	File-level	
Physical Server	Yes	Yes	Yes	Yes	File-level	
MS SQL Server (Standalone and FCI)	Yes	Yes	Yes	Yes	File-level	Supports MS SQL File-based and VDI-based backups.
Microsoft 365	Yes	Yes	Yes	Yes	File-level	
NAS (Generic NAS, NetApp, Isilon, Pure Storage FlashBlade)	Yes	Yes	Yes	Yes	File-level	Supports NAS volumes with NFSv3, NFSv4.1, SMB v1, v2.x, and v3 versions.
SAP HANA	Yes	Yes	Yes	Yes	Not Applicable	
MongoDB	Yes	Yes	Yes	Yes	Not Applicable	
Cassandra	Yes	Yes	Yes	Yes	Not Applicable	
IBM DB2 on Linux	Yes	Yes	Yes	Yes	Not Applicable	
SAP on Oracle for Linux	Yes	Yes	Yes	Yes	Not Applicable	

Workload	Backup	Recovery	Cloud Archival*	Replication	Granular Recovery	Notes
SAP on Oracle for Windows	Yes	Yes	Yes	Yes	Not Applicable	
Hadoop	Yes	Yes	Yes	Yes	Yes (Only Hadoop HDFS)	Supports protection of HDFS, Hive, and HBase objects.
PostgreSQL on Linux	Yes	Yes	Yes	Yes	Not Applicable	Supports instant restore.
SAP Sybase ASE on Windows	Yes	Yes	Yes	Yes	Not Applicable	Supported from 7.2.2_u1 version onwards.
SAP Sybase ASE on Linux	Yes	Yes	Yes	Yes	Not Applicable	Supported from 7.2.2_u1 version onwards.
Oracle Database	Yes	Yes	Yes	Yes	Not Applicable	Supports both Oracle Adapter and Oracle SBT Plug-in.
SAP MaxDB on Linux	Yes	Yes	Yes	Yes	Not Applicable	
SAP MaxDB on Windows	Yes	Yes	Yes	Yes	Not Applicable	
SAP Sybase IQ	Yes	Yes	Yes	Yes	Not Applicable	Supported from 7.2.2_u1 version onwards.

Workload	Backup	Recovery	Cloud Archival*	Replication	Granular Recovery	Notes
MySQL EE Commercial Edition	Yes	Yes	No	No	Database-level	

* DataProtect for cloud in Azure supports both **Cloud Archive with periodic full** and **Cloud Archive with Incremental Forever** archival formats.

For the list of supported external targets for Cloud Archive, see Supported Workflows and External Targets.

For information on registering an external target, see Register an External Target.

SmartFiles Support

DataProtect for cloud in Azure supports SmartFiles for SMB, NFS, and S3 protocols, with functionality limited to View Snapshots and Replication.

For more information, see SmartFiles (File and Object Services).

Marketplace Support

You can install Marketplace Apps on the DataProtect for cloud in Azure. For more information on Marketplace App, see Apps.

FortKnox Support

Cohesity FortKnox supports vaulting data from DataProtect for cloud in Azure to a cloud vault. For more information, see Cohesity FortKnox.

Multitenancy

From 7.2.2_u1 onwards, DataProtect for cloud in Azure supports the multitenancy feature. The multitenancy feature enables you to configure the multitenant environment on your Cohesity cluster and securely isolate each tenant in your environment. For more information, see Organizations (Multitenancy) .

Manage DataProtect for Cloud Nodes in Azure

For information on managing nodes of DataProtect for cloud in Azure, see Manage Nodes.

DataProtect for Cloud in Azure Object Lock

For DataProtect for cloud in Azure, you can configure Object Lock to secure the backed-up data. Enabling Object Lock prevents data from being modified, deleted, or overwritten on the object storage. You can configure Object Lock while registering the object storage as an external target to store the data.

Prerequisites for Object Lock

Before registering an object storage as an external target with Object Lock enabled, ensure the following:

- **For Azure external targets (Azure Hot Blob Storage)**: The Azure external target must have version-level immutability enabled on the storage container, which indicates that the storage account must also have version-level immutability. This property must be set at the time of target creation and cannot be enabled after creation.For more information, see Enable version-level immutability support on a container.

> **Note:**
> Avoid setting default retention on Azure target- this is not required as Cohesity locks the objects for the duration required. Large default retentions affect garbage collection and increase costs.

Considerations for Object Lock

- For the Azure target, the objects will be locked in the Locked mode by default.
- When backing up data to versioned buckets, ensure that you do not edit the storage class of objects directly. Editing the storage class of objects directly will create a new version of the object while the original version remains in the previous storage tier. Object-level locks will not be carried over to the new version.
- The expiry of the object lock will match the retention of the backup snapshots. However, the object lock will not update if you modify the expiry for archived snapshots after the Protection Group has run.
- Once enabled, Object Lock cannot be disabled.
- With Object Lock enabled, the storage utilization of external targets may be higher.
- If Object Lock compliance is not met for a backup, then the backup will fail.

DataProtect for Cloud in Azure Considerations

Review the following considerations for DataProtect for cloud in Azure:

- Cohesity does not support the features on DataProtect for cloud in Azure:
  - Direct migration from DataProtect for cloud (legacy) in Azure to DataProtect for cloud in Azure. As an alternative, you can deploy a new DataProtect for cloud in Azure and then replicate the data from DataProtect for cloud (legacy) in Azure to the newly deployed DataProtect for cloud in Azure.
  - CloudTier workflow.

    - Data movement policy to move data to archive tier s.
    - Policy-based Cloud Spin.
- DataProtect for cloud in Azure backend APIs are only V2 compliant; to automate workflows against DataProtect for cloud in Azure ensure to call the V2 APIs and not V1 APIs.
- From 7.2 version onwards, DataProtect for cloud in Azure supports Write Once Read Many (WORM) for CloudArchive with periodic full. The WORM model ensures that the objects written to the WORM-supported Azure targets cannot be tampered with (deleted or overwritten). The archives created are immutable for the duration configured. For the list of WORM supported Azure external targets, see Supported Workflows and External Targets.

DataProtect for Cloud in GCP

DataProtect for cloud in GCP is a Cohesity cluster deployed in GCP, designed to offer high performance and greater cluster capacity. This solution employs advanced data deduplication and compression techniques to significantly reduce data footprints and storage costs.

This section provides the following information on DataProtect for cloud in GCP:

Supported Regions for Deploying DataProtect for Cloud in GCP

The following table lists the regions you can deploy DataProtect for cloud in GCP using CLI and Helios:

Supported Regions for Deploying DataProtect for cloud in GCP Using CLI	Supported Regions for Deploying DataProtect for cloud in GCP Using Helios
In CLI, you can deploy DataProtect for cloud in GCP in all regions supported by the GCP cloud. For the list of supported regions, see Regions.	• africa-south1 • asia-east1 • asia-east2 • asia-northeast1 • asia-northeast2 • asia-northeast3 • asia-south1 • asia-south2 • asia-southeast1 • asia-southeast2 • australia-southeast1 • australia-southeast2 • europe-central2 • europe-north1 • europe-southwest1 • europe-west1 • europe-west10 • europe-west12 • europe-west2 • europe-west3 • europe-west4 • europe-west6 • europe-west8 • europe-west9 • me-central1 • me-central2 • me-west1 • northamerica-northeast1

Supported Regions for Deploying DataProtect for cloud in GCP Using CLI	Supported Regions for Deploying DataProtect for cloud in GCP Using Helios
	• northamerica-northeast2 • southamerica-east1 • southamerica-west1 • us-central1 • us-east1 • us-east4 • us-east5 • us-south1 • us-west1 • us-west2 • us-west3 • us-west4

Supported DataProtect for Cloud in GCP Configurations

Based on the performance and cluster capacity per cluster node requirement, Cohesity supports the following cluster configuration:

Cluster Configuration	Instance Type (Intel/AMD)	Disk Type	Cache Tier	Metadata Tier	Boot Disk
NGCE GCP Entry - Config 1	n2-standard16/n2d-standard16	pd-balanced for metadata and cache tiers pd-standard for boot disk	1 x 1 TB	1 x 1 TB	81 GB (pd-standard)
NGCE GCP Core - Config 2			2 x 1 TB	2 x 1 TB	
NGCE GCP Archive - Config 3			2 x 2 TB	2 x 2 TB	
NGCE GCP Performance - Config 4	n2-standard32/n2d-standard32		2 x 1 TB	2 x 1 TB	
Original (7.1.2 and below versions)	n2-standard32/n2d-standard32	pd-ssd for metadata tier pd-standard for cache and boot disk	1 x 2 TB	1 x 1.9 TB	81 GB (pd-standard)

Quota Requirement

The quotas required for instance types and disk types to deploy DataProtect for cloud in GCP depend on the node configuration and the number of nodes in the cluster. The following table lists the quotas requirement for instance type and disk types to deploy DataProtect for cloud in GCP.

Type	Quota Name	Quota consumed per node
Instance Type	n2-standard-16/n2-standard-16	• 16vCPUs for Entry, Core, Archive configurations. • 32vCPUs for Performance and Original configurations.

Type	Quota Name	Quota consumed per node
Disk Type	pd-balanced	2 to 8 TB depending on the configuration you choose.
	pd-standard	2 TB for Original configuration.
	pd-ssd	2 TB for Original configuration.

DataProtect for Cloud in GCP Permissions

The following table lists the permissions required for the GCP service account that is used for deploying DataProtect for cloud in GCP.

For information on backup and recovery permissions, see GCP VM.

Action	Permissions
Register Source and Native Backup	compute.addresses.create compute.addresses.createInternal compute.addresses.delete compute.addresses.deleteInternal compute.disks.create compute.disks.createSnapshot compute.disks.delete compute.disks.get compute.disks.list compute.disks.setLabels compute.disks.use compute.instances.attachDisk compute.instances.create compute.instances.delete compute.instances.detachDisk compute.instances.get compute.instances.list compute.instances.setDeletionProtection compute.instances.setLabels compute.instances.setMetadata compute.instances.setServiceAccount compute.instances.start compute.instances.stop compute.instances.update compute.instances.updateNetworkInterface compute.networks.get compute.projects.get compute.regions.list compute.snapshots.create compute.snapshots.delete compute.snapshots.get compute.snapshots.setLabels compute.snapshots.useReadOnly compute.subnetworks.get compute.subnetworks.list compute.subnetworks.use compute.subnetworks.useExternalIp compute.zones.list compute.zoneOperations.get compute.zoneOperations.getIamPolicy

Action	Permissions
	`resourcemanager.projects.get`

Cluster creation using the setup utility on the Control VM.	`compute.addresses.delete`
	`compute.addresses.get`
	`compute.addresses.useInternal`
	`compute.disks.create`
	`compute.disks.delete`
	`compute.disks.get`
	`compute.disks.list`
	`compute.disks.use`
	`compute.disks.useReadOnly`
	`compute.images.get`
	`compute.images.useReadOnly`
	`compute.instances.attachDisk`
	`compute.instances.create`
	`compute.instances.delete`
	`compute.instances.get`
	`compute.instances.list`
	`compute.instances.setDeletionProtection`
	`compute.instances.setMetadata`
	`compute.instances.setTags`
	`compute.instances.start`
	`compute.instances.stop`
	`compute.networks.get`
	`compute.subnetworks.get`
	`compute.subnetworks.use`
	`storage.multipartUploads.abort`
	`storage.multipartUploads.create`
	`storage.multipartUploads.list`
	`storage.multipartUploads.listParts`

	`compute.instances.list`
	`compute.instances.setDeletionProtection`
	`compute.instances.setMetadata`
	`compute.instances.setTags`
	`compute.instances.start`
	`compute.instances.stop`
	`compute.networks.get`
	`compute.subnetworks.get`
	`compute.subnetworks.use`

DataProtect for Cloud in GCP Cluster Setup

The initial setup instructions for DataProtect for cloud in GCP are available at Initial Cluster Setup.

Manage DataProtect for Cloud Nodes in GCP

For information on managing nodes of DataProtect for cloud in GCP, see Manage Nodes.

DataProtect for Cloud in GCP Supportability

Supported Sources and Workloads

The following table provides the mapping of the workflows that are supported on the sources DataProtect for cloud in GCP supports, as per the latest release:

Workload	Backup	Recovery	Cloud Archive*	Replication	Recovery Level	Notes
Firestore	Yes	Yes	Yes	Yes	Database-level	
BigQuery	Yes	Yes	Yes	Yes	Database-level	
Spanner	Yes	Yes	Yes	Yes	Database-level	
AlloyDB for PostgreSQL	Yes	Yes	Yes	Yes	Database-level	
Cloud SQL for SQL Server	Yes	Yes	Yes	Yes	Database-level	
Cloud SQL for MySQL	Yes	Yes	Yes	Yes	Database-level	
Cloud SQL for PostgreSQL	Yes	Yes	Yes	Yes	Database-level	
GCP VM	Yes	Yes	Yes	Yes	File-level	File-level recovery is not supported for GCP VMs with XFSv5 file system.
Cassandra	Yes	Yes	Yes	Yes	Not Applicable	
Hadoop	Yes	Yes	Yes	Yes	File-level (Only Hadoop HDFS)	Supports protection of HDFS, Hive, and HBase objects.
MS SQL Server (Standalone, AG, FCI)	Yes	Yes	Yes	Yes	File-level	Supports MS SQL File-based volume-based, and VDI-based backups.

Workload	Backup	Recovery	Cloud Archive*	Replication	Recovery Level	Notes
MongoDB	Yes	Yes	Yes	Yes	Not Applicable	
Google Cloud VMware Engine (GCVE)	Yes	Yes	Yes	No	File-level	On the GCVE, the default user (CloudOwner@gve.local) is missing the permission to access the Host -> Configuration -> Storage Partition Configuration. As a result, instant recovery fails, with the following error message: `Could not mount datastore on any host. Additional details: SOAP 1.1 fault 'ServerFaultCode [no subcode] - Permission to perform this operation was denied`. As a workaround, ensure that the default user is granted the Host -> Configuration -> Storage Partition Configuration permission.
Physical Server	Yes	Yes	Yes	Yes	File-level	
Cohesity View	Yes	Yes	Yes	Yes	File-level	

Workload	Backup	Recovery	Cloud Archive*	Replication	Recovery Level	Notes
NAS (Generic NAS, NetApp, Isilon, Pure Storage FlashBlade)	Yes	Yes	Yes	Yes	File-level	Supports NAS volumes with NFSv3, NFSv4.1, SMB v1, v2.x, and v3 versions.
Red Hat OpenShift	Yes	Yes	Yes	Yes	File-level	Supports only 4.14 version.
PostgreSQL on Linux	Yes	Yes	Yes	Yes	Not Applicable	Supports instant restore.
Oracle Database	Yes	Yes	Yes	Yes	Not Applicable	Supports both Oracle Adapter and Oracle SBT Plug-in.
SAP MaxDB on Linux	Yes	Yes	Yes	Yes	Not Applicable	
SAP MaxDB on Windows	Yes	Yes	Yes	Yes	Not Applicable	
SAP HANA	Yes	Yes	Yes	Yes	Not Applicable	
MySQL EE Commercial Edition	Yes	Yes	No	No	Database-level	

*DataProtect for cloud in GCP supports only Cloud Archive with **Incremental Forever** archival format.

For the list of supported external targets for Cloud Archive, see Supported Workflows and External Targets.

For information on registering an external target, see Register an External Target.

SmartFiles Support

DataProtect for cloud in GCP supports SmartFiles for SMB, NFS, and S3 protocols, with functionality limited to View Snapshots and Replication.

For more information, see SmartFiles (File and Object Services).

Marketplace Support

You can install Marketplace Apps on DataProtect for cloud in GCP. For more information on Marketplace App, see Apps.

Multitenancy

DataProtect for cloud in GCP supports the multitenancy feature. The multitenancy feature enables you to configure the multitenant environment on your Cohesity Platform and securely isolate each tenant in your environment. For more information, see Organizations (Multitenancy) .

DataProtect for Cloud in GCP Object Lock

On DataProtect for cloud in GCP, you can enable Object Lock for GCP cloud storage buckets while registering them as external targets. A GCP external target with Object Lock enabled can be:

- Used as the main backup location by associating with the Storage Domain (primary copy).
- Used for archiving (secondary copy).

Object Lock protects backup or archive data from accidental or malicious deletion or modification. It helps meet compliance requirements by making backed-up or archived data read-only for a specified period. You can configure Object Lock while registering the cloud storage bucket as an external target.

Prerequisites for Object Lock

Before registering a GCP cloud storage bucket as an external target with Object Lock enabled, ensure the GCP cloud storage bucket has versioning and Object Retention Lock enabled. For more information, see Object Rentention Lock. The Object Retention Lock property must be set at the time of the GCP cloud storage bucket creation and cannot be enabled after creation.

Considerations for Object Lock

- Object Lock is supported only if the GCP Cloud Storage bucket and the cluster are located in the same region.
- When creating the Protection Policy, avoid setting a long retention period, as Cohesity locks the objects for the entire duration. Longer retention periods can delay garbage collection and increase costs.
- For the GCP target, the objects will be locked in the Governance retention mode by default. To use the Compliance mode, contact Cohesity Support.
- When backing up data to versioned buckets, ensure that you do not edit the storage class of objects directly. Editing the storage class of objects directly will create a new

version of the object while the original version remains in the previous storage tier. Object-level locks will not be carried over to the new version.

- The expiry of the object lock will match the retention of the backup snapshots. However, the object lock will not update if you modify the expiry for archived snapshots after the Protection Group has run.
- Once enabled, Object Lock cannot be disabled.
- With Object Lock enabled, the storage utilization of external targets may be higher.
- If Object Lock compliance is not met for a backup, then the backup will fail.

DataProtect for Cloud in GCP Considerations

Cohesity does not support the following features on DataProtect for cloud in GCP:

- Direct migration from DataProtect for cloud (legacy) in GCP to DataProtect for cloud in GCP. As an alternative, you can deploy a new DataProtect for cloud in GCP and then replicate the data from DataProtect for cloud (legacy) in GCP to the newly deployed DataProtect for cloud in GCP.
- CloudArchive with periodic full .
- Write Once Read Many (WORM) for CloudArchive
- CloudTier workflow.
- Data movement policy to move data to archive tiers.
- Policy-based Cloud Spin.

Chapter 33: Tools

This chapter includes the following topics:

Using the Cohesity CLI 4597
Cluster Health Check 4752
Using the Secure Shell 4755
Cohesity REST API 4758

Using the Cohesity CLI

You can use the Cohesity Command Line Interface (CLI) locally or remotely to manage your Cohesity cluster.

Run the Cohesity CLI Locally

Before you begin:

Cohesity restricts SSH access to the host operating system shell, which means you can run custom scripts and private tools only on Secure Shell and not on Cohesity CLI (iris CLI). Cohesity recommends evaluating the security enhancements mentioned in the Secure Shell Considerations section and deciding whether to enable Secure Shell or leverage the Cohesity Cluster and Helios APIs.

Follow these steps to run the CLI commands on Secure Shell:

1. Get the IP address for any node of the Cohesity cluster. You can get the list of IP addresses from the Cohesity Cluster UI by selecting **Settings > Summary** and then selecting the **Nodes** tab.
2. Use the IP address to log into the node as the support user.

> **Note:** Make sure that you have enabled the Support user on the Cohesity cluster. For more information, see Enable Support User for Local Shell Access.

Command

```
ssh support@<node IP address>
```

Example

```
ssh support@111.1.1.1
```

3. When prompted, enter the password of the support user account.

```
support@111.1.1.1's password:
```

Once your password is successfully authenticated, the prompt changes, and the `support@restricted` prompt is displayed.

```
[support@restricted-cluster-1-node-4 ~]\>
```

4. Run the command to start the Cohesity CLI console as a local user.

```
[support@restricted-cluster-1-node-4 ~]$ iris_cli
```

You are prompted to enter the username and password. Enter the credentials of the local user account you use to log into the Cohesity cluster's User Interface.

Sample Output

```
[support@restricted-cluster-1-node-4 ~]$ iris_cli
```

```
Username: john
```

```
Password: .....
```

5. Once the local user account's password is successfully authenticated, the Cohesity CLI console opens. You can now run any CLI command.

Sample Output

```
john@111.1.1.1>cluster status
```

```
Username: john
```

```
Password: .....
```

If you only enter the CLI commands at the prompt and then enter your credentials when prompted (as shown in the example above), you're in the Interactive Mode.

Login with Active Directory User

You can log in to `iris_cli` with an Active Directory (AD) user by specifying the AD domain using the `-domain` flag.

Prerequisites

The cluster must be joined to one or more Active Directory domains. For more information, see Active Directory (AD) and Join Active Directory.

Steps to Log In with an AD User

1. After starting the `iris_cli`, use the `-domain` switch to specify the AD domain:

   ```
   iris_cli -domain <AD-domain-name>
   ```

2. When prompted, provide the username (in the format `<username>`) and the password for the AD user.

   Example

   ```
   Username: john
   ```

   ```
   Password: .....
   ```

> **Note:** Usernames must be provided as-is, as `iris_cli` does not support the NetBIOS (DOMAIN\username) or UPN format (username@domain). `iris_cli` also does not support login for SSO-based users (SAML).

Enable Support User for Local Shell Access

You need to use the **support** user account to log into the Cohesity bash shell using SSH.

By default, the support user account is disabled on the Cohesity node that is part of a Cohesity cluster. You need to enable the support user account by setting a password for the user account in the Cohesity Dashboard. Also, you can enable Linux sudo access for the support user account.

Set the Support User Password for the First Time

Using the Cohesity Dashboard or Cohesity CLI, you can set the password for the support user. You cannot retrieve the password once it is set. Therefore, ensure that you set a strong password that is longer and easy to remember. In case, if you want to reset the support user password and have forgotten the existing password, then contact Cohesity Support.

To set the support user password:

In the Cohesity Dashboard, select **Settings** > **Access Management**.

In the **Support user** section, under **Password**, click **Set Password** and define the new password for the support user account.

Also, from the Cohesity CLI, you can use the following `iris_cli` command to change the support user password:

```
iris_cli user linux-user linux-username=support linux-password=<password>
```

Enable Linux Sudo Access

When operating within the Host OS, without sudo access, the support user has read-only access privileges and limited read-write access privileges. To perform advanced operations within the Host OS that require privileged access, you need to enable Linux sudo access for the support user account.

Use the following `iris_cli` command to enable Linux sudo access for the support user:

```
iris_cli user linux-sudo-access enable=true duration-in-hours=xxx
```

> **Note:** You can enter a duration within the range of 1 to 720 hours.

To disable Linux sudo access for the support user, use the following `iris_cli` command:

```
iris_cli user linux-sudo-access enable=false
```

> **Note:** Apart from the `admin` user, if you use a local user account to enable Linux sudo access for the support user, ensure that you configure the local user account with the `Manage Linux user sudo access` privilege.

Update cohesity_console User Password

By default, the root user account is disabled on the Cohesity cluster. For operations that require root access, you can use the cohesity_console user account.

To update the cohesity_console user password, use the following iris_cli command:

```
iris_cli user linux-user linux-username=cohesity_console linux-pass-
word=<password>
```

Explore the Cohesity CLI

To view the top-level Cohesity CLI commands and help about the commands, enter `help`.

```
admin>help
```

To view the operations available for a command and help about the operations, enter the command, a space, and `help`.

```
admin>node help
```

To view the parameters of an operation and get help about the parameters, enter the command, a space, the operation, and `help`.

```
admin>node list help
```

To list the top-level commands that start with specified characters using command-line completion, enter some characters, and a tab. For example:

```
admin>vie<tab>
view view-box
```

To list the operations available for a command using command-line completion, enter the command, a space, and a tab. For example:

```
admin>node <tab>
```

To list the operations using command-line completion, enter the command, a space, one or more characters of the sub-command, and a tab.

```
admin>node l<tab>
list list-packages ls ls-free-nodes ls-pkgs
```

To list the parameters using command-line completion, enter the command, a space, the operation, a space, and a tab. For example:

```
admin>node list<tab>
list list-packages
admin>node list
```

To see a list of available Nodes on the Cohesity cluster.

```
admin>node list
```

To see the status of the Cohesity cluster.

```
admin>cluster status
```

To get details about the Cohesity cluster.

```
admin>cluster info
```

> **Note:** This is a small sample of the commands available from the Cohesity CLI. Explore the Cohesity CLI help for more options.

Key Sequences to Edit the Cohesity CLI Text

The following key sequences can be used to edit text in the Cohesity CLI prompt.

Key Sequence	Action
↑ (Up Arrow)	Show the previous command in the Cohesity CLI history.
↓ (Down Arrow)	Show the next command in the Cohesity CLI history.
Tab	Attempt command completion.
Control-u	Erase the current line of text.
Control-w	Delete the last word in the current line of text.
Control-a	Go to the first character in the current line of text.
Control-e	Go to the last character in the current line of text.
Control-b	Go back one word in the current line of text.
Control-k	Delete the rest of the text in the current line.

Use the Bash Shell on a Cohesity Node

This section describes how to access the Cohesity bash shell for troubleshooting and configuration.

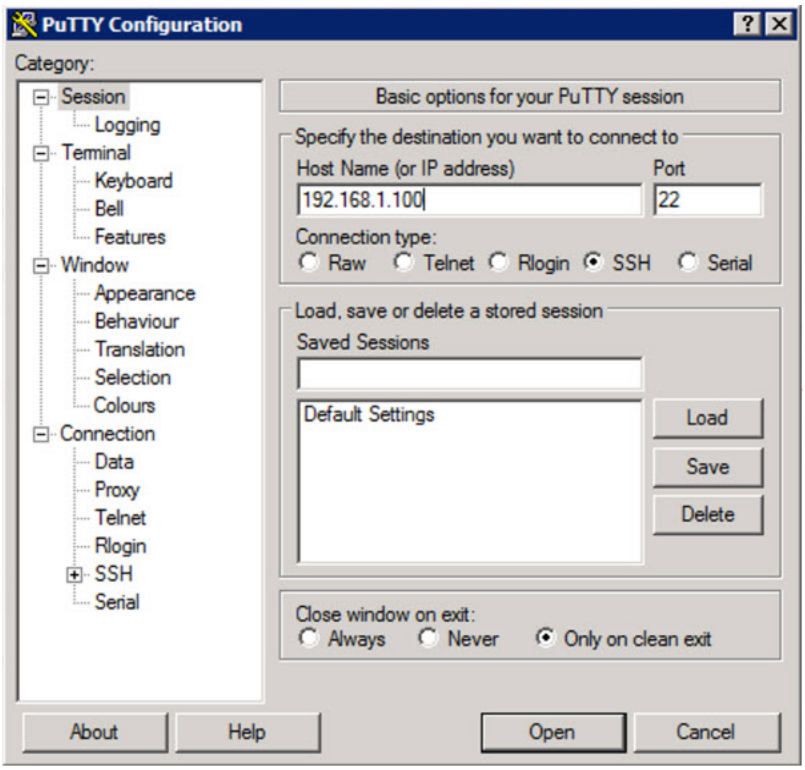
1. To log into the Cohesity cluster, use the DNS Name or IP that is used to browse into the Cohesity Dashboard. The bash shell can also be accessed from the IPMI remote console (IPMI, iLO, CIMC, or iDRAC, depending on the hardware vendor) of the node.
2. Use PuTTY (shown below), an SSH client, or IPMI remote console to log in to the cluster. Use the username `support` to log in to the cluster and specify the IP address.

   On a Mac, Unix, or Linux computer, use the ssh command:

   ```
   ssh support@<hostname>
   ```

   Example:

   ```
   ssh support@192.168.1.100
   ```



3. When prompted, enter the password.

> **Note:** This password refers to the console password and not the Cohesity UI credentials. You can provide the default password if the node is not part of a Cohesity cluster. For the default password of the support user account, contact Cohesity Support.

```
[support@192.168.1.100's password:
```

The `bash shell` prompt is displayed.

Run the Cohesity CLI Remotely

You can also run the Cohesity CLI on a Windows, macOS, or Linux system and remotely connect to the Cohesity cluster.

> **Note:** The user using a Mac with Apple Silicon needs to install Rosetta 2 to run the Cohesity CLI.

To download and start the remote version of the Cohesity CLI:

1. Download the appropriate CLI executable for your Operating System using one of the following methods:
   - Download from the Cohesity UI:
     a. Click **Help** (?) in the top right corner and click **Download CLI**.
     b. Find the appropriate CLI for your Operating System and click **Download** (↓).
   - Download over HTTP:

     Download a Cohesity CLI executable from one of the following URLs on the Cohesity cluster:

Windows	On Windows, you can download the Cohesity CLI using the following command in PowerShell or CMD: wget http://<*nodeIP*>/files/bin/cli/windows-x86_64/iris_cli.exe, where *<nodeIP>* is the IP address of one of the Nodes in the Cohesity cluster. Example: wget http://192.168.1.100/files/bin/cli/windows-x86_64/iris_cli.exe
macOS	On Mac, perform the following steps to download the Cohesity CLI: 1. curl http://<*nodeIP*>/files/bin/cli/darwin-x86_64/iris_cli -o iris_cli, where *<NodeIP>* is the IP address of one of the nodes on the Cohesity cluster. Example: curl http://198.51.100.12/files/bin/cli/darwin-x86_64/iris_cli -o iris_cli 2. chmod 755 iris_cli
Linux	On Linux, perform the following steps to download the Cohesity CLI: 1. wget http://<*nodeIP*>/files/bin/cli/linux-x86_64/iris_cli, where *<NodeIP>* is the IP address of one of the nodes on the Cohesity cluster. Example: wget http://198.51.100.12/files/bin/cli/linux-x86_64/iris_cli 2. chmod 755 iris_cli

2. Start an Operating System terminal or command prompt.
3. Change directories to the location of the CLI executable.
4. Start the CLI with the `-help` option to view all the start-up options.

Windows	`.\iris_cli.exe -help`
macOS	`./iris_cli -help`
Linux	`./iris_cli -help`

5. Specify the options to connect the Cohesity CLI remotely to the Cohesity cluster, as shown in the following example. Provide a cluster username and password.

   Specify one of the IP addresses for a Node in the Cohesity cluster with the `server` option:

   ```
   ./iris_cli -server=198.51.100.12
   ```

   When prompted, enter the username and password.

   Sample Output:

   ```
   ./iris_cli -server=198.51.100.12
   Username: admin
   Password: *****
   ```

   > **Note:** If you change the default port number (443) to connect to the Cohesity cluster, you must also specify the port number on the command line, for example: `-port="445"`

   The Cohesity CLI prompt appears. You can now enter the Cohesity CLI commands. For more information, see Explore the Cohesity CLI.

List of Cohesity CLI Commands

Command Name	Short Name	Description
active-directory	ad	To run any Active Directory related operations.
airgap-config		To run any Airgap config related operations.
alert		To run any alert related operations.
apps		To run any apps related operations.

Command Name	Short Name	Description
audit-logs		To run audit logs related operations
baseos-patch		To run any base OS patch related operations.
bond		To run any bond related operations.
chassis		To manage chassis in cluster.
cipher		To run any cipher related operations.
clientcsr		To run any clientcsr related operations.
cluster		To run any Cluster related operations.
csr		To run any csr related operations.
custom-reporting		To run any custom reporting related operations.
disk		To run any Disk related operations.
firewall-ipset		To run any Firewall ipset related operations.
firewall-profile		To run any Firewall profile related operations.
group		To run any Group related operations.
hyx-vlan		To run any Bifrost Vlan related operations.
interface-group		To run network interface group related operations.
interface		To run interface related operations.
ip		To run ip related operations.
ipmi		To run IPMI related operations on local and other nodes of the cluster.
kms		To run any KMS related operations.
ldap		To run any LDAP related operations.

Command Name	Short Name	Description
mfa-config		To run any cluster MFA config related operations.
network-reset		network configurations after doing a "set-to-factory-state" operation. These operations would not affect the data in the cluster.
nfs-share		To run any NFS share related operations.
node-csr		To run any node csr related operations.
node-group		To run node group related operations.
node		To run any Node related operations.
patch		To run any Patch related operations.
privilege		To run any Privilege related operations.
protection-job		To run any Protection Job related operations.
qos-profile		To run any Qos profile related operations.
rack		To manage racks in cluster.
remote-cluster	rc	To run any remote Cluster registration related operations.
role		To run any Role related operations.
route		To run any Static Route related operations. A Static Route designates which VLAN and Network Interfaces to use for communication with a particular destination network.
routing		Routing commands.
security-config		To run any security config related operations.
service-identity		To run any Service Identity related operations.

Command Name	Short Name	Description
set-option	set	To set or override existing CLI options at runtime.
snmp		To run any SNMP related operations
storage-domain	sd	To run any Storage Domain related operations.
support-bundle	bundle	To generate support bundle.
support-server	support	To run Support server and Support channel related operations.
swift		To run any Swift related operations.
sysctl		Command to update sysctl configuration for nodes.
syslog-server	syslog	To run any Syslog Server related operations.
system-app		To run any System app related operations.
trusted-cas		To run any trusted CA related operations.
uda-connector		To run any UDA connector related operations
user-quotas		To run any user quotas related commands.
user		To run any User related operations.
vault	vt	To run any Vault related operations.
view		To run any View related operations.
vlan		To run any Vlan related operations.

active-directory

To run any Active Directory related operations.

Operation	Short Name	Description
add-ca-path		To add Kerberos capath.
create	add	To create an account for the cluster in Active Directory.
delete	rm	To delete the cluster account from Active Directory.
enable-allowed-trusted-domains		Enable allowed trusted domains to only use them for authentication.
enable-trusted-domains-discovery		Enables or disables the discovery of Trusted Domains of an Active Directory.
list	ls	To list the Active Directory information.
list-ca-paths		To list the existing Kerberos capaths.
list-centrify-zones		To list the centrify zones of an active directory.
list-kerberos-closest-dc-locator-plugin		Lists the Windbind based closest Kerberos server dc locator plugin setting.
rediscover-trusted-domains		To re-discover trusted domains of a primary Active Directory domain.
remove-ca-path		To remove Kerberos capath.
set-allowed-trusted-domains		Sets the allowed trusted domains for an active directory
set-id-mapping-info		Sets the user id mapping info for an active directory domain.
set-ignored-trusted-domains		Sets the trusted domains to be ignored during trusted domain discovery.
set-kerberos-closest-dc-locator-plugin		Sets the Windbind based closest Kerberos server dc locator plugin setting. The change will be applied after bridge service is restarted.
set-ldap-provider		Sets the LDAP provider to Active Directory.
set-preferred-domain-controllers		Sets the preferred domain controllers to an Active Directory.
update-ldap-bind-credentials		To update the Ldap bind credentials of an Active Directory.
update-machine-accounts		To update the machine accounts of an active directory.

active-directory add-ca-path

To add Kerberos capath.

Parameter	Type	Required	Description
auth-domain	string	yes	FQDN of the client Auth domain.
cluster-domain	string	yes	FQDN of the cluster Active Directory domain.
intermediate-domain	string	yes	FQDN of the intermediate Active Directory domain.

active-directory create

To create an account for the cluster in Active Directory.

Parameter	Type	Required	Description
domain-controllers	list of strings	no	Comma separated values for the domain controllers of an Active Directory domain, these domain controllers will be mapped to Active Directory's domain name.
domain-name	string	yes	Domain name of the Active Directory.
enable-trusted-domain	bool	no	Enable Trusted Domain discovery.
machine-accounts	list of strings	yes	Comma separated values for Machine accounts to use with Active Directory.
ou	string	no	Org Unit for Active Directory
overwrite-existing-accounts	bool	no	Overwrites existing machine accounts in this active directory domain.
password	string	yes	Password of the User.
user-name	string	yes	Username of the User.
workgroup	string	no	Workgroup supported in Active Directory

active-directory delete

To delete the cluster account from Active Directory.

Parameter	Type	Required	Description
domain-name	string	yes	Domain name of the Active Directory.
password	string	yes	Password of the User.
user-name	string	yes	Username of the User.

active-directory enable-allowed-trusted-domains

Enable allowed trusted domains to only use them for authentication.

Parameter	Type	Required	Description
domain-name	string	yes	Domain name of the Active Directory.
enable	bool	yes	Whether to enable allowed trusted domains.

active-directory enable-trusted-domains-discovery

Enables or disables the discovery of Trusted Domains of an Active Directory.

Parameter	Type	Required	Description
domain-name	string	yes	Domain name of the Active Directory.
enable-trusted-domain	bool	yes	Enable Trusted Domain discovery.

active-directory list-centrify-zones

To list the centrify zones of an active directory.

Parameter	Type	Required	Description
domain-name	string	yes	Domain name of the Active Directory.

active-directory rediscover-trusted-domains

To re-discover trusted domains of a primary Active Directory domain.

Parameter	Type	Required	Description
domain-name	string	yes	Domain name of the Active Directory.

active-directory remove-ca-path

To remove Kerberos capath.

Parameter	Type	Required	Description
auth-domain	string	yes	FQDN of the client Auth domain.
cluster-domain	string	yes	FQDN of the cluster Active Directory domain.
intermediate-domain	string	yes	FQDN of the intermediate Active Directory domain.

active-directory set-allowed-trusted-domains

Sets the allowed trusted domains for an active directory.

Parameter	Type	Required	Description
allowed-trusted-domains	list of strings	no	Comma separated values for existing and new trusted domain to be allowed.
domain-name	string	yes	Domain name of the Active Directory.

active-directory set-id-mapping-info

Sets the user id mapping info for an active directory domain.

Parameter	Type	Required	Description
domain-name	string	yes	Domain name of the Active Directory.
fallback-gid	int	no	Specify the fallback fixed unix Gid.
fallback-gid-attr-name	string	no	Specify the fallback custom gid attribute name.

Parameter	Type	Required	Description
fallback-mapping-type	string	no	Specify the mapping type. Can be one of the following: kRid, kFixed.
fallback-uid	int	no	Specify the fallback fixed unix Uid.
fallback-uid-attr-name	string	no	Specify the fallback custom uid attribute name.
fallback-zone-centrify-schema	string	no	Specify the schema type of the fallback centrify zone. Should be one of: kCentrifyDynamicSchema_1_0, kCentrifyDynamicSchema_2_0, kCentrifyDynamicSchema_3_0, kCentrifyDynamicSchema_5_0, kCentrifySfu_3_0, kCentrifySfu_3_0_V5, kCentrifySfu_4_0, kCentrifyCdcRfc2307, kCentrifyCdcRfc2307_2, kCentrifyCdcRfc2307_3.
fallback-zone-description	string	no	Specify a description for this fallback centrify zone.
fallback-zone-distinguished-name	string	no	Specify a distinguished name for this fallback centrify zone.
gid	int	no	Specify the fixed Unix Group ID.
gid-attr-name	string	no	Specify the custom Group ID attribute name.
mapping-type	string	no	Specify the mapping type. Can be one of the following: kRid, kRfc2307, kSfu30, kCentrify, kFixed, kCustomAttributes, kLdapProvider, kNis.
remove-user-id-mapping-info	bool	no	Removes the current mapping between this Active Directory domain user to the user Id mapping information it is currently mapped to.
uid	int	no	Specify the fixed Unix User ID.
uid-attr-name	string	no	Specify the custom Unix User ID attribute name.
unix-root-user-sid	string	no	The Sid of the Active Directory domain user mapped to Unix root user.

Parameter	Type	Required	Description
zone-centrify-schema	string	no	Specify the schema type of the centrify zone. Should be one of: kCentrifyDynamicSchema_1_0, kCentrifyDynamicSchema_2_0, kCentrifyDynamicSchema_3_0, kCentrifyDynamicSchema_5_0, kCentrifySfu_3_0, kCentrifySfu_3_0_V5, kCentrifySfu_4_0, kCentrifyCdcRfc2307, kCentrifyCdcRfc2307_2, kCentrifyCdcRfc2307_3.
zone-description	string	no	Specify a description for this centrify zone.
zone-distinguished-name	string	no	Specify a distinguished name for this centrify zone.

active-directory set-ignored-trusted-domains

Sets the trusted domains to be ignored during trusted domain discovery.

Parameter	Type	Required	Description
clear-ignored-trusted-domains	bool	no	Removes the current mapping between this Active Directory to excluded trusted domains it is currently mapped to.
domain-name	string	yes	Domain name of the Active Directory.
ignored-trusted-domains	list of strings	no	Comma separated values for existing and new trusted domain to be ignored during trusted domain discovery.

active-directory set-kerberos-closest-dc-locator-plugin

Sets the Windbind based closest Kerberos server dc locator plugin setting. The change will be applied after bridge service is restarted.

Parameter	Type	Required	Description
enable-plugin	bool	yes	To set the Kerberos closest dc locator plugin on the cluster.

active-directory set-ldap-provider

Sets the LDAP provider to Active Directory.

Parameter	Type	Required	Description
clear-ldap-mapping	bool	no	Removes the current mapping between this Active Directory to the LDAP provider it is currently mapped to.
domain-name	string	yes	Domain name of the Active Directory.
ldap-id	int	no	Id of the LDAP provider.

active-directory set-preferred-domain-controllers

Sets the preferred domain controllers to an Active Directory.

Parameter	Type	Required	Description
active-directory-domain-name	string	yes	Domain name of the Active Directory.
clear-preferred-domain-controller	bool	no	Removes the current mapping between this Active Directory to the Preferred domain controller it is currently mapped to.
domain-controllers	list of strings	no	Comma separated values for the domain controllers of an Active Directory domain.
trusted-domain-name	string	no	Trusted domain name of an Active Directory to which preferred domain controllers are mapped to.If trusted domain name is not specified, then preferred domain controllers are mapped to Active Directory domain name.

active-directory update-ldap-bind-credentials

To update the Ldap bind credentials of an Active Directory.

Parameter	Type	Required	Description
clear-credentials	bool	no	To clear the Ldap bind credentials of an Active Directory.
domain-name	string	yes	Domain name of the Active Directory.
password	string	no	Password of the User.
user-name	string	no	Username of the User.

active-directory update-machine-accounts

To update the machine accounts of an active directory.

Parameter	Type	Required	Description
domain-name	string	yes	Domain name of the Active Directory.
machine-accounts	list of strings	yes	Comma separated values for Machine accounts to use with Active Directory.
overwrite-existing-accounts	bool	no	Overwrites existing machine accounts in this active directory domain.
password	string	yes	Password of the User.
user-name	string	yes	Username of the User.

airgap-config

To run any Airgap config related operations.

Operation	Short Name	Description
add-exception		To add exception firewall-profile for Airgap config.
list	ls	To list the Airgap configuration.
remove-exception		To remove exception firewall-profile for Airgap config.
update		To update an existing configuration for Airgap.

airgap-config add-exception

To add exception firewall-profile for Airgap config.

Parameter	Type	Required	Description
exception-profile	string	yes	Traffic matching these profiles are allowed when cluster is in Airgap mode.

airgap-config remove-exception

To remove exception firewall-profile for Airgap config.

Parameter	Type	Required	Description
exception-profile	string	yes	Traffic matching these profiles are allowed when cluster is in Airgap mode.

airgap-config update

To update an existing configuration for Airgap.

Parameter	Type	Required	Description
airgap-status	string	yes	Airgap status as Enable or Disable.
exception-profile	list of strings	no	Traffic matching these profiles are allowed when cluster is in Airgap mode.

alert

To run any alert related operations.

Operation	Short Name	Description
list	ls	To list the alerts.

alert list

To list the alerts.

Parameter	Type	Required	Description
end-time	datetime	no	End time of the time range in "YYYY-MM-DDTHH:mm" format. If specified, only the alerts that were raised before the end time will be fetched.
ids	list of strings	no	Comma separated list of alert IDs.
max-num	int	no	Maximum number of alerts to fetch.
resolution-ids	list of ints	no	Comma separated list of alert resolution IDs.

Parameter	Type	Required	Description
start-time	datetime	no	Start time of the time range in "YYYY-MM-DDTHH:mm" format. If specified, only the alerts that were raised after the start time will be fetched.
state	string	no	State of the alert. Valid values are NOTE, OPENand RESOLVED.
types	list of ints	no	Comma separated list of alert type IDs.

apps

To run any apps related operations.

Operation	Short Name	Description
update-apps-settings		Update apps settings.

apps update-apps-settings

Update apps settings.

Parameter	Type	Required	Description
allow-external-traffic	bool	no	Allow external traffic for apps.
apps-mode	"bare", "vm", "disable"	no	Edit apps mode. It can be either one of ["bare", "vm", "disable"]
marketplace-apps-mode	"bare", "vm", "disable"	no	Edit apps mode. It can be either one of ["bare", "vm", "disable"]

audit-logs

To run audit logs related operations

Operation	Short Name	Description
list	ls	List cluster audit logs

audit-logs list

List cluster audit logs

Parameter	Type	Required	Description
action	list of strings	no	Specifies a list of actions, only audit logs containing these actions will be returned.
category	list of strings	no	Specifies a list of categories/entity types, only audit logs containing these entity types will be returned.
end-time	int	no	Specifies a unix timestamp in microseconds, return only audit logs made defore the end time.
start-time	int	no	Specifies a unix timestamp in microseconds, return only audit logs made after the start time.

baseos patch

To run any base OS patch related operations.

Operation	Short Name	Description
apply		To apply the base OS patch on cluster.
download		To download the base OS patch on cluster.
get-list		To get the list of the base OS patches.
get-logs		To get the status and logs of the given patch operations.
remove		To cleanup the base OS patch files on cluster.

baseos-patch apply

To apply the base OS patch on cluster.

Parameter	Type	Required	Description
name	string	yes	Name of the base OS patch.

baseos-patch download

To download the base OS patch on cluster.

Parameter	Type	Required	Description
url	string	yes	Download the URL of the base OS patch.

baseos-patch get-logs

To get the status and logs of the given patch operations.

Parameter	Type	Required	Description
name	string	yes	Name of the base OS patch.

baseos-patch remove

To cleanup the base OS patch files on cluster.

Parameter	Type	Required	Description
force-remove	bool	no	Remove the base OS patch files even for the in-progress patch.
name	string	yes	Name of the base OS patch.

bond

To run any bond related operations.

Operation	Short Name	Description
create	add	To create a bond interface.
delete	rm	To delete a bond interface.
update	edit	To update a bond interface.

bond create

To create a bond interface.

Parameter	Type	Required	Description
bond-interface	string	yes	Name of the bond interface.
bond-slave-interface	list of strings	yes	Name of the bond slave interfaces separated by commas

bond delete

To delete a bond interface.

Parameter	Type	Required	Description
bond-interface	string	yes	Name of the bond interface.

bond update

To update a bond interface.

Parameter	Type	Required	Description
bond-interface	string	yes	Name of the bond interface.
bond-slave-interface	list of strings	yes	Name of the bond slave interfaces separated by commas

chassis

To manage chassis in cluster.

Operation	Short Name	Description
list	ls	To get all chassis or one chassis information in cluster.
update	edit	To update a chassis information. Set rack id with 0 will unassign the chassis to a rack.

chassis list

To get all chassis or one chassis information in cluster.

Parameter	Type	Required	Description
id	int	no	The id of a chassis.

chassis update

To update a chassis information. Set rack id with 0 will unassign the chassis to a rack.

Parameter	Type	Required	Description
id	int	yes	The id of a chassis.
name	string	no	Name of the chassis for the Node.
rack-id	string	no	The id of a rack which the chassis belongs to.

cipher

To run any cipher related operations.

Operation	Short Name	Description
list	ls	To list the enabled and disabled ciphers on the cluster.
list-object-store-ciphers		To list object store ciphers on the cluster.
update	edit	To modify the enabled and disabled ciphers on the cluster.
update-object-store-ciphers		To enable or disable a list of object store ciphers on the cluster. Bridge needs to be restarted to make the change in effect.

The list of ciphers on the clusters are separated by single space in the response. You can refer to the sample response below.

```
admin@127.0.0.1> cipher list
ENABLED CIPHERS             : [TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384 TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256 TLS_ECDHE_RSA_WITH_AES
_256_GCM_SHA384 TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256 TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA TLS_ECD
HE_RSA_WITH_AES_256_CBC_SHA TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA]
DISABLED CIPHERS            : []
```

cipher update

To modify the enabled and disabled ciphers on the cluster.

Parameter	Type	Required	Description
ciphers	list of strings	yes	A list of ciphers to be set as enabled or disabled on the cluster. The 'enable' parameter specifies whether to enable or disable these ciphers.
enable	bool	yes	Boolean value to specify whether to enable or disable a list of ciphers. True = enable, False = disable.

The list of ciphers on the clusters are separated by single space in the response. You can refer to the sample response below.

```
admin@127.0.0.1> cipher list
ENABLED CIPHERS              : [TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384 TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256 TLS_ECDHE_RSA_WITH_AES
_256_GCM_SHA384 TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256 TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA TLS_ECD
HE_RSA_WITH_AES_256_CBC_SHA TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA]
DISABLED CIPHERS             : []
```

cipher update-object-store-ciphers

To enable or disable a list of object store ciphers on the cluster. Bridge needs to be restarted to make the change in effect.

Parameter	Type	Required	Description
ciphers	list of strings	yes	A list of ciphers to be set as enabled or disabledon the cluster. The 'enable' parameter speciifies whether to enable ordisable these ciphers.
enable	bool	yes	Boolean value to specify whether to enable ordisable a list of ciphers. True = enable, False = disable.

The list of ciphers on the clusters are separated by single space in the response. You can refer to the sample response below.

```
admin@127.0.0.1> cipher list
ENABLED CIPHERS              : [TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384 TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256 TLS_ECDHE_RSA_WITH_AES
_256_GCM_SHA384 TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256 TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA TLS_ECD
HE_RSA_WITH_AES_256_CBC_SHA TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA]
DISABLED CIPHERS             : []
```

clientcsr

To run any clientcsr related operations.

Operation	Short Name	Description
create	add	To create csrs for client and server.
import		To import a certificate by csr.

clientcsr create

To create csrs for client and server.

Parameter	Type	Required	Description
city	string	yes	The locality attribute, which is part of the distinguished name definition. It is used to identify the city where the company is located or the Cluster is installed.
country	string	yes	The country attribute, which is part of the distinguished name definition. It is used to identify the country where the state is located. It is specified as two letter code defined by the ISO standard.
dns-names	list of strings	no	An alternative subject name component to be included in the certificate. It is used to identify the ways the Cluster will be accessed. It is given as a comma separated list of FQDNs. The default value is the Cluster's VIP hostname.
email-address	string	no	An alternative subject name component to be included in the certificate. Format is a standard e-mail address, for example joe@company.com.
host-ips	list of strings	no	An alternative subject name component to be included in the certificate. It is used to identify the ways the Cluster will be accessed. It is given as a comma separated list of IP addresses. The default value is the Cluster's VIP addresses.
key-size	int	no	The size of the keys in bits. The default is 2048 bits for the RSA keys and 256 bits for ECDSA.
key-type	string	no	The algorithm to be used to generate the key pair.RSA is the default value.
organization	string	yes	The organization attribute, which is part of the distinguished name definition. It is used to specify the name of the company.
organization-unit	string	yes	Specifies the organization unit attribute, which is part of the distinguished name definition. It is used to identify the specific department or business unit in the company that is owning the Cluster.

Parameter	Type	Required	Description
state	string	yes	The state attribute, which is part of the distinguished name definition. It is used to identify the state where the city is located.

clientcsr import

To import a certificate by csr.

Parameter	Type	Required	Description
client-certificate-path	string	yes	Path of client certificate file
server-certificate-path	string	yes	Path of server certificate file

cluster

To run any Cluster related operations.

Operation	Short Name	Description
add-etc-hosts		To add the info of a host to the cluster.
add-nodes	join	To add free nodes to the cluster.
add-ssh-keys		To add public SSH key to authorize access to the cluster.
add-subnet-to-whitelist		To allow a client subnet access to Views.
clear-etc-hosts		To clear the hosts file info stored on the Cluster.
create	add	To create a new cluster. Same number of node IPs, node IPMI IPs, and node IDs are expected. If node IDs are not specified, then node IPs are assumed to be configured on the desired nodes and their IDs will be queried.
delete-etc-hosts		To delete the info for one or more hosts of the cluster.

Operation	Short Name	Description
delete-ssl-certificate	rm-ssl-cert	To delete the SSL certificate from the Cluster.
fru-list	fru-ls	To list the available FRUs in the cluster
fru-locate		To Locate the Fru on Hardware.
fru-locate-list		To list all the Fru's being located currently on the cluster.
generate-source-certificate	gen-src-cert	To create a new certificate for agent authentication.
get-dns-server	ls-dns	To get the IP addresses of the DNS servers for the Cluster.
get-domain-names	ls-domains	To get the domain names of the cluster.
get-etc-hosts		To get the hosts info of the Cluster.
get-info	info	To get information about the cluster.
get-io-pref-tier	ls-io-tier	To get the preferred IO tier of the Cluster.
get-nfs-export-paths	ls-nfs-export-paths	To list NFS export paths accessible in the Cluster.
get-ntp-servers	ls-ntp	To get the list of the NTP servers for the Cluster.
get-proxy-servers	ls-proxies	To get the proxy servers for the Cluster.
get-subnet-whitelist	ls-sn-wl	To list client subnets with permissions to access Views.
get-subnets	ls-subnets	To get services reserved subnets in the cluster.
get-upgrade-status		To get the Cluster software upgrade status.
list-interfaces	ls-ifaces	To list the network interfaces.
list-packages	ls-pkgs	To list the available Cohesity software packages on a Cluster.
list-source-certificates	list-src-cert	To list all global certificates deployed from the cluster.

Operation	Short Name	Description
list-ssl-cert-details	ls-ssl-cert	To get the SSL certificate details of the Cluster.
ls-ssh-keys		List public SSH Keys.
query-replacement-procedure	qrp	To query the fru replacement steps.
register	claim	To register the cluster on helios by token.
remove-proxy-server	rm-proxy	To remove a proxy server from the cluster.
remove-ssh-keys		To remove public SSH key that authorizes access to the cluster.
remove-subnet-from-whitelist		To revoke a client subnet's permissions to access Views.
rotate-ssh-key		Run the above command to rotate cluster ssh keys on demand, this command will only work when there is no active cluster management operation in progress.
route-snapfs-traffic-broker		To route snapfs traffic through broker.
status		To get the status of the Cluster.
sync-ntp		To sync cluster-wide nodes to NTP server.
toggle-protrpc-encryption	tpenc	To either enable or disable protorpc encryption on the cluster.
update	edit	To update editable information of the cluster.
update-active-monitoring	edit-active-mon	To update active monitoring configuration: whether to enable/disable it and what authentication key to use.
update-dns-servers	edit-dns	To update the IP addresses of the DNS Servers for the cluster. Please use empty string to reset DNS Server IPs.
update-domain-names	edit-domains	To update the domain names of the cluster.
update-interfaces	edit-ifaces	To update the interfaces of the cluster.

Operation	Short Name	Description
update-ipmi-credential	edit-ipmi-cred	To update the IPMI username and password.
update-ntp-servers	edit-ntp	To edit the list of NTP servers for the cluster.
update-proxy-server	edit-proxy	To edit a proxy server of the cluster. Proxy servers are used for getting upgrade packages and proactive monitoring.
update-ssl-certificate	edit-ssl-cert	To update the SSL certificate to be used by the cluster. A self-signed SSL certificate is used by default.
update-subnet	edit-subnet	To update services reserved subnets in the cluster.
upgrade		To upgrade the software version on the cluster.
upgrade-check-list-tests		To list available upgrade check tests.
upgrade-check-run-tests		To run upgrade check tests.
upgrade-check-show-result		To show results of upgrade check tests.
upload-etc-hosts		To upload the hosts info to the cluster, the content of the hosts file will be uploaded.
upload-license		To upload valid license string.
virtual-robo-create		To create a new Virtual ROBO cluster.

cluster add-etc-hosts

To add the info of a host to the Cluster.

Parameter	Type	Required	Description
description	string	no	Description for the host.
host-domain-name	list of strings	yes	Comma separated list of host domain names.
host-ip	list of strings	yes	Comma separated list of host IPs.

cluster add-nodes

To add free nodes to the cluster.

Parameter	Type	Required	Description
chassis-serials	list of strings	no	Comma separated list of chassis serials.
dns-groups	list of strings	no	Comma separated list of DNS groups of the new nodes. Each entry should be specified in the following format: <group name1>/<node IP1>:<node IP2>:.../<DNS server IP1>...,<group name2>/<node IP3>/<DNS server IP2>,... For example: dns1/10.1.1.1:10.1.1.2/10.1.0.1:10.1.1.1,dns2/10.2.1.1/10.2.0.1
in-same-rack	bool	no	Specify whether the new nodes should belong to a rack.
node-ids	list of ints	no	Comma separated list of Node IDs.
node-ipmi-ips	list of strings	no	Comma separated list of Node IPMI IP addresses (IPv4 only).
node-ipmi-subnet-gateways	list of strings	no	Comma separated list of IPMI Subnetgateways.
node-ipmi-subnet-masks	list of strings	no	Comma separated list of IPMI Subnet masks. Mask should be a CIDR prefix or a dotted decimal for IPv4.
node-ips	list of strings	yes	Comma separated list of Node IP addresses (IPv4 or IPv6).
rack-ids	list of ints	no	Comma separated list of rack Ids.
subnet-gateways	list of strings	no	Comma separated list of gateways for subnet groups of the new nodes. This is used for multi subnets cluster.
subnet-mask-groups	list of strings	no	Subnet mask groups of the new nodes. Subnet should be either in CIDR prefix or in dotted decimal format. This is used for multiple subnets cluster.Each entry should be specified in the following format: <group name1>/<node IP1>:<node IP2>.../<subnet mask1>,...For example: zone1/10.1.1.1:10.1.1.2/255.255.255.0,zone2/10.2.1.1/20

Parameter	Type	Required	Description
use-as-compute-nodes	list of bools	no	Comma separated list of true or false values to indicate whether the corresponding node should be used only for compute.
vips	list of strings	no	Comma separated list of Virtual IP addresses.

cluster add-ssh-keys

To add public SSH key to authorize access to the cluster.

Parameter	Type	Required	Description
ssh-key-file-path	absolute file path	yes	Absolute file path for the public SSH keys that allows access to the Cluster.

cluster add-subnet-to-whitelist

To allow a client subnet access to Views.

Parameter	Type	Required	Description
subnet-ip	string	yes	IP of the client subnet.
subnet-mask-bits	int	no	Mask bits for the client subnet.
subnet-mask-ip4	string	no	Netmask for the IPv4 client subnet.
subnet-nfs-permission	string	no	Clients from this subnet can mount using NFS protocol. This can be kDisabled, kReadOnly, kReadWrite.
subnet-nfs-root-squash	bool	no	Clients from this subnet can mount as root on NFS. This can be Disabled, ReadOnly, ReadWrite.
subnet-s3-permission	string	no	Clients from this subnet can access using S3 protocol. This can be kDisabled, kReadOnly, kReadWrite.
subnet-smb-permission	string	no	Clients from this subnet can mount using SMB protocol. This can be kDisabled, kReadOnly, kReadWrite.

cluster create

To create a new Cluster. Same number of node IPs, node IPMI IPs, and node IDs are expected. If node IPs are already assigned, don't specify the node ID. If node IDs are not specified, then node IPs are assumed to be configured on the desired nodes and their IDs will be queried.

Parameter	Type	Required	Description
apps-subnet	string	yes	Configure the subnet IP for apps configuration
apps-subnet-mask	string	yes	Configure the subnet Mask for apps configuration
dns-groups	list of strings	no	Comma separated list of DNS groups of the cluster. Each entry should be specified in the following format: <group name1>/<node IP1>:<node IP2>:.../<DNS server IP1>:...,<group name2>/<node IP3>/<DNS server IP2>,... For example: dns1/10.1.1.1:10.1.1.2/10.1.0.1|10.1.1.1,dns2/10.2.1.1/10.2.0.1
dns-server-ips	list of strings	no	Comma separated list of DNS server IP addresses.
domain-names	list of strings	no	Comma separated list of search domain names. First name is also the Cluster domain name which is mandatory.
enable-software-encryption	bool	no	The cluster encryption is ON by default during the initial cluster setup and cannot be disabled later. Encryption will be OFF only if enable-software-encryption is explicitly set to false during cluster creation.
hostname	string	yes	Hostname for the Virtual IPs of the cluster partition.
ip-preference	int	no	Param to specify IP address preference, 1=IpV4(default) or 2=IpV6.
ipmi-password	string	no	IPMI password for the Cluster.
ipmi-subnet-gateway	string	no	IPMI Subnet gateway.
ipmi-subnet-mask	string	no	IPMI Subnet mask should be either in CIDR prefix or in dotted decimal for IPv4.
ipmi-username	string	no	IPMI username for the Cluster.

Parameter	Type	Required	Description
name	string	yes	Name of the Cluster.
node-ids	list of ints	no	Comma separated list of Node IDs.
node-ipmi-ips	list of strings	no	Comma separated list of Node IPMI IP addresses (IPv4 only).
node-ips	list of strings	yes	Comma separated list of Node IP addresses (IPv4 or IPv6).
ntp-auth-enable	bool	no	Flag to enable NTP with authentication.
ntp-auth-key-ids	list of ints	no	Comma separated list of NTP server auth key IDs corresponding to each NTP server auth key.
ntp-auth-keys	list of strings	no	Comma separated list of NTP server auth keys corresponding to each NTP server.
ntp-servers	list of strings	yes	Comma separated list of NTP servers IPs/hostnames.
rotation-period-days	int	no	Period in days when the data encryption key (DEK) is rotated. Default rotation period is 90 days.
subnet-gateway	string	no	Subnet gateway for the Cluster.
subnet-gateways	list of strings	no	Comma separated list of gateways for subnet groups of the cluster. This is used for multi subnets cluster.
subnet-mask	string	no	Subnet mask for the Cluster. Should be either in CIDR prefix or in dotted decimal.
subnet-mask-groups	list of strings	no	Subnet mask groups of the cluster. Subnet should be either in CIDR prefix or in dotted decimal format. This is used for multiple subnets cluster.Each entry should be specified in the following format: <group name1>/<node IP1>:<node IP2>:.../<subnet mask1>,...For example: zone1/10.1.1.1:10.1.1.2/255.255.255.0,zone2/10.2.1.1/20
trust-domain	string	no	Trust domain name of FQDN format.

Parameter	Type	Required	Description
use-as-compute-nodes	list of bools	no	Comma separated list of true or false values to indicate whether the corresponding node should be used only as compute node.
vips	list of strings	no	Comma separated list of Virtual IP addresses.

cluster delete-etc-hosts

To delete the info for one or more hosts of the Cluster.

Parameter	Type	Required	Description
host-domain-name	list of strings	no	Comma separated list of host domain names.
host-ip	list of strings	no	Comma separated list of host IPs.

cluster fru-list

To list the available FRUs in the cluster

Parameter	Type	Required	Description
node-id	int	no	ID of a Node.

cluster fru-locate

To Locate the Fru on Hardware.

Parameter	Type	Required	Description
fru-id	string	yes	Fru Id of Fru to be located/replaced
fru-type	string	yes	Type (disk,fan) of Fru to be located/replaced
node-id	int	yes	ID of a Node.
status-on	bool	yes	Fru locate status (on/off)

cluster generate-source-certificate

To create a new certificate for agent authentication.

Parameter Name	Description	Parameter Name	Description
cert-name	Name of the certificate file. Its naming format is ${cert-name}_<random_number>.cfg.	cert-name	Name of the certificate file. Its naming format is ${cert-name}_<random_number>.cfg.
cert-validity	The validity of the source certificate generated. The time is displayed in days.	cert-validity	The validity of the source certificate generated. The time is displayed in days.
host-name	The IP address/host name of the target system where you want to move the certificate. This is a mandatory parameter because the certificate generation process needs details of the host machine to generate public and private keys.	host-name	The IP address/host name of the target system where you want to move the certificate. This is a mandatory parameter because the certificate generation process needs details of the host machine to generate public and private keys.
host-target	The file directory path on the host machine where the certificate will be stored.	host-target	The file directory path on the host machine where the certificate will be stored.

Parameter Name	Description	Parameter Name	Description
host-uname and host-password	The username and password of any user on the host machine that can facilitate the transfer of certificate over an SSH tunnel.	host-uname and host-password	The username and password of any user on the host machine that can facilitate the transfer of certificate over an SSH tunnel.
Parameter Name	Description	Parameter Name	Description

cluster get-info

To get information about the Cluster.

Parameter	Type	Required	Description
show-stats	bool	no	To display the computed statistics.

cluster list-interfaces

To list the network interfaces.

Parameter	Type	Required	Description
cache	bool	no	To show interface cached information or not. Default is to read interface information from cache.

cluster query-replacement-procedure

To query the fru replacement steps

Parameter	Type	Required	Description
fru-id	string	no	Fru Id of Fru to be located/replaced
fru-type	string	no	Type (disk,fan) of Fru to be located/replaced

Parameter	Type	Required	Description
node-id	int	no	ID of a Node.
task-id	string	no	Task Id of Any Breakfix Task running in cluster

cluster register

To register the cluster on helios by token.

Parameter	Type	Required	Description
rigel-guid	int	no	To specify the guid to register the rigel with as cluster on helios. If not specified, node id is used as rigel guid.
token	string	yes	To specify the token to register the cluster on helios.

cluster remove-proxy-server

To remove a proxy server from the Cluster.

Parameter	Type	Required	Description
name	string	yes	Name of the proxy server.

cluster remove-ssh-keys

To remove public SSH key that authorizes access to the cluster.

Parameter	Type	Required	Description
ssh-key-file-path	absolute file path	yes	Absolute file path for the public SSH keys that allows access to the Cluster.

cluster remove-subnet-from-whitelist

To revoke a client subnet's permissions to access Views.

Parameter	Type	Required	Description
subnet-ip	string	yes	IP of the client subnet.

cluster route-snapfs-traffic-broker

To route snapfs traffic through broker.

Parameter	Type	Required	Description
enable	bool	yes	To enable or disable snapfs traffic through broker. If set to true, enables the snapfs traffic through broker in rigel. If set to false, disables it.

cluster toggle-protrpc-encryption

To either enable or disable protorpc encryption on the cluster.

Parameter	Type	Required	Description
enable-encryption	bool	yes	To enable or disable internode protorpc encryption, if the set to true the commannd shall enable protorpc encryption if set to false it shall disable.

cluster update

To update editable information of the Cluster.

Parameter	Type	Required	Description
authentication-type	string	no	The authentication type for the cluster. This can be password-only, certificate-only or password-and-certificate
cluster-audit-enabled	bool	no	Whether to enable Cluster Audit Logs.
cluster-audit-retention-days	int	no	Number of days to retain the Cluster Audit Logs.
cluster-audit-verbosity	bool	no	Whether to enable audit verbosity(audit log prev value and new value).
enable-local-groups	bool	no	Enable/Disable creating local groups.

Parameter	Type	Required	Description
enc-key-rotation-period-secs	int	no	Encryption key rotation period in seconds. It should be greater than or equal to 86400 seconds (a day).
filer-audit-enabled	bool	no	Whether to enable Filer Audit Logs.
filer-audit-retention-days	int	no	Number of days to retain the Filer Audit Logs.
local-auth-domain-name	string	no	Domain name for SMB local authentication.
multi-tenancy	bool	no	To enable or disable Multi-Tenancy.
new-name	string	no	New name of the Cluster for update.
ntp-servers-internal	bool	no	Flag to specify if the NTP servers are on internal network.
pcie-ssd-rebalance-delay-secs	int	no	Delay time in seconds for cluster PcieSSD storage tier.
sata-hdd-admission-control	int	no	Admission control for cluster SATA HDD storage tier.
smb-ad-disabled	bool	no	Disable SMB access for Active Directory Users.
tiering-audit-enabled	bool	no	Whether to enable Tiering Audit Logs.
tiering-audit-retention-days	int	no	Number of days to retain the Tiering Audit Logs.
time-zone	string	no	Timezone for displaying Time in Reports download.
turbo-mode	bool	no	To set or clear Turbo mode.
use-heimdall	bool	no	To enable or disable Heimdall.
viewbox-sharing	bool	no	To enable ViewBox Sharing.

cluster update-active-monitoring

To update active monitoring configuration: whether to enable/disable it and what authentication key to use.

Parameter	Type	Required	Description
enable	bool	yes	To enable/disable active monitoring.

cluster update-dns-servers

To update the IP addresses of the DNS Servers for the Cluster. Please use empty string to reset DNS Server IPs.

Parameter	Type	Required	Description
dns-server-ips	string	yes	Comma separated list of DNS server IP addresses.

cluster update-domain-names

To update the domain names of the cluster.

Parameter	Type	Required	Description
domain-names	list of strings	no	Comma separated list of search domain names. First name is also the Cluster domain name which is mandatory.

cluster update-interfaces

To update the interfaces of the cluster.

Parameter	Type	Required	Description
family	int	no	Param to specify IP address family, 1=IpV4(default) or 2=IpV6.
ids	list of ints	yes	Comma separated list of IDs.
interface-ips	string	no	Comma separated list of interface IP addresses (IPv4 only).
subnet-gateway	string	no	Subnet gateway for the Cluster.
subnet-mask-bits	int	no	Subnet mask bits for the Cluster.
unconfigure	bool	no	Whether to unconfigure the interfaces.

cluster update-ipmi-credential

To update the IPMI username and password.

Parameter	Type	Required	Description
ipmi-password	string	yes	IPMI password for the Cluster.
ipmi-username	string	yes	IPMI username for the Cluster.

cluster update-ntp-servers

To edit the list of NTP servers for the Cluster.

Parameter	Type	Required	Description
ntp-auth-enable	bool	no	Flag to enable NTP with authentication.
ntp-auth-key-ids	list of ints	no	Comma separated list of NTP server auth key IDs corresponding to each NTP server auth key.
ntp-auth-keys	list of strings	no	Comma separated list of NTP server auth keys corresponding to each NTP server.
ntp-servers	list of strings	yes	Comma separated list of NTP severs IPs/hostnames. cluster edit-ntp ntp-servers="xx.x1, xx.x2, xx.x3" Example: cluster edit-ntp ntp-servers="time.google.com, time2.google.com, time3.google.com"

cluster update-proxy-server

To edit a proxy server of the Cluster. Proxy servers are used for getting upgrade packages and proactive monitoring.

Parameter	Type	Required	Description
address	string	yes	FQDN or IP address of the proxy server.
name	string	yes	Name of the proxy server.

Parameter	Type	Required	Description
password	string	no	Password to use for the proxy server.
port	int	yes	Port to use for the proxy server.
schemes	list of strings	no	Comma separated list of schemes supported by the proxy server. Choose from http, or https.
username	string	no	Username to use for the proxy server.

cluster update-ssl-certificate

To update the SSL certificate to be used by the Cluster. A self-signed SSL certificate is used by default.

Parameter	Type	Required	Description
ssl-cert-private-key	absolute file path	yes	Absolute file path for the private key to be used in conjunction with the SSL certificate for the Cluster.
ssl-certificate	absolute file path	yes	Absolute file path for the SSL certificate to update the Cluster.

cluster update-subnet

To update services reserved subnets in the cluster.

Parameter	Type	Required	Description
desc	string	no	Description.
service-name	string	no	Name of the service. You can get the list of services by running "cluster status" command.
subnet-id	int	no	Subnet ID.
subnet-ip	string	yes	Subnet IP for the Cluster.
subnet-mask-bits	int	no	Subnet mask bits for the Cluster.
subnet-mask-ip4	string	no	Subnet mask for IPv4 type subnet of the Cluster.

cluster upgrade

To upgrade the software version on the Cluster.

Parameter	Type	Required	Description
force-validate-health-checks	bool	no	Force running health check tests as part of upgrade
id	int	no	ID of the Cluster.
skip-nodes	string	no	Comma separated list of node IDs on which upgrade checks will not run
skip-tests	string	no	Comma separated list of test case ids which will not run on all cluster nodes. Use command 'cluster upgrade-list-tests' to get the list of tests.
software-pkg-md5	string	no	MD5 Hash of the software package to be uploaded to the Node.
software-pkg-url	string	no	URL where Cohesity Software package is available.
target-version	string	no	Target software version to be used for upgrade.

cluster upgrade-check-list-tests

To list available upgrade check tests.

Parameter	Type	Required	Description
type	string	yes	Type of upgrade check tests, possible inputs are preupgrade or postupgrade

cluster upgrade-check-run-tests

To run upgrade check tests.

Parameter	Type	Required	Description
skip-nodes	list of strings	no	Comma separated list of node IDs on which upgrade checks will not run

Parameter	Type	Required	Description
skip-tests	list of strings	no	Comma separated list of test case ids which will not run on all cluster nodes. Use command 'cluster upgrade-list-tests' to get the list of tests.
type	string	yes	Type of upgrade tests, possible inputs are preupgrade or postupgrade

cluster upload-etc-hosts

To upload the hosts info to the cluster, the content of the hosts file will be uploaded.

Parameter	Type	Required	Description
file-path	string	no	Path of the hosts file to upload for cluster level /etc/hosts settings.

cluster upload-license

To upload valid license string.

Parameter	Type	Required	Description
license	string	yes	To upload valid license string.

cluster virtual-robo-create

To create a new Virtual ROBO cluster.

Parameter	Type	Required	Description
apps-subnet	string	no	Configure the subnet IP for apps configuration
apps-subnet-mask	string	no	Configure the subnet Mask for apps configuration
dns-server-ips	list of strings	yes	Comma separated list of DNS server IP addresses.
domain-names	list of strings	yes	Comma separated list of search domain names. First name is also the Cluster domain name which is mandatory.

Parameter	Type	Required	Description
enable-software-encryption	bool	no	Enable software encryption at Cluster level. WARNING: This option cannot be disabled later.
hostname	string	yes	Hostname for the Virtual IPs of the Cluster Partition.
ip-preference	int	no	Param to specify IP address preference, 1=IpV4(default) or 2=IpV6.
name	string	yes	Name of the Cluster.
node-ids	list of ints	no	Comma separated list of Node IDs.
node-ips	string	yes	Comma separated list of Node IP addresses (IPv4 or IPv6).
ntp-auth-enable	bool	no	Flag to enable NTP with authentication.
ntp-auth-key-ids	list of ints	no	Comma separated list of NTP server auth key IDs corresponding to each NTP server auth key.
ntp-auth-keys	list of strings	no	Comma separated list of NTP server auth keys corresponding to each NTP server.
ntp-servers	list of strings	yes	Comma separated list of NTP severs IPs/hostnames.
rotation-period-days	int	no	Period in days when data encryption key (DEK) is rotated. Default rotation period is 90 days.
subnet-gateway	string	no	Subnet gateway for the Cluster.
subnet-mask	string	yes	Subnet mask for the Cluster. Should be either in CIDR prefix or in dotted decimal.
trust-domain	string	no	Trust domain name of FQDN format.
vips	list of strings	no	Comma separated list of Virtual IP addresses. This is applicable only for Virtual Edition cluster create.

csr

To run any csr related operations.

Operation	Short Name	Description
create	add	To create a csr.
delete	rm	To delete a csr.
import		To import a certificate by csr.
list	ls	To list the csrs.

csr create

To create a csr.

Parameter	Type	Required	Description
city	string	yes	The locality attribute, which is part of the distinguished name definition. It is used to identify the city where the company is located or the Cluster is installed.
common-name	string	no	The common name attribute, which is part of the distinguished name definition. Common name is used to specify a context for the certificate, for example, the name of the Cluster to which the certificate is to be assigned. Default value is the name of the Cluster.
country	string	yes	The country attribute, which is part of the distinguished name definition. It is used to identify the country where the state is located. It is specified as two letter code defined by the ISO standard.
dns-names	list of strings	no	An alternative subject name component to be included in the certificate. It is used to identify the ways the Cluster will be accessed. It is given as a comma separated list of FQDNs. The default value is the Cluster's VIP hostname.
email-address	string	no	An alternative subject name component to be included in the certificate. Format is a standard e-mail address, for example joe@company.com.

Parameter	Type	Required	Description
host-ips	list of strings	no	An alternative subject name component to be included in the certificate. It is used to identify the ways the Cluster will be accessed. It is given as a comma separated list of IP addresses. The default value is the Cluster's VIP addresses.
key-size	int	no	The size of the keys in bits. The default is 2048 bits for the RSA keys and 256 bits for ECDSA.
key-type	string	no	The algorithm to be used to generate the key pair.RSA is the default value.
organization	string	yes	The organization attribute, which is part of the distinguished name definition. It is used to specify the name of the company.
organization-unit	string	yes	Specifies the organization unit attribute, which is part of the distinguished name definition. It is used to identify the specific department or business unit in the company that is owning the Cluster.
service-name	string	no	Service for which the csr is created.
state	string	yes	The state attribute, which is part of the distinguished name definition. It is used to identify the state where the city is located.

csr delete

To delete a csr.

Parameter	Type	Required	Description
id	string	yes	Csr ID.

csr import

To import a certificate by csr.

Parameter	Type	Required	Description
certificate-path	string	yes	The path of the file of the certificate to be imported.
id	string	yes	Csr ID.

csr list

To list the csrs.

Parameter	Type	Required	Description
ids	list of strings	no	Comma separated list of csr IDs.
service-name	string	no	Service for which the csr is created.

custom-reporting

To run any custom reporting related operations.

Operation	Short Name	Description
database	db	To get details for running database information.

disk

To run any Disk related operations.

Operation	Short Name	Description
identify	ident	To identify a disk on a node. Either a disk ID in the cluster, or a disk serial and the ID of the node that the disk is attached to need to be specified
list	ls	To list the disk details.

disk identify

To identify a disk on a node. Either a disk ID in the cluster, or a disk serial and the ID of the node that the disk is attached to need to be specified

Parameter	Type	Required	Description
cluster-id	int	no	ID of the Cluster.
disk-id	int	no	ID of the Disk.

Parameter	Type	Required	Description
identify	bool	yes	Flag to toggle identification LED status.

disk list

To list the disk details.

Parameter	Type	Required	Description
fetch-disk-usage-details	bool	no	Enable/Disable display of disk usage details.
ids	list of ints	no	Comma separated list of IDs.
include-marked-for-removal	bool	no	Include the nodes which have been marked for removal.
node-ids	list of ints	no	Comma separated list of Node IDs.
only-ready-for-removal	bool	no	Display disks which are ready for removal.
show-stats	bool	no	To display the computed statistics.
sum-disk-reservations	bool	no	To sum the disk reservations by different components across all the disks.

firewall-ipset

To run any Firewall ipset related operations.

Operation	Short Name	Description
list	`ls`	To list the IP sets for the firewall.

firewall-profile

To run any Firewall profile related operations.

Operation	Short Name	Description
activate		To activates a profile on a list of interfaces with a list of ipsets.
create	add	To create a collection of service ports with the protocol of each port for firewall.
deactivate		To deactivate a list of active firewall profiles, Each one will stop a profile on a list of interfaces with a list of ipsets.
delete	rm	To remove a list of profiles for firewall.

firewall-profile activate

To activates a profile on a list of interfaces with a list of ipsets.

Parameter	Type	Required	Description
action	string	no	To define the action of the rule set. It can be either "allow" or "deny".
desc	string	no	Description of the firewall rule sets.
interface-groups	list of strings	no	Comma separated list of network interface groups.
ipset-entries	list of strings	no	Comma separated list of subnets/ips for the firewall Ipsets.
profile-name	string	no	Name of the firewall profile.
revert-to-default	bool	no	To revert all firewall rules to default settings.

firewall-profile create

To create a collection of service ports with the protocol of each port for firewall.

Parameter	Type	Required	Description
directions	list of strings	no	Comma separated list of traffic directions. Direction can be "INPUT", "OUTPUT", or "FORWARD". "INPUT" is the default direction.

Parameter	Type	Required	Description
force	bool	no	Set to true to unlock the ports restriction.
name	string	yes	Name of the firewall profile.
ports	list of strings	yes	Comma separated list of service ports.

firewall-profile deactivate

To deactivate a list of active firewall profiles, Each one will stop a profile on a list of interfaces with a list of ipsets.

Parameter	Type	Required	Description
profile-names	list of strings	yes	Comma separated list of names for the firewall profile.

firewall-profile delete

To remove a list of profiles for firewall.

Parameter	Type	Required	Description
names	list of strings	yes	Comma separated list of names for the firewall profile.

group

To run any Group related operations.

Operation	Short Name	Description
add-smb-principal		To add SMB principals as member to the group. SMB principals can be added only if "smb-only" set to true for a group.
create	add	To create a new Group.
delete	rm	To delete a Group.
list	ls	To list Groups.

Operation	Short Name	Description
remove-smb-principal		To delete SMB principal from a group.
update	edit	To update a Group.

group add-smb-principal

To add SMB principals as member to the group. SMB principals can be added only if "smb-only" set to true for a group.

Parameter	Type	Required	Description
domain	string	no	Domain name of the principal.
name	string	yes	Name of the Group.
principal-name	string	no	Name of the SMB principal which may be a group or user.
sid	string	no	unique Security ID (SID) of the principal that look similar to windows domain SID.
type	string	no	Type can be a user or a group.

group create

To create a new Group.

Parameter	Type	Required	Description
description	string	no	Description of the Group.
domain	string	no	Domain identifies User's logging in domain.
name	string	yes	Name of the Group.
roles	list of strings	no	Comma separated list of Roles for the Group.
users	list of strings	no	Comma separated list of User SIDs in the Group.

group delete

To delete a Group.

Parameter	Type	Required	Description
domain	string	no	Domain identifies User's logging in domain.
names	list of strings	yes	Comma separated list of Group names.

group list

To list Groups.

Parameter	Type	Required	Description
domain	string	no	Domain identifies User's logging in domain.
name	string	no	Name of the Group.

group remove-smb-principal

To delete SMB principal from a group.

Parameter	Type	Required	Description
clear-smb-principals	bool	no	Removes all the SMB principals from the SMB group.
name	string	yes	Name of the Group.
principal-name	string	no	Name of the SMB principal which may be a group or user.

group update

To update a Group.

Parameter	Type	Required	Description
description	string	no	Description of the Group.
domain	string	no	Domain identifies User's logging in domain.
name	string	yes	Name of the Group.

Parameter	Type	Required	Description
roles	list of strings	no	Comma separated list of Roles for the Group.
users	list of strings	no	Comma separated list of User SIDs in the Group.

hyx-vlan

To run any Bifrost Vlan related operations.

Operation	Short Name	Description
create	add	To add a Bifrost VLAN for the cluster
delete	rm	To remove a Bifrost VLAN from the cluster
get	get	To get Bifrost VLAN for given IfaceGroupName for the cluster
tenant-disable		This disables tenant-facing components of Internal Bifrost for the provided tenant ids
tenant-enable		This enables tenant-facing components of Internal Bifrost for the provided tenant ids
update	edit	To update a Bifrost VLAN for the cluster

hyx-vlan create

To add a Bifrost VLAN for the cluster

Parameter	Type	Required	Description
desc	string	no	Description.
id	int	no	ID of the VLAN.
mtu	int	no	MTU for the interfaces.
state	string	no	This specifies the state of Bifrost VLAN. State can be UNKNOWN/ACTIVE/DISABLED/DELETING.

Parameter	Type	Required	Description
subnet-gateway	string	no	Subnet gateway for the Cluster.
subnet-ip-cidr	string	yes	Subnet IP CIDR
subnet-mask-bits	int	no	Subnet mask bits for the Cluster.
subnet-mask-ip4	string	no	Subnet mask for IPv4 type subnet of the Cluster.
tenant-id	string	no	To specify id of the tenant owning a resource.
type	string	yes	This specifies the type of Bifrost Vlan. Type can be EXTERNAL/INTERNAL.
vlan-interface-group	string	yes	Name of a network interface group.
vlan-ips	list of strings	no	Comma separated list of VLAN IP addresses.
vlan-name	string	no	VLAN Name for vlan-id created

hyx-vlan delete

To remove a Bifrost VLAN from the cluster

Parameter	Type	Required	Description
tenant-id	string	no	To specify id of the tenant owning a resource.
vlan-interface-group	string	yes	Name of a network interface group.

hyx-vlan get

To get Bifrost VLAN for given IfaceGroupName for the cluster

Parameter	Type	Required	Description
vlan-interface-group	string	yes	Name of a network interface group.

hyx-vlan tenant-disable

This disables tenant-facing components of Internal Bifrost for the provided tenant ids

Parameter	Type	Required	Description
tenant-ids	list of strings	yes	To specify multiple tenant ids.

hyx-vlan tenant-enable

This enables tenant-facing components of Internal Bifrost for the provided tenant ids

Parameter	Type	Required	Description
tenant-ids	list of strings	yes	To specify multiple tenant ids.

hyx-vlan update

To update a Bifrost VLAN for the cluster

Parameter	Type	Required	Description
desc	string	no	Description.
id	int	no	ID of the VLAN.
mtu	int	no	MTU for the interfaces.
state	string	no	This specifies the state of Bifrost VLAN. State can be UNKNOWN/ACTIVE/DISABLED/DELETING.
subnet-gateway	string	no	Subnet gateway for the Cluster.
subnet-ip-cidr	string	no	Subnet IP CIDR
subnet-mask-bits	int	no	Subnet mask bits for the Cluster.
subnet-mask-ip4	string	no	Subnet mask for IPv4 type subnet of the Cluster.
tenant-id	string	no	To specify id of the tenant owning a resource.

Parameter	Type	Required	Description
type	string	no	This specifies the type of Bifrost Vlan. Type can be EXTERNAL/INTERNAL.
vlan-interface-group	string	yes	Name of a network interface group.
vlan-ips	list of strings	no	Comma separated list of VLAN IP addresses.
vlan-name	string	no	VLAN Name for vlan-id created

interface-group

To run network interface group related operations.

Operation	Short Name	Description
create	add	To create the interface group in the cluster.
delete	rm	To delete the interface group in the cluster.
update	edit	To update the interface group in the cluster.

interface-group create

To create the interface group in the cluster.

Parameter	Type	Required	Description
group-name	string	yes	Name of a network interface group.
group-type	int	no	Type of a network interface group. 1(Bond Interfaces), 2 (Loopback Interfaces). Default is 1.
interface-name	string	no	Name of the bond interface.
node-ids	list of ints	yes	Comma separated list of Node IDs.

interface-group delete

To delete the interface group in the cluster.

Parameter	Type	Required	Description
group-name	string	yes	Name of a network interface group.

interface-group update

To update the interface group in the cluster.

Parameter	Type	Required	Description
add-node-ids	list of ints	no	Comma separated list of Node IDs to add.
group-name	string	yes	Name of a network interface group.
interface-name	string	no	Name of the bond interface.
remove-node-ids	list of ints	no	Comma separated list of Node IDs to remove.

interface

To run interface related operations.

Operation	Short Name	Description
list	ls	To list the network interfaces.
update	edit	To update interface params.

interface list

To list the network interfaces.

Parameter	Type	Required	Description
bondInterfaceOnly	bool	no	To show only bond interface info.
cache	bool	no	To show interface cached information or not. Default is to read interface information from cache.
include-bond-slave-details	bool	no	To include bond slave details.

Parameter	Type	Required	Description
include-stats	bool	no	To include interface statistics.
node-id	int	no	ID of a Node.

interface update

To update interface params.

Parameter	Type	Required	Description
bonding-mode	int	no	Bonding mode to use when bonding the NICs. Modes 1 (active-backup) and 4 (802.3ad) are supported. Mode 4 may require switch configuration. In cluster, the services need to be stopped before changing on primary interface group.
interface-name	string	yes	Name of the network interface. It can be bond interface, vlan interface or interface group.
lacp-rate	string	no	Rate option to use for link partner to transmit LACPDU packets in 802.3ad mode. Possible values are 0 (slow) and 1 (fast). Default setting is 0 (slow).
mtu	int	no	MTU for the interfaces.
xmit-hash-policy	string	no	Transmit hash policy to use for selection in 802.3ad mode. Possible values are 0 (layer2), 1 (layer3+4), and 2 (layer2+3). Default system setting is 1 (layer3+4).

ip

To run ip related operations.

Operation	Short Name	Description
config		To configure IP parameters on the interface.
delete	rm	To delete IP parameters on the interface.

ip config

To configure IP parameters on the interface.

Parameter	Type	Required	Description
family	int	no	Param to specify IP address family, 1=IpV4(default) or 2=IpV6.
interface-ips	string	no	Comma separated list of interface IP addresses (IPv4 only).
interface-name	string	yes	Name of the network interface. It can be bond interface, vlan interface or interface group.
interface-role	string	no	Role of the network interface. It can be primary, secondary.
node-ids	list of ints	no	Comma separated list of Node IDs.
subnet-gateway	string	no	Subnet gateway for the Cluster.
subnet-mask-bits	int	no	Subnet mask bits for the Cluster.

ip delete

To delete IP parameters on the interface.

Parameter	Type	Required	Description
family	int	no	Param to specify IP address family, 1=IpV4(default) or 2=IpV6.
interface-name	string	yes	Name of the network interface. It can be bond interface, vlan interface or interface group.
node-ids	list of ints	no	Comma separated list of Node IDs.

ipmi

To run IPMI related operations on local and other nodes of the cluster.

Operation	Short Name	Description
cluster-update-lan-info		Update IPMI LAN info in the cluster.
cluster-update-users		Update IPMI users in the cluster.
get-fru-info		To get IPMI FRU info.

Operation	Short Name	Description
get-lan-info		To get IPMI LAN info.
get-sdr-info		To get IPMI SDR info.
get-sel		To get the IPMI SEL list.
get-sel-info		To get IPMI SEL info.
list-users		To list IPMI users.
reset-bmc		To reset the BMC.
show-system-led-info		Show System LED information.

ipmi cluster-update-lan-info

Update IPMI LAN info in the cluster.

Parameter	Type	Required	Description
ipmi-subnet-gateway	string	no	IPMI Subnet gateway.
ipmi-subnet-mask	string	no	IPMI Subnet mask should be either in CIDR prefix or in dotted decimal for IPv4.
node-ipmi-ips	list of strings	no	Comma separated list of Node IPMI IP addresses (IPv4 only).
node-ipmi-subnet-gateways	list of strings	no	Comma separated list of IPMI Subnetgateways.
node-ipmi-subnet-masks	list of strings	no	Comma separated list of IPMI Subnet masks. Mask should be a CIDR prefix or a dotted decimal for IPv4.
node-ips	list of strings	no	Comma separated list of Node IP addresses (IPv4 or IPv6).

ipmi cluster-update-users

Update IPMI users in the cluster. For more information, see Manage IPMI Configuration Using the Cohesity CLI.

Parameter	Type	Required	Description
ipmi-password	string	no	IPMI password for the Cluster.
ipmi-username	string	no	IPMI username for the Cluster.
node-ipmi-passwords	list of strings	no	IPMI passwords for the given nodes.
node-ipmi-usernames	list of strings	no	IPMI usernames for the given nodes.
node-ips	list of strings	no	Comma separated list of Node IP addresses (IPv4 or IPv6).

ipmi get-fru-info

To get IPMI FRU info.

Parameter	Type	Required	Description
node-id	int	no	ID of a Node.
node-ip	string	no	Node IP addresses (IPv4 or IPv6).

ipmi get-lan-info

To get IPMI LAN info.

Parameter	Type	Required	Description
node-id	int	no	ID of a Node.
node-ip	string	no	Node IP addresses (IPv4 or IPv6).

ipmi get-sdr-info

To get IPMI SDR info.

Parameter	Type	Required	Description
node-id	int	no	ID of a Node.
node-ip	string	no	Node IP addresses (IPv4 or IPv6).

ipmi get-sel

To get the IPMI SEL list.

Parameter	Type	Required	Description
node-id	int	no	ID of a Node.
node-ip	string	no	Node IP addresses (IPv4 or IPv6).
verbose	bool	no	If set to true, more information is displayed.

ipmi get-sel-info

To get IPMI SEL info.

Parameter	Type	Required	Description
node-id	int	no	ID of a Node.
node-ip	string	no	Node IP addresses (IPv4 or IPv6).

ipmi list-users

To list IPMI users.

Parameter	Type	Required	Description
node-id	int	no	ID of a Node.
node-ip	string	no	Node IP addresses (IPv4 or IPv6).

ipmi reset-bmc

To reset the BMC.

Parameter	Type	Required	Description
node-id	int	no	ID of a Node.
node-ip	string	no	Node IP addresses (IPv4 or IPv6).

ipmi show-system-led-info

Show System LED information.

Parameter	Type	Required	Description
node-ip	string	no	Node IP address for which system LED information is displayed.

kms

To run any KMS related operations.

Operation	Short Name	Description
create-aws		Create a new aws KMS.
create-azure		Create a new Azure KMS.
create-kmip		Create a new kmip KMS.
delete	rm	To delete a KMS by Id.
list		To list KMS.
update-aws		Update an existing aws KMS.
update-kmip		Update an existing kmip KMS.

kms create-aws

Create a new aws KMS.

Parameter	Type	Required	Description
access-key-id	string	no	The AWS acount access key Id.
arn	string	no	The amazon resource number of the CMK.
auth-method	string	yes	The AWS Auth method.
ca-certificate-path	string	no	File path to ca-certificate.

Parameter	Type	Required	Description
iam-role-arn	string	no	Specify the IamRole ARN for CE. It can either kUseIAMUser or kUseIAMRole.
key-alias	string	no	Key alias of the CMK.
key-id	string	no	The amazon CMK key ID.
key-name	string	yes	Name of the KMS Key.
region	string	no	region
secret-access-key	string	no	The AWS account secret Access key.
vault-ids	list of ints	no	Comma separated list of vault ids.
verify-ssl	bool	no	Specify whether to verify SSL certificate when try to access aws kms server.
view-box-ids	list of ints	no	Comma separated list of Storage Domain IDs.

kms create-azure

Create a new Azure KMS.

Parameter	Type	Required	Description
azure-client-id	string	no	Azure Client Id.
azure-client-secret-key	string	no	Specify Azure client secret key.
azure-kms-auth-method	string	yes	The AWS Auth method.
azure-tenant-id	string	no	Azure Tenant Id.
customer-secret-name	string	no	Specifies the name of client secret stored in cohesity keyvault.
key-name	string	yes	Name of the KMS Key.
keyvault-key-name	string	no	Specify the Key name used to encrypt decrypt DEK.

Parameter	Type	Required	Description
keyvault-url	string	no	Specify the URL of the Azure key vault.
vault-ids	list of ints	no	Comma separated list of vault ids.
vault-owner	string	yes	Specifies if its a cohesity managed or customer managed key vault.
keyvault-key-name	string	no	Specify the Key name used to encrypt decrypt DEK.

kms create-kmip

Create a new kmip KMS.

Parameter	Type	Required	Description
additional-address	list of strings	no	Additional IP addresses or FQDNs of the KMS server.
ca-certificate-path	string	yes	File path to ca-certificate.
client-certificate	string	yes	File path to client-certificate.
client-key	string	yes	File path to client-key.
ip	string	yes	IP address or FQDN of the KMS server.
key-name	string	yes	Name of the KMS Key.
kmip-protocol-version	string	yes	kmip-protocol-version
port	int	yes	KMS Port. Default KMIP port is 5696.
vault-ids	list of ints	no	Comma separated list of vault ids.
view-box-ids	list of ints	no	Comma separated list of Storage Domain IDs.

kms delete

To delete a KMS by Id.

Parameter	Type	Required	Description
id	int	yes	The Id of a KMS server.

kms list

To list KMS.

Parameter	Type	Required	Description
id	int	no	The Id of a KMS server.

kms update-aws

Update an existing aws KMS.

Parameter	Type	Required	Description
access-key-id	string	no	The AWS acount access key Id.
ca-certificate-path	string	no	File path to ca-certificate.
id	int	yes	The Id of a KMS server.
key-name	string	yes	Name of the KMS Key.
secret-access-key	string	no	The AWS account secret Access key.
vault-ids	list of ints	no	Comma separated list of vault ids.
verify-ssl	bool	no	Specify whether to verify SSL certificate when try to access aws kms server.
view-box-ids	list of ints	no	Comma separated list of Storage Domain IDs.

kms update-kmip

Update an existing kmip KMS.

Parameter	Type	Required	Description
additional-address	list of strings	no	Additional IP addresses or FQDNs of the KMS server.
ca-certificate-path	string	no	File path to ca-certificate.
client-certificate	string	no	File path to client-certificate.
client-key	string	no	File path to client-key.
confirm	bool	yes	Confirming to update KMS server. Please make sure the new updated information is for thte same KMS server configured before.
id	int	yes	The Id of a KMS server.
ip	string	no	IP address or FQDN of the KMS server.
key-name	string	no	Name of the KMS Key.
kmip-protocol-version	string	no	kmip-protocol-version
port	int	no	KMS Port. Default KMIP port is 5696.
vault-ids	list of ints	no	Comma separated list of vault ids.
view-box-ids	list of ints	no	Comma separated list of Storage Domain IDs.

ldap

To run any LDAP related operations.

Operation	Short Name	Description
create	add	To add an LDAP provider to the cluster.
delete	rm	To delete an LDAP provider from the cluster.
update	edit	To update an LDAP provider to the cluster.

ldap create

To add an LDAP provider to the cluster.

Parameter	Type	Required	Description
active-directory-domain-name	string	no	The active directory domain that should be mapped to this LDAP.
attribute-common-name	string	no	Name of the LDAP attribute used for common name of an object.
attribute-gid	string	no	Name of the attribute used to lookup unix GID of an LDAP user.
attribute-member-of	string	no	Name of the LDAP attribute used to lookup members of a group.
attribute-uid	string	no	Name of the attribute used to lookup unix UID of an LDAP user.
attribute-user-name	string	no	Name of the LDAP attribute used to lookup a user by user ID.
auth-type	string	yes	Authentication type used while connecting to LDAP servers. This can be Simple or Anonymous.
base-distinguished-name	string	yes	Base distinguished name used as the base for LDAP search requests.
domain-name	string	no	Domain name of the LDAP provider.
ldap-name	string	yes	User defined name of the LDAP provider.
object-class-group	string	no	Name of the LDAP group object class for user accounts.
object-class-user	string	no	Name of the LDAP user object class for user accounts.
port	string	no	Port on which LDAP server is listening on.
preferred-ldap-servers	list of strings	no	Preferred LDAP servers in fully qualified domain name (FQDN) format or IP address format.
use-ssl	bool	no	Specifies whether to use SSL for LDAP connections.

Parameter	Type	Required	Description
user-distinguished-name	string	yes	User distinguished name that is used for LDAP authentication.
user-password	string	yes	User password that is used for LDAP authentication.

ldap delete

To delete an LDAP provider from the cluster.

Parameter	Type	Required	Description
ldap-id	int	yes	Id of the LDAP provider.

ldap update

To update an LDAP provider to the cluster.

Parameter	Type	Required	Description
active-directory-domain-name	string	no	The active directory domain that should be mapped to this LDAP.
auth-type	string	no	Authentication type used while connecting to LDAP servers. This can be Simple or Anonymous.
base-distinguished-name	string	no	Base distinguished name used as the base for LDAP search requests.
domain-name	string	no	Domain name of the LDAP provider.
ldap-id	int	yes	Id of the LDAP provider.
ldap-name	string	no	User defined name of the LDAP provider.
port	string	no	Port on which LDAP server is listening on.
preferred-ldap-servers	list of strings	no	Preferred LDAP servers in fully qualified domain name (FQDN) format or IP address format.

Parameter	Type	Required	Description
use-ssl	bool	no	Specifies whether to use SSL for LDAP connections.
user-distinguished-name	string	no	User distinguished name that is used for LDAP authentication.
user-password	string	no	User password that is used for LDAP authentication.

mfa-config

To run any cluster MFA config related operations.

Operation	Short Name	Description
list	ls	To list MFA config on the cluster.
update	edit	To update MFA config on the cluster.

mfa-config update

To update MFA config on the cluster.

Parameter	Type	Mandatory	Description
authentication-types	list of strings	no	Specifies cluster MFA authentication types: totp, email.
is-cluster-mfa-enabled	bool	no	Specifies if enable/disable cluster MFA.

nfs-share

To run any NFS share related operations.

Operation	Short Name	Description
configure		To configure NFS shares on the NFS server and mount them to all node in the cluster.

Operation	Short Name	Description
create-snapshot		To create snapshots of NFS shares on the NFS server.
delete-remote-storage		To unregister/remove a registeredremote storage.
list		To list all NFS shares in the cluster.
list-remote-storages		To list registered remote storages.
migrate		To migrate a NFS share to a different node in the cluster.
mount		To mount NFS shares to a node in the cluster. If the node ID is not specified, the NFS shares will be distributed and mounted to all nodes in the cluster.
register-remote-storage		To register/add a new remote storage.
update-data-vips		To update the registered FlashBlade data VIPs and use these data VIPs to remount all NFS shares.
update-remote-storage		To update info of a registeredremote storage.

nfs-share configure

To configure NFS shares on the NFS server and mount them to all node in the cluster.

Parameter	Type	Required	Description
available-capacity	int	yes	Total available capacity for creating NFS shares.
data-vips	list of strings	yes	Data VIPs for mounting NFS shares.

nfs-share create-snapshot

To create snapshots of NFS shares on the NFS server.

Parameter	Type	Required	Description
cluster-id	int	no	ID of the Cluster to take snapshot of all NFS shares that belong to the cluster.

Parameter	Type	Required	Description
nfs-share-names	list of strings	no	Comma separated list of NFS share names.
node-id	int	no	ID of the Node to take snapshot of all NFS shares that belong to the node.
suffix	string	no	Suffix to add to the snapshot name.

nfs-share delete-remote-storage

To unregister/remove a registeredremote storage.

Parameter	Type	Required	Description
id	int	yes	The id of registered remote storage.

nfs-share list

To list all NFS shares in the cluster.

Parameter	Type	Required	Description
cluster-id	int	no	ID of the Cluster.

nfs-share migrate

To migrate a NFS share to a different node in the cluster.

Parameter	Type	Required	Description
disk-id	int	yes	ID of the Disk.
node-id	int	yes	ID of the Node to which the NFS share is migrated.

nfs-share mount

To mount NFS shares to a node in the cluster. If the node ID is not specified, the NFS shares will be distributed and mounted to all nodes in the cluster.

Parameter	Type	Required	Description
data-vips	list of strings	yes	Data VIPs for mounting NFS shares.
nfs-share-names	list of strings	yes	Comma separated list of NFS share names.
node-id	int	no	ID of the Node to which the NFS share is mounted.
storage-tier	string	yes	Storage Tier to be assigned to the NFS share. It can be 'PCIeSSD', 'SATA-SSD' or 'SATA-HDD'.

nfs-share register-remote-storage

To register/add a new remote storage.

Parameter	Type	Required	Description
api-token	string	yes	Api token of the management server of remote storage.
ip	string	yes	Management ip address of remote storage.

nfs-share update-data-vips

To update the registered FlashBlade data VIPs and use these data VIPs to remount all NFS shares.

Parameter	Type	Required	Description
data-vips	list of strings	no	Data VIPs for mounting NFS shares.

nfs-share update-remote-storage

To update info of a registeredremote storage.

Parameter	Type	Required	Description
api-token	string	yes	Api token of the management server of remote storage.
id	int	yes	The id of registered remote storage.
ip	string	yes	Management ip address of remote storage.

node-csr

To run any node csr related operations.

Operation	Short Name	Description
create	add	To create a csr for the node.
import		To import and install signed csr and ca cert used to sign the certificate signing request.
update-hostnames		Update hostnames in the cluster when node-ids and hostnames are provided.

node-csr create

To create a csr for the node.

Parameter	Type	Required	Description
city	string	yes	The locality attribute, which is part of the distinguished name definition. It is used to identify the city where the company is located or the Cluster is installed.
common-name	string	no	The common name attribute, which is part of the distinguished name definition. Common name is used to specify a context for the certificate, for example, the name of the Node (attributed by node ip) to which the certificate is to be assigned.
country	string	yes	The country attribute, which is part of the distinguished name definition. It is used to identify the country where the state is located. It is specified as two letter code defined by the ISO standard.
dns-names	list of strings	no	An alternative subject name component to be included in the certificate. It is given as a comma separated list of FQDNs. If not passed, it shall not be set in the certificate request.
email-address	string	no	An alternative subject name component to be included in the certificate. Format is a standard e-mail address, for example joe@company.com.

Parameter	Type	Required	Description
host-ip	string	no	An alternative subject name component to be included in the certificate. The value passed should be the valid ip address of the node.
organization	string	yes	The organization attribute, which is part of the distinguished name definition. It is used to specify the name of the company.
organization-unit	string	yes	Specifies the organization unit attribute, which is part of the distinguished name definition. It is used to identify the specific department or business unit in the company that is owning the Node.
state	string	yes	The state attribute, which is part of the distinguished name definition. It is used to identify the state where the city is located.

node-csr import

To import and install signed csr and ca cert used to sign the certificate signing request.

Parameter	Type	Required	Description
cacert-path	string	yes	The path of the file of the ca certificate which was used to sign the csr for the node.
signedcert-path	string	yes	The path of the file of the signed certificate to be imported for the particular node.

node-csr update-hostnames

Update hostnames in the cluster when node-ids and hostnames are provided.

Parameter	Type	Required	Description
host-names	list of strings	yes	Comma separated list of hostnames. Run allsssh.sh hostname to get all the hostnames, or set the desried hostnames, The order should correspond to the same which was provided in node-ids.
node-ids	list of ints	yes	Type of a node group. Possible values are 1 (Zone), 2 (Bgp config), 3 (Ospf config) and 4 (Dns).

node-group

To run node group related operations.

Operation	Short Name	Description
create-bgp		To create a BGP node group.
create-dns		To create a DNS node group.
create-zone		To create a ZONE node group.
delete	rm	To delete the node group in the cluster.
list	ls	To list the node groups in the cluster.
update-bgp		To update a BGP node group.
update-dns		To update a DNS node group.
update-zone		To update a ZONE node group.

node-group create-bgp

To create a BGP node group.

Parameter	Type	Required	Description
group-name	string	yes	Name of a node group.
hold-time	int	no	BGP instance hold time in seconds.
keepalive-time	int	no	BGP instance keep alive interval in seconds.
local-as	int	yes	BGP peer local AS number.
node-ids	list of ints	yes	Comma separated list of Node IDs.
peer-address	list of strings	yes	Comma separated list of BGP IP addresses.
peer-description	list of strings	no	Comma separated list of BGP peer descriptions.
peer-hold-time	list of ints	no	Comma separated list of BGP peer hold times in seconds.

Parameter	Type	Required	Description
peer-keepalive-time	list of ints	no	Comma separated list of BGP peer keep alive intervals in seconds.
peer-remote-as	list of ints	yes	Comma separated list of BGP peer remote AS numbers.

node-group create-dns

To create a DNS node group.

Parameter	Type	Required	Description
dns-server-ips	list of strings	yes	Comma separated list of DNS server IP addresses.
group-name	string	yes	Name of a node group.
node-ids	list of ints	yes	Comma separated list of Node IDs.

node-group create-zone

To create a ZONE node group.

Parameter	Type	Required	Description
group-name	string	yes	Name of a node group.
node-ids	list of ints	yes	Comma separated list of Node IDs.
subnet-gateway	string	no	Subnet gateway for the Cluster.
subnet-ip	string	yes	Subnet IP for the Cluster.
subnet-mask-bits	int	yes	Subnet mask bits for the Cluster.

node-group delete

To delete the node group in the cluster.

Parameter	Type	Required	Description
group-name	string	yes	Name of a node group.

node-group list

To list the node groups in the cluster.

Parameter	Type	Required	Description
group-names	list of strings	no	Comma separated list of node group names.
group-type	int	no	Type of a node group. Possible values are 1 (Zone), 2 (Bgp config), 3 (Ospf config) and 4 (Dns).

node-group update-bgp

To update a BGP node group.

Parameter	Type	Required	Description
add-node-ids	list of ints	no	Comma separated list of Node IDs to add.
group-name	string	yes	Name of a node group.
hold-time	int	no	BGP instance hold time in seconds.
keepalive-time	int	no	BGP instance keep alive interval in seconds.
peer-address	list of strings	no	Comma separated list of BGP IP addresses.
peer-description	list of strings	no	Comma separated list of BGP peer descriptions.
peer-hold-time	list of ints	no	Comma separated list of BGP peer hold times in seconds.
peer-keepalive-time	list of ints	no	Comma separated list of BGP peer keep alive intervals in seconds.
peer-remote-as	list of ints	no	Comma separated list of BGP peer remote AS numbers.
remove-node-ids	list of ints	no	Comma separated list of Node IDs to remove.

node-group update-dns

To update a DNS node group.

Parameter	Type	Required	Description
add-node-ids	list of ints	no	Comma separated list of Node IDs to add.
dns-server-ips	list of strings	no	Comma separated list of DNS server IP addresses.
group-name	string	yes	Name of a node group.
remove-node-ids	list of ints	no	Comma separated list of Node IDs to remove.

node-group update-zone

To update a ZONE node group.

Parameter	Type	Required	Description
add-node-ids	list of ints	no	Comma separated list of Node IDs to add.
group-name	string	yes	Name of a node group.
remove-node-ids	list of ints	no	Comma separated list of Node IDs to remove.
subnet-gateway	string	no	Subnet gateway for the Cluster.
subnet-ip	string	no	Subnet IP for the Cluster.
subnet-mask-bits	int	no	Subnet mask bits for the Cluster.

node

To run any Node related operations.

Operation	Short Name	Description
configure-network		To configure network on nodes before cluster is created.
delete	rm	To mark the Node for removal.
discover-free-nodes	ls-free-nodes	To list the free nodes.
full-info		To get whole info of the node.

Operation	Short Name	Description
identify	ident	To identify a node in a chassis.
list	ls	To list the Node details.
list-packages	ls-pkgs	To list the available Cohesity software packages on a Node.
status		To get the status of the Node.
upload-package	upload-pkg	To upload a software package to the Node.

node configure-network

To configure network on nodes before cluster is created.

Parameter	Type	Required	Description
bonding-mode	string	no	Bonding mode to use when bonding the NICs. Modes 1 (active-backup) and 4 (802.3ad) are supported. Mode 4 may require switch configuration. In cluster, the services need to be stopped before changing on primary interface group.
ipmi-password	string	no	IPMI password for the Cluster.
ipmi-subnet-gateway	string	no	IPMI Subnet gateway.
ipmi-subnet-mask	string	no	IPMI Subnet mask should be either in CIDR prefix or in dotted decimal for IPv4.
ipmi-username	string	no	IPMI username for the Cluster.
node-ids	list of ints	yes	Comma separated list of Node IDs.
node-ipmi-ips	list of strings	no	Comma separated list of Node IPMI IP addresses (IPv4 only).
node-ips	list of strings	yes	Comma separated list of Node IP addresses (IPv4 or IPv6).
subnet-gateway	string	yes	Subnet gateway for the Cluster.
subnet-mask	string	yes	Subnet mask for the Cluster. Should be either in CIDR prefix or in dotted decimal.

node delete

To mark the Node for removal.

Parameter	Type	Required	Description
id	int	yes	ID of a Node.

node identify

To identify a node in a chassis.

Parameter	Type	Required	Description
cluster-id	int	yes	ID of the Cluster.
id	int	yes	ID of a Node.
identify	bool	yes	Flag to toggle identification LED status.

node list

To list the Node details.

Parameter	Type	Required	Description
cluster-partition-ids	list of ints	no	Comma separated list of Cluster Partition IDs.
ids	list of ints	no	Comma separated list of Node IDs.
include-marked-for-removal	bool	no	Include the nodes which have been marked for removal.
include-only-unassigned-nodes	bool	no	Include only the nodes which have not been assigned to any Cluster.
show-stats	bool	no	To display the computed statistics.
show-system-disks	bool	no	To display the system disks details.

node upload-package

To upload a software package to the Node.

Parameter	Type	Required	Description
cancel	bool	no	Cancel any ongoing package upload.
software-pkg-file-path	string	no	Local file path where the Cohesity Software package is available.
software-pkg-md5	string	no	MD5 Hash of the software package to be uploaded to the Node.
software-pkg-url	string	no	URL where Cohesity Software package is available.
software-version	string	no	Software version of the package.

patch

To run any Patch related operations.

Operation	Short Name	Description
apply		To apply dependent patches.
history		To list patch operations.
import		To import a patch or a hotfix.
list	ls	To list Patch details.
revert		To revert dependent patches.
status		To get the status of the current or the last patch operations.

patch apply

To apply dependent patches.

Parameter	Type	Required	Description
all	bool	no	Apply all the available patches.

Parameter	Type	Required	Description
service-name	string	no	Apply the patch for the service name.

patch history

To list patch operations.

Parameter	Type	Required	Description
service-name	string	no	If a service name is given, the patch operations for the service are shown. Otherwise, all operations are shown.

patch import

To import a patch or a hotfix.

Parameter	Type	Required	Description
file-path	string	yes	Local path to the patch or the hotfix file.

patch list

To list Patch details.

Parameter	Type	Required	Description
applied	bool	no	If applied is given, or set to true, shows the applied patches. By default, shows the available patches.
details	bool	no	If details is given, or set to true, shows the fixed issues. By default, shows only the number of fixed issues.
service-name	string	no	If a service name is given, only the patch for the service is shown. Otherwise, all patches are shown.

patch revert

To revert dependent patches.

Parameter	Type	Required	Description
service-name	string	yes	Name of the service whose patch should be reverted.

patch status

To get the status of the current or the last patch operations.

Parameter	Type	Required	Description
details	bool	no	If details is given, or set to true, shows the progress of operation for each service on each node.

privilege

To run any Privilege related operations.

Operation	Short Name	Description
list	ls	To list Privileges.

privilege list

To list Privileges.

Parameter	Type	Required	Description
name	string	no	Name of the Privilege to list

protection-job

To run any Protection Job related operations.

Operation	Short Name	Description
cancel		To cancel a running protection job.

protection-job cancel

To cancel a running protection job.

Parameter	Type	Required	Description
id	int	no	Id of the job.
name	string	no	Name of the job.

qos-profile

To run any Qos profile related operations.

Operation	Short Name	Description
activate		To activate a profile on a list of interfaces with a list of ipsets.
create	add	To create a collection of service ports with the protocol of each port for QoS.
deactivate		To deactivate a list of active QoS profiles, Each one will stop a profile on matching packets.
delete	rm	To remove a list of profiles for QoS.
feature		To enable/disable Qos feature.
list	ls	To list the groups of qos profiles.
list-active	ls-active	To list all the active QoS profiles. Each attachment activates a profile on specific ipsets.
revert-to-default		To revert all QoS profile to factory default configuration

qos-profile activate

To activate a profile on a list of interfaces with a list of ipsets.

Parameter	Type	Required	Description
desc	string	no	Description of the QoS rule sets.
ipset-entries	list of strings	no	Comma separated list of subnets/ips for the firewall Ipsets.

Parameter	Type	Required	Description
mark-dscp	int	yes	To mark dscp value in the outgoing packet.
profile-name	string	yes	Name of the QoS profile.

qos-profile create

To create a collection of service ports with the protocol of each port for QoS.

Parameter	Type	Required	Description
direction	string	no	Data Traffic direction that can be only ""OUTPUT""
force	bool	no	Set to true to unlock the ports restriction.
name	string	yes	Name of the QoS profile.
ports	list of strings	no	Comma separated list of service ports.
priority	int	no	Decides the order in which rule is applied. Lower the number higher the priority.

qos-profile deactivate

To deactivate a list of active QoS profiles, Each one will stop a profile on matching packets.

Parameter	Type	Required	Description
profile-names	list of strings	yes	Comma separated list of names for the QoS profile.

qos-profile delete

To remove a list of profiles for QoS.

Parameter	Type	Required	Description
names	list of strings	yes	Comma separated list of names for the QoS profile.

qos-profile feature

To enable/disable Qos feature.

Parameter	Type	Required	Description
enable	bool	yes	To enable/disable Qos feature.

rack

To manage racks in cluster.

Operation	Short Name	Description
create	add	To add a rack to cluster.
list	ls	To get all racks or one rack information in a cluster.
update	edit	To update a rack.

rack create

To add a rack to cluster.

Parameter	Type	Required	Description
chassis-ids	list of ints	no	List of chassis in a rack.
location	string	no	The location of a rack.
name	string	yes	The name of rack.

rack list

To get all racks or one rack information in a cluster.

Parameter	Type	Required	Description
id	int	no	The id of a rack.

rack update

To update a rack.

Parameter	Type	Required	Description
chassis-ids	list of ints	no	List of chassis in a rack.
id	int	yes	The id of a rack.
location	string	no	The location of a rack.
name	string	no	The name of rack.

remote-cluster

To run any remote Cluster registration related operations.

Operation	Short Name	Description
add-bandwidth-limit-override-window	add-blow	To add a bandwidth limit override window.
add-storage-domain-mapping		To add local Storage Domain to remote Storage Domain mapping. Only one to one mapping is allowed between local Storage Domains and remote Storage Domains.
create	add	To register a remote Cluster.
delete	rm	To delete the registration of a remote Cluster.
delete-storage-domain-mapping		To delete the local Storage Domain to remote Storage Domain mapping.
list	ls	To list the registration information for remote Clusters.
list-remote-storage-domains		To list the Storage Domains of the remote Cluster.
update	edit	To update registration of remote Cluster.

remote-cluster add-bandwidth-limit-override-window

To add a bandwidth limit override window.

Parameter	Type	Required	Description
bandwidth-limit	int	yes	Bandwidth limit in bytes/second from the local Cluster to the remote Cluster.
cluster-id	int	yes	ID of the remote Cluster.
end-time	string	yes	Bandwidth limit override window end time in hh:mm format.
start-time	string	yes	Bandwidth limit override window start time in hh:mm format.
timezone	string	no	Timezone used for bandwidth limit enforcement.
week-days	list of strings	no	Comma separated list of week days in the format su,m,tu,w,th,f,sa.

remote-cluster add-storage-domain-mapping

To add local Storage Domain to remote Storage Domain mapping. Only one to one mapping is allowed between local Storage Domains and remote Storage Domains.

Parameter	Type	Required	Description
cluster-id	int	yes	ID of the remote Cluster.
local-storage-domain-id	int	no	ID of the Local Storage Domain.
local-storage-domain-name	string	no	Name of the Local Storage Domain.
remote-storage-domain-id	int	no	ID of the Remote Storage Domain.
remote-storage-domain-name	string	no	Name of the Remote Storage Domain.

remote-cluster create

To register a remote Cluster.

Parameter	Type	Required	Description
all-endpoints-reachable	bool	no	Whether any endpoint on the remote Cluster is reachable from this cluster.
bandwidth-limit	int	no	Bandwidth limit in bytes/second from the local Cluster to the remote Cluster.
compression-enabled	bool	no	Flag to enable or disable the compression.
encryption-key	string	no	Key for encryption. Enter the same key in the local and remote cluster to set up encryption for replication traffic.
interface-name	string	no	Name of the network interface. It can be bond interface, vlan interface or interface group.
password	string	yes	Password of the user to connect to the remote Cluster.
remote-ips	list of strings	yes	Ip addresses to connect to nodes of remote Cluster
user-name	string	yes	Username of the user to connect to the remote Cluster.

remote-cluster delete

To delete the registration of a remote Cluster.

Parameter	Type	Required	Description
cluster-id	int	yes	ID of the remote Cluster.

remote-cluster delete-storage-domain-mapping

To delete the local Storage Domain to remote Storage Domain mapping.

Parameter	Type	Required	Description
cluster-id	int	yes	ID of the remote Cluster.
local-storage-domain-id	int	no	ID of the Local Storage Domain.

Parameter	Type	Required	Description
local-storage-domain-name	string	no	Name of the Local Storage Domain.
remote-storage-domain-id	int	no	ID of the Remote Storage Domain.
remote-storage-domain-name	string	no	Name of the Remote Storage Domain.

remote-cluster list

To list the registration information for remote Clusters.

Parameter	Type	Required	Description
ids	list of ints	no	Comma separated list of IDs.
names	list of strings	no	Comma separated list of remote Cluster names.

remote-cluster list-remote-storage-domains

To list the Storage Domains of the remote Cluster.

Parameter	Type	Required	Description
cluster-id	int	yes	ID of the remote Cluster.
cluster-partition-ids	list of ints	no	Comma separated list of IDs.
ids	list of ints	no	Comma separated list of IDs.
include-marked-for-removal	bool	no	Include the nodes which have been marked for removal.
names	list of strings	no	Comma separated names of the Storage Domains.
show-stats	bool	no	To display the computed statistics.

remote-cluster update

To update registration of remote Cluster.

Parameter	Type	Required	Description
all-endpoints-reachable	bool	no	Whether any endpoint on the remote Cluster is reachable from this cluster.
bandwidth-limit	int	no	Bandwidth limit in bytes/second from the local Cluster to the remote Cluster.
cluster-id	int	yes	ID of the remote Cluster.
compression-enabled	bool	no	Flag to enable or disable the compression.
encryption-key	string	no	Key for encryption. Enter the same key in the local and remote cluster to set up encryption for replication traffic.
interface-name	string	no	Name of the network interface. It can be bond interface, vlan interface or interface group.
password	string	no	Password of the user to connect to the remote Cluster.
remote-ips	list of strings	no	Ip addresses to connect to nodes of remote Cluster
user-name	string	no	Username of the user to connect to the remote Cluster.

role

To run any Role related operations.

Operation	Short Name	Description
create	add	To create a new Role.
delete	rm	To delete a Role.
list	ls	To list Roles.
update	edit	To update a Role.

role create

To create a new Role.

Parameter	Type	Required	Description
description	string	no	Description of the Role.
name	string	yes	Name of the Role.
privileges	list of strings	no	Comma separated list of Privileges.

role delete

To delete a Role.

Parameter	Type	Required	Description
names	list of strings	yes	Name of the Roles to delete.

role list

To list Roles.

Parameter	Type	Required	Description
name	string	no	Name of the Role.

role update

To update a Role.

Parameter	Type	Required	Description
description	string	no	Description of the Role.
name	string	yes	Name of the Role.
privileges	list of strings	no	Comma separated list of Privileges.

route

To run any Static Route related operations. A Static Route designates which VLAN and Network Interfaces to use for communication with a particular destination network.

Operation	Short Name	Description
create	add	To add a new Static Route.
delete	rm	To remove an existing Static Route.
list	ls	To list all the configured routes.

route create

To add a new Static Route.

Parameter	Type	Required	Description
advmss	int	no	TCP MSS (advmss) value exchanged during connection establishment for the clients reachable by this route.
desc	string	no	Description.
dest-network	string	yes	Destination network: ip/prefix.
interface-group	string	no	Name of a network interface group.
interface-name	string	no	Interface Name such as bond0. It is only used on free node.
mtu	int	no	MTU for the static route.
next-hop	string	yes	Next hop to destination network.
node-group	string	no	Name of a node group. This is only required in multiple subnet cluster.

route delete

To remove an existing Static Route.

Parameter	Type	Required	Description
dest-network	string	yes	Destination network: ip/prefix.
interface-group	string	no	Name of a network interface group.

Parameter	Type	Required	Description
interface-name	string	no	Interface Name such as bond0. It is only used on free node.
node-group	string	no	Name of a node group. This is only required in multiple subnet cluster.

routing

Routing commands.

Operation	Short Name	Description
show-bgp-neighbors		Shows neighbors information of BGP.
show-bgp-nexthop		Shows nexthop information of BGP.
show-bgp-statistics		Shows statistics information of BGP.
show-bgp-summary		Shows BGP summary.

routing show-bgp-neighbors

Shows neighbors information of BGP.

Parameter	Type	Required	Description
all-nodes	bool	no	On all nodes.

routing show-bgp-nexthop

Shows nexthop information of BGP.

Parameter	Type	Required	Description
all-nodes	bool	no	On all nodes.

routing show-bgp-statistics

Shows statistics information of BGP.

Parameter	Type	Required	Description
all-nodes	bool	no	On all nodes.

routing show-bgp-summary

Shows BGP summary.

Parameter	Type	Required	Description
all-nodes	bool	no	On all nodes.

security-config

To run any security config related operations.

Operation	Short Name	Description
update	edit	To update the security config on the cluster.

security-config update

To update the security config on the cluster.

Parameter	Type	Required	Description
ad-mapping	string	no	Specifies which field to map in AD user. It can be chosen from "SamAccountName", "UserPrincipalName".
certificate-mapping	string	no	Specifies which field to map in Certificates. It can be chosen from "CommonName", "EmailAddress", "UserPrincipalName".
classified-data-msg	string	no	Specifies the classified data message.
enable-mapping-based-auth	bool	no	Specifies if mapping based certificate authentication is enabled or not
failed-login-lock-duration-mins	int	no	Specifies the time duration within which the consecutive failed login attempts causes a local user account to be locked.

Parameter	Type	Required	Description
inactivity-time-days	int	no	Specifies the lockout inactivity time range in days.
include-lower-letter	bool	no	Specifies if the password needs to have at least one lowercase letter.
include-number	bool	no	Specifies if the password needs to have at least one number.
include-special-char	bool	no	Specifies if the password needs to have at least one special character.
include-upper-letter	bool	no	Specifies if the password needs to have at least one uppercase letter.
is-data-classified	bool	no	Specifies whether to mark the web page data classified/unclassified.
limit-sessions	bool	no	Specifies if limitations on number of active sessions is enabled or not.
login-token-timeout-hours	int	no	Specifies login token timeout in hours. Should be between 1 and 24 hours.
max-failed-login-attempts	int	no	Specifies the maximum number of consecutive fail login attempts.
max-lifetime-days	int	no	Specifies the maximum password lifetime in days.
min-length	int	no	Specifies the password minimum length.
min-lifetime-days	int	no	Specifies the minimum password lifetime in days.
num-diff-chars	int	no	Specifies the number of characters in the new password that needs to be different from the old password (only applicable when changing the user's own password).
num-disallowed-old-pwd	int	no	Specifies the minimum number of old passwords that are not allowed for changing the password.
session-absolute-timeout	int	no	Specifies absolute session expiration time in seconds.

Parameter	Type	Required	Description
session-inactivity-timeout	int	no	Specifies inactivity session expiration time in seconds.
session-limit-per-user	int	no	Specifies maximum number of active sessions allowed per user. This applies only when limit sessions is enabled.
session-limit-system-wide	int	no	Specifies maximum number of active sessions allowed system wide. This applies only when limit sessions is enabled.

service-identity

To run any Service Identity related operations.

Operation	Short Name	Description
add-disabled-ports		To add disabled ports for service identity
rm-disable-ports		To remove disable ports for service identity
status		Show service identity status

service-identity add-disabled-ports

To add disabled ports for service identity.

Parameter	Type	Mandatory	Description
ports	string	yes	Comma seperated list of disabled ports

service-identity rm-disable-ports

To remove disable ports for service identity.

Parameter	Type	Mandatory	Description
ports	string	yes	Comma seperated list of disabled ports

set-option

To set or override existing CLI options at runtime.

Operation	Short Name	Description
output		To control the CLI output format.

set-option output

To control the CLI output format.

Parameter	Type	Required	Description
format	string	yes	Desired CLI output format at runtime, e.g. default, json, prettyjson.

snmp

To run any SNMP related operations

Operation	Short Name	Description
set-option	set	To set the SNMP settings on the cluster.

snmp set-option

To set the SNMP settings on the cluster.

Parameter	Type	Required	Description
auth-password	string	no	SNMP Authorization Password (default:username)
auth-protocol	string	no	SNMP Auth Protocol (for SNMP v3), possible values: MD5 or SHA
nms-server	string	no	NMS IP or Hostname
operation	string	no	Enable/disable the SNMP, possible values: enable or disable
priv-password	string	no	SNMP Privacy Password (default: authPassword)
priv-protocol	string	no	SNMP Priv Protocol (for SNMP v3), possible values: AES or DES in Galois/Counter Mode.

Parameter	Type	Required	Description
security-level	string	no	SNMP Security Level(for SNMP v3), possible values: noAuthNoPriv or authNoPriv or authPriv
sys-contact	string	no	System Contact
sys-desc	string	no	System Description
sys-engine-id-type	int	no	SNMP engineIDType specifies the engineIDshould be built from. Possible values: 0(Random), 1 (IPv4 address, default), 2 (IPv6 address), 3(MAC address).
sys-location	string	no	System Location
sys-name	string	no	System Name
sys-objid	string	no	System Object Id
user	string	no	SNMP User(for v3) or Community(for v2) Name
user-type	string	no	SNMP User type, possible values: read or write or trap
version	string	no	SNMP version, possible values: 2 or 3

storage-domain

To run any Storage Domain related operations.

Operation	Short Name	Description
add-subnet-to-whitelist	add-st-wl	To add a subnet to a view's subnet whitelist
create	add	To create a new Storage Domain.
get-subnet-whitelist	ls-st-wl	To get a view's subnet whitelist
list	ls	To list Storage Domain details.
remove-subnet-from-whitelist	rm-st-wl	To remove a subnet from a view's subnet whitelist
update	edit	To update editable information of a Storage Domain.

storage-domain add-subnet-to-whitelist

To add a subnet to a view's subnet whitelist

Parameter	Type	Required	Description
desc	string	no	Description.
id	int	no	ID of a Storage Domain.
name	string	no	Name of the Storage Domain.
subnet-ip	string	yes	Subnet IP for the Cluster.
subnet-mask	string	yes	Subnet mask for the Cluster. Should be either in CIDR prefix or in dotted decimal.
subnet-nfs-permission	string	no	Clients from this subnet can mount using NFS protocol. This can be kDisabled, kReadOnly, kReadWrite.
subnet-nfs-root-squash	bool	no	Clients from this subnet can mount as root on NFS. This can be Disabled, ReadOnly, ReadWrite.
subnet-s3-permission	string	no	Clients from this subnet can access using S3 protocol. This can be kDisabled, kReadOnly, kReadWrite.
subnet-smb-permission	string	no	Clients from this subnet can mount using SMB protocol. This can be kDisabled, kReadOnly, kReadWrite.

storage-domain create

To create a new Storage Domain.

Parameter	Type	Required	Description
active-directory-domain-name	string	no	The active directory domain this view box should be mapped to. Users from this active directory will be given permission to view contents in this storage domain, when accessing through SMB.
app-marker-detection	bool	no	Whether to support app marker detection.
brick-size	int	no	Brick size in bytes used to create blobs.

Parameter	Type	Required	Description
cluster-partition-id	int	no	ID of a Cluster Partition.
cluster-partition-name	string	no	Name of a Cluster Partition.
compression	string	no	Level of compression to use. Values are low or off.
dedup-enabled	bool	no	Flag to turn on/off post-processing deduplication. Deduplication is on by default. Inline deduplication cannot be turned on, if post-processing deduplication is off.
default-user-quota	int	no	Default user quota in GiB for this Storage Domain.
default-user-quota-alert-limit	int	no	Default user quota limit in GiB for this Storage Domain.
default-user-quota-alert-threshold-percentage	int	no	Default user quota threshold alert percentage for this Storage Domain.
default-view-quota	int	no	Default quota in GiB for views created in the Storage Domain. Set -1 to remove the value.
default-view-quota-alert-limit	int	no	Default alerting threshold in GiB for views created in the Storage Domain. Set -1 to remove the value.
ec-num-data	int	no	Number of data stripes for erasure coding.
ec-num-failures	int	no	Number of failures to tolerate for erasure coding.
encryption-enabled	bool	no	Flag to turn on encryption. If encryption is on, it cannot be turned off later.
erasure-coding-enabled	bool	no	To enable erasure coding.

Parameter	Type	Required	Description
inline-compress-enabled	bool	no	Flag to turn on/off inline compression.If deduplication is done inline, then it is recommended that compression should also be done inline. Also, this parameter will have no effect unless compression is enabled.
inline-dedup-enabled	bool	no	Flag to turn on/off inline deduplication. This parameter will have no effect, unless deduplication is enabled.
inline-erasure-coding	bool	no	Whether erasure coding should be done inline.
ldap-id	int	no	Id of the LDAP provider.
name	string	yes	Name of the Storage Domain.
num-failures	int	no	Disk fault tolerance factor for this storage domain. Specifies maximum number of disk faults tolerated.
num-node-failures-tolerated	int	no	Node fault tolerance factor for this storage domain. Specifies maximum number of node faults tolerated.
purpose	string	yes	To inherit the recommended configurations and tunables optimized for NetBackup DirectIO.
quota	int	no	Maximum allowed quota in GiB. Set -1 to remove the value.
quota-alert-limit	int	no	Threshold in GiB, over which an alert will be sent. Set -1 to remove the value.
s3-buckets-allowed	bool	no	Whether creation of S3 bucket is allowed in the Storage Domain.
subnet-ip	string	no	Subnet IP for the Cluster.
subnet-mask-bits	int	no	Subnet mask bits for the Cluster.
subnet-mask-ip4	string	no	Subnet mask for IPv4 type subnet of the Cluster.
subnet-nfs-permission	string	no	Clients from this subnet can mount using NFS protocol. This can be kDisabled, kReadOnly, kReadWrite.

Parameter	Type	Required	Description
subnet-nfs-root-squash	bool	no	Clients from this subnet can mount as root on NFS. This can be Disabled, ReadOnly, ReadWrite.
subnet-s3-permission	string	no	Clients from this subnet can access using S3 protocol. This can be kDisabled, kReadOnly, kReadWrite.
subnet-smb-permission	string	no	Clients from this subnet can mount using SMB protocol. This can be kDisabled, kReadOnly, kReadWrite.
vault-id	int	no	ID of the Vault.
vault-name	string	no	Name of the Vault.

storage-domain get-subnet-whitelist

To get a view's subnet whitelist

Parameter	Type	Required	Description
id	int	no	ID of a Storage Domain.
name	string	no	Name of the Storage Domain.

storage-domain list

To list Storage Domain details.

Parameter	Type	Required	Description
cluster-partition-ids	list of ints	no	Comma separated list of IDs.
ids	list of ints	no	Comma separated list of IDs.
include-marked-for-removal	bool	no	Include the nodes which have been marked for removal.
names	list of strings	no	Comma separated names of the Storage Domains.
show-stats	bool	no	To display the computed statistics.

storage-domain remove-subnet-from-whitelist

To remove a subnet from a view's subnet whitelist

Parameter	Type	Required	Description
id	int	no	ID of a Storage Domain.
name	string	no	Name of the Storage Domain.
subnet-ip	string	yes	Subnet IP for the Cluster.

storage-domain update

To update editable information of a Storage Domain.

Parameter	Type	Required	Description
active-directory-domain-name	string	no	The active directory domain this view box should be mapped to. Users from this active directory will be given permission to view contents in this storage domain, when accessing through SMB.
app-marker-detection	bool	no	Whether to support app marker detection.
brick-size	int	no	Brick size in bytes used to create blobs.
compression	string	no	Level of compression to use. Values are low or off.
dedup-enabled	bool	no	Flag to turn on/off post-processing deduplication. Deduplication is on by default. Inline deduplication cannot be turned on, if post-processing deduplication is off.
default-user-quota	int	no	Default user quota in GiB for this Storage Domain.
default-user-quota-alert-limit	int	no	Default user quota limit in GiB for this Storage Domain.
default-user-quota-alert-threshold-percentage	int	no	Default user quota threshold alert percentage for this Storage Domain.

Parameter	Type	Required	Description
default-view-quota	int	no	Default quota in GiB for views created in the Storage Domain. Set -1 to remove the value.
default-view-quota-alert-limit	int	no	Default alerting threshold in GiB for views created in the Storage Domain. Set -1 to remove the value.
ec-num-data	int	no	Number of data stripes for erasure coding.
ec-num-failures	int	no	Number of failures to tolerate for erasure coding.
erasure-coding-enabled	bool	no	To enable erasure coding.
id	int	no	ID of a Storage Domain.
inline-compress-enabled	bool	no	Flag to turn on/off inline compression.If deduplication is done inline, then it is recommended that compression should also be done inline. Also, this parameter will have no effect unless compression is enabled.
inline-dedup-enabled	bool	no	Flag to turn on/off inline deduplication. This parameter will have no effect, unless deduplication is enabled.
inline-erasure-coding	bool	no	Whether erasure coding should be done inline.
ldap-id	int	no	Id of the LDAP provider.
name	string	no	Name of the Storage Domain.
new-name	string	no	New name of the Storage Domain to update.
num-failures	int	no	Disk fault tolerance factor for this storage domain. Specifies maximum number of disk faults tolerated.
num-node-failures-tolerated	int	no	Node fault tolerance factor for this storage domain. Specifies maximum number of node faults tolerated.

Parameter	Type	Required	Description
quota	int	no	Maximum allowed quota in GiB. Set -1 to remove the value.
quota-alert-limit	int	no	Threshold in GiB, over which an alert will be sent. Set -1 to remove the value.
remove-active-directory-domain-mapping	bool	no	Removes the current mapping between this storage domain to the Active Directory domain it is currently mapped to.
remove-ldap-provider-mapping	bool	no	Removes the current mapping between this storage domain to the LDAP provider it is currently mapped to.
s3-buckets-allowed	bool	no	Whether creation of S3 bucket is allowed in the Storage Domain.
vault-id	int	no	ID of the Vault.
vault-name	string	no	Name of the Vault.
iris_cli storage-domain update name=NameOfStorageDomain compression=high	string	no	Sets the compression level to high on this Storage Domain.

support-bundle

To generate support bundle.

Operation	Short Name	Description
generate		To generate support bundle.

support-server

To run Support server and Support channel related operations.

Operation	Short Name	Description
add-authorized-user		To add an authorized user to login to cluster via support server.
host-access		To enable/disable host shell access.
host-access-token		To generate access token inorder to get access code from Cohesity for gaining host shell access
list	ls	List details of the Cohesity support server.
ls-host-access		List details of the Cohesity node access.
remove-authorized-user		To remove an authorized user to login to cluster via support server.
support-channel	rt	To enable/disable the support channel.
update	edit	Update the details of the Cohesity support server.

support-server add-authorized-user

To add an authorized user to login to cluster via support server.

Parameter	Type	Required	Description
ssh-key-file-path	string	yes	Absolute file path for the public SSH keys that allows access to the Cluster.
user-name	string	yes	Username of the User.
version	int	no	Version of Cohesity RT server. If set to 1(default), then the config will be applied to server version 1. If set to 2, then the config will be applied to server version 2.

support-host-access

To enable/disable host shell access.

Parameter	Type	Required	Description
access-code	string	no	Node Acces code supplied by support team.
tsh-enable	bool	no	Enable/Disable node tsh(teleport) access.

support-server list

List details of the Cohesity support server.

Parameter	Type	Required	Description
version	int	no	Version of Cohesity RT server. If set to 1(default), then the config will be applied to server version 1. If set to 2, then the config will be applied to server version 2.

support-server remove-authorized-user

To remove an authorized user to login to cluster via support server.

Parameter	Type	Required	Description
clear-all	bool	no	To clear all authorized users of support server.
user-name	string	no	Username of the User.
version	int	no	Version of Cohesity RT server. If set to 1(default), then the config will be applied to server version 1. If set to 2, then the config will be applied to server version 2.

support-server support-channel

To enable/disable the support channel.

For example: To enable support channel, run the following command:

```
iris_cli support support-channel enable=1 duration-in-hours=1
```

Parameter	Type	Required	Description
duration-in-hours	int	no	Duration in hours from current time till when the support channel will be enabled. Valid values are 1 - 720 hours. **Note:** duration-in-hours is mandatory when enable=1 is entered.
enable	bool	yes	Enable/Disable the support channel.

support-server update

Update the details of the Cohesity support server.

Parameter	Type	Required	Description
hostname	string	no	Hostname for the Cohesity support server.
port	int	no	Modify the port number for support channel.
private-key-file-loc	absolute file path	no	Absolute file path of the private key (SSH) for the support channel.
server-config-params	absolute file path	no	Server config params in a JSON file.
session-recording	bool	no	Enable/Disable the support channel session recording.
username	string	no	Username for the support channel.
version	int	no	Version of Cohesity RT server. If set to 1(default), then the config will be applied to server version 1. If set to 2, then the config will be applied to server version 2.

swift

To run any Swift related operations.

Operation	Short Name	Description
register		To register a Swift service on Keystone server.
unregister		To unregister a Swift service on Keystone server.

swift register

To register a Swift service on Keystone server.

Parameter	Type	Required	Description
domain-name	string	no	Specifies the domain name for 'Domain' scope. It only applys when 'scope-type' is 'Domain'.

Parameter	Type	Required	Description
password	string	no	Specifies the password of Keystone user.
project-domain-name	string	no	Spcifies the domain name for 'Project' scope. It only applys when 'scope-type' is 'Project'.
project-name	string	no	Specifies the project name for 'Project' scope. It only applys when 'scope-type' is 'Project'.
scope-type	string	no	Specifies the scope type. It can be 'Project' or 'Domain'.
tenant-id	string	yes	Specifies the id of tenant whose Swift service will be registered.
user-domain	string	no	Specifies the domain of Keystone user.
username	string	no	Specifies the Keystone username.

swift unregister

To unregister a Swift service on Keystone server.

Parameter	Type	Required	Description
domain-name	string	no	Specifies the domain name for 'Domain' scope. It only applys when 'scope-type' is 'Domain'.
password	string	no	Specifies the password of Keystone user.
project-domain-name	string	no	Spcifies the domain name for 'Project' scope. It only applys when 'scope-type' is 'Project'.
project-name	string	no	Specifies the project name for 'Project' scope. It only applys when 'scope-type' is 'Project'.
scope-type	string	no	Specifies the scope type. It can be 'Project' or 'Domain'.
tenant-id	string	yes	Specifies the id of tenant whose Swift service will be unregistered.
user-domain	string	no	Specifies the domain of Keystone user.
username	string	no	Specifies the Keystone username.

sysctl

Command to update sysctl configuration for nodes.

Operation	Short Name	Description
update	edit	Update sysctl configuration to nodes or cluster

sysctl update

Update sysctl configuration to nodes or cluster

Parameter	Type	Required	Description
sysctl-conf-names	list of strings	yes	Comma separated list of sysctl config names.
value	list of strings	yes	Comma separated list of sysctl config values.

syslog-server

To run any Syslog Server related operations.

Operation	Short Name	Description
create	add	To add a Syslog Server to the Cluster. Cohesity audit and some common audits will be added by default
delete	rm	To remove an existing Syslog Server from the Cluster.
list	ls	To list all the Syslog Servers in the Cluster.
status		To check the syslog server status in cluster.
update	edit	To update an existing Syslog Server in the Cluster.
update-audit-tags		To update audit tags used in cluster.

syslog-server create

To add a Syslog Server to the Cluster. Cohesity audit and some common audits will be added by default

Parameter	Type	Required	Description
address	string	yes	Hostname or IP address of the Syslog Server.
ca-certificate-path	string	no	Specifies the syslog server ca certificate file path
cluster-audit	bool	no	Deprecated. Send Cluster Audit Logs to the Syslog Server. Default is true.
dataprotection-events	bool	no	Deprecated. Send Dataprotection Event Logs to the Syslog Server. Default is false.
enable	bool	no	Specifies whether to enable the syslog server.
facilities	list of strings	no	The logs of specified facilites sent to the syslog server.
filer-audit	bool	no	Deprecated. Send Filer Audit Logs to the Syslog Server. Default is true.
message-patterns	list of strings	no	The message with the patterns will be sent to the syslog server.
name	string	no	Name or Description of the Syslog Server.
port	int	yes	Port where the Syslog Server listens.
program-names	list of strings	no	The logs of specified programes sent to the syslog server.
protocol	string	no	Protocol used by the Syslog Server. Default is tcp.
raw-message-patterns	list of strings	no	The raw message with the patterns will be sent to the syslog server.
ssh-events-log	bool	no	Deprecated. Send ssh login event logs to the syslog server. Default is false.

syslog-server delete

To remove an existing Syslog Server from the Cluster.

Parameter	Type	Required	Description
all-syslog-servers	bool	no	Select all syslog servers in cluster.
id	int	no	The Id of a syslog server.

syslog-server list

To list all the Syslog Servers in the Cluster.

Parameter	Type	Required	Description
id	int	no	The Id of a syslog server.

syslog-server status

To check the syslog server status in cluster.

Parameter	Type	Required	Description
ids	list of ints	no	List of syslog server Ids.

syslog-server update

To update an existing Syslog Server in the Cluster.

Parameter	Type	Required	Description
address	string	no	Hostname or IP address of the Syslog Server.
ca-certificate-path	string	no	Specifies the syslog server ca certificate file path
cluster-audit	bool	no	Deprecated. Send Cluster Audit Logs to the Syslog Server. Default is true.
dataprotection-events	bool	no	Deprecated. Send Dataprotection Event Logs to the Syslog Server. Default is false.
enable	bool	no	Specifies whether to enable the syslog server.
facilities	list of strings	no	The logs of specified facilites sent to the syslog server.
filer-audit	bool	no	Deprecated. Send Filer Audit Logs to the Syslog Server. Default is true.
id	int	yes	The Id of a syslog server.
is-append	bool	no	Append logging parameters to the syslog server.

Parameter	Type	Required	Description
message-patterns	list of strings	no	The message with the patterns will be sent to the syslog server.
name	string	no	Name or Description of the Syslog Server.
port	int	no	Port where the Syslog Server listens.
program-names	list of strings	no	The logs of specified programes sent to the syslog server.
protocol	string	no	Protocol used by the Syslog Server. Default is tcp.
raw-message-patterns	list of strings	no	The raw message with the patterns will be sent to the syslog server.
ssh-events-log	bool	no	Deprecated. Send ssh login event logs to the syslog server. Default is false.

syslog-server update-audit-tags

To update audit tags used in cluster.

Parameter	Type	Required	Description
alert-audit-tag-name	string	no	Paramter to specify alert audit tag.
cluster-audit-tag-name	string	no	Paramter to specify cluster-audit tag.
dataprotection-events-tag-name	string	no	Paramter to specify dataprotection-events tag.
filer-audit-tag-name	string	no	Paramter to specify filer-audit tag.

system-app

To run any System app related operations.

Operation	Short Name	Description
Status		To get the status of the System apps.

trusted-cas

To run any trusted CA related operations.

Operation	Short Name	Description
list	ls	To list all trusted CAs on the cluster.
register		To register a trusted CA on the cluster.
unregister		To unregister a trusted CA on the cluster.
validate		To re-validate a trusted CA on the cluster.

trusted-cas list

To list all trusted CAs on the cluster.

Parameter	Type	Required	Description
ids	list of strings	no	Comma seperated list of trusted CA Ids to fetch.
names	list of strings	no	Comma seperated list of trusted CA Names to fetch.

trusted-cas register

To register a trusted CA on the cluster.

Parameter	Type	Required	Description
desc	string	no	Specifies Description of certificate being registered.
file-path	string	yes	Specifies filepath to PEM file with certificate to be registered.
name	string	yes	Specifies name of the certificate being registered.
only-validate	bool	no	If true, the certificates are only validated not registered.

trusted-cas unregister

To unregister a trusted CA on the cluster.

Parameter	Type	Required	Description
id	string	yes	Specifies the Id of trusted CA to be operated on.

trusted-cas validate

To re-validate a trusted CA on the cluster.

Parameter	Type	Required	Description
id	string	yes	Specifies the Id of trusted CA to be operated on.

uda-connector

To run any UDA connector related operations.

Operation	Short Name	Description
add-or-update-all		Add/Update all UDA connector configs
create	add	To add a new UDA connector
delete	rm	To delete a UDA connector
get		To get a list of UDA connectors in the system
update	edit	To update a UDA connector

uda-connector create

To add a new UDA connector.

Parameter	Type	Required	Description
package-path	string	yes	Path of the folder containing all the json config files for a UDA connector

uda-connector delete

To delete a UDA connector.

Parameter	Type	Required	Description
id	int	yes	Unique id of a UDA connector

uda-connector get

connectors in the system.

Parameter	Type	Required	Description
filter-index-config	bool	no	If true, only prints out the index config
id	int	no	Unique id of a UDA connector

uda-connector update

To update a UDA connector.

Parameter	Type	Required	Description
package-path	string	yes	Path of the folder containing all the json config files for a UDA connector

user-quotas

To run any user quotas related commands.

Operation	Short Name	Description
create	add	To create a user quota policy in a view.
delete	rm	To delete a user quota policy in a view.
list		To list user quota policies for a view, a user or both.
update	edit	To update a user quota policy in a view.

user-quotas create

To create a user quota policy in a view.

Parameter	Type	Required	Description
alert-limit	int	no	Threshold in GiB, over which an alert will be sent. Set -1 to remove the value.
alert-threshold-percentage	int	no	Threshold percentage over which an alert will be sent.
hard-limit	int	no	Maximum allowed quota in GiB. Set -1 to remove the value.
user-sid	string	no	The SID of the user.
user-unix-uid	int	no	The Unix User ID of the user.
view-name	string	yes	Name of the View.

user-quotas delete

To delete a user quota policy in a view.

Parameter	Type	Required	Description
all	bool	no	Deletes all user quota policies for this view.
user-sids	list of strings	no	Comma separated list of user SIDs.
user-unix-uids	list of ints	no	Comma separated list of UNIX User IDs.
view-name	string	yes	Name of the View.

user-quotas list

To list user quota policies for a view, a user or both.

Parameter	Type	Required	Description
cookie	string	no	Opaque string returned in a previous command output to get the next set of entries in the output.
exclude-within-alert-threshold	bool	no	Exclude the users whose usage is within the alert threshold limit.

Parameter	Type	Required	Description
include-usage	bool	no	Include logical usage of users in this view.
page-count	int	no	Limit the number of entries in the command output.
summary	bool	no	To fetch the summary of user quotas for a view or a user.
user-sid	string	no	The SID of the user.
user-unix-uid	int	no	The Unix User ID of the user.
view-name	string	no	Name of the View.

user-quotas update

To update a user quota policy in a view.

Parameter	Type	Required	Description
alert-limit	int	no	Threshold in GiB, over which an alert will be sent. Set -1 to remove the value.
alert-threshold-percentage	int	no	Threshold percentage over which an alert will be sent.
default-alert-limit	int	no	Default alert limit after which an alert is generated.
default-alert-threshold-percentage	int	no	Default threshold percentage of hard limit over which an alert is generated.
default-hard-limit	int	no	Default hard limit in bytes.
enable	bool	no	Enable user quota policies for this view.
hard-limit	int	no	Maximum allowed quota in GiB. Set -1 to remove the value.
user-sid	string	no	The SID of the user.
user-unix-uid	string	no	The Unix User ID of the user.
view-name	string	yes	Name of the View.

user

To run any User related operations.

Operation	Short Name	Description
create	add	To create a new User.
delete	rm	To delete the specified users.
delete-sessions		Deletes all active sessions for a user or all active system wide sessions
get-linux-user-mfa	lingetmfa	Get MFA config for linux support user.
linux-bash-access		To get bash access for the Linux 'support' User.
linux-sudo-access		To get sudo access for the Linux 'support' User.
linux-user	linusr	Updates password for linux user support
list	ls	To list User details.
reset-s3-secret-key		To reset the S3 account secret access key for a User.
update	edit	To update editable information of a User.
update-linux-user-mfa	linupdmfa	Updates MFA mode for linux support user.

user create

To create a new User.

Parameter	Type	Required	Description
additional-group-names	list of strings	no	Comma separated list of additional group names of the User.
domain	string	no	Domain identifies User's logging in domain.
effective-time	datetime	no	Effective time in "YYYY-MM-DDTHH:mm" format when User's credentials will be effective.
email-address	string	no	Email address of a User.

Parameter	Type	Required	Description
expiry-time	datetime	no	Expire time of the User in "YYYY-MM-DDTHH:mm" format
password	string	no	Password of the User.
primary-group-name	string	no	Primary group name of the User.
roles	string	no	Comma separated list of supported roles for users (valid roles are ADMIN, OPS, VIEW).
user-description	string	no	Description of the User.
user-name	string	yes	Username of the User.

user delete

To delete the specified users.

Parameter	Type	Required	Description
domain	string	no	Domain identifies User's logging in domain.
user-names	list of strings	yes	Comma separated list of User names of the existing users.

user delete-sessions

Deletes all active sessions for a user or all active system wide sessions

Parameter	Type	Required	Description
user-sid	string	no	The SID of the user.

user linux-sudo-access

To get sudo access for the Linux 'support' User.

Parameter	Type	Required	Description
enable	bool	yes	If set to true, sudo access will be enabled.

Parameter	Type	Required	Description
duration-in-hours	int	yes	Defines the number of hours for which sudo access remains active.

user linux-user

Updates password for linux user support

Parameter	Type	Required	Description
current-password	string	no	Current linux password. Needed only when updating the password.
linux-password	string	yes	New linux password
linux-username	string	yes	Linux username

user list

To list User details.

Parameter	Type	Required	Description
domain	string	no	Domain identifies User's logging in domain.
email-addresses	list of strings	no	Comma separated list of email addresses of the users.
user-names	list of strings	no	Comma separated list of User names of the existing users.

user reset-s3-secret-key

To reset the S3 account secret access key for a User.

Parameter	Type	Required	Description
domain	string	no	Domain identifies User's logging in domain.
user-name	string	yes	Username of the User.

user update

To update editable information of a User.

Parameter	Type	Required	Description
additional-group-names	list of strings	no	Comma separated list of additional group names of the User.
current-password	string	no	Current password of the User.
domain	string	no	Domain identifies User's logging in domain.
effective-time	datetime	no	Effective time in "YYYY-MM-DDTHH:mm" format when User's credentials will be effective.
email-address	string	no	Email address of a User.
expiry-time	datetime	no	Expire time of the User in "YYYY-MM-DDTHH:mm" format
is-account-locked	bool	no	Indicate whether to lock/unlock a user account.
is-user-exempt-from-mfa	bool	no	Indicate whether to disable MFA for a user.
new-user-name	string	no	Name to which the users name should be changed.
password	string	no	Password of the User.
primary-group-name	string	no	Primary group name of the User.
remove-additional-groups	bool	no	To remove an existing additional groups of the user.
remove-primary-group	bool	no	To remove an existing primary group of the user.
roles	string	no	Comma separated list of supported roles for users (valid roles are ADMIN, OPS, VIEW).
user-description	string	no	Description of the User.
user-name	string	yes	Username of the User.

user update-linux-user-mfa

Updates MFA mode for linux support user.

Parameter	Type	Required	Description
authentication-type	string	no	Specifies Linux support user mfa authentication type: either totp, email.
current-password	string	no	Current linux password. Needed only when updating the password.
disable	bool	no	Specifies whether MFA for linux support user should be disabled.

vault

To run any Vault related operations.

Operation	Short Name	Description
create	add	To add a new Vault.
list	ls	To list the existing Vaults.
update	edit	To update an existing Vault.

vault create

To add a new Vault.

Parameter	Type	Required	Description
aws-access-key-id	string	no	AWS access key id for AWS service account.
aws-c2s-agency	string	no	AWS C2S agency for AWS C2S service account.
aws-c2s-base-url	string	no	AWS C2S base-url for AWS C2S service account.
aws-c2s-ca-cert-key-file-loc	absolute file path	no	Absolute file path for CA Cert key of AWS C2S service account.
aws-c2s-client-cert-key-file-loc	absolute file path	no	Absolute file path for client certificate key of AWS C2S service account.

Parameter	Type	Required	Description
aws-c2s-client-priv-key-file-loc	absolute file path	no	Absolute file path for client private key of AWS C2S service account.
aws-c2s-mission	string	no	AWS C2S mission for AWS C2S service account.
aws-c2s-role	string	no	AWS C2S role for AWS C2S service account.
aws-c2s-secret-key	string	no	AWS C2S secret key for AWS C2S service account.
aws-credential-blob	absolute file path	no	AWS credential blob to authenticate with credential endpoint.
aws-credential-endpoint	string	no	AWS credential REST endpoint that generates the security token.
aws-region	string	no	AWS region (e.g. us-east-1, us-west-1 etc.) for AWS service account.
aws-secret-access-key	string	no	AWS secret access key for AWS service account.
azure-client-id	string	no	Azure Client Id.
azure-storage-access-key	string	no	Storage access key for Azure service account.
azure-storage-account-name	string	no	Storage account name for Azure service account.
bucket-name	string	no	Name of the bucket or container inside the target Vault.
compression-enabled	bool	yes	Flag to enable or disable the compression.
dedup-enabled	bool	no	Flag to turn on/off post-processing deduplication. Deduplication is on by default. Inline deduplication cannot be turned on, if post-processing deduplication is off.
desc	string	no	Description of the Vault.

Parameter	Type	Required	Description
encryption-enabled	bool	yes	Flag to enable or disable the encryption.
forever-incremental-enabled	bool	no	Support forever incremental archive for archival vaults.
goog-client-email	string	no	Client email of Google service account.
goog-client-priv-key-file-loc	absolute file path	no	Absolute file path for client private key of Google service account.
goog-project-id	string	no	Project ID of Google service account.
incremental-enabled	bool	no	Support incremental archive for archival vaults.
kms-server-id	int	no	The Id of a KMS server.
name	string	yes	Name of the Vault.
nas-host	string	no	IP or host name of the NAS service host.
nas-kerberos-realm-name	string	no	NAS Kerberos realm name.
nas-mount-path	string	no	Mount path on the NAS service host.
nas-nfs-security-type	string	no	NAS NFS security type.
nas-nfs-version-number	string	no	NAS NFS version number.
nas-password	string	no	NAS service password.
nas-share-type	string	no	Mounted volume share type, e.g. CIFS, NFS. Default is NFS.
nas-username	string	no	NAS service username.
oracle-access-key-id	string	no	Access key id for Oracle service account.

Parameter	Type	Required	Description
oracle-region	string	no	Region (e.g. us-east-1) for Oracle service account.
oracle-secret-access-key	string	no	Secret access key for Oracle service account.
oracle-tenant	string	no	Tenant for Oracle service account.
qstar-host	string	no	IP or DNS name of QStar service host.
qstar-integral-volumes	list of strings	no	Comma separated names of QStar Integral Volumes.
qstar-password	string	no	QStar service password.
qstar-port	int	no	QStar WEB services API port.
qstar-share-type	string	no	Mounted QStar Integral Volume share type, e.g. CIFS, NFS. Default is CIFS.
qstar-use-https	bool	no	Use https for QStar service. Default is false.
qstar-username	string	no	QStar service username.
s3-compatible-service-url	string	no	Service URL for S3 compatible cloud.
s3-compatible-signature-version	int	no	Signature version fo S3 compatible cloud. Default is 4.
s3-compatible-use-https	bool	no	Use https for S3 compatible cloud. Default is true.

Parameter	Type	Required	Description
tier-type	string	no	Tier of the vault. For AWS, supported tier-types are Amazon-S3-standard, Amazon-S3-standard-IA, Amazon-S3-One-Zone-IA, Amazon-S3-Intelligent, Amazon-S3-Glacier, Amazon-S3-Glacier-Deep-Archive, Amazon-glacier and Amazon-S3-Glacier-IR. For Azure, supported tier types are Azure-archive, Azure-cool and Azure-hot. For GCP, supported tier types are Google-nearline, Google-coldline, Google-regional and Google-multi-regional. For Oracle, supported tier types are Oracle-standard and Oracle-archive.
usage-type	string	yes	Usage purpose of the Vault. It can be either archival or cloud-spill.
vault-type	string	no	Type of the Vault. For Archival usage, valid types are Azure, Azure-Gov-Cloud, Amazon, AWS-Gov-Cloud, Amazon-C2S, Google, Oracle, S3-compatible, NAS, and QStar-Tape. For Cloud-spill usage, valid types are NAS, S3-compatible, for AWS, vaults are Amazon, AWS-Gov-Cloud and supported tier is Amazon-S3-standard, for Azure, vaults are Azure, Azure-Gov-Cloud and supported tier is Azure-hot, for GCP, vault is Google and supported tiers are Google-regional and Google-multi-regional, for Oracle vault is Oracle and supported tier is Oracle-standard.
view-box-name	string	no	Name of the Storage Domain.

vault list

To list the existing Vaults.

Parameter	Type	Required	Description
id	int	no	ID of the Vault.
name	string	no	Name of the Vault.

vault update

To update an existing Vault.

Parameter	Type	Required	Description
aws-access-key-id	string	no	AWS access key id for AWS service account.
aws-credential-blob	absolute file path	no	AWS credential blob to authenticate with credential endpoint.
aws-credential-endpoint	string	no	AWS credential REST endpoint that generates the security token.
aws-region	string	no	AWS region (e.g. us-east-1, us-west-1 etc.) for AWS service account.
aws-secret-access-key	string	no	AWS secret access key for AWS service account.
azure-client-id	string	no	azure-client-id
azure-storage-access-key	string	no	Storage access key for Azure service account.
azure-storage-account-name	string	no	Storage account name for Azure service account.
compression-enabled	bool	no	Flag to enable or disable the compression.
desc	string	no	Description of the Vault.
encryption-enabled	bool	no	Flag to enable or disable the encryption.
forever-incremental-enabled	bool	no	Support forever incremental archive for archival vaults.
full-archive-interval-days	int	no	Interval in number of days between two Full archives.
goog-client-email	string	no	Client email of Google service account.

Parameter	Type	Required	Description
goog-client-priv-key-file-loc	absolute file path	no	Absolute file path for client private key of Google service account.
id	int	yes	ID of the Vault.
incremental-enabled	bool	no	Support incremental archive for archival vaults.
kms-server-id	int	no	The Id of a KMS server.
nas-host	string	no	IP or host name of the NAS service host.
nas-kerberos-realm-name	string	no	NAS Kerberos realm name.
nas-mount-path	string	no	Mount path on the NAS service host.
nas-nfs-security-type	string	no	NAS NFS security type.
nas-nfs-version-number	string	no	NAS NFS version number.
nas-password	string	no	NAS service password.
nas-share-type	string	no	Mounted volume share type, e.g. CIFS, NFS. Default is NFS.
nas-username	string	no	NAS service username.
new-name	string	no	Name of the Vault.
qstar-host	string	no	IP or DNS name of QStar service host.
qstar-integral-volumes	list of strings	no	Comma separated names of QStar Integral Volumes.
qstar-password	string	no	QStar service password.
qstar-port	int	no	QStar WEB services API port.

Parameter	Type	Required	Description
qstar-share-type	string	no	Mounted QStar Integral Volume share type, e.g. CIFS, NFS. Default is CIFS.
qstar-use-https	bool	no	Use https for QStar service. Default is false.
qstar-username	string	no	QStar service username.
s3-compatible-service-url	string	no	Service URL for S3 compatible cloud.
s3-compatible-signature-version	int	no	Signature version fo S3 compatible cloud. Default is 4.
s3-compatible-use-https	bool	no	Use https for S3 compatible cloud. Default is true.
view-box-name	string	no	Name of the Storage Domain.

view

To run any View related operations.

Operation	Short Name	Description
activate-saved-aliases		Activates the saved aliases of a cloned view.
add-subnet-to-whitelist	add-st-wl	To add a subnet to a view's subnet whitelist
allow-mount-on-windows		Allow mount path of the View to be mounted on windows machines.
cancel-failover		This command will cancel an in-progress failover on the specified view.
clone		To clone a View from an existing View.
clone-directory		To clone (or recursively copy) the contents of a directory from a source path to a destination path in the same View or a different View.
create	add	To create a new View.

Operation	Short Name	Description
create-alias		To create a View Alias.
delete	rm	To delete an existing View.
delete-alias		To delete a View Alias.
failover		This command will initiate a failover on the specified view.
get-file-lock-status		Fetches the lock details of a file in a view.
get-subnet-whitelist	ls-st-wl	To get a view's subnet whitelist
list	ls	To list View details.
list-failover		This command will list all failovers on the specified view.
list-nfs-connections	ls-nfs-con	To list the active NFS connections for views.
list-nlm-locks	ls-nl	To list the acquired NLM locks.
list-smb-connections	ls-smb-con	To list the active SMB connections for views.
list-smb-file-opens	ls-sfo	To list the active SMB file opens for views.
lock		To lock a View. A locked view cannot be modified or deleted.
lock-file		Locks a file in a view.
overwrite		To overwrite a target view with contents of source view.
remove-subnet-from-whitelist	rm-st-wl	To remove a subnet from a view's subnet whitelist
rename	ren	To rename a view.
unlock		To unlock a View.
update	edit	To update an existing View.

view activate-saved-aliases

Activates the saved aliases of a cloned view.

Parameter	Type	Required	Description
name	string	yes	Name of the View.

view add-subnet-to-whitelist

To add a subnet to a view's subnet whitelist

Parameter	Type	Required	Description
desc	string	no	Description.
name	string	yes	Name of the View.
subnet-ip	string	yes	Subnet IP for the Cluster.
subnet-mask	string	yes	Subnet mask for the Cluster. Should be either in CIDR prefix or in dotted decimal.
subnet-nfs-permission	string	no	Clients from this subnet can mount using NFS protocol. This can be kDisabled, kReadOnly, kReadWrite.
subnet-nfs-squash	string	no	Clients from this subnet can mount as root or all or none on NFS. This can be kNone, kRootSquash, kAllSquash.
subnet-s3-permission	string	no	Clients from this subnet can access using S3 protocol. This can be kDisabled, kReadOnly, kReadWrite.
subnet-smb-permission	string	no	Clients from this subnet can mount using SMB protocol. This can be kDisabled, kReadOnly, kReadWrite.

view allow-mount-on-windows

Allow mount path of the View to be mounted on windows machines.

Parameter	Type	Required	Description
enable	bool	yes	To allow/disallow the mount path of the View to be mounted on windows machines using NFS protocol.
name	string	yes	Name of the View.

view cancel-failover

This command will cancel an in-progress failover on the specified view.

Parameter	Type	Required	Description
id	int	yes	Specifies the view id.

view clone

To clone a View from an existing View.

Parameter	Type	Required	Description
datalock-expiry-usecs	int	no	Datalock duration in microseconds of the cloned view, the cloned view can only be deleted by a Data Security Officer until the datalock expires.
disable-inline-dedup	bool	no	Disable the inline dedup for the View. You can only turn off inline dedup for the View, if it is on for the containing Storage Domain.
name	string	yes	Name of the cloned View.
qos-policy	string	no	QoS Policy of the View. For example, it can be 'Backup Target High', 'Backup Target Low', 'Backup Target SSD', 'TestAndDev High', 'TestAndDev Low', 'Filer High', 'Filer Low', 'Backup Target Auto' etc.
source-view-name	string	yes	Name of the source View to be cloned.
view-description	string	no	Description of the View.

view clone-directory

To clone (or recursively copy) the contents of a directory from a source path to a destination path in the same View or a different View.

Parameter	Type	Required	Description
destination-directory-name	string	yes	The name of the new directory that is created in the specified destination directory when the contents of the source directory is cloned. The new directory must not exist.
destination-directory-path	string	yes	The directory path of the destination directory where the cloned new directory will be created. Path must include the View name e.g. /View1/Path.
source-directory-path	string	yes	The full path of the source directory in the View to clone (or recursively copy) from. Path must include the View name e.g. /View1/Path.

view create

To create a new View.

Parameter	Type	Required	Description
allow-case-insensitive	bool	no	Whether to allow case insensitive names for files and directories.
disable-inline-dedup	bool	no	Disable the inline dedup for the View. You can only turn off inline dedup for the View, if it is on for the containing Storage Domain.
enable-antivirus	bool	no	Enable antivirus scan on this view. If enabled, at least one of "enable-scan-on-access" or "enable-scan-on-close" should also be enabled.
enable-fast-durable-handle	bool	no	Whether to enable fast durable handle. If set to true, view open handle will be kept in memory, which results in a higher performance. But the handles cannot be recovered if the node or service crashes.
enable-live-indexing	bool	no	Enable live indexing feature for the view.
enable-minion	bool	no	Enable minion feature for the view.

Parameter	Type	Required	Description
enable-nfs-kerberos-authentication	bool	no	Enable kerberos authentication in NFS.
enable-nfs-kerberos-integrity	bool	no	Enable kerberos integrity in NFS.
enable-nfs-kerberos-privacy	bool	no	Enable kerberos privacy in NFS.
enable-nfs-unix-authentication	bool	no	Enable unix authentication in NFS.
enable-nfs-view-discovery	bool	no	Enable View disoverability in NFS.
enable-offline-caching	bool	no	Enable offline file caching of this view.
enable-pinning	bool	no	Enable pinning on this view. If enabled, the chunk files accessed from this view will be pinned to SSD tier.
enable-s3-folder-support	bool	no	Whether to allow s3 folder support feature on the View.
enable-scan-on-access	bool	no	Enable antivirus scan when view is accessed.
enable-scan-on-close	bool	no	Enable antivirus scan when view is closed.
enable-smb-encryption	bool	no	Enable SMB encryption on this view alias.
enable-smb-oplock	bool	no	Whether to enable SMB oplock. If enabled, a client will be able to cache data locally.
enable-smb-view-discovery	bool	no	Enable View disoverability in SMB.

Parameter	Type	Required	Description
file-autolock-after-idle-duration	string	no	Specify the duration to lock a file that has not been accessed or modified (ie. has been idle) for a certain duration of time. For example: 2Y3M1D for 2 years, 3 months and 1 day. Do not set if it is required to disable auto lock.
file-extension-filter-blacklist	string	no	Creates a blacklist to disallow certain file extensions.
file-extension-filter-whitelist	string	no	Creates a whitelist to only allow certain file extensions.
file-lock-default-retention-duration	string	no	Specify a default retention duration for files in this view, if file lock is enabled for this view. Set to forever if the required default retention period is forever. For example: 2Y3M1D for 2 years, 3 months and 1 day.
file-lock-expiry-date	datetime	no	Specify a definite timestamp in "YYYY-MM-DDTHH:MM" format for retaining the file.
file-lock-max-retention-duration	string	no	Specify a maximum duration for which any file in this view can be retained for. For example: 2Y3M1D for 2 years, 3 months and 1 day. Set to forever if the required retention duration is forever.
file-lock-min-retention-duration	string	no	Specify a minimum retention duration after a file gets locked. The file cannot be modified or deleted during this timeframe. For example: 2Y3M1D for 2 years, 3 months and 1 day. Set forever if the required retention duration is forever.
file-lock-mode	string	no	Specify the mode of file lock. Possible values are: 'compliance' (default value) and 'enterprise'.
file-lock-protocol	string	no	Sets the file locking protocol. Possible values are: 'read-only', 'set-atime'.
filer-audit-enabled	bool	no	Whether to enable Filer Audit Logs.
name	string	yes	Name of the View.

Parameter	Type	Required	Description
pin-time-secs	int	no	Pin the chunk files accessed from this view to SSD tier for this long. By default, we pin the chunk files indefinitely.
project-domain	string	no	The Keystone project domain.
project-name	string	no	The Keystone project name.
protocol	list of strings	no	Array of protocols for the view. Valid values are NFS, NFS4, SMB, S3 and Swift and are specified in a comma separated string. Default if not mentioned during view creation will be taken as NFS, SMB and S3(Read-only)
protocol-mode	list of strings	no	Array of mode for protocols in the view. Valid values are ReadOnly (or 'r') and ReadWrite (or 'w') and are specified in a comma separated string. Number of items in the string should be equal to items in 'protocol' options or should be empty. Empty denotes that all protocols will be taken as ReadWrite mode.
qos-policy	string	no	QoS Policy of the View. For example, it can be 'Backup Target High', 'Backup Target Low', 'Backup Target SSD', 'TestAndDev High', 'TestAndDev Low', 'Filer High', 'Filer Low', 'Backup Target Auto' etc.
quota	int	no	Maximum allowed quota in GiB. Set -1 to remove the value.
quota-alert-limit	int	no	Threshold in GiB, over which an alert will be sent. Set -1 to remove the value.
quota-inherit	bool	no	Whether to inherit quota from Storage Domain. The default value of this parameter is set to true.
s3-key-mapping-type	string	no	Specifies the type of S3 key mapping config. Possible values are 'Random','Short','Long','Hierarchical' and 'ObjectId'.
security-style	string	no	Set security style in the View. This can be Native, Unified, Ntfs.
smb-access-based-enumeration	bool	no	Enable Access Based Enumeration for SMB

Parameter	Type	Required	Description
storage-domain-id	int	no	ID of a Storage Domain.
storage-domain-name	string	no	Name of the Storage Domain.
tenant-id	string	no	To specify id of the tenant owning a resource.
user-domain	string	no	The Keystone user domain.
user-name	string	no	The Keystone user name.
view-category	string	no	Category of the View. Valid values are 'BackupTarget', 'FileServices' and 'ObjectServices'. If category is not defined by user then by default 'FileServices' is selected.
view-description	string	no	Description of the View.

view create-alias

To create a View Alias.

Parameter	Type	Required	Description
alias	string	yes	Alias for the view. It allows a path inside the View to be mounted using the Alias name.
view-name	string	yes	Name of the View.
view-path	string	yes	Full path of the directory inside a view.

view delete

To delete an existing View.

Parameter	Type	Required	Description
name	string	yes	Name of the View.

view delete-alias

To delete a View Alias.

Parameter	Type	Required	Description
alias	string	yes	Alias for the view. It allows a path inside the View to be mounted using the Alias name.

view failover

This command will initiate a failover on the specified view.

Parameter	Type	Required	Description
id	int	yes	Specifies the view id.
type	string	yes	Specifies the view failover type. Type can be one of 'Planned', 'Unplanned' and 'Finalize'.

view get-file-lock-status

Fetches the lock details of a file in a view.

Parameter	Type	Required	Description
view-name	string	yes	Name of the View.
view-path	string	yes	Full path of the directory inside a view.

view get-subnet-whitelist

To get a view's subnet whitelist

Parameter	Type	Required	Description
name	string	yes	Name of the View.

view list

To list View details.

Parameter	Type	Required	Description
ids	list of ints	no	Comma separated list of View ids.

Parameter	Type	Required	Description
names	list of strings	no	Comma separated list of View names.
storage-domain-ids	list of ints	no	Comma separated list of Storage Domain IDs.
storage-domain-names	list of strings	no	Comma separated names of the Storage Domains.

view list-failover

This command will list all failovers on the specified view.

Parameter	Type	Required	Description
id	int	yes	Specifies the view id.

view list-nfs-connections

To list the active NFS connections for views.

Parameter	Type	Required	Description
names	list of strings	no	Comma separated list of View names.

view list-nlm-locks

To list the acquired NLM locks.

Parameter	Type	Required	Description
cookie	string	no	Opaque string returned in a previous command output to get the next set of entries in the output.
file-path	string	no	File path relative to the NFS mount path.
name	string	no	Name of the View.
page-count	int	no	Limit the number of entries in the command output.
verbose	bool	no	If set to true, more information is displayed.

view list-smb-connections

To list the active SMB connections for views.

Parameter	Type	Required	Description
names	list of strings	no	Comma separated list of View names.

view list-smb-file-opens

To list the active SMB file opens for views.

Parameter	Type	Required	Description
cookie	string	no	Opaque string returned in a previous command output to get the next set of entries in the output.
file-path	string	no	File path of an SMB file relative to the SMB mount path.
name	string	no	Name of the View.
page-count	int	no	Limit the number of entries in the command output.

view lock

To lock a View. A locked view cannot be modified or deleted.

Parameter	Type	Required	Description
name	string	yes	Specifies the name of the view to lock.

view lock-file

Locks a file in a view.

Parameter	Type	Required	Description
file-lock-expiry-date	datetime	no	Specify a definite timestamp in "YYYY-MM-DDTHH:MM" format for retaining the file.
view-name	string	yes	Name of the View.
view-path	string	yes	Full path of the directory inside a view.

view overwrite

To overwrite a target view with contents of source view.

Parameter	Type	Required	Description
source-view-name	string	yes	Name of the Source View to copy contents from.
target-view-name	string	yes	Name of the Target View to be overwritten.

view remove-subnet-from-whitelist

To remove a subnet from a view's subnet whitelist

Parameter	Type	Required	Description
clear-all	bool	no	Set this field to true to clear all subnet white list.
name	string	yes	Name of the View.
subnet-ip	string	no	Subnet IP for the Cluster.

view rename

To rename a view.

Parameter	Type	Required	Description
name	string	yes	Name of the View.
new-name	string	yes	New Name of the View.

view unlock

To unlock a View.

Parameter	Type	Required	Description
name	string	yes	Specifies the name of the view to unlock.

view update

To update an existing View.

Parameter	Type	Required	Description
clear-auto-lock	bool	no	Clears the Auto Lock duration from the file lock config of the view.
clear-expiry-timestamp	bool	no	Clears the expiry timestamp from the file lock config of the view.
clear-max-retention-time	bool	no	Clears the max retention duration from the file lock config of the view.
clear-min-retention-time	bool	no	Clears the min retention duration from the file lock config of the view.
disable-inline-dedup	bool	no	Disable the inline dedup for the View. You can only turn off inline dedup for the View, if it is on for the containing Storage Domain.
enable-antivirus	bool	no	Enable antivirus scan on this view. If enabled, at least one of "enable-scan-on-access" or "enable-scan-on-close" should also be enabled.
enable-fast-durable-handle	bool	no	Whether to enable fast durable handle. If set to true, view open handle will be kept in memory, which results in a higher performance. But the handles cannot be recovered if the node or service crashes.
enable-minion	bool	no	Enable minion feature for the view.
enable-nfs-kerberos-authentication	bool	no	Enable kerberos authentication in NFS.
enable-nfs-kerberos-integrity	bool	no	Enable kerberos integrity in NFS.
enable-nfs-kerberos-privacy	bool	no	Enable kerberos privacy in NFS.
enable-nfs-unix-authentication	bool	no	Enable unix authentication in NFS.

Parameter	Type	Required	Description
enable-nfs-view-discovery	bool	no	Enable View disoverability in NFS.
enable-offline-caching	bool	no	Enable offline file caching of this view.
enable-pinning	bool	no	Enable pinning on this view. If enabled, the chunk files accessed from this view will be pinned to SSD tier.
enable-scan-on-access	bool	no	Enable antivirus scan when view is accessed.
enable-scan-on-close	bool	no	Enable antivirus scan when view is closed.
enable-smb-oplock	bool	no	Whether to enable SMB oplock. If enabled, a client will be able to cache data locally.
enable-smb-view-discovery	bool	no	Enable View disoverability in SMB.
file-autolock-after-idle-duration	string	no	Specify the duration to lock a file that has not been accessed or modified (ie. has been idle) for a certain duration of time. For example: 2Y3M1D for 2 years, 3 months and 1 day. Do not set if it is required to disable auto lock.
file-extension-filter-blacklist	string	no	Creates a blacklist to disallow certain file extensions.
file-extension-filter-whitelist	string	no	Creates a whitelist to only allow certain file extensions.
file-lock-default-retention-duration	string	no	Specify a default retention duration for files in this view, if file lock is enabled for this view. Set to forever if the required default retention period is forever. For example: 2Y3M1D for 2 years, 3 months and 1 day.
file-lock-expiry-date	datetime	no	Specify a definite timestamp in "YYYY-MM-DDTHH:MM" format for retaining the file.

Parameter	Type	Required	Description
file-lock-max-retention-duration	string	no	Specify a maximum duration for which any file in this view can be retained for. For example: 2Y3M1D for 2 years, 3 months and 1 day. Set to forever if the required retention duration is forever.
file-lock-min-retention-duration	string	no	Specify a minimum retention duration after a file gets locked. The file cannot be modified or deleted during this timeframe. For example: 2Y3M1D for 2 years, 3 months and 1 day. Set forever if the required retention duration is forever.
file-lock-mode	string	no	Specify the mode of file lock. Possible values are: 'compliance' (default value) and 'enterprise'.
file-lock-protocol	string	no	Sets the file locking protocol. Possible values are: 'read-only', 'set-atime'.
filer-audit-enabled	bool	no	Whether to enable Filer Audit Logs.
name	string	yes	Name of the View.
pin-time-secs	int	no	Pin the chunk files accessed from this view to SSD tier for this long. By default, we pin the chunk files indefinitely.
project-domain	string	no	The Keystone project domain.
project-name	string	no	The Keystone project name.
protocol	list of strings	no	Array of protocols for the view. Valid values are NFS, NFS4, SMB, S3 and Swift and are specified in a comma separated string. Default if not mentioned during view creation will be taken as NFS, SMB and S3(Read-only)
protocol-mode	list of strings	no	Array of mode for protocols in the view. Valid values are ReadOnly (or 'r') and ReadWrite (or 'w') and are specified in a comma separated string. Number of items in the string should be equal to items in 'protocol' options or should be empty. Empty denotes that all protocols will be taken as ReadWrite mode.

Parameter	Type	Required	Description
qos-policy	string	no	QoS Policy of the View. For example, it can be 'Backup Target High', 'Backup Target Low', 'Backup Target SSD', 'TestAndDev High', 'TestAndDev Low', 'Filer High', 'Filer Low', 'Backup Target Auto' etc.
quota	int	no	Maximum allowed quota in GiB. Set -1 to remove the value.
quota-alert-limit	int	no	Threshold in GiB, over which an alert will be sent. Set -1 to remove the value.
quota-inherit	bool	no	Whether to inherit quota from Storage Domain. The default value of this parameter is set to true.
security-style	string	no	Set security style in the View. This can be Native, Unified, Ntfs.
smb-access-based-enumeration	bool	no	Enable Access Based Enumeration for SMB
tenant-id	string	no	To specify id of the tenant owning a resource.
use-file-extension-filter	bool	no	Enables or Disables the existing filter on file extensions for the view.
view-category	string	no	Category of the View. Valid values are 'BackupTarget', 'FileServices' and 'ObjectServices'. If category is not defined by user then by default 'FileServices' is selected.
view-description	string	no	Description of the View.

vlan

To run any Vlan related operations.

Operation	Short Name	Description
add-dns-zone		To add a dns zone name and vips mappingfor a VLAN interface in the Cluster.
create	add	To add a VLAN for the Cluster.

Operation	Short Name	Description
delete	rm	To remove a VLAN from the Cluster.
remove-dns-zones		To remove dns zone for a VLAN interfacein the Cluster.
update	edit	To edit a VLAN for the Cluster.
update-dns-zone		To update dns zone for a VLAN interfacein the Cluster.

vlan add-dns-zone

To add a dns zone name and vips mappingfor a VLAN interface in the Cluster.

Parameter	Type	Required	Description
dns-zone-name	string	yes	To remove internal dns entries specified by given dns host name.
dns-zone-vips	list of strings	yes	To update internal dns vips.
vlan-interface-group	string	yes	Name of a network interface group.

vlan create

To add a VLAN for the Cluster.

Parameter	Type	Required	Description
apps-ips	list of strings	no	Comma separated list of VLAN IP addresses for Apps.
ecmp-enabled	bool	no	When set, ECMP will be enabled in the vlan.
family	int	no	Param to specify IP address family, 1=IpV4(default) or 2=IpV6.
hostname	string	no	Hostname for the VLAN IPs.
id	int	yes	ID of the VLAN.
interface-group	string	no	Name of a network interface group.

Parameter	Type	Required	Description
subnet-gateway	string	no	Subnet gateway for the Cluster.
subnet-ip	string	no	Subnet IP of the VLAN.
subnet-mask-bits	int	no	Subnet mask bits for the Cluster.
subnet-mask-ip4	string	no	Subnet mask for IPv4 type subnet of the Cluster.
vlan-ips	list of strings	no	Comma separated list of VLAN IP addresses.
vlan-name	string	no	VLAN Name for vlan-id created

For example:

```
iris_cli vlan create id=100 interface-group=intf_group1 vlan-ips-
s=150.0.0.1,150.0.0.2,150.0.0.3 subnet-gateway=150.0.0.100 subnet-mask-bits-
s=24 subnet-ip=150.0.0.0
```

vlan delete

To remove a VLAN from the Cluster.

Parameter	Type	Required	Description
vlan-interface-group	string	no	Name of a network interface group.

For example:

```
iris_cli vlan delete vlan-interface-group=intf_group1.100
```

vlan remove-dns-zones

To remove dns zone for a VLAN interfacein the Cluster.

Parameter	Type	Required	Description
dns-zone-names	list of strings	yes	Name of a network interface group.
vlan-interface-group	string	yes	Name of a network interface group.

vlan update

To edit a VLAN for the Cluster.

Parameter	Type	Required	Description
add-apps-ips	list of strings	no	Comma separated list of IPs to add to the VLAN for Athena Apps.
add-ips	list of strings	no	Comma separated list of IPs to add to the VLAN.
family	int	no	Param to specify IP address family, 1=IpV4(default) or 2=IpV6.
hostname	string	no	Hostname for the VLAN IPs.
pool-name	string	no	To group the follower IPs to a pool.
remove-hostname	bool	no	Whether to remove the configured Hostname for the VLAN IPs.
remove-ips	list of strings	no	Comma separated list of VLAN IP addresses to remove from the VLAN.
subnet-gateway	string	no	Subnet gateway for the Cluster.
subnet-ip	string	yes	Subnet IP of the VLAN.
subnet-mask-bits	int	no	Subnet mask bits for the Cluster.
subnet-mask-ip4	string	no	Subnet mask for IPv4 type subnet of the Cluster.
vlan-interface-group	string	yes	Name of a network interface group.
vlan-name	string	no	VLAN Name for vlan-id created

vlan update-dns-zone

To update dns zone for a VLAN interfacein the Cluster.

Parameter	Type	Required	Description
add-resolved-vips	list of strings	no	To add resolved vips to the zone.

Parameter	Type	Required	Description
dns-zone-name	string	yes	To remove internal dns entries specified by given dns host name.
dns-zone-vips	list of strings	yes	To update internal dns vips.
remove-resolved-vips	list of strings	no	To remove resolved vips from the zone.
vlan-interface-group	string	yes	Name of a network interface group.

Cluster Health Check

hc_cli is a Cohesity support-automation tool which checks for commonly seen issues on a Cohesity cluster. The output of the verbose command includes links to a knowledge base article which describes how to resolve the error. After using hc_cli to perform the initial checks, you need to open a case with Cohesity Support to review your cluster's health.

Run hc_cli

To run hc_cli, run the `hc_cli` run command.

To view results, run the `hc_cli show --failed` command.

To view the built-in help, run the `hc_cli` command without any arguments or append `-h` at the end of the command:

```
$ hc_cli
usage: hc_cli.py [-h]
{debug,ls-tests,show,run,version,generate-doc,status} ...
hc_cli.py: error: too few arguments
```

See the following table for a list of hc_cli commands and description.

Operation	Description

debug	• Runs utilities which are more resource-intensive, collect system state, or are informational.
	• Available utilities are:
	  • performance_traces.py
	  • For the Backup Manager service:
	  • get_magneto_vm_protection_flags.py
	  • get_job_hierarchy.py
	  • For the Cluster Manager service:
	  • top_cpu.py
	  • services_memory_check.py
	  • network_errors.py
	  • For the Indexing service:
	  • yoda_persistent_queue.py

ls-tests	• Lists available lists.

show	• Prints the most recent results.
	• Available flags include:
	  • **-h/--help**: Prints help output.
	  • **-C/--current-node**: Prints output from only the current node.
	  • **-F/--failed**: Prints only failed checks.
	  • **-v/--verbose**: Prints verbose output.

Operation	Description

run	• Initiates a run.
	• Available parameters are:
	  • **-h/--help**: Prints help output.
	  • **--test-ids**: Runs only the specified tests.
	  For example, `hc_cli run --test-ids=10003,10010` runs only tests 100003 and 10010.
	  • **-u/--username & -p/--password**: Defines a non-standard UI username and password. If not defined, credentials default to username admin and password admin.
	  Example: `hc_cli -u mario -p mushroomkingdom`.
	  • **-v/--verbose**: Prints verbose output. If not specified, prints only pass or fail status.
	  • **--type**: Runs all checks of a certain type. Options are:
	  • **hardware**: hardware-level checks.
	  • **software**: Cohesity software-specific checks.
	  • **network**: network checks and configuration validation checks.
	  • **-C/--current-node**: Runs hc_cli only on the current node.
	  • **--max-timeout**: Configures a timeout value. Generally recommended only for larger clusters where hc_cli might run for an extended period. A value of 99999 covers larger clusters.

version	• Displays the build time of the installed hc_cli package.
generate-doc	• Prints the built-in documentation.

status	• Prints run status.
	• Status values are:
	  • **Runs Ready** if no run is in progress.
	  • **Running** if a run is in progress.

clean	• Removes hc_cli and support-toolbox from the ~/bin directory.

Available Checks

To fetch the available checks from the cluster, run the `generate-doc` command.

Sample available checks:

Test ID	Test Name	Type	Category
10001	SAS Controller / smartctl Error Check	kHardware	kEssential, kSmartFiles, kPreUpgrade, kPostUpgrade
10002	Iostat Disk Utilization Percentage Check	kHardware	kEssential, kSmartFiles
10003	Custom Binary Check	kSoftware	kPreUpgrade
10004	Partition Size Utilization Check	kSoftware	kEssential
10006	Helios Connectivity Check	kSoftware	kEssential

Using the Secure Shell

The Secure Shell restricts SSH access to the host operating system shell, further tightening access to the Cohesity cluster while still providing users with the ability to execute CLI commands, run diagnostic tools, and access logs. In previous releases, support users could log on to Cohesity nodes using SSH and access the host operating system shell. Access to the host operating system is now restricted through SSH.

The Secure Shell can be accessed using only the support user account. To enable the support user account, see Manage Support User.

Using the Secure Shell, you can perform the following:

- Run iris_cli commands
- View the logs (read-only)
- Basic connectivity checks

> **Note:**
> The basic connectivity checks can be performed using the following utilities:
>
> - ping and curl will be available from 6.8.1 and later versions.
> - dig/host, nping, tcptraceroute, and elinks will be available from 6.8.1_u7 and later versions.

Considerations

After upgrading to the 6.8 or later releases, the secure shell might have the following impact on your existing Cohesity deployments:

- If you run custom scripts using ssh on your Cohesity cluster, the scripts might fail. In this case, Cohesity recommends the following:
  - Verify if there is an alternate method to use Cohesity CLI commands or REST API and update your scripts accordingly.
  - Verify if a corresponding Cohesity CLI command is available in the supported list of CLI commands; if so, use the supported CLI command. For more information, see Using the Secure Shell. If the CLI command is not available in the supported list of commands, contact Cohesity Support to enable the CLI command.
- The private binary or tools running on the Cohesity nodes might fail. Contact Cohesity Support for options to install private binaries or tools.
- Sudo access is disabled by default. For support channel access, you need to enable sudo access for the support user to the host shell using the following command:

```
iris_cli user linux-sudo-access enable=true duration-in-hours=xxx
```

> **Note:** You can enter a duration within the range of 1 to 720 hours.

Secure Shell Prompt

To identify whether you are running the secure shell, once you log into the shell using the support user account, the shell prompt displays the term "***restricted***," this suggests that you have logged into the Secure Shell of a Cohesity node.

For example:

```
$ ssh support@10.x.x.16
support@10.1.4.16's password:
Last login: Fri Dec 17 03:32:32 UTC 2021 from 10.2.209.99 on pts/1
Last login: Fri Dec 17 03:46:25 2021 from 10.2.209.99
***************** Welcome to Cohesity *****************

WARNING: Unauthorized access to this system is forbidden.
By accessing this system, you agree that your actions
may be monitored if unauthorized usage is suspected.

*********************************************************
[support@restricted-haswell2-bqkp91500082-node-2 ~]\> iris_cli
 Username: admin
 'admin' Password:
```

Enable Host Shell Access

You can access the host shell on port 2222 using the ***support*** user account.

To enable host shell access:

1. Log on to the node's secured shell using the ***support*** user. Use the following command:

   ```
   $ ssh support@<node_IP>
   ```

   Where `node_IP` is the IP address of the node in your Cohesity cluster.

2. Log on to the `iris_cli` and generate a support token using the following command:

   ```
   $ iris_cli support host-access-token
   ```

   > **Note:** By default, the support token is only valid for an hour. You can extend the support token validity for up to 12 hours using the following command: `iris_cli support host-access-token validity-in-hours=12`

3. Obtain the Cohesity cluster information using the following command:

   ```
   $ iris_cli cluster info
   ```

4. Share the following details with Cohesity Support to generate an access code:
   - Host Access Token generated in step 2
   - Cluster ID obtained in step 3
   - Cohesity Software Version obtained in step 3
   - The number of hours you require the host shell access

5. After you receive the access code from Cohesity Support, enable host shell access using the following command in `iris_cli`:

   ```
   $  iris_cli support host-access ssh-enable=true access-code=<access_
   code>
   ```

   Where `access_code` is the access code you received from Cohesity Support.

   > **Important:** Ensure that you enable host shell access before the support access token you generated in **Step 2** expires.

6. Access the host shell of the node on port 2222 using the ***support*** user. Use the following command:

   ```
   $ ssh support@<node_IP> -p 2222
   ```

Cohesity REST API

Cohesity provides a REST API that supports programmatically interfacing with a Cohesity cluster, for example:

- Send a `GET /public/protectionJobs` REST API request that returns all the Protection Groups found on a Cohesity cluster.
- Send a `GET /public/protectionSources/virtualMachines` REST API request that returns all the VMs found in a protected Source (vCenter Server) that are registered on a Cohesity cluster.

Complete REST API documentation is available on the Cohesity Developer Portal.

Cohesity provides ready-to-use integrations with the automation and orchestration tools of your choice to streamline your operations. Under the hood, all integrations are powered by the Cohesity REST API. For more information, see API Integrations.

View and Run the API Directly on a Cluster

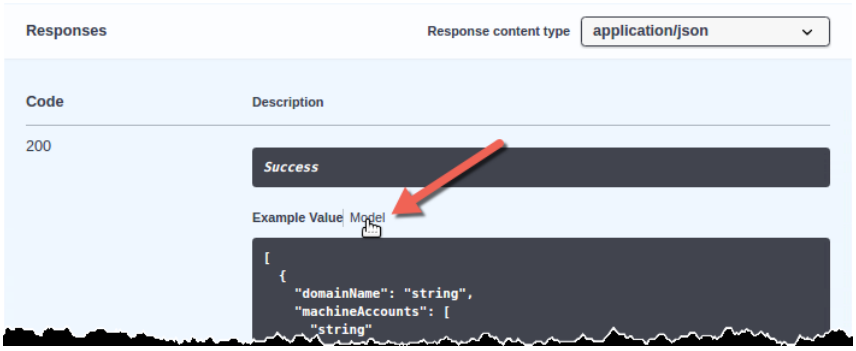
Cohesity also provides a REST API interface directly on the Cohesity cluster which provides documentation and the ability to run operation requests directly against the Cohesity cluster and view the response.

1. Log in to the Cohesity Dashboard from a browser by entering a Node IP Address or VIP IP address of a Cohesity cluster into the browser address bar.
2. Click the ? icon in the upper right corner and select **REST API**.

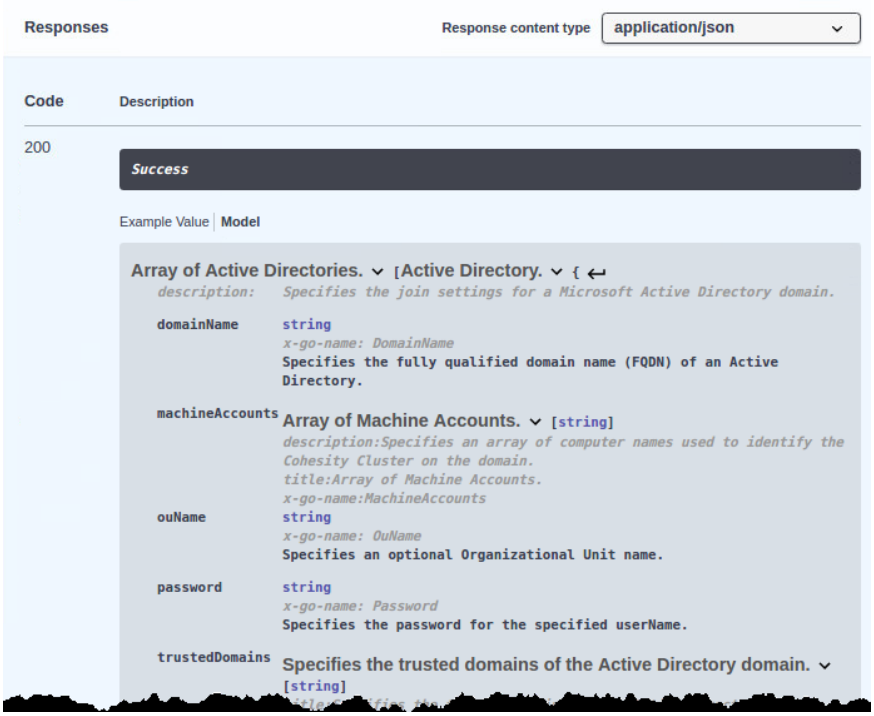
   A new browser tab opens and the Cohesity REST API operations are displayed as nested under group tags such as **AccessTokens** and **Active Directory**.

   > **Note:** By default, **AccessTokens** are used. **Sessions** will be used if session management is enabled.

3. To view the documentation on the response:
   a. Click **Model** next to **Example Value**.



b. Keep clicking to expand the documentation hierarchy.



4. To run an operation:
   a. Click on the operation to expand it.
   b. Click **Try it out**.
   c. Enter any required parameters.
   d. Click **Execute**.

   The operation is run against the Cohesity cluster you are logged in to and the results are displayed under the Response body.

Specifying Access Credentials

When you run Cohesity REST API operations from the browser, the Cohesity cluster uses the Login credentials you specified to log in to the Cohesity Dashboard.

You can run the Cohesity REST API operations programmatically in two ways:

1. Access tokens
2. Sessions

Access Tokens

> **Note:** By default, AccessTokens are used.

From your REST client program, you must make a `POST /public/accessTokens` request to supply the valid Login credentials before calling other Cohesity REST API operations. This POST request returns an access token and type in the response that is generated by the Cohesity cluster. Subsequent requests to other Cohesity REST API operations must specify the returned access token and type by setting `Authorization` in the http header in the following format:

```
Authorization: <token_type> <access_token>
```

The generated token is valid for 24 hours. If a request is made with an expired token, the `Token expired` error message is returned. Add code to your REST client to check for this error and request another access token before reissuing the request.

Sessions

> **Note:** Sessions will be used if session management is enabled.

From your REST client program, you must make a `POST /public/v2/users/sessions` request to supply the valid Login credentials before calling other Cohesity REST API operations. This POST request returns the session id in the response that is generated by the Cohesity cluster.

If session management is enabled, the subsequent requests to other Cohesity REST API operations must specify the returned session id by setting the session-id header in the http header in the following format:

```
session-id: "oxxx0yyyyy81Rzzzz//aaaaaO7qbbbbbAcccccc="
```

The session id is valid till the Inactivity Timeout (1 hour) or Absolute Timeout (24 hours).

If a request is made with an expired session id, the expired error message is returned. Add code to your REST client to check for this error and request another session id before reissuing the request.

Generate an API Key

To generate an API key:

1. Navigate to **Settings** > **Access Management** and click **API Keys**.

   > **Note:** By default, the API Key is disabled. Contact Cohesity Support to enable the feature.

2. Click **Add API Key**.
3. Select the user for which the API key should be generated.
4. Enter a **Name** for the API key.

5. Click **Add** to generate the API key.
6. Copy the API key to use with the application.

Chapter 34: Supplemental Information

This chapter includes the following topics:

- Open Source in Cohesity Products 4763
- Explore Our Videos 4764
- Helios Documentation 4765
- Cohesity Hardware Data Sheets and Compliance Guide 4765
- Hardware Replacement 4765
- Technical Guides 4765
- Cohesity Support 4765
- Glossary 4766
- Documentation Archive 4770
- Documentation Feedback 4771

Open Source in Cohesity Products

The tables below include information regarding open source software (OSS) distributed in or with the version of the Product (as such term is defined in the Cohesity EULA).

To request a similar list with respect to other versions, please send a request to: oss@cohesity.com.

Cohesity Product: Software

Cohesity Product	Version	Link
Cohesity Software	7.3	OSS List

Cohesity Product	Version	Link
Cohesity Software	7.2.2_u2	OSS List
Cohesity Software	7.2.2_u1	OSS List
Cohesity Software	7.2.2	OSS List
Cohesity Software	7.2.1	OSS List
Cohesity Software	7.2	OSS List
Cohesity Software	7.1.2_u4	OSS List
Cohesity Software	7.1.2	OSS List
Cohesity Software	7.1.1	OSS List
Cohesity Software	7.1	OSS List
Cohesity Software	7.0.1	OSS List
Cohesity Software	7.0	OSS List
Cohesity Software	6.8.2	OSS List
Cohesity Software	6.8.1_u2	OSS List
Cohesity Software	6.8.1	OSS List
Cohesity Software	6.6	OSS List

Explore Our Videos

You can learn about Cohesity products and solutions by watching videos on the Cohesity How-to Videos page.

Helios Documentation

Helios is Cohesity's SaaS-based management platform that provides a single dashboard and global management of all your Cohesity Clusters. For more information, see Helios Documentation.

Cohesity Hardware Data Sheets and Compliance Guide

- Cohesity Model C2xx5 (C2305, C2505, C2515, and C2605)
- Cohesity Model C3000
- Cohesity Model C4000
- Cohesity Model C5000
- Cohesity Model C6000
- Cohesity Model CX8000
- Safety and Compliance Guide
- Cohesity Media Sanitization Brief

Hardware Replacement

Hardware replacement procedures (PDFs) are available at: Hardware Universe.

Technical Guides

Additional Solution Guides, White Papers, Deployment Guides, Reference Architectures and Best Practices are available at Technical Guides.

Cohesity Support

Reach Cohesity Support

There are several ways to create a Cohesity support case.

- Go to Cohesity Support, to search in our knowledge base; or contact us by phone - United States and Canada: 1-855-9CO-HESI (926-4374), option 2.
- Log in to the Cohesity Support Portal to create a new case.
- Click the (**?**) icon on the Cohesity UI and select Support Portal.

Support/Service Assistance

First, contact the Service Provider that you have contracted for service and support. If you work directly with Cohesity and have a product warranty/entitlement, repair pricing, or technical support-related question, see your options below:

- To find solutions to your product issues or for suggestions or best practices, visit the Cohesity Knowledge Base.
- Log in to the Cohesity Support Portal to create a new case.
- To monitor your open cases, log in to the portal and click the **Cases** tab on the home page. This page should have all the case statuses and updates. You can also view individual case status.

Cohesity Software Running on Partner Hardware

For Cohesity software running on qualified third-party hardware, the following support workflow applies:

1. The customer may contact Cohesity Support first if the issue cannot be determined as a hardware issue.

   > **Note:** Cohesity cannot process hardware replacement requests for partner hardware.

2. Cohesity Support triages the issue. If it is a software issue, Cohesity Support continues to work on it.
3. If it is a hardware/firmware issue or is suspected to be a hardware/firmware issue, Cohesity provides information about the issue to the customer and requests that the customer open a support ticket with the appropriate partner.
4. If needed, Cohesity Support can join a three-way call with the partner and the customer.
5. The customer informs Cohesity Support on the progress of the partner's case.

Glossary

A

Agent

A lightweight software that is installed on Operating systems like Windows, Linux, AIX, Solaris, HP-UX etc running on a Physical Server or a Virtual machine enabling communication between OS and Cohesity to protect data.

B

Backup
: A recoverable snapshot of a registered source, such as a physical or virtual server, database or storage array, created by a Protection Group, used to protect against data loss or corruption.

C

Clone
: The ability to clone objects from snapshots created by a Protection Group. The cloned objects are copied to a new location, rehydrated and restored to a running state.

Cloud Tier
: The process of moving rarely used and inactive data to the cloud when HDD usage on the Cohesity cluster exceeds a certain threshold.

CloudArchive
: The process of copying snapshots created by Protection Groups from the Cohesity cluster to a registered external target.

CloudArchive Direct
: The process of archiving data directly to an external target without retaining a copy of the data on the cluster. Only the metadata and indexes, required for quick search and recovery, are stored on the cluster.

CloudRetrieve
: The process of retrieving an archived Protection Group and its run details from an external target to a different cluster. Used for geo-redundancy and disaster recovery.

Cluster
: An instance of Cohesity Data Cloud (Self-Managed).

D

Data In
: Data sent from a protected source to Cohesity.

Data Written
: Data to be written post-deduplication.

Deduplication
: The process of eliminating redundant copies of data to reduce storage usage on the cluster.

  The Inline Deduplication process deduplicates data as it is written to the cluster and the Post-process deduplication deduplicates data after it is written to the cluster.

E

External Target
: Any storage location outside the Cohesity cluster where data is stored. They can be for cloudarchive, cloudarchive direct, or cloud tier.

F

Firewall Attachment
: An active Cohesity rule that includes a profile and multiple ipsets.

Firewall Profile
: A group of TCP or UDP ports.

Full Archive
: A full copy of a Protection Group that is archived.

I

Incremental Archive
: An archive that records just the changed data since the most recent archive.

Inline Deduplication
: The process of eliminating redundant copies of data as the data is written to a Cohesity view.

Instant Mount
: A fast and reliable way to access data via the instant volume mounting feature. Some benefits include granular recovery of Microsoft Exchange, SQL and SharePoint data.

L

Logical Data
: Data residing in a protected source.

N

Node
: A physical or virtual appliance that runs the Cohesity software. One or more nodes comprise a Cohesity cluster.

P

Cohesity Data Cloud (Self-Managed)
: The Cohesity software consolidates secondary data and applications, including backups, files, objects, test/dev, and analytics, on a single, software-defined platform.

Protection Policy
: Business mapping on reusable settings that define how often to protect (RTO), how long to retain, how many copies to create like, archive, replication, tape, and where to store the data.

Protection Group
: A backup job that runs repeatedly, based on an associated policy, to back up data from a source and store it on the cluster. A Protection Group uses the schedules and

settings defined in the policy to determine when and how backups are captured, archived or replicated, the operational management of data to be protected etc.

R

Registration
: The process of registering a source with the Cohesity cluster so the source can be protected.

Remote Adapter Protection Group
: A backup job that runs scripts or executables on a remote Linux machine, typically for sources that are not supported by Cohesity.

Replication
: The process of automatically copying Protection Group snapshots from one Cohesity cluster to another Cohesity cluster for data resiliency purposes.

S

Source
: An object in the IT infrastructure of your company that you want to protect, such as a VM, physical server, Pure Storage volume, MS SQL Server, and NAS files.

Storage Consumed
: Data written with all copies required for honoring the resiliency setting.

Storage Domain
: A named storage location on a cluster. A storage domain defines deduplication, compression, erasure coding, fault tolerance and more. Views are created in storage domains. Storage domains were formerly known as View Boxes.

T

Test&Dev
: The process of cloning a VM, database, or view from a backup or existing file share for test and development purposes.

V

View
: A named storage location in the storage domain in a Cohesity cluster, which has NFS, SMB, and S3 mount paths.

Documentation Archive

Cohesity maintains and updates documentation for the versions listed in the following set of tables.

Actively Updated

The following documentation sets are actively updated for the time period from general availability (GA) to end of support (EoS). Active documentation updates include changes to the release notes, procedures, support matrix, fixed issues, and so forth.

Version	Release Notes	Release Date
7.3.1 documentation	7.3.1 release notes	First released December 2025
7.3 documentation	7.3 release notes	First released October 2025
7.2.2 documentation	7.2.2 release notes	First released March 2025
7.2.1 documentation	7.2.1 release notes	First released November 2024
7.2 documentation	7.2 release notes	First released July 2024
7.1.2 documentation	7.1.2 release notes	First released March 2024 *This is a designated long-term support release version.*
6.8.2 documentation	6.8.2 release notes	First released March 2024 *This is a designated long-term support release version.*

As-is

The following documentation sets remain available, but Cohesity no longer provides updates. For more information on EoS of a release version, see Cohesity Products End of Support and End of Life.

Version	Release Notes	Release Date
7.1.1 documentation	7.1.1 release notes	First released December 2023
7.1 documentation	7.1 release notes	First released September 2023
7.0.1 documentation	7.0.1 release notes	First released June 2023

Version	Release Notes	Release Date
7.0 documentation	7.0 release notes	First released January 2023
6.8.1 documentation	6.8.1 release notes	First released December 2020
6.8 documentation	6.8 release notes	First released May 2022
6.6 documentation	6.6 release notes	First released December 2020
6.5.1 documentation	6.5.1 release notes	First released August 2020

Documentation Feedback

We encourage you to provide feedback so that we can improve our documentation. Click here to send us your feedback!

Ensure that you provide the following details in your email:

- Document name
- Topic name
- Page number
