Groups ... 3483
Teams ... 3502
Replicate Microsoft 365 Data ... 3519

Chapter 15: Physical Servers ... 3521

Plan and Prepare for Physical Server Protection ... 3522
Register or Edit a Physical Server ... 3528
Network Bandwidth and CPU Throttling for Physical Server ... 3542
Add or Edit a Protection Group for Physical Servers ... 3544
Manage the Physical Server Backup Configuration ... 3564
Start On-demand Multiple Protection Runs for Physical Server ... 3568
Source-Side Deduplication and Cache Optimization for Physical Server ... 3569
Protect Windows Failover Cluster ... 3570
Protect File Server Role deployed on Windows Server Failover Cluster ... 3571
Physical Server Recovery ... 3573

Chapter 16: MS Applications ... 3607

Active Directory ... 3607
MS Exchange Server ... 3624

Chapter 17: SAN Volume ... 3643

IBM Storage FlashSystem ... 3643
Pure Storage ... 3651
HPE Alletra Storage MP ... 3661

Chapter 18: Hadoop ... 3665

Core components ... 3665
Hadoop Features ... 3666
Plan and Prepare for Hadoop Protection ... 3666
Register a Hadoop Source ... 3672
Backup Hadoop ... 3674
Recover Hadoop ... 3683

Chapter 19: About the Remote Adapter ... 3687

Recommendations for Dedupe-focused Backups with RMAN ... 3690
Add or Edit a Remote Adapter Protection Group ... 3691
About SAP HANA Database Backups ... 3695
SAP on Oracle ... 3744

Chapter 20: Kubernetes 3795
Plan and Prepare for Protecting Kubernetes Clusters 3795
Register and Manage Kubernetes Cluster 3800
Upgrade Velero and Datamover 3808
Backup Kubernetes Cluster Resources, PVCs, and Namespaces 3810
Recover Kubernetes 3824
Red Hat OpenShift Virtualization 3835
Chapter 21: About Bare Machine Recovery 3881
CBMR and CoBMR Comparison 3882
CBMR 3882
CoBMR 3887
Chapter 22: Manage External Targets 3899
CloudArchive Direct 3900
Archive Object Lock 3908
Archive Data Over AWS PrivateLink 3911
Archive Data Over Azure Private Endpoints 3912
Register an External Target 3917
AWS Security Token Service Support 3992
Kerberos Authentication for NAS External Target 3994
QStar Tape Configuration 4001
Unregister an External Target 4001
Chapter 23: Disaster Recovery 4003
About Replication 4003
Replication and Remote Access Setup 4021
About CloudRetrieve 4033
About Failover Ready 4038
Disaster Recovery Using CloudSpin 4039
Disaster Recovery Using CloudEdition 4039
Chapter 24: Manage Sources 4041
Manage Existing Sources Using Actions Menu Options 4042
Maintenance Mode 4042
Register Applications Running on Virtual Servers 4043
Manage Registered Applications Running on Virtual Servers 4043
Manage Cohesity Installed Agents Running on Virtual Servers 4043
Manage Existing Physical Servers Using the Actions Menu 4044
Health Check for SQL Sources 4044
Chapter 25: Manage Protection Groups 4049
Cancel Replication and Archive Copy Tasks of a Protection Run 4051

Delete Protection Groups, Snapshots and Objects 4052
Protection Group Run Issues 4057
Add or Remove a Legal Hold to a Snapshot 4057
Failover a Protection Group 4059

Chapter 26: Manage Recovery 4071

Use Wildcard * in Search for Recovery 4071
Cancel a Recovery 4072

Chapter 27: Cohesity Agents 4073

What are Cohesity Agents? 4073
What Do Cohesity Agents Do? 4073
Cohesity Agents Deployment in Different Scenarios 4074
Install and Manage Cohesity Agents 4075
Cohesity Java Agent Upgrade 4075
Install and Manage the Agent on Windows Servers 4077
Install and Manage the Agent on Linux Servers 4087
Install and Manage the Agent on Hyper-V Linux VMs 4111
Install and Manage the Cohesity Java Agent on AIX Servers 4113
Install and Manage the Agent on Solaris Servers 4117
Install and Manage the Agent on HP-UX Servers 4119
Deploy Cohesity Agent from the Cohesity UI 4122
Troubleshoot Cohesity Agent 4141

Chapter 28: NoSQL and Hadoop Service 4147

Supported Software 4147
Features 4148
Prerequisites 4149
Process Overview 4149
Install NoSQL and Hadoop Service 4150
Run the NoSQL and Hadoop Service 4152
Verify the Status of NoSQL and Hadoop Service 4153
Using NoSQL and Hadoop Data sources 4153
Post Installation Procedures 4153
Managing NoSQL and Hadoop Services 4169
Additional Configuration for NoSQL and Hadoop Services 4176
Monitor the NoSQL and Hadoop Service Health 4182
FAQs on NoSQL and Hadoop Services 4189

Chapter 29: Test & Dev (Cloning) 4193

Test & Dev Overview 4194
Clone Views 4195
Clone VMs 4197

Clone Databases 4213
Test & Dev Using CloudSpin 4219
Clone vCloud Director (vCD) VMs 4219

Chapter 30: Monitoring 4221

Performance 4222
Monitor Performance of Workloads 4225
Configure and Test SNMP 4232
Storage Statistics 4238
Health Dashboard 4250
Reports 4442
Audit Logs 4490
Advanced Diagnostics 4514

Chapter 31: Virtual Edition 4529

Cohesity Virtual Edition 4530
Initial Virtual Edition Cluster Setup 4531
Configure vSphere Availability for Virtual Edition for VMware 4531
Extend the Capacities of a Virtual Edition for VMware 4532

Chapter 32: DataProtect for Cloud 4543

DataProtect for Cloud in AWS 4543
DataProtect for Cloud in Azure 4558
DataProtect for Cloud in GCP 4579

Chapter 33: Tools 4597

Using the Cohesity CLI 4597
Cluster Health Check 4752
Using the Secure Shell 4755
Cohesity REST API 4758

Chapter 1: Cohesity 7.3.1

Cohesity is at the forefront of AI-powered data security and management, revolutionizing how organizations protect, manage, and derive value from their data across the data center, edge, and cloud. With a robust ecosystem of partners, Cohesity offers comprehensive solutions that defend against cybersecurity threats through immutable backups, AI-based threat detection, and rapid recovery at scale. Cohesity's innovative approach ensures data security and efficient management, whether delivered as a service, self-managed, or through a Cohesity-powered partner. Dive into our documentation to explore the full breadth of our transformative solutions.

> **Note:** Features and functionalities herein may become subject to a separate license requirement/fee (even if free during an initial period).

Getting Started

If you are ready to:

- Set up the Cohesity cluster for the first time, see Hardware Universe
- Create users, see Users and Groups
- Protect objects, see Protection Overview
- View new features, see What's New?
- The list of "Fixed Issues" for all the releases are available exclusively in the Fixed Issues Online Help topic under the Release Notes. This information is not included in the offline downloadable PDF version of the Help.

Explore Our Videos

You can learn about Cohesity products and solutions by watching videos on the Cohesity How-to Videos page.

Chapter 2: Supportability

This chapter includes the following topics:

- Supported Software 16
- Supported Workflows and External Targets 65
- Supported Multitenancy Workflows 65
- Supported Multitenancy Workflows for Hybrid Extender 66
- Supported Multitenancy Workflows for Hybrid Extender Realms 66
- Supported Cloud Spin and Other Workflows 113
- Supported Platforms for Heterogeneous Cohesity cluster 113
- Agent Compatibility Within a Cohesity cluster 117
- DataProtect for Cloud Supportability 121
- Replication Compatibility 137
- Supportability for Qualifications 138

Supported Software

Microsoft Hyper-V

Hyper-V	Versions	Guest OS	Notes
Hyper-V Standalone, SCVMM & Cluster	2012R2, 2016, 2019, 2022, 2025	For the list of supported guest OS , see the supported operating system of Physical Servers. The following guest OS are also supported: • Oracle Linux 8.x, 7.x, 6.x • FreeBSD 12-12.1, 11.1-11.3, 11.0, 10.0-10.3, 9.1-9.3, 8.4	• For agent-based file level restores only 64-bit guest operating systems are supported. • Cohesity does not support the backup of Hyper-V VMs with shared disks. • Cohesity supports Hyper-V in the Desktop and Server Core installation modes. • Cohesity supports Hyper-V in the Nano Server installation mode with Windows Server 2016. Nano Server 2019 is used as a container and you cannot install Microsoft Hyper-V inside the container. It is primarily used for non-containerized installations. • Azure Local 23H2 is supported only on Standalone and Cluster. **Note:** This is an early-access feature. Contact your Cohesity account team to enable Azure Local 23H2.
	Azure Local 23H2		

Note: Azure Local was previously known as Azure Stack HCI.

Nutanix Acropolis Hypervisor

Application	AOS Version	File System	Notes
AHV (Acropolis Hypervisor)	5.1.1, 5.5.3.1, 5.8.2, 5.10.x, 5.15, 5.16, 5.17.x, 5.18.1, 5.19.1, 5.20, 6.5.x, 6.8, and 6.10.x, 7.0.1, 7.3.x	XFS, NTFS, Ext4, Ext3, Ext2, BTrFS	Cohesity supports application-consistent backups, VM recovery, and file and folder recovery in Nutanix Acropolis Hypervisors.

Nutanix Cloud Clusters (NC2)

AHV	Notes
Nutanix Cloud Clusters AHV on AWS	NC2 is supported only with on-premises Cohesity clusters.
Nutanix Cloud Clusters AHV on Azure	
GCP	

RHV

RHV	File System	Notes
4.0, 4.1, 4.2, 4.3, 4.4	XFS, NTFS, Ext4, Ext3, Ext2, BTrFS	Cohesity supports RHV only until version 6.8.1. While you can still protect your RHV sources in 7.0 or later releases, the Cohesity Support team will not provide assistance.

VMware

vCenter, vSphere, ESXi	Virtual Machine Hardware	Guest OS	Virtual Disk Transport Method	vRealize Orchestrator and vRealize Automation	Notes
9.0	9, 10, 11, 13, 14, 15, 17, 18, 19, 20, 21	For the list of guest OS supported for VM, file-based, and volume-based backups, see Physical Servers. For the list of guest OS supported for Indexing of File Systems, see Supported File Systems for Indexing.	By default, the Cohesity cluster uses the NBDSSL (encrypted) transport method. NBDSSL uses SSL to encrypt the data.	See this link about the Cohesity vRO plugin	For Linux OSs: LVM2 For LVM2 volumes of types Linear, Striped, Mirrored or Mirrored + Striped, only file downloads are supported. RAID is not supported. File recovery to source requires VMware Tools (or Open VM Tools), rsync and NFS client. You must use a license with the vSphere Storage API when instantly recovering a VMware VM from a Cohesity Cluster to a vSphere datastore. For more information, see the Recovering a VMware VM returns the message "License not available to

vCenter, vSphere, ESXi	Virtual Machine Hardware	Guest OS	Virtual Disk Transport Method	vRealize Orchestrator and vRealize Automation	Notes
					perform the operation" KB article. The qualification of VMware vSphere 7.0 U2 does not include the support of the new features and functions introduced in VMware vSphere 7.0 U2. Cohesity recommends increasing the default HTTPS connection limit after upgrading to vSphere 7.0 and later. For details, see the KB article. For the list of data objects and properties Cohesity clusters can protect, see the KB article. vSAN ESA is now supported.
8.0 U3, 8.0 U2, 8.0 U1, 8.0	9, 10, 11, 13, 14, 15, 17, 18, 19, 20, 21				
7.0 U3	9, 10, 11, 13, 14, 15, 17, 18, 19				
7.0 U2	9, 10, 11, 13, 14, 15, 17, 18, 19				
7.0 U1	9, 10, 11, 13, 14, 15, 17, 18				
7.0	9, 10, 11, 13, 14, 15, 17				
6.7 U3	9, 10, 11, 13, 14, 15				
6.7 U2	9, 10, 11, 13, 14, 15				
6.7	9, 10, 11, 13, 14				

> **Note:** All vSphere or ESXi patches are supported as long as the base version or update itself is supported.

For more information, see ESXi/ESX hosts and compatible virtual machine hardware versions list (2007240).

VMware vCloud Director

vCloud Director	VMware vCenter version qualified with vCD	vCD Extension Version	Notes
10.6.1	8.0U, 7.0U	See this link.	• Contact your Cohesity account team to enable vCD 10.4.1. • You can recover vCD objects in the same location or in an alternate location in vCD. • You can recover vCD VMs and standalone VMs to VMware vCenter and vice-versa.
10.6			
10.5.1	7.0.1		
10.5			
10.4.2			
10.4.1	7.0		
10.4			

VMware Cloud Infrastructure

VMware Cloud Infrastructure
VMware Cloud (VMC) on AWS
Azure VMware Solution (AVS)
Google Cloud VMware Engine (GCVE)

> **Note:** VMware Cloud (VMC) on AWS supports stretched cluster Software-Defined Data Center (SDDC) which provides an additional layer of resiliency.

Virtual Edition

Hypervisor	Cluster Type
VMware	• Single-Node Cluster • Multi-Node Cluster
Microsoft Hyper-V	• Single-Node Cluster
Nutanix AHV	• Single-Node Cluster • Multi-Node Cluster
Red Hat Enterprise Linux	• Single-Node Cluster • Multi-Node Cluster
AlmaLinux	• Single-Node Cluster • Multi-Node Cluster
OCI Linux KVM	• Multi-Node Cluster

Physical Servers

> **Note:** Applicable to both file-based and volume-based backups.

For information on prerequisites and considerations, see Prerequisites and Considerations.

Operating System	File System	CPU Architecture	Notes
Windows 10 Desktop Edition Windows 11	NTFS	x64	
Windows Server 2025 Core Windows Server 2022 Core Windows Server 2019 Core Windows Server 2016 Core	NTFS	x64	

Operating System	File System	CPU Architecture	Notes
Windows Server 2025 Windows Server 2022 Windows Server 2019 Windows Server 2016 Windows Server 2012 Windows Server 2012 R2 Windows Server 2008 R2	NTFS	x64	Cohesity supports Microsoft failover clusters that are compatible with these Windows Server versions. Windows Server 2008 R2 data contained in a volume larger than 2040 GB can be recovered via an alternate registered Physical Server running Windows Server 2012 or later.

Operating System	File System	CPU Architecture	Notes
CentOS 6.0+, 7.0 - 7.9, 8.0, 8.3, 9.0	ext3, ext4, xfs, cvfs, zfs	x64	
Oracle Linux (OEL) 6.x, 7.0 - 7.7, 7.9, 8.0, 8.2 - 8.10, 9.0 - 9.6		x64	
RHEL 6.4, 6.7+, 7.0 - 7.9, 8.0 - 8.10, 9.0 - 9.7, 10.0-10.1		x64 PowerPC (RHEL 8, 8.6, 9.0) Linux on z/Architecture (9.x) ARM (aarch64) (RHEL 9.x)	• Only file-based backup is supported for Linux on PowerPC. • Cohesity supports the little-endian architecture for PowerPC.
Rocky Linux 8.7 - 8.10, 9.0 - 9.7		x64	With physical clusters indexing and file-recovery through downloads are supported. This is an early-access feature. Contact Cohesity Support to use this functionality.
Alma Linux 8.10, 9.0 - 9.7		x64	
SUSE Linux Enterprise Server 11 SP4, 12 SP3,12 SP4, 12 SP5, 15, 15 SP3, 15 SP4, 15 SP5, 15 SP6, SP7		x64 PowerPC (SLES 12 SP5, 15 SP3, 15 SP4, SP5, SP6, SP7)	
openSUSE 15.1, 15.3, 15.4		x64	

Operating System	File System	CPU Architecture	Notes
Ubuntu 14.04, 16.04, 18.04, 19.04, 20.04, 22.04, 23.04, 24.04		x64	
Debian 9.6, 10, 11.2, 12.x		x64	
Amazon Linux 2		x64	Amazon Linux 2 is supported only for file-based backup.
Amazon Linux 2023		x64	Amazon Linux 2023 is supported only for file-based backup.

Operating System	File System	CPU Architecture	Notes
AIX 7.1 TL3 SP0 or later AIX 7.2 AIX 7.3	JFS, JFS2, CDRFS, VxFS, MMFS, GPFS, NFS (over the network), AutoFS	IBM POWER7, POWER8, POWER9, POWER10	AIX 7.3 is supported only for file-based backup.

Operating System	File System	CPU Architecture	Notes
	Note: JFS(*) - Cohesity has tested the support of JFS using the Cohesity Java Agent only on AIX version 6.1 64-bit TL7. Since AIX OS upgrades are backward compatible, JFS file system is also supported on AIX versions 7.1 64-bit and 7.2 64-bit.		

Operating System	File System	CPU Architecture	Notes
Solaris 10, 11	ZFS (native Solaris 11), UFS (native Solaris 10), VxFS, NFS (over the network), SMBFS (over the network)	SPARC V9 x86_64	
HP-UX 11i v3 (B.11.31)	VxFS file system (Version 6.1.0.000)	Intel Itanium (IA64)	See Install and Manage the Agent on HPUX Servers for installation steps.

> **Note:** ReFS file system is supported on applicable Windows Server editions, through file-based protection.

Storage Snapshot Providers

Snapshot Provider	Version	Notes
Cisco HyperFlex	3.5+	iSCSI, FC and FCoE protocols are supported. Registering HPE Alletra 5000 and 6000 as a source is an Early Access feature.
Pure Storage FlashArray	4.10.9, 5.x, 6.x	
Nimble Storage	5.0, 5.1, 5.2	
HPE Alletra 5000	6.1, 6.x	
HPE Alletra 6000	6.x	
NetApp ONTAP	9.x	
Nutanix	Nutanix 5.15	iSCSI protocol is supported.
IBM Storage FlashSystem	8.6.0.0 or later Hardware Model: IBM Storage FlashSystem 5200	Cohesity does not support External Storage on IBM Storage FlashSystem.

SAN

SAN	Version
Pure Storage FlashArray	4.10.9, 5.x, 6.x

SAN	Version
IBM Storage FlashSystem	Software Version: 8.6.0.2 or later. Hardware Models: • IBM Storage FlashSystem 5045 model • IBM Storage FlashSystem 5200 model • IBM Storage FlashSystem 5300 model • IBM Storage FlashSystem 7300 model • IBM Storage FlashSystem 9100 model • IBM Storage FlashSystem 9200 model • IBM Storage FlashSystem 9500 model • IBM SAN Volume Controller SA2 and SV2 models • IBM SAN Volume Controller SV3 model **Note:** Cohesity does not support External Storage on IBM Storage FlashSystem

Microsoft SQL Server

Supported OS Versions	Microsoft SQL Server Versions						
	Express 2016	Express 2017	Express 2019	2016	2017	2019	2022
Microsoft Windows 2016 (64-bit)	✔	✔	✔	✔	✔	✔	✔
Microsoft Windows 2019 (64-bit)	✔	✔	✔	✔	✔	✔	✔
Microsoft Windows 2022 (64-bit)	✔	✔	✔	✔	✔	✔	✔

Supported OS Versions	Microsoft SQL Server Versions						
	Express 2016	Express 2017	Express 2019	2016	2017	2019	2022
Red Hat Enterprise Linux (RHEL) 7.x	✗	✗	✗	✗	✗	✓	✗

- MS SQL Server 32-bit deployment is not supported with the agent-based approach. It is recommended to use the Native SQL dump to Cohesity SMB for backups.
- MS SQL Server 64-bit running on Windows 64-bit is supported.
- SQL databases and logs residing on Clustered Shared Volumes (CSV) can be protected using Cohesity's VDI based backup method.
- FILESTREAM databases can be protected using Cohesity's VDI and Volume based backup method.
- Memory-optimized databases can be protected using Cohesity's VDI based backup method.
- MS SQL Server on Red Hat Enterprise Linux (RHEL) 7.x is an Early Access feature. Contact Cohesity Account team to enable this feature.
- Only VDI-based backups are currently supported on Linux OS.
- Amazon Custom RDS supports protection of SQL Server 2022 and SQL Server 2019.
- For recovering a database to an Amazon RDS Custom SQL Server, the recovery destination path must be under the **D:\rdsdbdata** folder.

SAP HANA (Cohesity Connector Agents)

Supported OS Versions	SAP HANA Version

Microsoft Windows Server 2019	✓	✓	✓	✓	✓	✓	✓

Note:

- For RHEL 6 and OEL 6, ensure that the Cohesity version is 6.9 and above.
- Oracle 23c version is supported from Cohesity cluster version 6.8.2 and later.

NoSQL and Hadoop Platforms

Platform	Supported Versions
Apache Cassandra	4.1, 4.0
Cloudera Data Platform (Private Cloud base)	7.3.1, 7.1.9, 7.1.7
Couchbase	7.2.6, 7.2, 7.1, 7.0
Datastax Enterprise	6.8.x, 5.1.x **Note:** Supports IPv6 on DataStax Enterprise 6.x only.
MongoDB	8.0, 7.0

MongoDB via Ops Manager

> **Note:** Only Enterprise MongoDB clusters are supported.

Supported OS Versions	MongoDB Ops Manager Version: 8.0.8, 8.0.10 - 8.0.16 MongoDB Cluster/Deployment Version: 7.x_ent, 8.x_ent
Red Hat Enterprise Linux (RHEL) 8.x	✅
Red Hat Enterprise Linux (RHEL) 9.x	✅

NAS

Vendor	Version	Notes
Dell EMC Isilon	8.0, 8.1, 8.2, 9.0.x - 9.4.x, 9.5.x, 9.7.x, 9.8.x, 9.9.x, 9.10.x, 9.11.x, 9.12.x	• Cohesity supports backing up SMB version 2 and 3 shares. • Cohesity uses SMB version 2 for NetApp backups by default. • Cohesity does not support restoring NAS volumes and data using SMB v1.
NetApp ONTAP Cluster-Mode		
Cohesity file-runner based backup approach	8.2, 8.3, 9.3, 9.5, 9.6, 9.7, 9.8, 9.9.1, 9.10.x, 9.11.x, 9.12.x, 9.13.x, 9.14.x, 9.15.x, 9.16.x, 9.17.x	
NetApp SnapDiff-based backup approach	9.8, 9.9.1, 9.10.x, 9.11.x, 9.12.x, 9.13.x, 9.14.x, 9.15.x, 9.16.x, 9.17.x	
Pure Storage FlashBlade	2.2.4+, 3.0+, 3.2.x, 4.1.x, 4.4.x, 4.5.x	
Elastifile EFS	3.1.0.31+	
IBM GPFS	4.2.x, 5.0.x, 5.1.x	
Generic NAS	All vendors supporting NFS (v3, v4.1) and SMB (v1+, v2+, v3+)	

Supported File Systems for Indexing

Cohesity supports indexing for the file systems listed in this table:

Protection Group Type	Operating System	Supported File Systems
Virtual Server	Supported OS of Physical Server	ext2, ext3, ext4, xfs, and ntfs
	Linux	btrfs **Note:** Cohesity does not support the indexing of btrfs filesystem created on multiple devices using the `mkfs.btrfs` command.
Physical Server (Block-based)	Supported OS	ext2, ext3, ext4, xfs, and ntfs
	Linux	btrfs **Note:** Cohesity does not support the indexing of btrfs filesystem created on multiple devices using the `mkfs.btrfs` command.
Physical Server (File-based)	Supported OS	Agnostic of the file system
NAS	Not applicable	NFS, SMB/CIFS

Microsoft Applications

Application	Version	Availability	Notes
Active Directory	Windows 2025 Windows 2022 Windows 2019 Windows 2016 Windows 2012, 2012 R2 Windows 2008 R2		Kerberos and NTLM authentication are supported when accessing shares on an AD-joined Cohesity cluster.
Exchange on virtual servers	Exchange 2019 Exchange 2016 Exchange SE 2025	DAG and standalone	Running on supported Windows servers. Requires Ontrack® software and license for granular recovery of Microsoft Exchange mailbox objects.
Exchange on physical servers	Exchange 2019 Exchange 2016 Exchange SE 2025	DAG and standalone	Ontrack® PowerControls™ 9.2 or later is required for granular recovery. Cohesity recommends to use the latest version Ontrack® PowerControls™.
Microsoft SharePoint	Microsoft SharePoint Server 2016 Microsoft SharePoint Server 2019	Ontrack® PowerControls™ 9.2 or later is required for granular recovery*. Cohesity recommends to use the latest version of Ontrack® PowerControls™.	

*Ontrack® PowerControls™ license validation requires a 2-way TCP communication over HTTPS (port 443) using TLSv1.2 or later.

Veritas Cluster Server

Veritas Cluster Server	Notes
7.4.1 running on RHEL 7.x	Cohesity supports backup and restore of Oracle DBs running on VCS.
7.4.3 running on OEL 7	

Red Hat High Availability (Pacemaker) Cluster

Pacemaker version	Notes
2.x on RHEL 8.x 2.x on RHEL 9.x	Cohesity supports Pacemaker clusters starting with the 2.1 release.

LDAP

LDAP Version
3

QStar Archive Storage Manager

QStar ASM	Notes
7.0.8061	Cohesity supports QStar ASM 7.0.8061 installed on Windows Server 2016, 2019, and 2022.

	RHEL	6.4, 6.7+, 7.0 - 7.9, 8.0, 8.2 - 8.6, 9.0	x64	
	Debian	9.6, 10, 11.2	x64	

Kubernetes Clusters

Kubernetes Cluster	Version
Vanilla Kubernetes	1.14 - 1.21, 1.23 - 1.34
Red Hat OpenShift	4.4 - 4.19
VMware Tanzu Kubernetes Grid (TKGm, multi-cloud version)	1.2.1, 1.3.0, 1.4.0, 1.5.3, 1.5.4, 1.6.0, 1.6.1
VMware Tanzu Kubernetes Grid Service	1.19
Rancher (RKE2)	1.32

> **Note:**
> - Cohesity supports Red Hat OpenShift only on the x86_64 architecture.
> - Cohesity does not support Kubernetes environments running on Nutanix Kubernetes Platform (NKP). Backup and restore operations for Kubernetes clusters deployed on NKP may fail. Support for this environment will be announced when available.

KubeVirt

Platform	Version
Red Hat OpenShift	4.17 - 4.19

> **Note:** Cohesity supports Red Hat OpenShift only on the x86_64 architecture.

Velero

Velero Version	Kubernetes Version	Notes
v1.15.0	v1.18 and later	
V1.8.1	Earlier than v1.18	

S3-Compatible Storage

Cohesity has qualified the following S3-compatible storage systems for data protection. However, any S3-compatible storage that adheres to the AWS S3 protocol is supported for data protection.

S3-Compatible Storage	Version
Dell EMC ECS	3.8.1.2.140142.3df35ef5802

S3-Compatible Storage	Version
Pure Storage Flashblade	3.3.7, 4.5.6
NetApp StorageGrid	11.9.0.3
MinIO	20241107005220.0.0
IBM Cloud Object Storage	N/A

Cloud Services

Supported Cloud Services for Backup and Recovery

Cloud Provider	Services
AWS	EC2
	S3 Bucket
	RDS
	Aurora
Azure	Azure VM
GCP	GCP VM

Supported Operating Systems for Cloud VM Backup and Recovery

Operating System	File System	Notes
Windows 10 Desktop Edition **Note:** Cohesity supports the Enterprise Edition of Windows 10 Desktop Edition.	NTFS	Backup using Cloud Snapshot Management (CSM) is independent of operating systems. Full backup and restore using native snapshot is independent of operating systems. The operating systems mentioned in the Operating System column are applicable only for File/Folder Level Recovery.
Windows 2019 64-bit Windows 2016 64-bit Windows 2012, 2012 R2 64-bit Windows 2008 R2 64-bit	NTFS	
CentOS 5.10 64-bit, 6.0+ 64-bit, 7.0 - 7.9 64-bit, 8.0 64-bit	ext3, ext4, xfs	
OEL 5.11 - 5.8 64-bit, 6.x 64-bit, 7.0 - 7.9 64-bit, 8.2 64-bit		
RHEL 5.11 - 5.8 64-bit, 6.7+ 64-bit, 7.0 - 7.9 64-bit, 8.0 - 8.2 64-bit		
SUSE Linux Enterprise Server 11 SP4 64-bit, 12 SP4 64-bit, 12.3 64-bit, 15.0 64-bit		
openSUSE 15.1 64-bit		
Ubuntu 14.x 64-bit, 16 64-bit, 18 64-bit, 19.x 64-bit, 20 64-bit		
Debian 6.0.0-6.0.8 64 bit, 7.0.0-7.8.0 64 bit, 8.0.0 64 bit, 9.6 64-bit, 10 64-bit		
Fedora Server 19-21 64 bit		

Failover from VMware to AWS

Operating System	File System
Windows 2022 64-bit Windows 2019 64-bit Windows 2016 64-bit Windows 2012, 2012 R2 64-bit Windows 10 Desktop Edition	NTFS
Ubuntu 14.x 64-bit, 16 64-bit, 18 64-bit, 20 64-bit	ext3, ext4, xfs
RHEL 6.7+ 64-bit, 7.0 - 7.9 64-bit, 8.0 - 8.2 64-bit	
CentOS 6.0+ 64-bit, 7.0 - 7.9 64-bit, 8.0 64-bit	
OEL 5.11 - 5.8 64-bit, 6.x 64-bit, 7.0 - 7.9 64-bit	
SUSE Linux Enterprise Server 11 64 bit, 12 64 bit	
Debian 6.0.0-6.0.8 64 bit, 7.0.0-7.8.0 64 bit, 8.0.0 64 bit	
Fedora Server 19-21 64 bit	

Failover from VMware to Azure

Operating System	File System
Windows 2022 64-bit Windows 2019 64-bit Windows 2016 64-bit Windows 2012, 2012 R2 64-bit Windows 10 Desktop Edition	NTFS
RHEL 6.7+ 64-bit, 7.0 - 7.9 64-bit, 8.0 - 8.2 64-bit	ext3, ext4, xfs
CentOS 6.0+ 64-bit, 7.0 - 7.9 64-bit, 8.0 64-bit	

Azure Stack Hub

Supported Azure Stack Hub Versions
• 2102 • 2008 • 2005

CloudSpin

Source	Destination	Supported OS
VMware	AWS	**BIOS boot** Microsoft Windows Server 2019, 2016, 2012, 2012 R2, 2008, 2008 R2. Microsoft Windows 7 (Home, Professional, Enterprise, Ultimate), Windows 8 (Home, Professional, Enterprise), Windows 8.1 (Professional, Enterprise), Windows 10 (Home, Professional, Enterprise, Education). CentOS 5.1-5.11, 6.1-6.8, 7.0-7.9, 8.0-8.2. Debian 6.0.0-6.0.8, 7.0.0-7.8.0, 8.0.0. Oracle Linux 5.10-5.11, 6.1-6.10, 7.0-7.6. RHEL 5.1-5.11, 6.1-6.9, 7.0-7.9, 8.0-8.2. SUSE Linux Enterprise Server 11 with Service Pack 1, Service Pack 2 and Service Pack 3, SUSE Linux Enterprise Server 12 with Service Pack 1 - Service Pack 5, SUSE Linux Enterprise Server 15 with Service Pack 1 and Service Pack 2. Ubuntu 12.04, 12.10, 13.04, 13.10, 14.04, 14.10, 15.04, 16.04, 16.10, 17.04, 18.04, and 20.04. **UEFI boot** Windows Server 2012, 2016, 2019 Ubuntu 16, 18

Source	Destination	Supported OS
VMware	Azure	**BIOS boot** Windows Server 2008, 2012, 2016, 2019. CentOS 5.10 64-bit, 6.0+ 64-bit, 7.0 - 7.9 64-bit, 8.0 64-bit. RHEL 5.8 - 5.11 64-bit, 6.7+ 64-bit, 7.0 - 7.9 64-bit, 8.0 - 8.2 64-bit. **UEFI boot** Windows Server 2012, 2016, 2019.
Hyper-V	Azure	**BIOS and UEFI boot** Windows 2008, 2012, 2016, 2019. CentOS 5.10 64-bit, 6.0+ 64-bit, 7.0 - 7.9 64-bit, 8.0 64-bit. RHEL 5.8 - 5.11 64-bit, 6.7+ 64-bit, 7.0 - 7.9 64-bit, 8.0 - 8.2 64-bit. Ubuntu 14, 16, 18, 20.

Supported Workflows and External Targets

For more information, see Supported Workflows and External Targets in the online help.

Supported Multitenancy Workflows

For more information, see Supported Multitenancy Workflows in the online help.

Supported Multitenancy Workflows for Hybrid Extender

For more information, see Supported Multitenancy Workflows for Hybrid Extender in the online help.

Supported Multitenancy Workflows for Hybrid Extender Realms

This sections lists the supported multitenancy workflows for Hybrid Extender Realms.

Protection Group and External Targets Workflows (Hybrid Extender Realms)

- Virtual Server (VMs) and Physical Server Workflows (Hybrid Extender Realms)
  - Protection Based Workflow
  - Archival Based Workflow
  - Replication Based Workflow
- Databases Workflows (Hybrid Extender Realms)
  - Protection Based Workflow for MS SQL VM
  - Archival Based Workflow for MS SQL VM
  - Replication Based Workflow for MS SQL VM
  - Protection Based Workflow for MS SQL Volume-base, File-based, and Native Backup
  - Archival Based Workflow for MS SQL Volume-base, File-based, and Native Backup
  - Replication Based Workflow for MS SQL Volume-base, File-based, and Native Backup
  - Protection Based Workflow for Oracle
  - Archival Based Workflow for Oracle
  - Replication Based Workflow Oracle

Legend for Charts Below:

Yes = Supported

No = Not Supported

N/A = Not Applicable

CA = Cluster Administrator

TA = Tenant Administrator

Create = Create for an Org

Delete = Delete from Cluster

Assign = Assign to an Org

Un-assign = Un-assign from an Org

Virtual Server (VMs) and Physical Server Workflows (Hybrid Extender Realms)

Protection Based Workflow

Categories	Workflows	Sources				
		ESXi VM Servers	Physical Servers (Windows - Block Based)	Physical Servers (Windows - File Based)	Physical Servers (Linux - Block Based)	Physical Servers (Linux - File Based)
REGISTRATION	Register a source	Supported (CA, TA)	Supported (TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Refresh object hierarchy	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Refresh Application registration	N/A	N/A	N/A	N/A	N/A
	Auto-protect new objects	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	No

Categories	Workflows	Sources

Protection Based Workflow for MS SQL VM

Categories	Workflows	Sources
		MS SQL VM
REGISTRATION	Register a source	Supported (CA,TA)
	Refresh object hierarchy	Supported (CA,TA)
	Refresh Application registration	Yes using VM edit workflow
	Auto-protect new objects	Supported (CA,TA)
BACKUP	Incremental backup with CBT	Yes as log-based incremental
	Full backup with CBT	Supported (CA,TA)
	Incremental backup with SQL server differential	N/A
	Full backup without CBT	Supported (CA,TA)
	Ability to run a log backup in parallel to a full backup.	N/A
	Backup, archive and replicate now	Supported at DB and server level both
	CloudSpin to AWS and Azure	N/A

Categories	Workflows	Sources
		MS SQL VM
RECOVER	Recovering an entity in the Job Run	Yes
	Recover an entire backup job run	Yes as crash-consistent VM not as SQL restore
	Recover a SQL DB to the original server and instance	No
	Recover a SQL DB to the original server but a different instance	No
	Recover a SQL DB to a different server that has the same SQL version	No
	Recover DB to Alternate Instance with overwite	No
	Recover a SQL DB to a different server that has a different SQL version (Based on MS requirements)	No
	Instant volume mount	No
	Crash-consistent recover for apps	Supported (CA,TA)
CLONE	Clone an object of a job run	No
	Clone all the objects of a job run	No
	Clone db to FCI instance	No
	Crash-consistent recover for apps	Supported (CA,TA)
DB Migration	SQL DB Migration without auto sync	N/A
	SQL DB Migration with auto sync	N/A
TEARDOWN	Tear down objects	Supported (CA,TA)
	Tear down instant volume mount	Supported (CA,TA)

Categories	Workflows	Sources
		MS SQL VM
CANCEL	Cancel a running job run	Supported (CA,TA)
	Cancel a running clone or recover tasks	Supported (CA,TA)
DELETE SNAPSHOT	Delete a local snapshot of a job run	Supported (CA,TA)
FILE RECOVERY	Search for files or folders	Supported (CA,TA)
	Browse for a backed-up object	Supported (CA,TA)
	Download files/folders	Supported (TA)
	Recover files	Supported (CA,TA)
	Download a VMX file	Supported (TA)
VIRTUAL DISKS RECOVERY	Recover Virtual Disks	N/A
CONVERT AND DEPLOY	Register Azure source and clone VMs to Azure	N/A
	Register AWS source and clone VMs to AWS	N/A

Archival Based Workflow for MS SQL VM

Categories	Workflows	Sources
		MS SQL VM
ARCHIVAL	Archive an incremental backup	Supported (Not for log backup)(CA,TA)
	Archiving an incremental backup with SQL server differential	N/A
	Archive a full backup	Supported (Not for log backup)(CA,TA)

Categories	Workflows	Sources
		MS SQL VM
RECOVER	Recover a single object of a job run from an archive to a source	Supported (No Databases, Only Files and VM)(CA,TA)
	Recover an entire backup job run from an archive to a source	No
	Instant volume mount from an archive	No for SQL (use VM or physical)
	Crash-consistent recover for apps from an archive	Yes for files & VMs but not DBs
DB Migration	SQL DB Migration without auto sync	N/A
	SQL DB Migration with auto sync	N/A
CLONE	Clone objects of a job run from an archive	No
	Clone all objects of a job run from an archive	No
	clone db to FCI	N/A
	Crash-consistent clone for apps from an archive	No
CANCEL	Cancel a running archival task	Supported (CA,TA)
	Cancel a running clone or recover task that is retrieving from an archive	No
DELETE SNAPSHOT	Delete an archived snapshot of a job run from the external target	Supported (CA,TA)

Categories	Workflows	Sources
		MS SQL VM
FILE RECOVERY	Search for files or folders from an archive	Supported (CA,TA)
	Browse for files or folders from an archive snapshot	No
	Download files and folders from an archive	Supported (TA)
	Recover files from an archive to a source (to the same and different sources)	No
	Download n VMX file from an archive	N/A
VIRTUAL DISKS RECOVERY	Recover Virtual Disks	N/A
CLOUD RETRIEVE - SEARCH & RETRIEVE	Search for an object in an external target	Supported for volume based job(CA)
	Download metadata for all runs of a job	Supported for volume based job(CA)
	Download a snapshot (archived data) for a job run	Supported for volume based job(CA)
CLOUD RETRIEVE - CLONE	Clone objects of a job run from an archive	Supported for volume based job
	Clone all objects of a job run from an archive	No
	clone DB to FCI	N/A
CLOUD RETRIEVE - RECOVER	Recover objects of a job run from an archive to a source	Supported for volume based job
	Recover all objects of job run from an archive to a source	No
	Instant volume mount from an archive	Not Supported for SQL (use VM or physical, volume based)(CA,TA)

Categories	Workflows	Sources
		MS SQL VM
CLOUD RETRIEVE - FILE RECOVERY	Search files or folders from downloaded snapshot	Supported for volume based job
	Search files or folders from the metadata of a retrieved job run	Supported for volume based job (CA,TA)
	Browse files or folders from a retrieved snapshot	Supported for volume based job (CA,TA)
	Browse files or folders from the metadata of a downloaded job run	Supported for volume based job (CA,TA)
	Download files and folders from an archive	Supported for volume based job(TA)
	Recover files from an archive to a source (to the same and different sources)	Supported for volume based job (CA,TA)
	Download a VMX file from an archive	N/A
CLOUD RETRIEVE - VIRTUAL DISKS RECOVERY	Recover Virtual Disks	N/A

Replication Based Workflow for MS SQL VM

Categories	Workflows	Sources
		MS SQL VM
REPLICATION	Replicate an incremental backup with CBT to a remote cluster	Yes as log-based incremental
	Replicate an incremental backup with SQL server differential to a remote cluster	N/A
	Replicate a full backup with CBT to a remote cluster	Supported (CA,TA)
	Replicate a full backup without CBT to a remote cluster	Supported (CA,TA)

Categories	Workflows	Sources
		MS SQL VM
FAILOVER	Failover an inactive Job on a remote cluster	No
RECOVER	Recover a single object of a job run from a remote cluster	Supported (CA,TA)
	Recover an entire backup job run from a remote cluster	Yes as crash-consistent, not as SQL restore
	Recover a SQL DB from a remote cluster to another SQL server with the same SQL version	Supported (CA,TA)
	Recover a SQL DB from a remote cluster to different SQL server with a different SQL version	Supported (CA,TA)
	Instant volume mount of replicated data	Supported (CA,TA)
	Crash-consistent recover for apps from a remote cluster	Supported (CA,TA)
DB Migration	SQL DB Migration without auto sync	N/A
	SQL DB Migration with auto sync	N/A
CLONE	Clone an object of a job run from a remote cluster	Supported (CA,TA)
	Clone all objects of a job run from a remote cluster	Supported as Crash Consistent VM not as SQL Clone(CA,TA)
	clone db to FCI	N/A
	Crash-consistent clone for apps from a remote cluster	Supported (CA,TA)

	Create a snapshot in Azure and replicate to another region	N/A	N/A

Supported Cloud Spin and Other Workflows

For more information, see Supported Cloud Spin and Other Workflows in the online help.

Supported Platforms for Heterogeneous Cohesity cluster

Cohesity supports heterogeneous Cohesity cluster that spans nodes of different Cohesity hardware platforms and Cohesity-qualified partner hardware platforms.

Within a heterogeneous Cohesity cluster, you can have a combination of:

- Multiple Cohesity hardware platforms.
- Cohesity hardware platforms and hardware platforms from any one partner.
- Hardware platforms from a partner.

You can create a new Cohesity cluster with heterogeneous nodes or add heterogeneous nodes to an existing Cohesity cluster and combine all the nodes' storage capacities and performance in a Cohesity cluster.

Hardware Compatibility Within a Cohesity cluster

> **Important:** Cohesity recommends using the Sizer tool for guidance on mixing nodes within a cluster.

The heterogeneous Cohesity cluster support has evolved since Cohesity version 6.1. From 6.1 release, more platforms can be combined to form a heterogeneous Cohesity cluster.

> **Note:**
> - Creating a new heterogeneous cluster, or expanding an existing cluster to make it Heterogeneous must only be done after consulting your Cohesity accounts team.
> - Creating incorrect combinations of heterogeneous clusters without prior consultation with your Cohesity accounts team risks undesirable consequences. Reverting this can be complicated and time-consuming.
> - Use the Cohesity Sizer tool for checking the heterogenous cluster options for both Cohesity C-Series and OEM Hardware platforms.

Before you create a heterogeneous Cohesity cluster, review and follow the guidelines below:

- Cohesity does not recommend mixing All-Flash (nodes with SSDs) and hybrid nodes (nodes with HDDs) in the same Cluster.
- Hardware platforms from only one partner can be combined with Cohesity hardware platforms to form a heterogeneous Cohesity cluster. For example, you cannot form a heterogeneous Cohesity cluster with Cohesity hardware, Cisco, and HPE hardware platforms.
- Performance sizing should be done at 104% of the performance-gated nodes suggested by the sizer, using the highest-performance node.
- Mixing Hybrid Platforms
  - Equivalent Node Type - Two hybrid node types are considered equivalent if:
    - Their CPU/SSD ratio is within 10% of each other.
    - They have the same number of hard disks (HDDs).
    - The total HDD capacity of the nodes should be within 25% of each other.
  - Mixing Equivalent Nodes - In a heterogeneous cluster, if two platforms are equivalent, the combined number of total nodes in the cluster should be greater than or equal to the recommended number of nodes per the EC configuration.
  - Mixing Non-Equivalent Nodes - In a heterogeneous cluster, if two platforms are non-equivalent, then the minimum number of nodes for each equivalence-node type must be as per the EC configuration recommendation.

    For more details on the recommended number of nodes, see the Disk and Node Resiliency in Cohesity Fault Tolerance—Data Integrity for Modern Web-scale Environments.

Hardware Compatibility Matrix

The following table lists the Cohesity and partner hardware platforms compatible with Cohesity-Series and all other OEM platforms to form a heterogeneous cluster:

> **Note:**
> - New nodes that are added to the cluster should have the same or more CPU cores and the same or more SSD capacity (total SSD capacity) than the existing nodes in the cluster.
> - Hardware platforms from only one partner can be combined with Cohesity hardware platforms to form a heterogeneous cluster. However, you can combine any models from the same partner hardware.

Vendor	Cohesity C-Series	Cisco	Dell	HPE	Lenovo	Intel	Fujitsu	Super Micro
Cohesity C-Series	✓	✓	✓	✓	✓	✓	✓	✓
Cisco	✓	✓	✗	✗	✗	✗	✗	✗
Dell	✓	✗	✓	✗	✗	✗	✗	✗
HPE	✓	✗	✗	✓	✗	✗	✗	✗
Lenovo	✓	✗	✗	✗	✓	✗	✗	✗
Intel	✓	✗	✗	✗	✗	✓	✗	✗
Fujitsu	✓	✗	✗	✗	✗	✗	✓	✗
SuperMicro	✓	✗	✗	✗	✗	✗	✗	✓

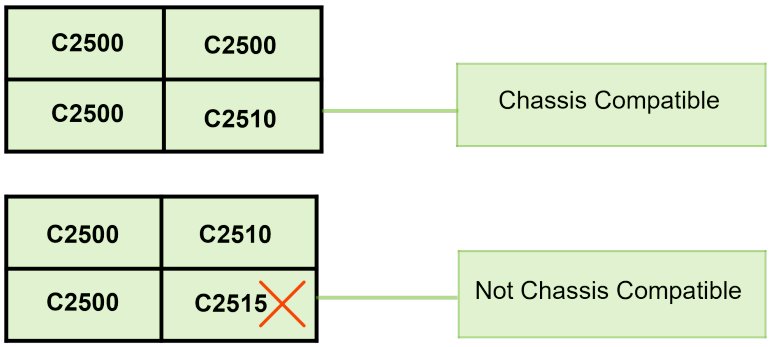
> **Note:** Pure FlashRecover is not supported in a heterogeneous cluster configuration.

> **Important:**
> Refer the Hardware Universe Help for the following information:
>
> - For a complete list of all the supported C-Series and OEM platforms.
> - For a complete list of all the End-Of-Sale C-Series and OEM platforms, see the End-Of-Sale Platforms section.
> - Minimum supported Cohesity versions for C-Series and OEM platforms.

You can combine compute or general-purpose nodes with Cohesity hardware platforms or any models from the same partner hardware to form a heterogeneous Cohesity cluster. For more information on compute nodes, see Manage Compute Nodes.

Node Coexistence Compatibility Within a Chassis

The table below shows which node hardware models can coexist within one chassis. For example, a C2510 node can be physically added to a chassis with C2500 nodes. However, it is not supported for a C2515 node to be physically added to a chassis with C2500 nodes.



The green check ✓ in the table cell below indicates compatibility. Hardware combinations with no checks are not compatible.

> **Note:** For C4000, C5000, C6000, and CX8000 the node hardware models cannot coexist within the same chassis.

Hardware Model	C2100	C2300	C2500	C2510	C2105	C2305	C2505	C2515	C2605
C2100	✓								

Hardware Model	C2100	C2300	C2500	C2510	C2105	C2305	C2505	C2515	C2605
C2300		✓							
C2500			✓	✓					
C2510			✓	✓					
C2105					✓				
C2305						✓			
C2505							✓	✓	✓
C2515							✓	✓	✓
C2605							✓	✓	✓

> **Note:** For C4000, C5000, CX8000 and CNG2, the node hardware models cannot coexist within the same chassis. This limitation does not apply to the C6000, since C6000 is a single-node chassis.

Agent Compatibility Within a Cohesity cluster

This page details the Linux and Windows agent compatibility within a Cohesity cluster.

You must install the Cohesity Agent on Physical servers, SQL servers, Exchange servers, and other Hypervisor environments you want to protect.

The Cohesity versions and Cohesity Agent versions specified in the following matrix include their respective minor release versions. For example, Cohesity 6.8.1 version support is also applicable for 6.8.1_u1, 6.8.1_u2, and 6.8.1_ux versions, where x denotes the minor/update release version number.

Similarly, Cohesity Agent 6.8.1 version support is also applicable for 6.8.1_u1, 6.8.1_u2, and 6.8.1_ux versions.

> **Note:**
> Legends:
> ✅ - Supported
> ❌ - Not Supported

Cohesity Linux Agent Compatibility Matrix

Cohesity Agent Versions	Cohesity Versions						
	7.3.1	7.3	7.2.2	7.2.1	7.2	7.1.2	6.8.2
7.3.1	✅	❌	❌	❌	❌	❌	❌
7.3	✅	✅	❌	❌	❌	❌	❌
7.2.2	✅	✅	✅	❌	❌	❌	❌
7.2.1	✅	✅	✅	✅	❌	❌	❌
7.2	✅	✅	✅	✅	✅	❌	❌
7.1.2	✅	✅	✅	✅	✅	✅	❌
6.8.2	✅	✅	✅	✅	✅	✅	✅

> **Note:** Cohesity recommends upgrading the Agent version to the same version as the Cohesity cluster version. For more information, see Install and Manage the Agent on Linux Servers.

Cohesity Windows Agent Compatibility Matrix

Cohesity Agent Versions	Cohesity Versions						
	7.3.1	7.3	7.2.2	7.2.1	7.2	7.1.2	6.8.2
7.3.1	✓	✗	✗	✗	✗	✗	✗
7.3	✓	✓	✗	✗	✗	✗	✗
7.2.2	✓	✓	✓	✗	✗	✗	✗
7.2.1	✓	✓	✓	✓	✗	✗	✗
7.2	✓	✓	✓	✓	✓	✗	✗
7.1.2	✓	✓	✓	✓	✓	✓	✗
6.8.2	✓	✓	✓	✓	✓	✓	✓

> **Note:** Cohesity recommends upgrading the Agent version to the same version as the Cohesity cluster version. For more information, see Install and Manage the Agent on Windows Servers.

Cohesity AIX Agent Compatibility Matrix

Cohesity Agent Versions	Cohesity Versions						
	7.3.1	7.3	7.2.2	7.2.1	7.2	7.1.2	6.8.2
7.3.1	✓	✗	✗	✗	✗	✗	✗
7.3	✓	✓	✗	✗	✗	✗	✗
7.2.2	✓	✓	✓	✗	✗	✗	✗

Cohesity Agent Versions	Cohesity Versions						
	7.3.1	7.3	7.2.2	7.2.1	7.2	7.1.2	6.8.2
7.2.1	✓	✓	✓	✓	✗	✗	✗
7.2	✓	✓	✓	✓	✓	✗	✗
7.1.2	✓	✓	✓	✓	✓	✓	✗
6.8.2	✓	✓	✓	✓	✓	✓	✓

> **Note:** Cohesity recommends upgrading the Agent version to the same version as the Cohesity cluster version. For more information, see Install and Manage the Cohesity Java Agent on AIX Servers.

Cohesity Solaris Agent Compatibility Matrix

Cohesity Agent Versions	Cohesity Versions						
	7.3.1	7.3	7.2.2	7.2.1	7.2	7.1.2	6.8.2
7.3.1	✓	✗	✗	✗	✗	✗	✗
7.3	✓	✓	✗	✗	✗	✗	✗
7.2.2	✓	✓	✓	✗	✗	✗	✗
7.2.1	✓	✓	✓	✓	✗	✗	✗
7.2	✓	✓	✓	✓	✓	✗	✗
7.1.2	✓	✓	✓	✓	✓	✓	✗
6.8.2	✓	✓	✓	✓	✓	✓	✓

> **Note:** For more information, see Install and Manage the Agent on Solaris Servers.

Cohesity HP-UX Agent Compatibility Matrix

Cohesity Agent Versions	Cohesity Versions						
	7.3.1	7.3	7.2.2	7.2.1	7.2	7.1.2	6.8.2
7.3.1	✓	✗	✗	✗	✗	✗	✗
7.3	✓	✓	✗	✗	✗	✗	✗
7.2.2	✓	✓	✓	✗	✗	✗	✗
7.2.1	✓	✓	✓	✓	✗	✗	✗
7.2	✓	✓	✓	✓	✓	✗	✗

6.8.2	✗	✗	✗	✗	✗	✗	✗

DataProtect for Cloud Supportability

This section covers the supportability information of the DataProtect for Cloud:

- DataProtect for Cloud in AWS Supportability
- DataProtect for Cloud in Azure Supportability
- DataProtect for Cloud in GCP Supportability

DataProtect for Cloud in AWS Supportability

Supported Sources and Workloads

The following table provides the mapping of the workflows that are supported on the sources DataProtect for cloud in AWS supports, as per the latest release:

Workload	Backup	Recovery	Cloud Archive*	Replication	Recovery Level	Notes
Amazon RDS for MySQL	Yes	Yes	Yes	Yes	Database-level (with ingest-based protection) Instance-level (with snapshot-based protection)	Supports both snapshot-based and ingest-based protection.
Amazon Aurora MySQL	Yes	Yes	Yes	Yes	Database-level (with ingest-based protection) Cluster-level (with snapshot-based protection)	Supports both snapshot-based and ingest-based protection.
Amazon Redshift Cluster	Yes	Yes	Yes	Yes	Database-level	Supports only ingest-based protection.
Amazon DocumentDB	Yes	Yes	Yes	Yes	Database-level	Supports only ingest-based protection.
Amazon RDS for Oracle	Yes	Yes	Yes	Yes	Instance-based	Supports both ingest based and snapshot-based protection.
Amazon DynamoDB	Yes	Yes	Yes	Yes	Table-level	Supports only ingest-based protection.

Workload	Backup	Recovery	Cloud Archive*	Replication	Recovery Level	Notes
Amazon RDS PostgreSQL	Yes	Yes	Yes	Yes	Database-level (with ingest-based protection) Instance-level (with snapshot-based protection)	Supports both ingest based and snapshot-based protection.
Amazon Aurora PostgreSQL	Yes	Yes	Yes	Yes	Database-level (with ingest-based protection) Cluster-level (with snapshot-based protection)	Supports both ingest based and snapshot-based protection.
Amazon RDS for Microsoft SQL Server (MS SQL)	Yes	Yes	Yes	Yes	Database-level (with ingest-based protection) Instance-level (with snapshot-based protection)	Supports both ingest based and snapshot-based protection.
Amazon RDS for MariaDB	Yes	Yes	Yes	No	Instance-level	Supports only snapshot-based protection

Workload	Backup	Recovery	Cloud Archive*	Replication	Recovery Level	Notes
Amazon RDS Custom for Oracle					Database-level (with ingest-based protection) Instance-level (with snapshot-based protection)	Supports both ingest based and snapshot-based protection.
Amazon RDS Custom for SQL Server	Yes	Yes	Yes	No	No	
AWS EC2	Yes	Yes	Yes	Yes	File-level	File-level recovery is not supported for EC2 instances with XFSv5 file system.
AWS S3	Yes	Yes	Yes	Yes	File-level	Granular recovery of S3 objects with prefixes is supported.
VMware Cloud (VMC)	Yes	Yes	Yes	No	File-level	Multi-tenancy should be enabled and hybrid extender needs to be configured. Supported from 7.2.2_u2 version onwards.
Nutanix AHV Prism Central	Yes	Yes	Yes	Yes	File-level	

Workload	Backup	Recovery	Cloud Archive*	Replication	Recovery Level	Notes
Acropolis: Acropolis Standalone Cluster	Yes	Yes	Yes	Yes	File-level	
Physical Server for Windows and Linux	Yes	Yes	Yes	Yes	File-level	Supports both file-based and block-based backups.
MS SQL Server (Standalone,AG, and FCI)	Yes	Yes	Yes	Yes	File-level	Supports MS SQL File-based and VDI-based backups.
Microsoft 365	Yes	Yes	Yes	Yes	File-level	

Workload	Backup	Recovery	Cloud Archive*	Replication	Recovery Level	Notes
NAS (Generic NAS, NetApp, Isilon, Pure Storage FlashBlade)	Yes	Yes	Yes	Yes	File-level	• Supports NAS volumes with NFSv3, NFSv4.1, SMB v1, v2.x, and v3 versions. • NetApp: Supports only File-Runner-based backup. SnapDiff-based backup is not supported. • Isilon: Supports both File-runner and CFT-based backups.
SAP HANA on Linux (x86)	Yes	Yes	Yes	Yes	Not Applicable	
MongoDB	Yes	Yes	Yes	Yes	Not Applicable	
Cassandra	Yes	Yes	Yes	Yes	Not Applicable	

Workload	Backup	Recovery	Cloud Archive*	Replication	Recovery Level	Notes
Hadoop	Yes	Yes	Yes	Yes	File-level (Only Hadoop HDFS)	Supports protection of HDFS, Hive, and HBase objects.
Oracle Database	Yes	Yes	Yes	Yes	Not Applicable	Supports both Oracle Adapter and Oracle SBT Plug-in.
IBM DB2 on Linux	Yes	Yes	Yes	Yes	Not Applicable	
PostgreSQL on Linux	Yes	Yes	Yes	Yes	Not Applicable	Supports instant restore.
SAP on Oracle for Linux	Yes	Yes	Yes	Yes	Not Applicable	
SAP on Oracle for Windows	Yes	Yes	Yes	Yes	Not Applicable	
SAP MaxDB on Linux	Yes	Yes	Yes	Yes	Not Applicable	
SAP MaxDB on Windows	Yes	Yes	Yes	Yes	Not Applicable	
MySQL EE Commercial Edition	Yes	Yes	No	No	Database-level	

*DataProtect for cloud in AWS supports only Cloud Archive with **Incremental Forever** archival format.

- DataProtect for cloud in AWS supports Write Once Read Many (WORM) for Cloud Archive with incremental forever archival format. The WORM model ensures that the objects written to the WORM-supported targets cannot be tampered with (deleted or overwritten). The archives created are immutable for the duration configured. For the list of external targets with WORM support,

For the list of supported external targets for Cloud Archive, see Supported Workflows and External Targets.

For information on registering an external target, see Register an External Target.

SmartFiles Support

DataProtect for cloud in AWS supports SmartFiles for SMB, NFS, and S3 protocols, with functionality limited to View Snapshots and Replication.

For more information, see SmartFiles (File and Object Services).

Marketplace Support

You can install Marketplace Apps on DataProtect for cloud in AWS. For more information on Marketplace App, see Apps.

FortKnox Support

Cohesity FortKnox supports vaulting data from DataProtect for cloud in AWS to a cloud vault. For more information, see Clusters.

Multitenancy

DataProtect for cloud in AWS supports the multitenancy feature. The multitenancy feature enables you to configure the multitenant environment on your Cohesity Platform and securely isolate each tenant in your environment. For more information, see Organizations (Multitenancy) .

DataProtect for Cloud in Azure Supportability

Supported Sources and Workloads

The following table provides the mapping of the workflows that are supported on the sources DataProtect for cloud in Azure supports, as per the latest release:

Workload	Backup	Recovery	Cloud Archival*	Replication	Granular Recovery	Notes
Azure Blob and Azure Data Lake Storage	Yes	Yes	Yes	Yes	File-level	
Azure SQL	Yes	Yes	Yes	Yes	Database-level	
Azure Table Storage	Yes	Yes	Yes	Yes	Table-level	

Workload	Backup	Recovery	Cloud Archival*	Replication	Granular Recovery	Notes
Azure Cosmos DB - Table	Yes	Yes	Yes	Yes	Table-level	
Azure Cosmos DB - Cassandra	Yes	Yes	Yes	Yes	Keyspace - level	
Azure Cosmos DB - NoSQL	Yes	Yes	Yes	Yes	Database-level	
Azure Cosmos DB - MongoDB	Yes	Yes	Yes	Yes	Database-level	
Azure PostgreSQL	Yes	Yes	Yes	Yes	Database-level	
Azure MySQL	Yes	Yes	Yes	Yes	Database-level	
Azure VMware Solution (AVS)	Yes	Yes	Yes	Yes	File-level	Supported from 7.2.2_u2 version onwards.

Workload	Backup	Recovery	Cloud Archival*	Replication	Granular Recovery	Notes
Azure VM	Yes	Yes	Yes	Yes	No	**Note:** Files and folder recovery of Azure VM is an Early Access feature on DataProtect for cloud in Azure. Contact your Cohesity account team to enable the feature.
Nutanix AHV Prism Central	Yes	Yes	Yes	Yes	File-level	

Workload	Backup	Recovery	Cloud Archival*	Replication	Granular Recovery	Notes
Acropolis: Acropolis Standalone Cluster	Yes	Yes	Yes	Yes	File-level	
Physical Server	Yes	Yes	Yes	Yes	File-level	
MS SQL Server (Standalone and FCI)	Yes	Yes	Yes	Yes	File-level	Supports MS SQL File-based and VDI-based backups.
Microsoft 365	Yes	Yes	Yes	Yes	File-level	
NAS (Generic NAS, NetApp, Isilon, Pure Storage FlashBlade)	Yes	Yes	Yes	Yes	File-level	Supports NAS volumes with NFSv3, NFSv4.1, SMB v1, v2.x, and v3 versions.
SAP HANA	Yes	Yes	Yes	Yes	Not Applicable	
MongoDB	Yes	Yes	Yes	Yes	Not Applicable	
Cassandra	Yes	Yes	Yes	Yes	Not Applicable	
IBM DB2 on Linux	Yes	Yes	Yes	Yes	Not Applicable	
SAP on Oracle for Linux	Yes	Yes	Yes	Yes	Not Applicable	

Workload	Backup	Recovery	Cloud Archival*	Replication	Granular Recovery	Notes
SAP on Oracle for Windows	Yes	Yes	Yes	Yes	Not Applicable	
Hadoop	Yes	Yes	Yes	Yes	Yes (Only Hadoop HDFS)	Supports protection of HDFS, Hive, and HBase objects.
PostgreSQL on Linux	Yes	Yes	Yes	Yes	Not Applicable	Supports instant restore.
SAP Sybase ASE on Windows	Yes	Yes	Yes	Yes	Not Applicable	Supported from 7.2.2_u1 version onwards.
SAP Sybase ASE on Linux	Yes	Yes	Yes	Yes	Not Applicable	Supported from 7.2.2_u1 version onwards.
Oracle Database	Yes	Yes	Yes	Yes	Not Applicable	Supports both Oracle Adapter and Oracle SBT Plug-in.
SAP MaxDB on Linux	Yes	Yes	Yes	Yes	Not Applicable	
SAP MaxDB on Windows	Yes	Yes	Yes	Yes	Not Applicable	
SAP Sybase IQ	Yes	Yes	Yes	Yes	Not Applicable	Supported from 7.2.2_u1 version onwards.

Workload	Backup	Recovery	Cloud Archival*	Replication	Granular Recovery	Notes
MySQL EE Commercial Edition	Yes	Yes	No	No	Database-level	

* DataProtect for cloud in Azure supports both **Cloud Archive with periodic full** and **Cloud Archive with Incremental Forever** archival formats.

For the list of supported external targets for Cloud Archive, see Supported Workflows and External Targets.

For information on registering an external target, see Register an External Target.

SmartFiles Support

DataProtect for cloud in Azure supports SmartFiles for SMB, NFS, and S3 protocols, with functionality limited to View Snapshots and Replication.

For more information, see SmartFiles (File and Object Services).

Marketplace Support

You can install Marketplace Apps on the DataProtect for cloud in Azure. For more information on Marketplace App, see Apps.

FortKnox Support

Cohesity FortKnox supports vaulting data from DataProtect for cloud in Azure to a cloud vault. For more information, see Cohesity FortKnox.

Multitenancy

From 7.2.2_u1 onwards, DataProtect for cloud in Azure supports the multitenancy feature. The multitenancy feature enables you to configure the multitenant environment on your Cohesity cluster and securely isolate each tenant in your environment. For more information, see Organizations (Multitenancy) .

DataProtect for Cloud in GCP Supportability

Supported Sources and Workloads

The following table provides the mapping of the workflows that are supported on the sources DataProtect for cloud in GCP supports, as per the latest release:

Workload	Backup	Recovery	Cloud Archive*	Replication	Recovery Level	Notes
Firestore	Yes	Yes	Yes	Yes	Database-level	
BigQuery	Yes	Yes	Yes	Yes	Database-level	
Spanner	Yes	Yes	Yes	Yes	Database-level	
AlloyDB for PostgreSQL	Yes	Yes	Yes	Yes	Database-level	
Cloud SQL for SQL Server	Yes	Yes	Yes	Yes	Database-level	
Cloud SQL for MySQL	Yes	Yes	Yes	Yes	Database-level	
Cloud SQL for PostgreSQL	Yes	Yes	Yes	Yes	Database-level	
GCP VM	Yes	Yes	Yes	Yes	File-level	File-level recovery is not supported for GCP VMs with XFSv5 file system.
Cassandra	Yes	Yes	Yes	Yes	Not Applicable	
Hadoop	Yes	Yes	Yes	Yes	File-level (Only Hadoop HDFS)	Supports protection of HDFS, Hive, and HBase objects.
MS SQL Server (Standalone, AG, FCI)	Yes	Yes	Yes	Yes	File-level	Supports MS SQL File-based volume-based, and VDI-based backups.

Workload	Backup	Recovery	Cloud Archive*	Replication	Recovery Level	Notes
MongoDB	Yes	Yes	Yes	Yes	Not Applicable	
Google Cloud VMware Engine (GCVE)	Yes	Yes	Yes	No	File-level	On the GCVE, the default user (CloudOwner@gve.local) is missing the permission to access the Host -> Configuration -> Storage Partition Configuration. As a result, instant recovery fails, with the following error message: `Could not mount datastore on any host. Additional details: SOAP 1.1 fault 'ServerFaultCode [no subcode] - Permission to perform this operation was denied.` As a workaround, ensure that the default user is granted the Host -> Configuration -> Storage Partition Configuration permission.
Physical Server	Yes	Yes	Yes	Yes	File-level	
Cohesity View	Yes	Yes	Yes	Yes	File-level	

Workload	Backup	Recovery	Cloud Archive*	Replication	Recovery Level	Notes
NAS (Generic NAS, NetApp, Isilon, Pure Storage FlashBlade)	Yes	Yes	Yes	Yes	File-level	Supports NAS volumes with NFSv3, NFSv4.1, SMB v1, v2.x, and v3 versions.
Red Hat OpenShift	Yes	Yes	Yes	Yes	File-level	Supports only 4.14 version.
PostgreSQL on Linux	Yes	Yes	Yes	Yes	Not Applicable	Supports instant restore.
Oracle Database	Yes	Yes	Yes	Yes	Not Applicable	Supports both Oracle Adapter and Oracle SBT Plug-in.
SAP MaxDB on Linux	Yes	Yes	Yes	Yes	Not Applicable	
SAP MaxDB on Windows	Yes	Yes	Yes	Yes	Not Applicable	
SAP HANA	Yes	Yes	Yes	Yes	Not Applicable	
MySQL EE Commercial Edition	Yes	Yes	No	No	Database-level	

*DataProtect for cloud in GCP supports only Cloud Archive with **Incremental Forever** archival format.

For the list of supported external targets for Cloud Archive, see Supported Workflows and External Targets.

For information on registering an external target, see Register an External Target.

SmartFiles Support

DataProtect for cloud in GCP supports SmartFiles for SMB, NFS, and S3 protocols, with functionality limited to View Snapshots and Replication.

For more information, see SmartFiles (File and Object Services).

Marketplace Support

You can install Marketplace Apps on DataProtect for cloud in GCP. For more information on Marketplace App, see Apps.

Multitenancy

DataProtect for cloud in GCP supports the multitenancy feature. The multitenancy feature enables you to configure the multitenant environment on your Cohesity Platform and securely isolate each tenant in your environment. For more information, see Organizations (Multitenancy) .

Replication Compatibility

Replication automatically makes copies of snapshots captured by a Protection Group on one Cohesity cluster and copies them to a second Cohesity cluster.

The following table indicates the replication compatibility between Cohesity clusters running different versions.

	To 6.8.2	To 7.1.2	To 7.2	To 7.2.1	To 7.2.2	To 7.3	To 7.3.1
Replicating from 6.8.2	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Replicating from 7.1.2	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Replicating from 7.2	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Replicating from 7.2.1	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Replicating from 7.2.2	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Replicating from 7.3	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Replicating from 7.3.1	Yes	Yes	Yes	Yes	Yes	Yes	Yes

Replication 1.0 and 2.0

Replication 1.0 and 2.0 are replication algorithms used by Cohesity to compare and transmit data between the source cluster and the target cluster.

- Replication 1.0 computes the changed files/directories by scanning the entire volume and then transmits the changed metadata to the target cluster.
- Replication 2.0 leverages SnapTree to efficiently determine the changed entries and transmits the changes to the target cluster.

> **Note:**
> - Replication 2.0 is the default replication protocol and is also used for S3 view replications.
> - By default, a Protection Group starts using Replication 2.0 after two replications. The Protection Group corresponding to these two replications must have happened after upgrading to 2.0. To immediately use Replication 2.0, Cohesity recommends canceling all intermediate runs where backup happened before the upgrade.

Supportability for Qualifications

This topic provides information regarding Cohesity's aims around time frames for qualifying newly released versions of operating systems, applications, and databases. This document is for information purposes only. It does not amend or supplement any contract and is not a warranty, commitment, or obligation of any kind. The information in this document is subject to change without notice, and no third party should rely on it to make any decisions.

Workloads

The workloads covered by this document are categorized into the following tiers:

- Tier 1
- Tier 2

> **Note:** Qualifications of new releases of workloads will only include certification of current Cohesity Generally Available capabilities. New capabilities are part of feature releases. Cohesity will only qualify new third-party vendor releases as far back as the most recent Cohesity LTS release. The third-party vendors determine major and minor release designations.

Cohesity Estimates Based on Vendor Release GA Date

Workload	Major Release	Minor Release
Tier 1	1 Quarter	2 Months
Tier 2	2 Quarters	1 Quarter

Tier 1

Categories	Supported Software
Operating Systems	Windows, Oracle Linux, Red Hat Linux, AIX, SLES/SuSe Linux
Applications	Microsoft SQL Server, Oracle, Cassandra, MySQL, SAP HANA, SAP Oracle, DB2, PostgreSQL, Active Directory
Hypervisors	VMware, Nutanix AHV, Kubernetes (Vanilla and Red Hat Openshift)
NAS	Dell Isilon, NetApp, Pure Storage FlashBlade

Tier 2

Categories	Supported Software
Operating Systems	Debian, Ubuntu, FreeBSD, Solaris, HP-UX
Applications	Couchbase, SAP Sybase, SAP MaxDB, MariaDB, Hadoop, MongoDB, Microsoft Exchange (on-prem), CockroachDB, HDFS
Hypervisors	KVM/RHV, Microsoft Hyper-V, Kubernetes (VMware Tanzu)
NAS	Elastifile, Nimble, IBM GPFS

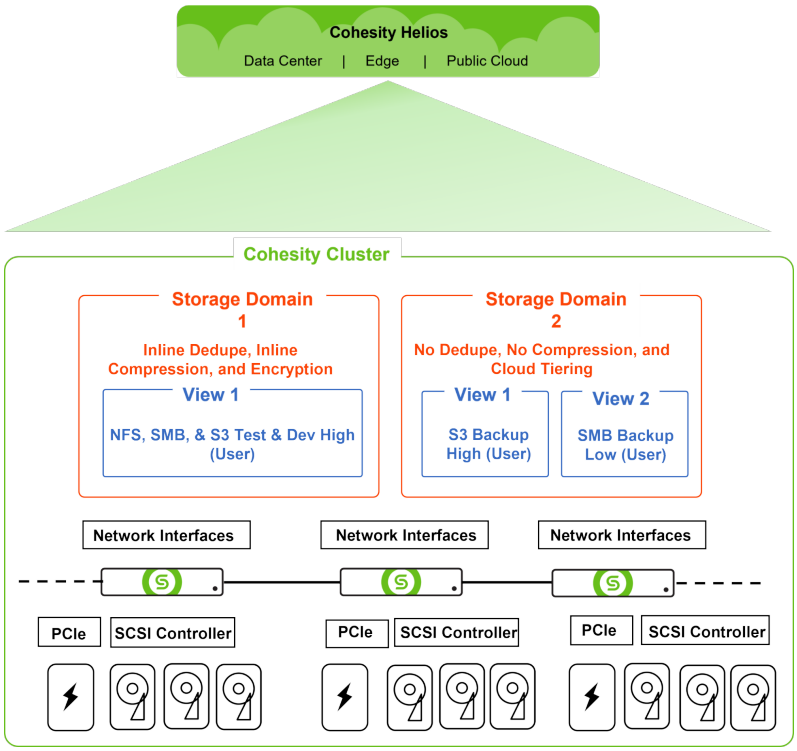
Chapter 3: Data Protection Key Concepts

This chapter includes the following topics:

- Cohesity Cluster Architecture 141
- Protection Overview 145
- About Scale Out 157
- About Cloud Archival 159
- About Cloud Tier 162
- About Tape Archival 163
- About Fault Tolerance 167
- Secure Software Development Practices 177
- Cohesity Security Features 184
- MegaFile 210
- Data Retention for Audits 213
- Dynamic Disk Support 216

Cohesity Cluster Architecture

This section describes the components that make up a Cohesity cluster.



Nodes

A Cohesity node contains CPU with spinning disk or flash storage that is preinstalled with the Cohesity software. A Cohesity cluster can be hosted on:

- Datacenters: Running on x86-based server consisting of three or more physical nodes.
- Edge: A single node ROBO running on x86-based physical servers or a Virtual Edition cluster running on hypervisor with a single node or multiple nodes, depending on the hypervisor.
- Public Cloud: Cloud Edition Cohesity cluster deployed on public clouds like Amazon Web Services, Microsoft Azure and Google Cloud Platform.

A node can be in one of the following states:

- Available on the Network but not assigned to the cluster
- Assigned to the cluster

Storage Domains

A Storage Domain, formerly known as a View Box, is a named storage location on a cluster. At the storage domain level, settings like fault tolerance, encryption, and storage efficiencies are applied. A Storage Domain contains Views. When you configure a Protection

Group, you specify a Storage Domain and during a Protection Group Run, the Cohesity cluster stores the Snapshots in that Storage Domain.

If Deduplication is on, the Cohesity cluster eliminates duplicate blocks of repeating data stored on the Cohesity cluster, thus reducing the amount of storage space needed to store data. You may want to disable deduplication and here are some possible reasons:

- The speed of backing up on the Storage Domain is more important than conserving the disk space used to store the Snapshots or files. For example the Storage Domain contains a View and you want fast writes to that View (Datastore).
- You are storing backups on the Cohesity cluster that were created by another backup product that already deduplicates the data.

If Inline Deduplication is on, deduplication occurs when the Cohesity cluster writes the data to the Cohesity View. If Inline Deduplication is off, deduplication occurs after the Cohesity cluster writes the data to the Cohesity View.

Views

A Cohesity view provides a storage location with one or more of these protocols namely NFS, SMB, S3 and SWIFT in a storage domain on the Cohesity cluster.

The NFS mount path can be mounted onto systems using the NFS protocol. The SMB mount path can be mounted onto systems as an SMB share.

You can use the view to store data such as files, backup snapshots, and cloned VMs. Views can only be mounted on any machines specified in the allowlist subnets. A view also acts as a datastore during the VM cloning process and during VM recovery. You can select the SWIFT protocol and a create SWIFT-only view for OpenStack environments.

You can create a view for the following three categories:

- File Shares
- Backup Target
- Object Services

You can select the **Read/Write** protocol and, optionally, select the **Read-only** protocol.

You can create a Cohesity view only by using a template. The template can be a predefined template or a custom template. For more information, see:

- Create Views Using a Predefined Template
- Create Views Using a Custom Template

> **Note:** If you are using Kerberos (AD or MIT), you must create a view using the same storage domain that is mapped to AD/MIT-Kerberos + LDAP.

For more information, see Create Views Using a Predefined Template and Add Subnets to Allowlists.

Views can be used to store data such as files and directories. For example, other backup products can store data on a view that is hosted on the Cohesity cluster. To access a view from your system, you must mount the view.

The table below summarizes the features at the storage domain and view levels, and how they are inherited.

Features	Storage Domain	View
Fault tolerance	Erasure Coding (EC) Replication Factor (RF)	Inherits storage domain fault tolerance settings and cannot be changed for the View.
Storage efficiency	Deduplication (inline, post-process, or disabled) Compression (inline, post-process, or disabled)	Inherits storage domain efficiencies OR Can be overwritten at the View level to be post-process if at the storage domain level is inline, but cannot be disabled.
Encryption	Enabled or disabled	Inherits storage domain's settings and cannot be changed for the View.
Cloud Tier	Inherits cluster settings, unless overwritten at the storage domain level.	Inherits storage domain's settings and cannot be changed for the View.
QoS Policy	N/A	Set for each View.

Protection Overview

Cohesity consolidates data protection, management and web-scale storage onto a unified platform. Easy integration with the VMware ecosystem provides a plug-and-play experience for virtualization admins and significantly reduces the complexity of protecting data. With physical workload support as well, Cohesity is an end-to-end data protection solution that enables businesses to instantly see a full index of their environment and choose the objects they want to protect. These objects can then be protected with easy-to-use protection policies that can be customized based on retention period or application group.

Protection is the process of safeguarding your organization's data. Cohesity uses the following terminology for protection components.

- **Source:** An object in your organization that you want to protect, such as a VM, physical server, Pure Storage volume, MS SQL Server and NAS.
- **Agent:** The Cohesity software that you install on physical servers and certain VM hypervisors to enable Cohesity to protect them.
- **Registration:** The process of registering the source with the Cohesity cluster.
- **Policy:** A collection of reusable settings that define how and when sources are protected, replicated and archived. You select a policy when configuring a Protection Group.
- **Protection Group:** A backup job that runs repeatedly, based on an associated policy, to back up data from a source and store it on the cluster.
- **Remote Adapter Protection Group:** A backup job that runs scripts or executables on a remote Linux machine, typically for sources that are not supported by Cohesity.
- **External Target:** A software environment outside the cluster, such as a cloud or tape management system, which can be used for archiving inactive data for long-term retention on less expensive storage.

For various workloads (sources), Cohesity's incremental-forever strategy relies on change block technology that is either developed by Cohesity or by the vendor Cohesity is integrating with. There are battled-tested technologies and it is highly unlikely that you will ever face data corruption. However, in the case of a mission-critical workload, Cohesity already enables you to mitigate against this in multiple ways with the following existing functionality:

- By performing a backup validation. For example, using Database consistency checker.
- As a part of your regular database restore runs
- As a part of your regular VM or database clones
- You may take a periodic full backup

Cohesity recommends a first full and incremental forever approach to backup all workloads (sources) with the exception for Oracle(SBT based backup) and SQL (VDI-based) where Cohesity recommends periodic full backups.

The common high-level steps to protect sources are:

1. Download and install the agent software on the source. This is required only for physical servers and some hypervisors.
2. Register the source with the cluster.
3. Choose a policy provided by Cohesity or create your own.
4. Create a Protection Group to back up the source.

The Backup Manager Service is responsible for handling all the requests from the Cohesity Data Cloud (Self-Managed) and APIs. A multi-node cluster environment with a large amount of data increases the load on the primary instance of the Backup Manager Service which increases the response time of Cohesity Data Cloud (Self-Managed and API calls. For enabling a read-only replica of the Backup Manager Service, see Backup Manager Service Replica.

About Recovering VMs

Cohesity provides the ability to recover Protected Objects (such as VMs) from a Snapshot created earlier by a Protection Group. You can recover VMs from a Cohesity cluster or a currently registered archive. You can recover VMs to their original location or a new location. Follow these procedures to recover VMs from a Cohesity cluster: Recover VMs to the Original LocationRecover VMs to a New LocationYou can also watch the VMware VM Recovery video to learn how to recover a VMware VM to an original or new location..

The Recover task extracts the VM files (such as the VMDK files) stored in Snapshots and creates new instances of the VMs in their original locations or in a new location depending on the options you choose during recovery:

- Recover to the Original Location—Recover the VM files (such as the VMDK files) to their original datastores and create new instances of the VMs in the original Resource Pool available in the original Source.
- Recover to a New Location—Recover the VM files (such as the VMDK files) to an alternate datastore and create new instances of the VMs in an alternate Resource Pool of a registered Source.
- Recover from a Cloud Archive—Recover the VM files from a registered archive (External Target) and place them in a View on the Cohesity cluster.

During recovering VMs, one of the following methods is used to identify the ESXi hosts that have access to the required Datastore:

- If all the hosts have access to the required Datastore then VMware is responsible to select the ESXi hosts based on load balancing.
- If only some of the hosts have access to the required Datastore, a random host from the available list of hosts that have access to the required Datastore is selected.

For more details about recovering VMs using the Cohesity Dashboard, see Recover VMs.

Recover to the Original Location

While recovering VMs, you can choose to recover the VM files (such as the VMDK files) to their original datastores and create new instances of the VMs in the original Resource Pool of the original Source as described in the figure and procedure below.

The following example shows one VMware VM being recovered, but you can select multiple VMs to recover if the Snapshots of the VMs are stored in the same Storage Domain. The action steps in the following procedure are represented in the figure below with blue numbered time squares:

.

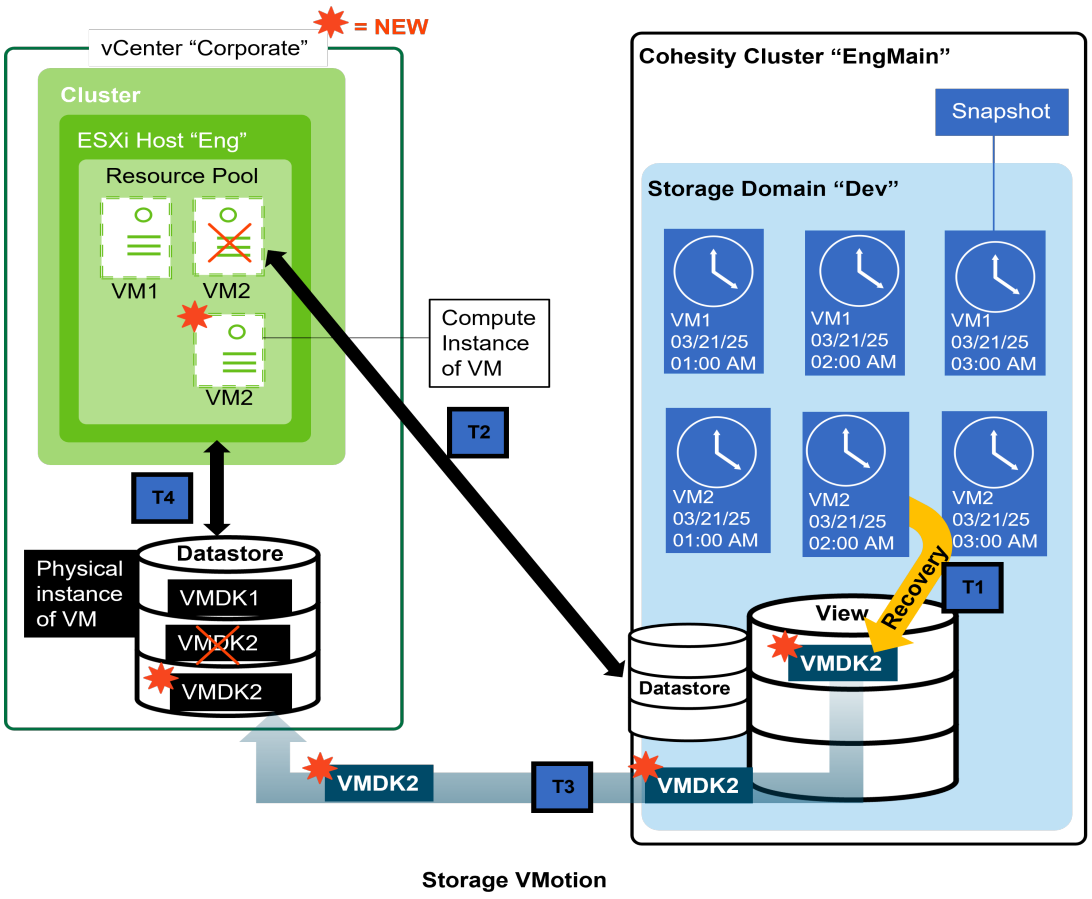
The VM Recover task consists of the following actions:

T1) The Cohesity cluster extracts the VM files (such as the VMDK files) stored in Snapshots and places the new VM files in a temporary View. In this example, a new VMDK2 is created from the Snapshot of VM2 made on 03/21/2025 at 02:00 AM.

T2) New instances of the VMs are created in the original Resource Pool by using the new VMDKs from the temporary View. In this example, the new VM2, using VMDK2, is created in the Resource Pool. The View temporarily becomes the datastore for the VMs as represented by the black line between the Resource Pool and View (datastore). The VMs can be used immediately and you do not have to wait until the VMDK files are completely recovered to the original datastore.

T3) The Cohesity cluster migrates the VM files (such as the VMDKs) using Storage vMotion to the original datastore and any changes made to the data on the VM during the recovery process are preserved. The temporary View is deleted when Storage vMotion is completed.

T4) After the VM files are recovered, the VMs use the VM files in the original datastore. In this example, after VMDK2 is fully recovered, VM2 uses VMDK2 located in the original datastore.



Storage VMotion

Recover to a New Location

While recovering VMs, you can choose to recover the VM files (such as the VMDK files) to a specified datastore and create new instances of the VMs in a specified Resource Pool of a registered Source as described in the figure and procedure below. The VMs do not need to be recovered to their original Resource Pool and the VM files do not need to be recovered to the original datastore.

The following example depicts a VMware VM being recovered. The action steps in the following procedure are represented in the figure below with blue numbered time squares: T1 .

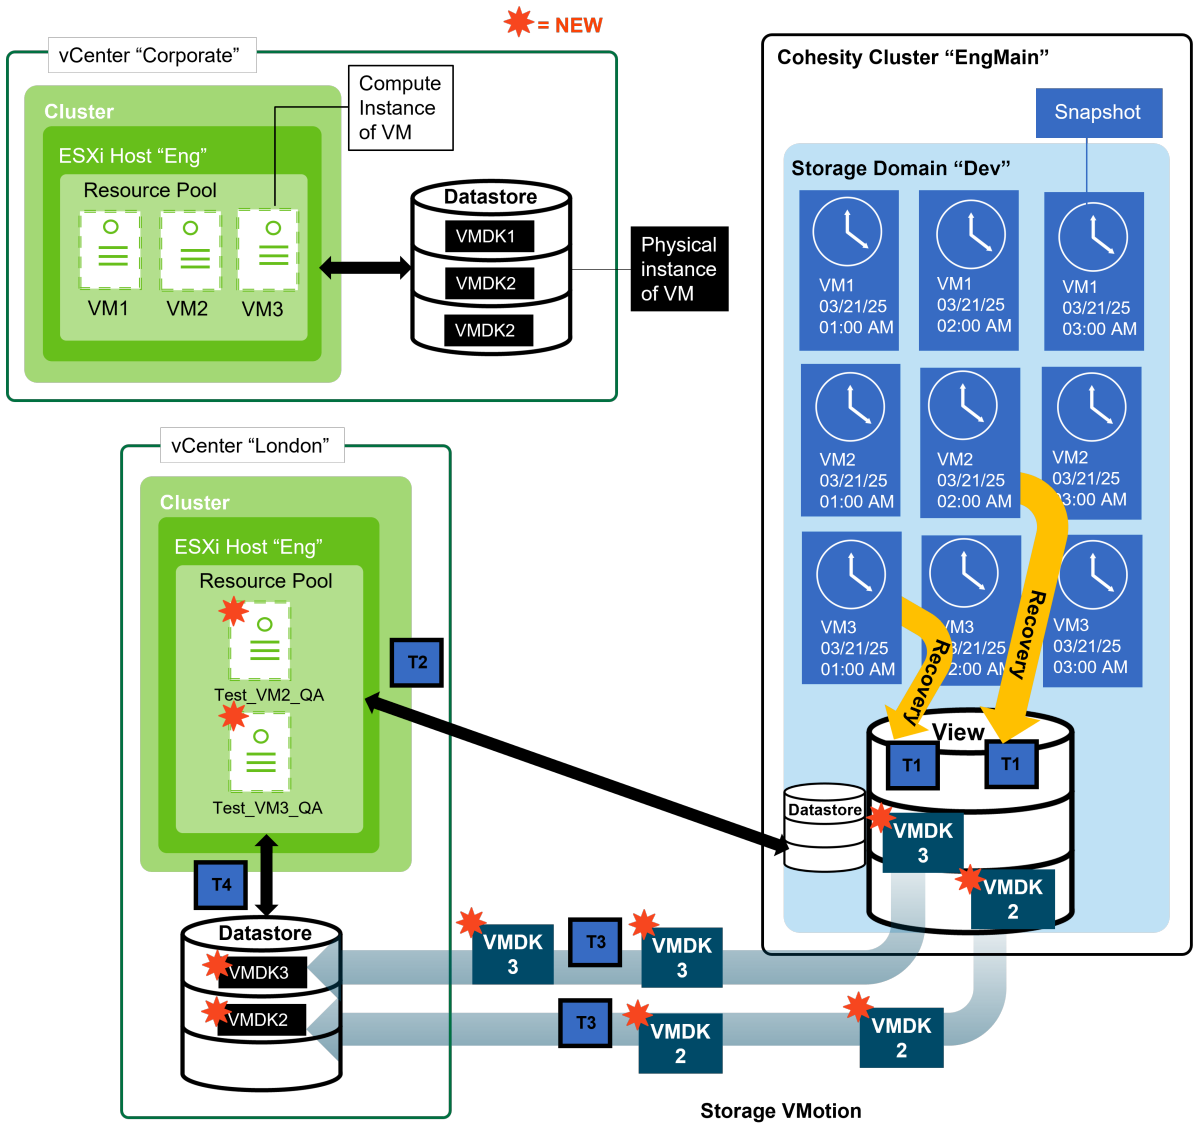
T1) The Cohesity cluster extracts the VM files (such as the VMDK files) stored in Snapshots and places the new VM files in a temporary View. In this example, a new VMDK2 is created from the Snapshot of VM2 made on 03/21/2025 at 02:00 AM and a new VMDK3 is created from the Snapshot of VM3 made on 03/21/2025 at 01:00 AM.

T2) New instances of the VMs are created in the specified Resource Pool by mounting the new VMDKs from the temporary View. In this example, a new VM2 is created by mounting VMDK2 and a new VM3 is created by mounting VMDK3. The View temporarily becomes the datastore for the VM as represented by the black line

between the Resource Pool and View (datastore). The VM can be used immediately and you do not have to wait until the VMDK is completely recovered to the datastore. You can optionally choose to add a suffix and a prefix to the new VM name. For example you can specify the Prefix `Test_` and the Suffix `_QA` and when VM2 is recovered, the new VM that is created is called `Test_VM2_QA`.

T3) The Cohesity cluster migrates the VM files (such as the VMDKs) using Storage vMotion to the specified datastore and any changes made to the data on the VMs during the recovery process are preserved. The temporary View is deleted when Storage vMotion is completed.

T4) After the VM files are recovered, the VMs use the VMDK files stored in the datastore on the Source. In this example, after VMDK2 is fully recovered, `Test_VM2_QA` uses VMDK2 located in the datastore of the vCenter "London" Source. In addition, after VMDK3 is fully recovered, `Test_VM3_QA` uses VMDK3 located in the datastore of the vCenter "London" Source.



Recover VMs to Multiple Datastores

When you recover VMs to a new location, you can choose multiple target datastores from a specified resource pool of a registered source.

Before you recover multiple VMs to multiple datastores, review and understand these factors:

- You can select multiple datastores only when recovering VMs to a new location.
- The number of target datastores you can select is limited to the number of VMs selected for recovery.
- The VMs are recovered to the selected datastores based on the size of the VMs, free space available in the datastores, successful restore attempts, and other factors.
- One VM will be restored to one datastore.

For more details about recovering VMs using the Cohesity Dashboard, see Recover VMs.

Recover VMs to vCloud Director Using Storage Profiles

You can recover VMs to an alternate vCloud Director location based on the vCloud Director Storage Profiles.

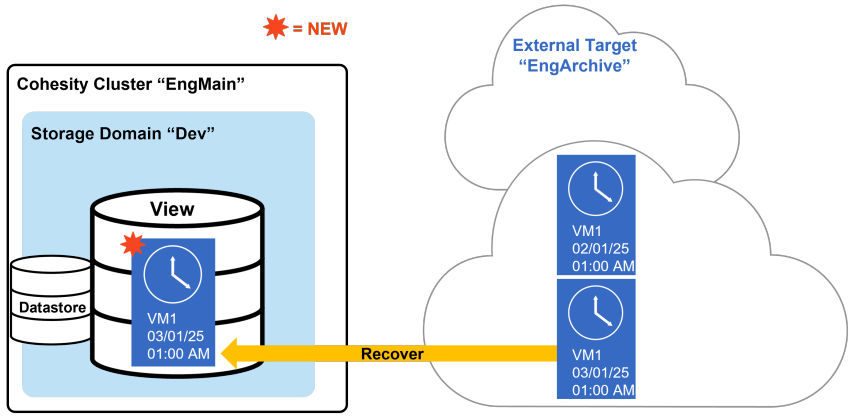
Before you recover VMs to the vCloud Director, review and understand these factors:

- You can select one vCloud Director Storage Profile for a recovery job.
- VMs are recovered to datastores that are compatible with the Storage Profile.
- The datastore to which the VMs are recovered is selected based on the size of the VMs, free space available in the datastores, successful restore attempts, and other factors.
- Instant Recovery is only supported if the target recovery location is explicitly specified while creating a recovery job (recover to a new location).

For more details about recovering VMs using the Cohesity Dashboard, see Recover VMs.

Recover from a Cloud Archive

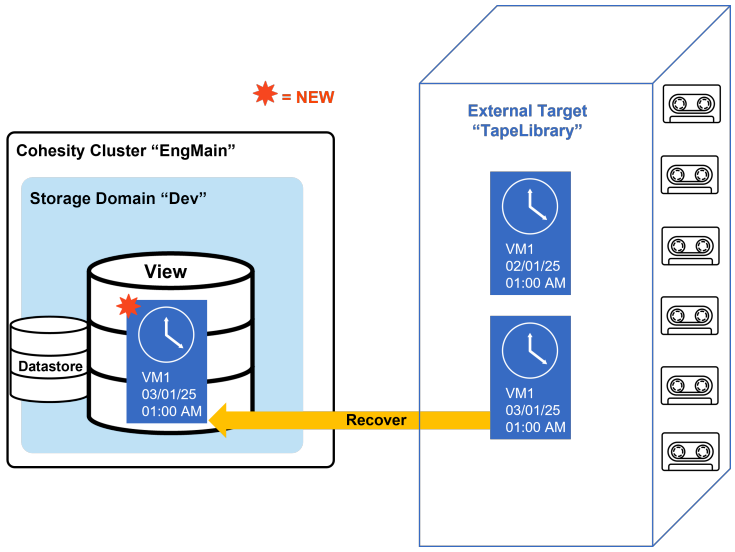
While recovering VMs, you can choose to recover the VM files from a currently registered archive (External Target). The recovery process is the same as recovering from the Cohesity cluster.



Recover from a Tape Archive

While recovering VMs, you can choose to recover the VM files from a currently registered archive (External Target). The recovery process is the same as recovering from the Cohesity cluster.

When recovering from a tape archive, the Cohesity Dashboard displays the list of tapes required for recovery and their respective details. You can still create a recovery task if some tapes are offline. Recovery can also progress if some tapes are offline. When an offline tape is required for recovery to continue, Cohesity raises an alert and displays a message with the recovery task that needs attention.



About File Recovery

Cohesity provides the ability to recover files and folders from a Snapshot created earlier by a Protection Group. Files and folders can be recovered to their original location or to a newly specified location, which can be within the original Source or a different one. You can choose to retain the recovered files' and folders' original (at the time of the backup) permissions and attributes. You can also download files and folders from selected Snapshots that were created by a Cohesity Protection Group. However, only items that were indexed when the Snapshot was created can be downloaded (this does not apply to NAS). Recovering and searching for files and folders in Snapshots created by other backup software is not supported.

This Recover task extracts the files stored in Snapshots and creates new instances of them in their original location or a new location depending on the options you choose during recovery. You can also choose to download a file or folder.

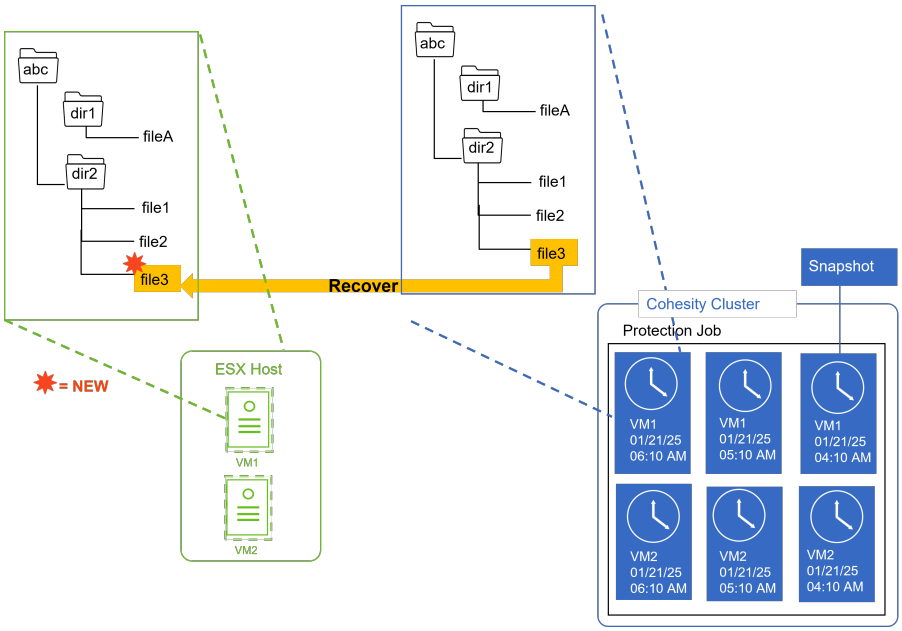
- Recover Files or Folders—Recover files or folders to the original location or a new location.
- Download a File or Folder—Download a file or folder from an existing Snapshot.

Refer to the respective source sections for more information about recovery and downloads.

Recover Files or Folders

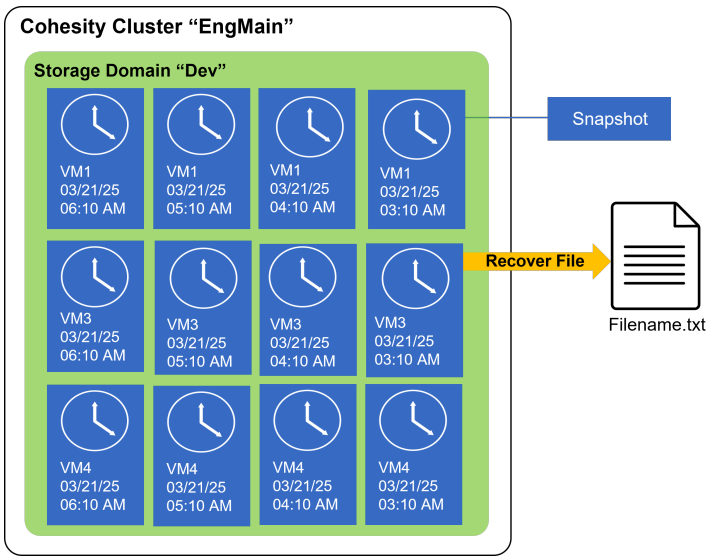
While recovering files, you can choose to recover to the original location or a new location.

In the figure below, one file is recovered to its original location on a VM, but you can select multiple files to recover if they are from the same Snapshot.



Download a File or Folder

In the figure below, one file is downloaded, but you can download multiple files and folders at once if they are from the same Snapshot. The Snapshot can reside on the local Cohesity cluster or on archives.



About Instant Volume Mount

Cohesity provides a fast and reliable way to access your data via the instant volume mounting feature. Some benefits include granular recovery of Microsoft Exchange and SharePoint data. Cohesity's simple workflows can instantly mount backup volumes to the Ontrack® PowerControls™ application, enabling application owners to perform granular recovery.

The following table lists the Cohesity backed-up solutions and the associated Ontrack® PowerControls™ application versions required to perform granular recoveries.

Cohesity Backed Up Applications	Supported Ontrack PowerControls Versions
Microsoft Exchange 2010 and later	9.2 and later

> **Note:** Microsoft Exchange (on-premises) requires Ontrack® software and license for granular recovery of Microsoft Exchange mailbox objects.

Instant volume mounting is supported for virtual and physical environments. This feature allows the selected backup volumes to be made available at the target location where you can then complete the desired operations. Instant Volume Mount is available for backed-up volumes, whether they are stored locally on the Cohesity cluster or archived to a registered external target.

For instructions on how to use the Cohesity Dashboard to instantly mount volumes, see Instant Volume Mount.

Mount Volumes

Backup volumes from a Snapshot can be mounted to a target in a registered Source or to a registered physical Server.

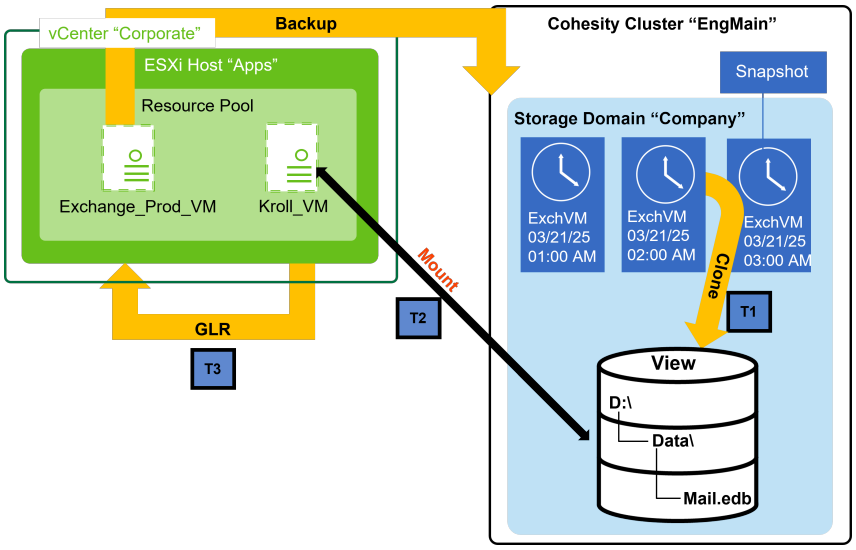
The following example depicts mounting a volume from a backup of a Microsoft Exchange VM to an Ontrack VM in the same vCenter to recover data. The action steps in the following procedure are represented in the figure below with blue numbered time squares:

T1) The Cohesity cluster clones the volume stored in a Snapshot and places them in a temporary View.

T2) The volume in the temporary View is mounted to the Ontrack_VM as represented by the black line between the Resource Pool and View.

T3) Now you can use the Ontrack_VM to perform the desired Granular Level Recovery (GLR) operations and recover data to the Exchange_Prod_VM.

Tear down the mounted volume when you are finished working with it.

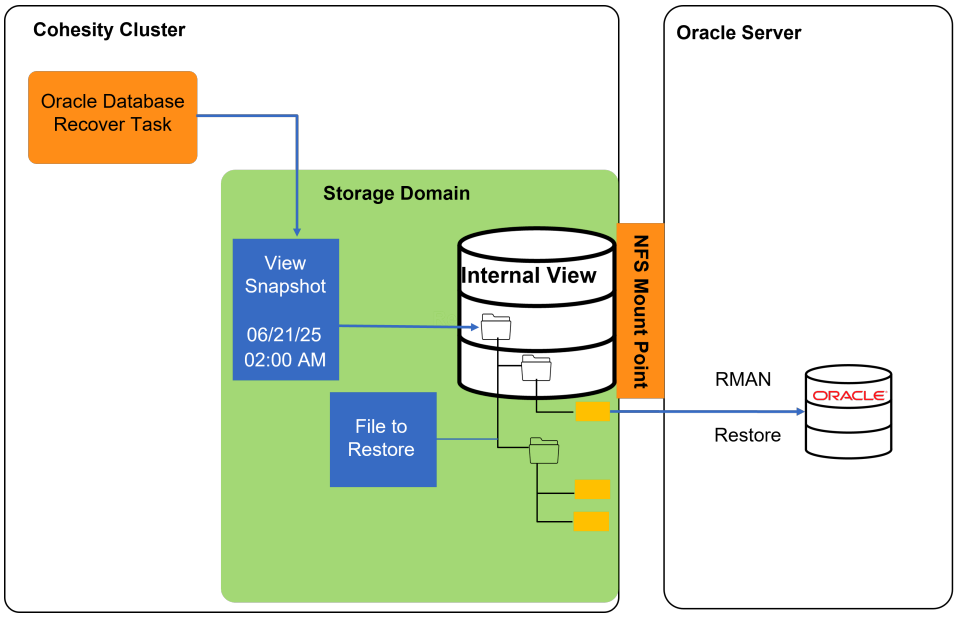


About Recovering Oracle Database

Cohesity provides the ability to recover the entire Oracle Database to its original location or to a different Oracle server that is registered on the Cohesity cluster. When restoring to the database's original location, you can perform a point-in-time recovery. You can also overwrite the original database.

An Oracle Database Recovery Task performs the following sub-tasks:

1. Determines which files to restore based on the specified recovery options.
2. Creates a View and copies the required files to the View.
3. Mounts the View on the Oracle server.
4. Runs the Cohesity-managed RMAN recovery scripts to perform the restore.
5. Optionally applies transaction logs to the database for the specified point in time.
6. Unmounts and deletes the View.



About Recovering Storage Volumes

Cohesity provides the ability to recover protected storage volumes from a Cohesity Snapshot created earlier by a Protection Group. The options to recover storage volumes are as follows:

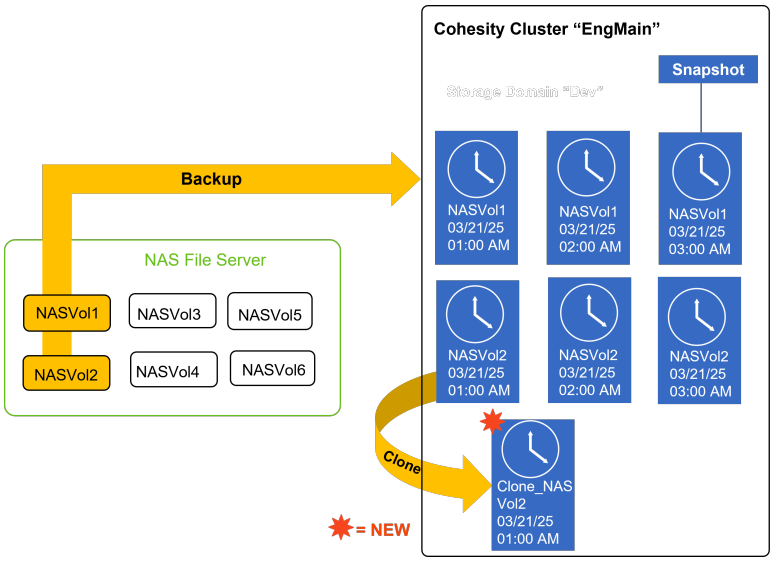
- Recover Storage Volumes to the Original Location
- Recover Storage Volumes to a New Location
- Recover Storage Volumes as a Cohesity View

For instructions on how to recover storage volumes, see Recover NAS Storage Volumes.

Recover Storage Volumes on NAS

The following example depicts recovering data from a backup of NAS volumes and recovering one Snapshot.

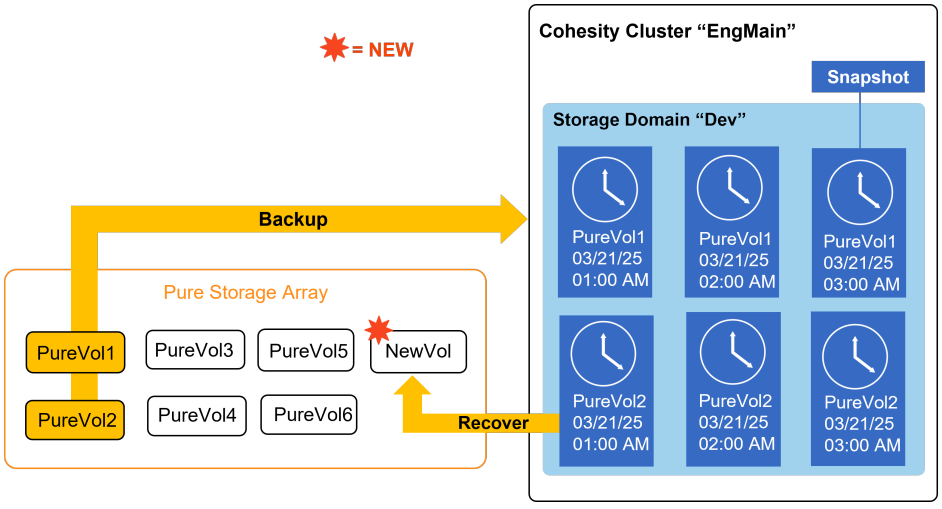
During recovery, the Cohesity cluster utilizes SpanFS to instantly clone a volume's backed up data to a new View within the Cluster.



Recover Storage Volumes on Pure Storage

The following example depicts recovering data from a backup of Pure Storage volumes and recovering one volume back to the same array.

During recovery, the Cohesity cluster copies data from the Cluster to the storage array as a new storage volume.



About Scale Out

Cohesity's scale out capability allows organizations to start with the right-size data platform that is ideal for their environment, and scale out as needed, on their own terms, one node at a time. No more pre-paying hefty upfront expenses for anticipated growth or incurring hidden costs associated with forklift upgrades of traditional scale-up systems.

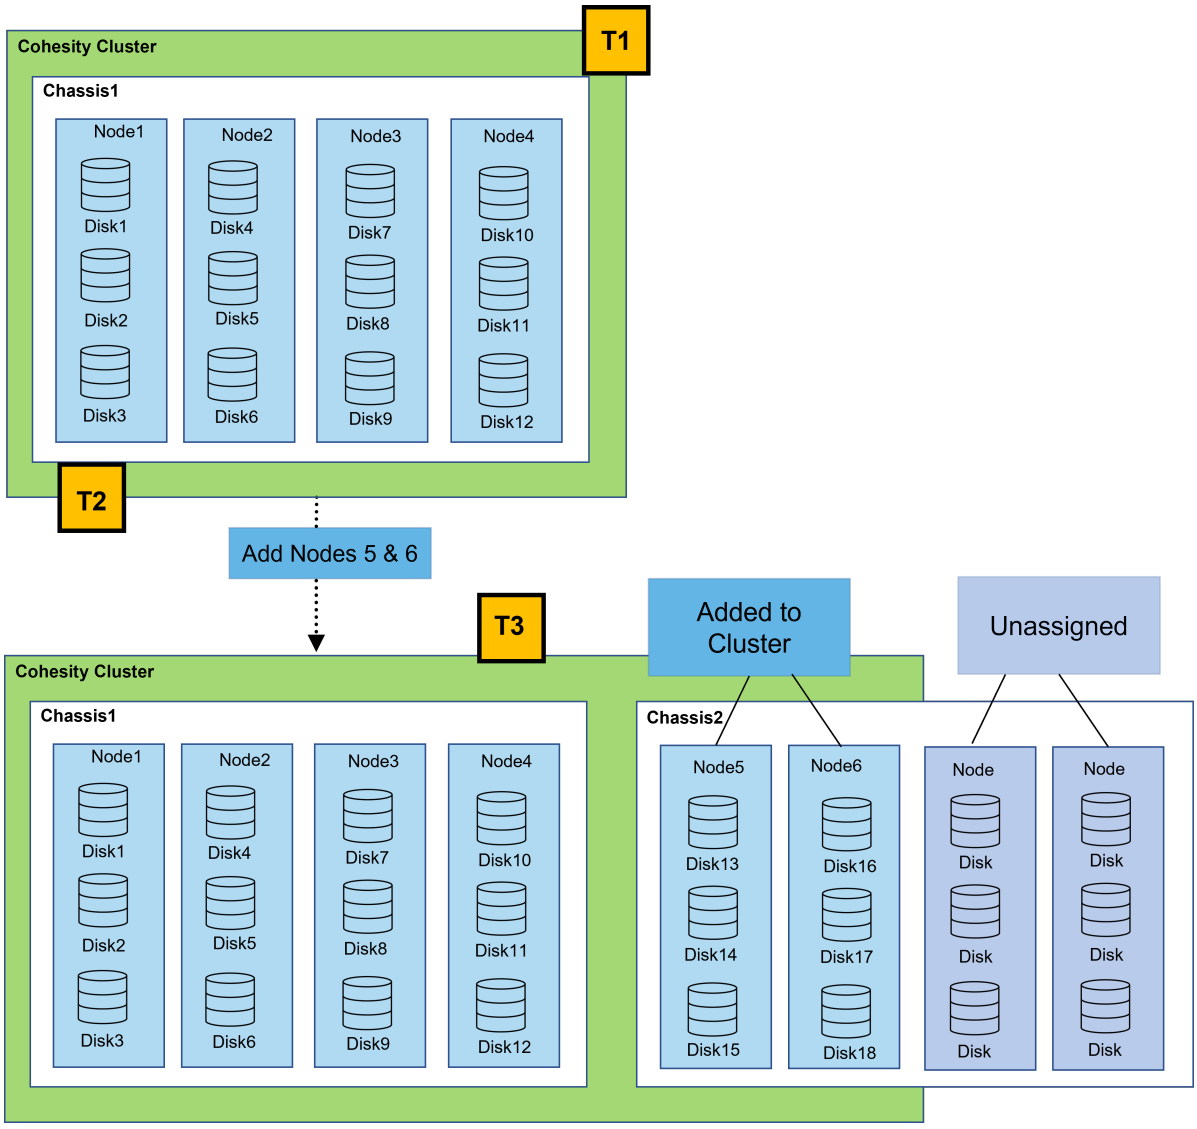
The Cohesity cluster scales out horizontally. To increase the storage capacity and improve performance, you can add additional Nodes to the Cluster as represented by the procedure and figure below. The steps in the following procedure are represented in the figures with black numbered time squares: T1 .

T1) In this example, all the Nodes in Chassis#1 are assigned to the Cohesity cluster.

T2) Using the Cohesity Dashboard, two Nodes from Chassis#2 are selected to be added to the Cluster.

T3) The Cohesity cluster adds the selected Nodes from Chassis#2 to the Cluster. After new Nodes are added, the disk capacity of the Cluster is immediately increased and available for use by Protection Groups, Clone tasks and Recovery tasks. This addition of more Nodes improves performance because additional CPUs, memory, and disk bandwidth are available to the Cluster. Also, the Cluster distributes the blocks from existing Nodes to the new Nodes. In addition, the Cluster replicates the metadata about the block distribution onto these new Nodes.

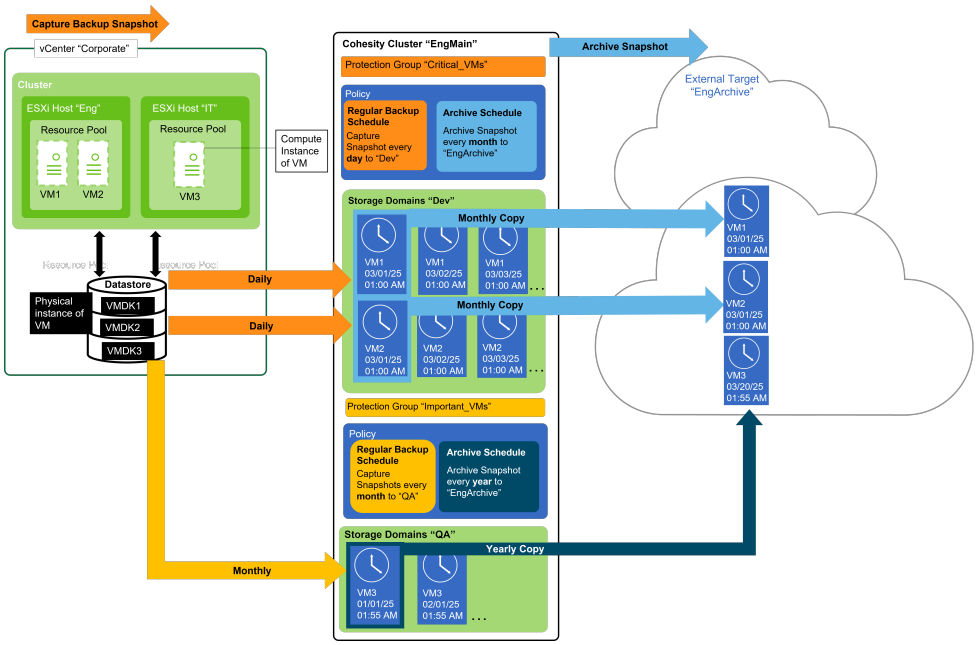
The remaining Nodes in Chassis#2 are unassigned. These unassigned Nodes can be added to this Cluster at a later date or used to create another Cluster with the addition of another Node from another Chassis. (A Cluster requires at least three Nodes.)



About Cloud Archival

The Cohesity cloud archive feature enables you to simplify off-site data management by integrating your archive solution with the Cohesity cluster. Archive's benefits include long-term data retention on low-cost storage to meet compliance and retention requirements. Optional incremental archival and source-side deduplication result in lower cloud capacity consumption, faster archive times and lower network bandwidth consumption during archival and retrieval.

Cohesity archive automatically copies an existing Snapshot created by Protection Groups located in a Cohesity cluster and stores it on a registered External Target.



You specify a protection schedule in a Policy and that protection schedule defines how often a Protection Group using that Policy runs. In the example above, the "Critical_VMs" Protection Group, using a policy with a daily protection schedule, is capturing Snapshots of VM1 and VM2 and storing those Snapshots in the "Dev" Storage Domain. The "Important_VMs" Protection Group, using a different policy with a monthly protection schedule, is capturing Snapshots of VM3 and storing those Snapshots in the "QA" Storage Domain.

You can optionally specify an archive schedule in a Policy. The archive schedule defines how often Snapshots are copied from a Storage Domain in the Cohesity cluster and saved in an External Target by a Protection Group using that Policy. In the example above, the "Critical_VMs" Protection Group is making monthly copies of the Snapshots in the "Dev" Storage Domain and storing those Snapshots in the External Target named "EngArchive". The "Important_VMs" Protection Group is making yearly copies of the Snapshots in the "QA" Storage Domain and also storing those Snapshots in the External Target named "EngArchive".

The archive schedule for copying snapshots cannot be more often than the protection schedule for capturing snapshots. For example if snapshots are captured daily, the Cohesity cluster cannot archive them hourly but it can archive them daily or any value less often than daily.

Register an External Target

To specify an archive schedule for a Policy, you must register an External Target in the Cohesity cluster. Registering an External Target makes it eligible to be used by the Cohesity cluster. Data on an External Target resides outside of the Cohesity environment and is separate from the data stored on the local and remote Cohesity clusters. External Targets

can be cloud or tape and can be used for archiving or as a Cloud Tier. The Cohesity cluster requires the External Target's login credentials so a handshake can occur.

For detailed instructions, see Register an External Target.

External Target Encryption

When registering an External Target so it can receive archive data from your Cohesity cluster, you can choose to turn on encryption. When you turn on encryption, the data is encrypted before it is transferred to the registered Target. Using its own internal key management system, the Cohesity cluster generates a key. This key and data are encrypted and sent to the External Target over a secure channel (SSL).

With this configuration, to accomplish decryption, you do not need to upload keys, nor does the Cohesity cluster integrate with KMS or a similar key management system. When retrieving data from an encrypted External Target, the Cohesity cluster generates a key dynamically (which exists in memory only) that the Cohesity cluster uses to decrypt the key that is stored on the External Target. Only Cohesity knows how to decrypt the data because the key is based on markers within the stored data. Now the Cohesity cluster, and only a Cohesity cluster, can read data from the External Target. Even if an outside entity has access to the External Target, they cannot read the data because they cannot generate a key to decrypt the key stored on the External Target.

You can also restore a Cohesity cluster's archived data from the External Target if you lose access to the Cohesity cluster or data that is on the Cluster. To do this, you must have the lost Cluster's ID and your External Target credentials.

Cohesity recommends you store the cluster ID by registering the cluster at Cohesity Support Portal. Note that performing "clean data" on a Cohesity cluster and then re-installing changes the Cluster ID. Remember to store this new Cluster ID.

Additional Security

If you have selected **Internal KMS** or **KMIP Compliant** as the **Key Management Service (KMS) Type** for encryption, then you can enable additional security for the external target. By enabling additional security, you can manage the key manually instead of Cohesity managing the encryption key for data that is transferred out. If you choose to manage the key manually, then after registering the external target with the Cohesity cluster, you must download the key from the external target's details page and store it in a secure location outside of the Cohesity cluster. With additional security, only the Cohesity clusters where you have explicitly provided the encryption key can download data from that external target. However, the source Cohesity cluster (the cluster that archived the data) does not require the encryption key of the external target.

About Cloud Tier

Cohesity Cloud Tier enables an additional storage tier where cold data can be stored. After you register supported existing cloud storage as a Cloud Tier target with the Cohesity cluster, you can enable Cloud Tier to move rarely used and inactive data to the cloud when HDD used capacity exceeds a set threshold (typically 80%). To reduce the storage cost and network utilization, down-tiered data is always compressed in addition to being encrypted regardless of the cluster and Storage Domain settings. For deduplication, however, the down-tiered data in the External Target reflects the same deduplication settings as in the Storage Domain on the cluster. Cloud Tier benefits include utilizing low-cost cloud storage for rarely used and inactive data, allowing you to reclaim Cohesity cluster capacity for often used data. The actual amount of data that can be tiered to Cloud Tier depends on the deduplication ratio of your data. If the deduplication ratio is high, less data can be tiered to the cloud. As a general guideline, however, Cloud Tier roughly doubles your capacity.

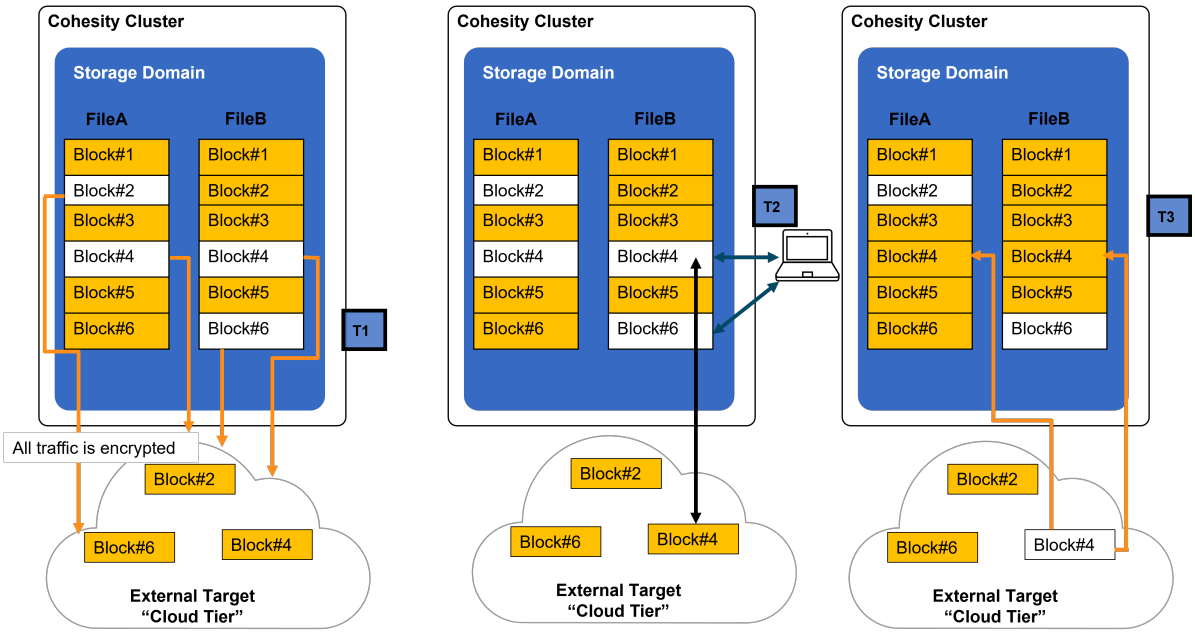
The action steps in the following procedure are represented in the figure below with blue numbered time squares: T1 . The procedure assumes cloud storage is already registered as Cloud Tier and the HDD used capacity is beyond the threshold.

The Cloud Tier process consists of the following actions:

T1) A Cohesity cluster's Storage Domain contains two files, FileA and FileB. Both files contain data blocks that the Cohesity cluster recognizes as cold so it moves the data blocks to the Cloud Tier. Note that files may share data blocks, as indicated by Block#4 in the diagram.

T2) A system accesses FileB data Block#4 and Block#6. The Cohesity cluster recognizes that Block #6 is located on the Cluster and Block#4 is located on the Cloud Tier, but this difference is transparent to the Storage Domain and the system accessing the file.

T3) If, based on additional file access, the Cohesity cluster determines that Block#4 is no longer cold, that data block is moved from the Cloud Tier to the Cohesity cluster.



Register an External Target

To enable Cloud Tier for a Storage Domain, you must register an External Target in the Cohesity cluster. Registering an External Target makes it eligible to be used by the Cohesity cluster.

For detailed instructions, see Register an External Target.

Enable Cloud Tier

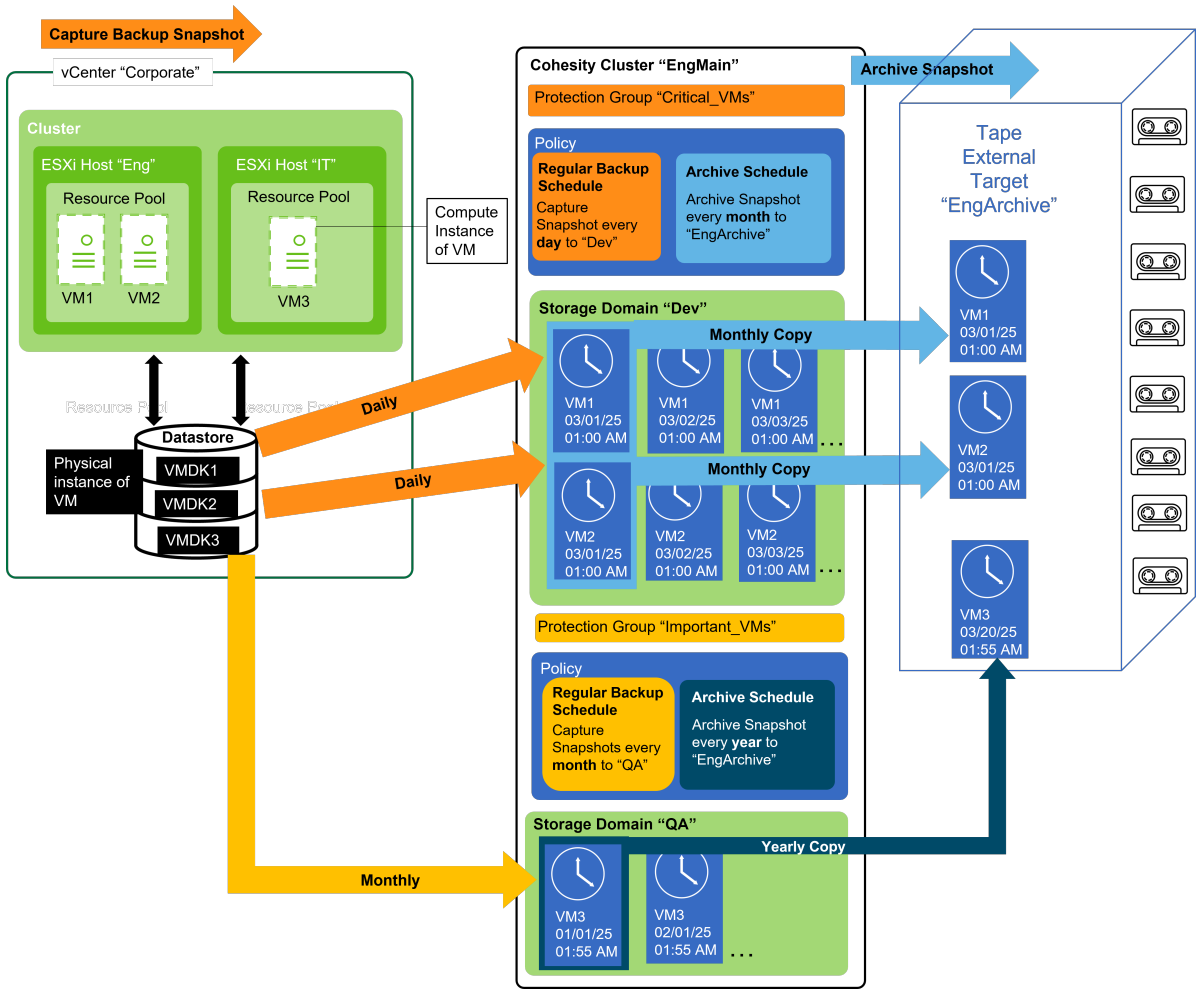
You enable Cloud Tier at the Storage Domain level. For detailed instructions, see Create or Edit Storage Domains.

About Tape Archival

The Cohesity tape archive feature enables you to create tape archives for long-term data retention.

The tape archival feature is supported with the QStar software only.

When archiving to tape, Cohesity automatically copies an existing Snapshot created by Protection Groups located in a Cohesity cluster and stores on a registered tape External Target. The Snapshot is stored in an Integral Volume that has already been defined in QStar. Cohesity software encryption can optionally be turned on. Compression is turned on by default.



You specify a protection schedule in a Policy and that protection schedule defines how often a Protection Group using that Policy runs. In the example above, the "Critical_VMs" Protection Group, using a policy with a daily protection schedule, is capturing Snapshots of VM1 and VM2 and storing those Snapshots in the "Dev" Storage Domain. The "Important_VMs" Protection Group, using a different policy with a monthly protection schedule, is capturing Snapshots of VM3 and storing those Snapshots in the "QA" Storage Domain.

You can optionally specify an archive schedule in a Policy. The archive schedule defines how often Snapshots are copied from a Storage Domain in the Cohesity cluster and saved in an External Target by a Protection Group using that Policy. In the example above, the "Critical_VMs" Protection Group is making monthly copies of the Snapshots in the "Dev" Storage Domain and storing those Snapshots in the External Target named "EngArchive". The "Important_VMs" Protection Group is making yearly copies of the Snapshots in the "QA" Storage Domain and also storing those Snapshots in the External Target named "EngArchive".

The archive schedule for copying snapshots cannot be more often than the protection schedule for capturing snapshots. For example if snapshots are captured daily, the Cohesity cluster cannot archive them hourly but it can archive them daily or any value less often than daily.

Register a Tape External Target

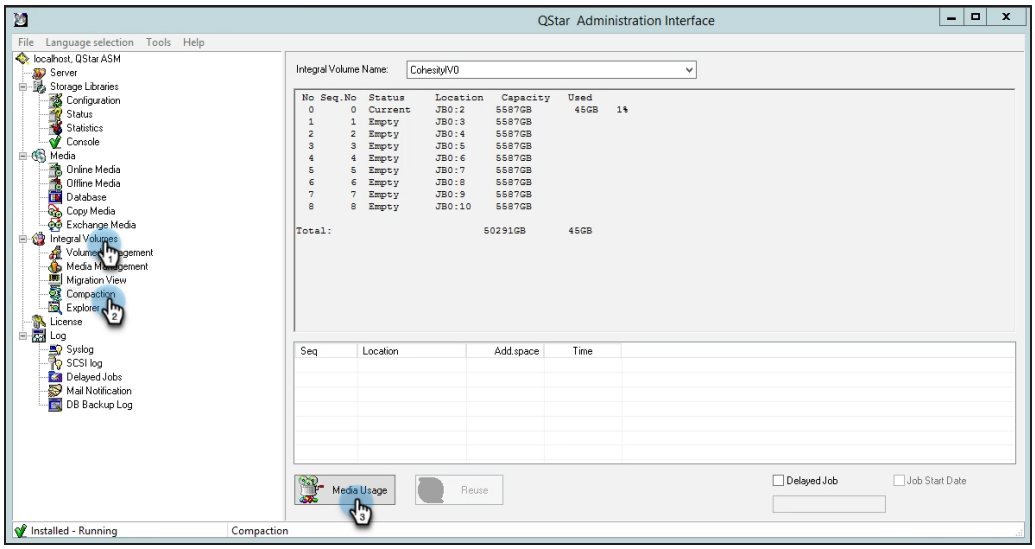
To specify an archive schedule for a Policy, you must register an External Target in the Cohesity cluster. Registering an External Target makes it eligible to be used by the Cohesity cluster. Data on an External Target resides outside of the Cohesity environment and is separate from the data stored on the local and remote Cohesity clusters. External Targets can be cloud or tape and can be used for archiving or as a Cloud Tier. The Cohesity cluster requires the External Target's login credentials so a handshake can occur.

For detailed instructions, see Register an External Target.

How to Reuse a Tape

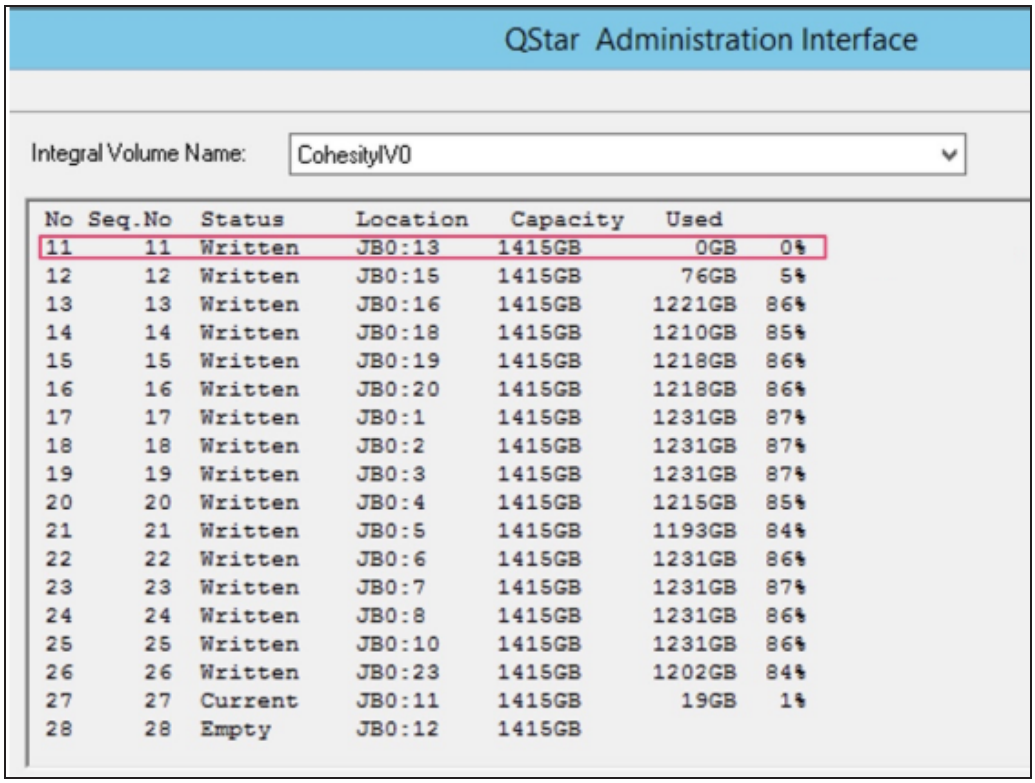
To reuse a tape (QStar), perform the steps below:

1. In the QStar Administration Interface, select **Integral Volumes** > **Compaction**.
2. Click **Media Usage**. This will populate the list of tapes that are online and offline.



3. In the "**Used**" column, look for 0GB (0% utilization). This indicates that there is no active data on the disk. In the example below, JB0:13, shows 0% utilization.

> **Note:** Cohesity recommends to reuse tapes that are 0% utilized.



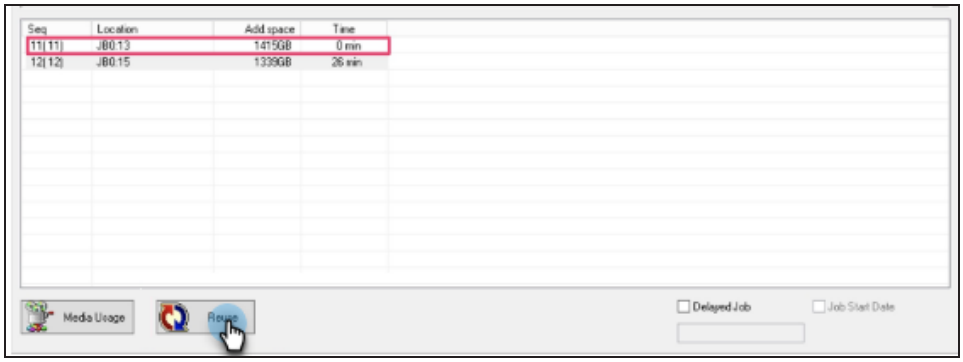
No	Seq.No	Status	Location	Capacity	Used	
11	11	Written	JB0:13	1415GB	0GB	0%
12	12	Written	JB0:15	1415GB	76GB	5%
13	13	Written	JB0:16	1415GB	1221GB	86%
14	14	Written	JB0:18	1415GB	1210GB	85%
15	15	Written	JB0:19	1415GB	1218GB	86%
16	16	Written	JB0:20	1415GB	1218GB	86%
17	17	Written	JB0:1	1415GB	1231GB	87%
18	18	Written	JB0:2	1415GB	1231GB	87%
19	19	Written	JB0:3	1415GB	1231GB	87%
20	20	Written	JB0:4	1415GB	1215GB	85%
21	21	Written	JB0:5	1415GB	1193GB	84%
22	22	Written	JB0:6	1415GB	1231GB	86%
23	23	Written	JB0:7	1415GB	1231GB	87%
24	24	Written	JB0:8	1415GB	1231GB	86%
25	25	Written	JB0:10	1415GB	1231GB	86%
26	26	Written	JB0:23	1415GB	1202GB	84%
27	27	Current	JB0:11	1415GB	19GB	1%
28	28	Empty	JB0:12	1415GB		

4. If the tape is offline:
    1. Select **Integral Volumes** > **Compaction**.
    2. From the "**Seq No**" column, make a note of the sequence number of the offline tape.
    3. Select **Media** > **Offline Media**.
    4. Match the "**Seq No**" with the "**Barcode**" of the tape.
    5. Load the tape that matches the barcode to the tape library.

    > **Note:** Once the tape is successfully loaded, an offline tape becomes online.

5. To reuse the tape:
    1. Select **Integral Volumes** > **Compaction**.
    2. From the bottom pane, select the tape.
    3. Click **Reuse**. This will add the tape to the queue for writing.

> **Note:** Reusing a tape will erase the existing data on the tape.



For the supported workflows for QStar, see Supported Workflows and External Targets.

About Fault Tolerance

Cohesity's highly resilient and fault-tolerant platform ensures organizations can continue conducting business during the following events:

- Hardware or software failure
- Maintenance and upgrades with non-disruptive rolling software upgrades

This topic describes how the Cohesity cluster is highly resilient and fault tolerant.

Cohesity provides fault tolerance at the following levels:

- **Cluster:** The failure domain settings at the cluster level protect the cluster against node, chassis or rack failures. You can specify how many node, chassis, or rack failures the cluster can tolerate while continuing to run and maintain strict consistency. For example, a cluster can survive during a catastrophic hardware (motherboard) failure on a node, a chassis backplane failure, or a power outage on a rack.
- **Storage Domain:** You can configure fault tolerance to survive disk, node, chassis or rack failures at a storage domain level (granular) than at the cluster level (global). A storage domain configured to survive three-disk failures will not lose data even if there are simultaneous three disk failures. In addition, erasure coding (EC) and redundancy factor (RF) levels allow for a further file data resiliency at the stripe level.
- **Metadata**: The Distributed Metadata Store is a fast key-value store containing all the metadata in the Cohesity cluster. It is a fault-tolerant store that Cohesity uses for keeping track of all the data and other stats in the system. Metadata is stored on SSD for performance reasons.

  How metadata is replicated depends on the configured resiliency:

- **1 Failure**: Tolerates either a single node or a single SSD failure.
- **2 Failures**: Tolerates either two nodes or two SSD failures.

For more details on Fault Tolerance and Best Practices, see Cohesity Fault Tolerance—Data Integrity for Modern Web-scale Environments.

Plan and configure fault tolerance based on your requirements. Use the alerts and advanced diagnostics features to monitor and protect your cluster against failures.

Prerequisites and Considerations

Review the following prerequisites and considerations to configure fault tolerance.

Prerequisites

Before you configure fault tolerance, ensure the following prerequisites:

- To enable rack as a failure domain at the global cluster level, every available chassis must be associated with a rack ID.
- All the nodes on a chassis must have the same rack ID.
- Minimum Component Requirements.

  The following table provides the minimum number of components (node, chassis, or rack) required in the Cohesity cluster to tolerate one failure of the respective component.

Component	Minimum Number of Components	Failures Tolerated
Rack	3	1
	5	2
Chassis	3	1
	5	2
Node	3	1
	5	2

Considerations

Before you configure fault tolerance, ensure that you understand the following conditions and considerations:

- You cannot delete a rack after you add and assign it to one or more chassis.
- After a rack is associated with a chassis, you cannot remove a chassis or reassign it to another rack.
- Maximum Number of Failures Tolerated.

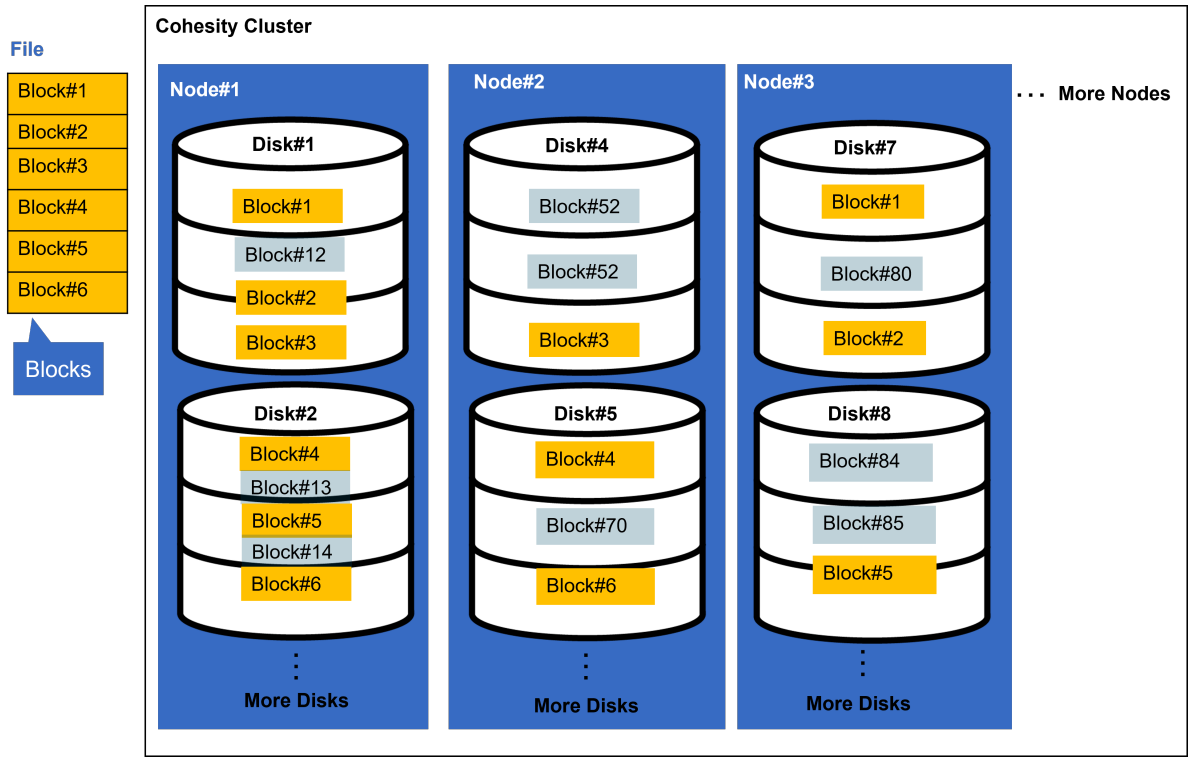
  The following table provides the maximum number of component failures tolerated by a Cohesity cluster.

Component	Maximum Number of Simultaneous Failures Tolerated
Rack	2
Chassis	2
Node	2
HDD	3
SSD	2

For more information about configuring fault tolerance, RF, and EC options at a storage domain level, see Create or Edit Storage Domains.

Data Redundancy

The Cohesity cluster provides data redundancy to protect against disk, node, chassis, or rack failures. When files are stored on the Cluster, the Cluster breaks up the data into blocks that are distributed across the Cluster with a replication factor of two. This means that the Cluster stores two copies of each block on different disks and different Nodes. In the example below, one copy of Block#1 is stored on Disk#1 of Node#1 and the second copy is stored on Disk#7 of Node#3.



If a block is unavailable because a disk or a Node is unavailable and enough disk space exists on the remaining Nodes, the Cluster creates a new block on a different Node and a different disk from the existing copy of the block —always maintaining the replication factor of two. The Cluster makes itself fault tolerant again and no data is lost during this block restoration process.

> **Note:** The Cohesity rebalancing algorithm always creates a new copy of a block on a different disk and a different Node. Therefore, if a disk or Node becomes unavailable, another copy of the block exists on a different disk and Node or disk.

Disk Resilience

If a disk becomes unavailable, the blocks in that disk are unavailable to the Cluster. The Cluster detects that these blocks are under-replicated and replicates them from existing copies of the blocks in the Cluster as shown in the figures and procedure below. The steps in the following procedure are represented in the figures with orange numbered time squares: T1.

The data restoration process is described in the following example steps:

T1) When the Cohesity cluster determines that Disk#10 has errors, the Cohesity cluster generates a `DiskNotHealthy` Alert informing the Administrator of the problem. The

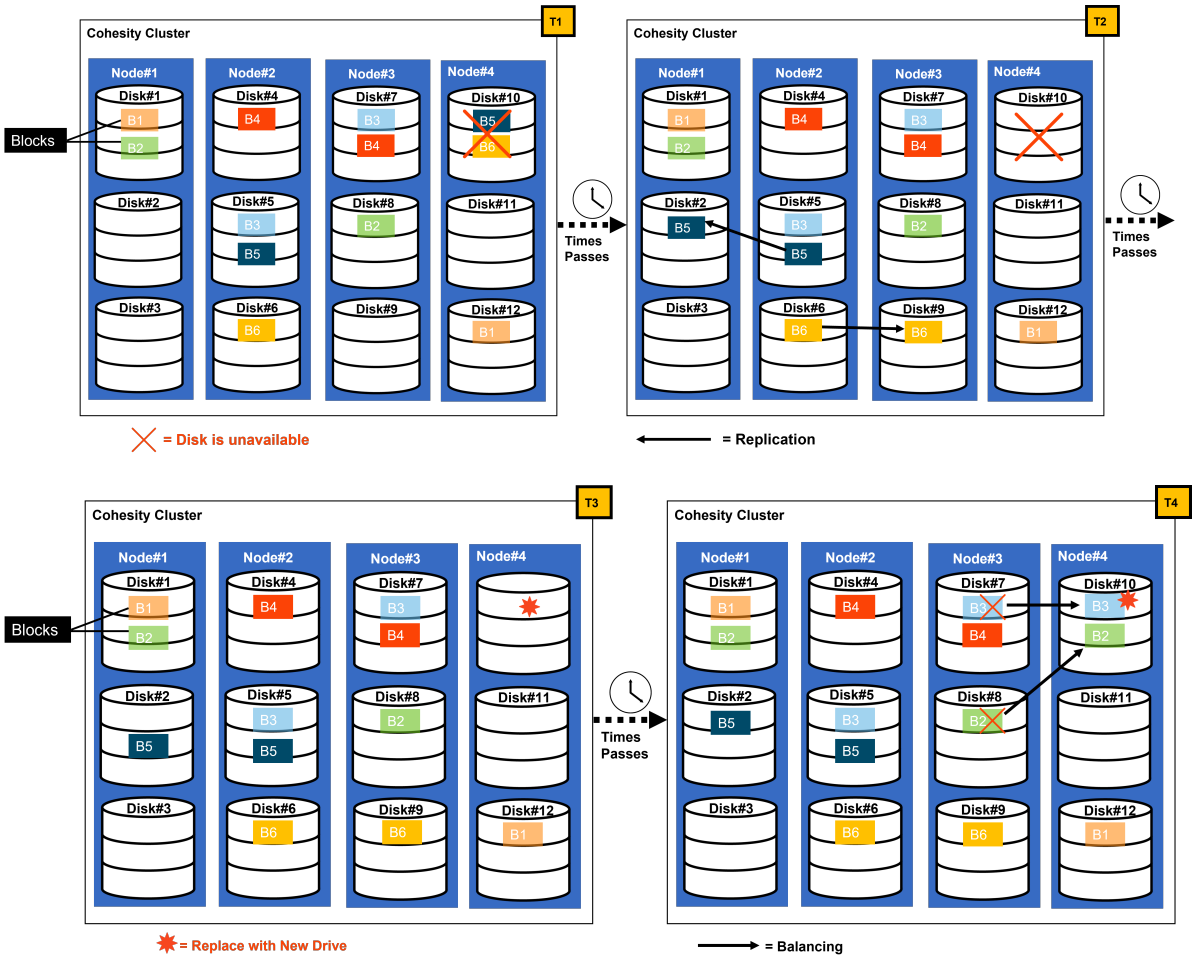
administrator triggers the disk replacement process by marking the disk offline and removing the disk.

T2) The Cohesity cluster periodically scans the blocks and determines that some blocks are under-replicated and replicates them. In this example, the Cohesity cluster determines that there is a single instance of Blocks#5 and Block#6 (because Disk#10 is unavailable) and so it finds the copies of these blocks and replicates them on other Nodes.

T3) An administrator replaces Disk#10 with a new Drive.

T4) The Cohesity cluster assimilates the new disk into the Cluster to restore the disk space capacity. The Cluster also distributes blocks to the new disk to improve performance.

No data is lost during this data restoration process.



Node Resilience

If a Node becomes unavailable, the Disks in that Node are also unavailable to the Cluster. The blocks in the Disks are unavailable and the Cluster detects that these blocks are under-

replicated and replicates them from existing copies of the blocks in the Cluster as shown in the figures and procedure below. The steps in the following procedure are represented in the figures with orange numbered time squares: T1.

The data restoration process is described in the following example steps:

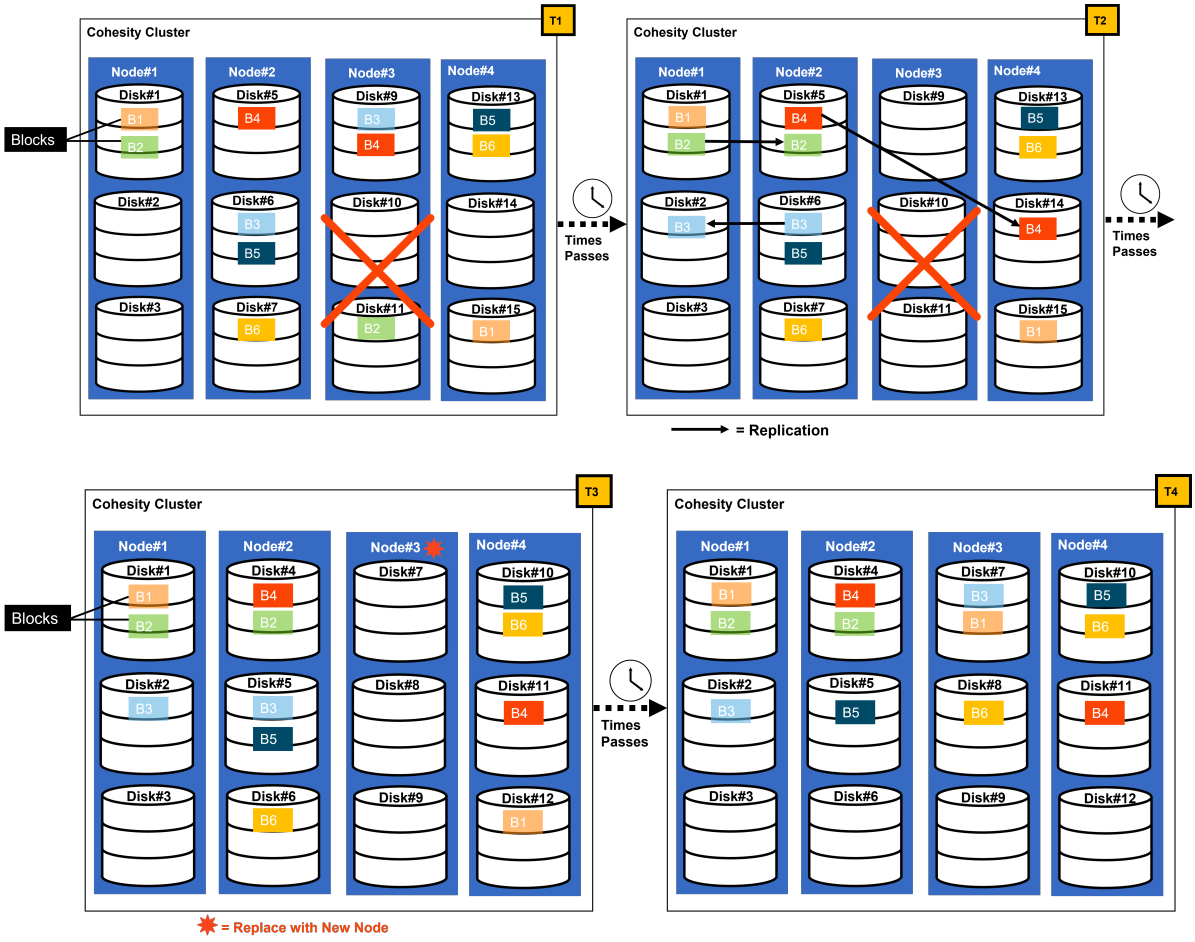
T1) Node#3 and all its disks (Disk#9, Disk#10 and Disk#11) are unavailable to the Cluster. Therefore, blocks (Block#3, Block#4 and Block#2) are unavailable to the Cluster.

T2) The Cluster periodically scans the blocks and determines that some blocks are under-replicated and replicates them. In this example, the Cluster determines that there is a single instance of Block#2, Block#3 and Block#4 (because Node#3 is unavailable) and so it finds the copies of these blocks and replicates them on other Nodes.

T3) An administrator replaces Node#3 with a new Node.

T4) The Cluster assimilates the new Node into the Cluster to restore the disk space capacity. The Cluster also rebalances the blocks to the new Node to improve performance.

No data is lost during this data restoration process.



Node Failure or Node Down on a Three-Node Cohesity cluster

A three-node Cohesity cluster can sustain a node failure or node down and continues to satisfy the I/O read and write requests. The Cohesity cluster has the ability to automatically switch to an appropriate redundancy during a node failure or node down, and switch back when the cluster is restored back to the original state.

For example, if EC2:1 is configured with a fault tolerance setting of 1D:1N, the cluster switches to RF2 to maintain similar levels of data redundancy. Once the node is replaced, the cluster switches back to EC2:1.

A node failure or node down on a three-node Cohesity cluster will cause I/Os to fail under the following scenarios:

- **The cluster is in the process of healing from a previous disk/node failure** - If the data is not fully healed, turning off another node will result in data unavailability.
- **A node on the cluster is reaching its full capacity** - Turning off the node will result in the cluster triggering the healing and filling up space on the other two nodes.

> **Note:** During the above scenarios, the Cohesity cluster can tolerate a quick reboot.

For more details about node resiliency settings, see Disk and Node Resilience Settings.

Chassis Resilience

A chassis is a collection of one or more Cohesity nodes in a single form-factor. A chassis can contain up to four nodes. Cohesity provides protection levels for chassis resiliency that can be set separately for each storage domain. The allowed values depend on the fault tolerance settings. You can select the minimum failures to tolerate and the system adjusts the available options for RF and EC accordingly. For more details about chassis resiliency settings, see Chassis Resilience Settings.

Rack Resilience

A rack is typically a single tower of Cohesity-qualified appliances connected to a top-level switch. A single rack can include one or more chassis. It can also contain client or server machines from other vendors. Cohesity provides protection levels for rack resiliency that can be set separately for each storage domain. The allowed values depend on the fault tolerance settings. You can select the minimum failures to tolerate and the system adjusts the available options for RF and EC accordingly. For more details about rack resiliency settings, see Rack Resilience Settings.

Usable Storage

The following figure shows the formatted usable capacity based on various EC and RF settings. For example, an EC X:2 scheme provides a lower usable capacity than an EC X:1 scheme but a higher resilience by allowing for two stripe unit failures.

Node VIP Fail-over

The Cohesity cluster maintains a pool of Virtual IP addresses that it assigns to the Nodes as needed. If a Node goes down, the Cluster fails over the VIP to a different Node. Network traffic continues to be routed to the same VIP address but processing occurs on the new Node now associated with the VIP. Therefore, any Protection Groups or Recovery tasks running on the original Node continue to run on the new Node without interruption.

Network Redundancy

Each Node in a Cohesity cluster contains two 10 Gigabit Network Interface Controller (NIC) Cards with either SFP+ or RJ45 ports. If both NIC Cards are cabled into switches and one of the NIC Cards fails, the Node can continue to send and receive network requests using the other NIC card because the two NIC Cards are network bonded. Cohesity recommends cabling the two ports of a Node to different switches, so that if one switch goes down, the network traffic can reach the Node on the other switch.

Memory Redundancy

A dual in-line memory module (DIMM) failure either partial or full is considered a hardware component failure. In such cases, the node cannot function and therefore the failed DIMM must be replaced with a new DIMM for the node to resume memory operations.

CPU Redundancy

Each Node in a Cohesity cluster contains two CPU units housed in two CPU sockets. If one CPU unit fails, the Node can continue to process using the second CPU unit. The CPU units can be easily replaced because they are housed in CPU sockets.

Software and Hardware Failures on Cohesity cluster

The following table describes common software or hardware component failures and their Cohesity remedies. During any of these failures, all operations of the cluster, such as backups and recovery, file IO, replication, and archival are unaffected. For most, the self-

healer automatically heals the failure and brings the Cohesity cluster back to a normal state. The scenarios are listed in the increasing order of ease of resolution.

Failure	Remedy
Rack Failure	Cohesity can sustain up to two simultaneous rack failures. A minimum of three racks in your cluster is required to tolerate one rack failure. File data is reconstructed from the surviving rack that have units from the same stripes as the failed rack. This reconstructed data is placed in racks that have available (spare) capacity.
Chassis Failure	Cohesity can sustain up to two simultaneous chassis failures. A minimum of three chassis in your cluster is required to tolerate one chassis failure. File data is reconstructed from the surviving chassis that have units from the same stripes as the failed chassis. This reconstructed data is placed in chassis that have available (spare) capacity.
Node Failure	Cohesity cluster can sustain up to two simultaneous node failures. A minimum of three nodes in your cluster is required to tolerate one node failure. Some aspects for a node or a disk failure are: • Node failure results in both file data and metadata failures. • File data is recovered from the erasure coding or replication scheme. Metadata is recovered from one of the replicas.
HDD Failure	Cohesity cluster can sustain up to three simultaneous HDD failures at any point in time. HDDs are used to store the Distributed File Data. The number of HDD failures that can be tolerated depends on the RF or EC settings. Chunk files are units of replication. Cohesity cluster ensures that there is always a chunk file replica on other nodes, and internal chunk files representing the same user object (or user file) are spread across multiple disks.
SSD Failure	Cohesity cluster can sustain up to two simultaneous SSD failures. SSDs are used to store the Distributed Metadata and the Distributed Journal, and are replicated on either 2 or 3 nodes. Parts of the Distributed Metadata and Journal are stored on every node of the Cohesity cluster. An SSD failure can be considered the same as a node failure.

Failure	Remedy
Network Failure	Each node gets its own Node IP address, a VIP address, and a hardware management IPMI address. The DNS is set up to do round-robin, which gives each VIP a turn to satisfy client read or write requests and equally distributes them across all the nodes. **VIP Failover**: Cohesity cluster has a heartbeat mechanism that detects a node failure. If the directly connected network link goes down, the VIP of the failed node gets reassigned to another node, and node re-balancing similar to a node failure is initiated. Cohesity cluster nodes are typically configured with 2x10GbE connected to two separate switches. This allows for failure of a single switch or a single network port, while still allowing continuous operation. For more details, see Optimal Network Designs with Cohesity.
Boot Device Failure	Cohesity cluster boot device is isolated to a separate partition on flash. Since the Cohesity File System is already saved within persistent hard drives, there is no impact on a boot device crash. There is no inconsistency or file system repair required.
Power Supply	Cohesity cluster supports having a redundant power supply per chassis so that if one goes down, the other can still power the nodes.
Fans	Cohesity support a fan redundancy of N+1 (there is one extra fan per chassis). Hence, they will support one per node and an extra one to cover for failures.

Other Scenarios

The following table covers several other likely scenarios and how Cohesity cluster responds to each of the scenarios.

Event	Response
Node Addition	Cohesity cluster re-balancing is initiated by the self-healer. Every time a new node is added, part of the existing file data and metadata from the remaining nodes is rebalanced to the new node. This is done at a chunk-file level. The larger the cluster size, the faster the re-balancing. Common scenarios for node addition: • Cohesity cluster expansion, for example from 4 to 5 nodes. • Failed node replacement, when the Cohesity cluster size remains the same. For example, one node in a 4-node cluster fails and is replaced.

Event	Response
Node Removal	Node removal involves the removal of a node from the Cohesity cluster. When this happens, the Cohesity cluster re-balancing is initiated. Similar to a node addition, after a node failure or a node removal, the Cohesity cluster is restored. The file data and metadata are rebalanced on the surviving nodes. If the number of nodes falls to 2, there is an alert and the write policy changes from an EC-to an RF-based one, and writes continue. If a replacement node is added, the file data and metadata are re-balanced back to the replacement node. If a node goes down, other replicas ensure that newer disks are selected to store the data chunks that were lost from that node. Common scenarios for node removal from a Cohesity cluster are: • Node removal (graceful) during a hardware refresh. • Node failure. For example, one node in a 4-node cluster fails and needs to be replaced.
Node is Temporarily Down	This occurs when the node is assumed to be non-responsive after a timeout and re-balance has already kicked-in. The self-healer will stop healing (redistributing) when the node comes back. If the healing process is interrupted, some chunks will be over-replicated compared to others, but those chunks will be cleaned up later by the garbage-collection process
Attached Network is Temporarily Down	The node that is not reachable will be considered to be down. The self-healing process kicks in and re-balances the active nodes. When the network to the node is restored, the extra data and metadata replicas are cleaned up by the garbage collector.
Node Failure and Insufficient Space	If there is a node failure and the remaining nodes do not have sufficient available space to support the file data and metadata from the failed node, the self-healer will not perform re-balancing. In such cases, an alert is raised until a new node is added.
Non-Disruptive and Rolling Upgrades	Cohesity cluster architecture allows for a sequential node-by-node upgrade. Nodes can be upgraded to the latest versions without any interruption to client IOs. Any active IO access through the VIP (Virtual IP address) is transferred as the VIP is seamlessly transferred to another node.
Fault Tolerance with Cohesity for the Edge	Cohesity for the Edge is the virtual platform running as a VM on either VMware vSphere or Microsoft Hyper-V hypervisors using commodity hardware. An environment such as ESX or VMware vSAN with shared infrastructure can provide VM/storage migration capabilities on the underlying host failures.

Secure Software Development Practices

Cohesity reviews security at each phase of the software development life cycle. Vulnerability scanners are run to assess the state of the operating system, networking layer and services running on the Cohesity cluster. The scan results give the current open ports

on the Cohesity cluster. Any unused open ports and services are vulnerable. Hence, by default, these unused ports are closed. The kernel or system libraries are also updated for known vulnerabilities.

In addition to using a third-party software to conduct security assessments, Cohesity has its own in-house, dedicated Security Team to assess and improve security hardening in the product for each release.

Cohesity does not use outsourced or subcontracted components in the product. Some system integrators are used to build integration plugins, but that code is quality assurance tested and certified by our Engineering and QA Teams.

Cohesity is certified for FIPS 140-2 compliance.

Our Software Release Lifecycle

Cohesity regularly releases software updates, supporting a variety of capabilities—from new features to fixes. Cohesity software release types and their lifecycles are summarized in the below table.

Release Type	Description	Lifecycle
Feature Releases	Feature releases deliver new features. The numbering format for them follows this pattern 6.8, 7.0, etc.	Feature releases are supported for a minimum of 6 months from the first availability of it. A feature release is available via the controlled rollout process (see section below) and it progresses through various stages before it may earn LTS designation.
Maintenance Releases	Maintenance releases deliver fixes and minor enhancements in a release. They are indicated by the third digit of the release number such as 6.8.1. We may deliver intermediate update releases which contain fixes and minimal enhancements. These releases are represented by "_u<YYYYMMDD>" after the 3 digits, such as 6.8.1_u2 0240415.	The lifecycle of maintenance releases is aligned to that of a feature release and/ or LTS release. Urgent fixes might be addressed with a patch that is always included in all subsequent patch or maintenance releases.

Release Type	Description	Lifecycle
Patch Releases	Patches are urgent fixes delivered for maintenance releases. They are indicated by 'p<YYYYMMDD>' for product fixes and 'p<YYYYMMDD>s1' for product fixes plus CVEs (Common Vulnerabilities and Exposures) fixes. They are provided as needed (about 2 to 6 weeks).	Patches are rolled up cumulatively into the next maintenance release.
LTS (Long-Term Support)	LTS is a designation made for a feature release when specific stringent quality and stability requirements are met. From the moment a feature release earns an LTS designation, it is referred to as an LTS release. Our goal is to have two LTS releases available to customers at any given time.	LTS releases are supported for 12 months from the date of LTS designation and minimum of 6 months of overlapping coverage between two LTS releases and are available to all customers. Customers using LTS releases are encouraged to upgrade to the latest maintenance release as each becomes available.

The diagram below illustrates the software string key.

Release	Software Versioning Scheme	Naming Scheme	Example
Major	SemVer	X.Y _release-YYYYMMDD_SHA	7.0_release-20230925_2fecc890
Minor	SemVer	X.Y.Z_release-YYYYMMDD_SHA	7.1.1_release 20231128_900a8df7
Unified Release "U"	CalVer	X.Y_release-uYYYYMMDD-SHA X.Y.Z_release-uYYYYMMOD-SHA	6.8_release-u20231219-b55c185c 6.8.1_release-u20231219-b55c185c
Product Patch "P"	CalVer	X.Y-pYYYYMMDD ##-SHA X.Y.Z-pYYYYMMDD-##-SHA	7.1-p20240204-00-f210474 7.1.1-020240204-00-210474e
Security Patch "S"	CalVer	X.Y-pYYYMMDDs1-##-SHA X.Y.Z-pYYYYMMDDs1-##-SHA	7.1-p20240204s1-00-f210474e 7.1.1-p20240204s1-00-f210474e
Hotfix	CalVer	«service name»-X.Y_pYYYYMMDD-patch-##-SHA or «service name>-X.Y.Z_pYYYYMMDD-patch-##-SHA	atom-7.1_p20240204-patch-00-f210474e atom-7.1.1_p20240204-patch-00-f210474e

Release Controlled Rollout Process

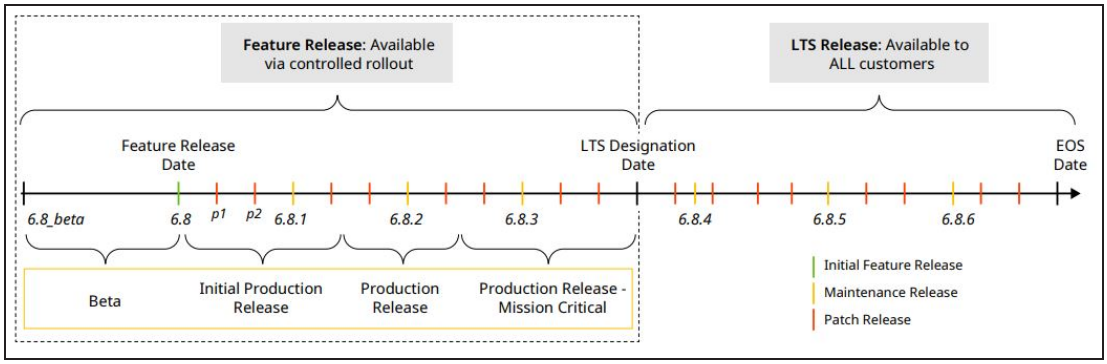
Every feature release is controlled for a while and requires Cohesity approval for access. A controlled rollout process provides staged quality gates to ensure the release is stable and suitable for all production environments. Feature releases follow the standard support processes and customers can request access through the Cohesity account team or Cohesity Support. These releases are only visible to approved customers on downloads.cohesity.com.

Feature Release Stages

A feature release progresses through four stages:

1. **Beta:** This release is intended for non-production environments for feature verification and testing
2. **Initial Production Release (IPR):** This release is intended for non-mission critical workloads.
3. **Production Release (PR):** This release is intended for non-mission critical workloads and proof-of-concepts.
4. **Production Release Mission Critical (PRMC):** This release is intended for all workloads including mission-critical workload.

The diagram below illustrates an example of a feature release progressing through the stages and earning LTS designation:



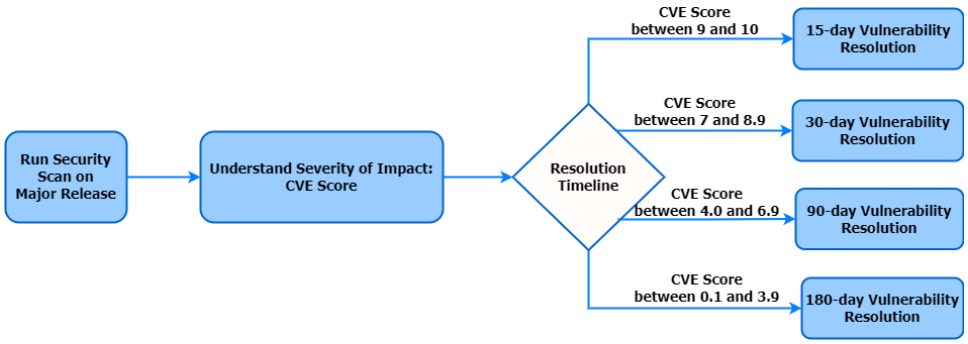
You can refer to the Cohesity Global Support and Services Handbook for more information LTS, Feature, and Maintenance releases.

Security Vulnerabilities

Cohesity's dedicated Security Team assesses and responds to security vulnerabilities reported in the products. We proactively inform customers of vulnerabilities via Support Portal alerts and emails. Knowledge Base (KB) articles are published to document the impact of the vulnerability and any required next steps.

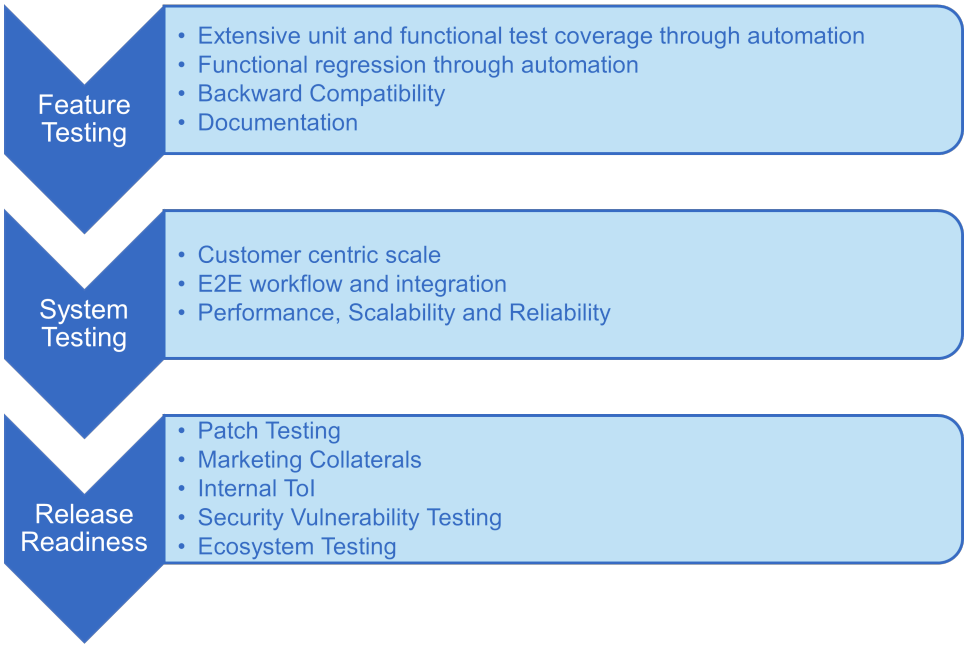
Critical vulnerabilities are prioritized and fixes are generally implemented in the next product release. Cohesity resolves vulnerabilities based on their impact (as evaluated by Cohesity). We provide:

- **15-day resolution**. If the CVE score is between 9.0 and 10.0.
- **30-day resolution**. If the CVE score is between 7.0 and 8.9.
- **90-day resolution**. If the CVE score is between 4.0 and 6.9.
- **180-day resolution**. If the CVE score is between 0.1 and 3.9.



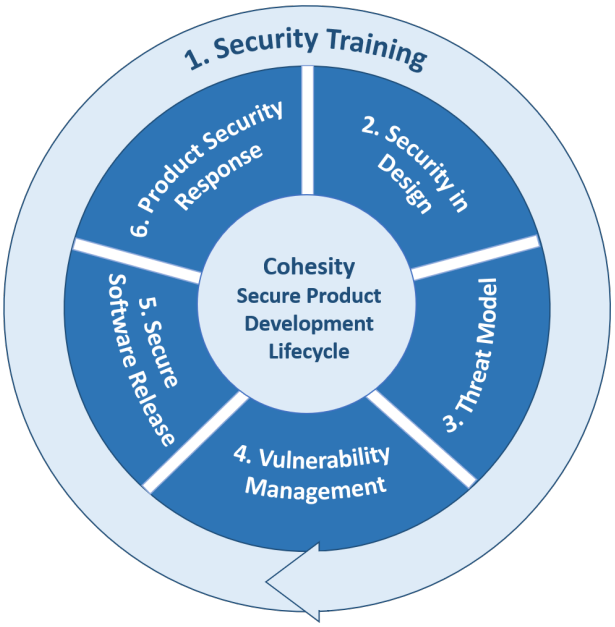
Cohesity Testing Stages

Cohesity performs extensive feature testing, system testing and release readiness testing. The following figure demonstrates the activities performed for each testing stage.



Secure Product Development Lifecycle

Cohesity follows a Secure Product Development Lifecycle to deliver secure products with the security vulnerabilities contained throughout the product's lifecycle. Cohesity follows the following six practices for the Secure Product Development Lifecycle (SPDL).



Security Training

Cohesity mandates secure coding training for all the developers to follow security best practices in product development. Teams in Cohesity such as developers, product managers, development managers, release management, and QA are provided with adequate training, awareness, and resources to influence product security during the product development lifecycle successfully.

Security in Design

In the design phase of product development, security is fundamental to develop highly secure systems and applications. To ensure the products' security posture and compliance or certification requirements are maintained with new features, design documents and design reviews are used to align the product design with the current security best practices. Cohesity follows security principles such as secure by default, fail securely, secure crypto algorithms, and so on.

Threat Model

The threat model is an engineering technique used to identify threats, attacks, vulnerabilities, and countermeasures that could affect an application or system. The threat model assists in design practice to meet security objectives in design and reduce risk. The threat model also helps in effective vulnerability management. Cohesity regularly updates the published product threat model based on new features and changes in threats.

Vulnerability Management

Cohesity adapts some of the best vulnerability management guidances from ISO 27001:2013 Control A.12.6.1 and NIST Cybersecurity framework Version 1.1 (Controls RA-1, RA-5, IP-12, CM-8, MI-3). For vulnerability management, Cohesity follows the following six practices.

Vulnerability Management Policy

Vulnerability management policy defines the severity classification of vulnerabilities based on the CVSS score and SLA for each severity class. It also defines the metrics for the backporting of security defects.

Penetration Testing

Penetration testing of products is conducted using third-party engagement and internal continuous mode using various automated techniques integrated into the release cycle. The potential vulnerabilities found in penetration testing are addressed as per the vulnerability management policy.

Static Code and Binary Analysis

Static analysis security testing (SAST) is an automated testing technique used to analyze source code to identify security flaws. Cohesity conducts static code and binary analysis using well known commercial off-the-shelf (COTS) tools.

Dynamic Scanning

COTS DAST scanners are integrated into the development pipeline to scan all significant development branches. Any vulnerabilities found are addressed meeting the SLA defined in the vulnerability management policy. Automated regression tests of previous vulnerabilities are run to avoid any security regression issues in future releases.

Third-Party Component Security

All imports of third-party components are tested for security risks. The third-party software inventory is maintained to assist in security risk mitigation and third-party component vulnerability patching. Third-party vulnerability patching follows a vulnerability management policy. Third-party component security also covers OEM firmware like BIOS and BMC software.

Product Infra and Tools Support

Engineering infrastructure tools are always maintained up to date, and security protections are configured. Security checks or options for compiler and linker are always enforced.

Secure Software Release

Cohesity follows a secure software release practice that brings predictability to the security posture of software releases. An acceptable level of security quality metrics is defined, and Cohesity ensures that each release meets the minimum goal.

JIRA workflows are defined to track the complete vulnerability life cycle using JIRA labels and fields and hence provide visibility of the release's security posture at any given time.

Product Incident Response

Cohesity uses a product incident response plan that supports analysis, mitigation, and remediation of vulnerabilities in the products. The plan also covers responsible disclosure from third-party researchers and customers.

Secure Acceptance Procedure

Cohesity uses the following procedures to ensure the integrity of its hardware and software products.

Hardware

Cohesity products are built by contract manufacturers (CM). CMs ensure the integrity of the products by:

1. Building to controlled specifications documented in Cohesity's Product Lifecycle Management (PLM) system and their shop floor control systems.
2. Performing tests jointly developed by the CM and Cohesity.

Software

The software image provided to customers is protected by using the SHA256 and MD5 hashing technique.

1. The customer logs on to the Cohesity Support Portal.

   In the downloads section, a link to a software package is provided, along with the corresponding MD5 checksum and SHA256 for the software package.
2. The customer downloads the software package and compares its checksum with the checksum provided on the Cohesity Support Portal. They might use commands such as:

   ```
   md5sum <software-package>.tar.gz
   sha265sum <software-package>.tar.gz
   ```
3. If the MD5 checksum or SHA256 values do not match, the integrity of the software package may have been compromised. The customer can try downloading the software package again to resolve the issue. If necessary, they can contact Cohesity Support for further assistance.

Cohesity Security Features

This topic explains how Cohesity builds security into the Cohesity cluster and is intended for:

- Administrators responsible for the configuration, maintenance and operation of the Cohesity cluster.
- Security engineers reviewing Cohesity for compliance with their company's security policies.

The Cohesity cluster provides the following security features.

Data Segmentation

The Cohesity cluster architecture provides virtual data isolation through Storage Domains. Each Storage Domain encrypts the data stored in it using its own independent keys.

During initial cluster setup, encryption can be enabled for the entire cluster so that the data in all Storage Domains will be encrypted. If encryption is not enabled during cluster creation, it can be enabled at the Storage Domain level. Note that once encryption is set during cluster or Storage Domain creation, it can not be disabled later.

Each Cohesity View is assigned a Quality of Service (QoS) Policy. A QoS Policy determines the priority of I/O (when contention occurs).

Data at Rest Security

The Cohesity file system provides full at-rest encryption based on the strong AES-256-GCM (Galois/Counter Mode) standard. Only 256-bit keys are used for encryption. The encryption architecture provides high security while maintaining the flexibility to optimally leverage the available hardware and software resources.

The built-in software-based encryption is hardware-accelerated through the latest Intel processors that support the AES-NI instruction set. Due to hardware acceleration, the software-based encryption route has minimal impact on performance.

Keys can be obtained in three ways:

- Internal Key Manager
- External Key Manager
- Cloud-based Key Manager

Keys can be rotated periodically. The default rotation is set to 90 days.

User data is encrypted before it is stored on any storage media used. The data is decrypted after it is read from the storage media in memory. The storage media can be SSD, HDD, tape, and cloud storage. This includes credentials for data sources protected by Cohesity.

Physical agents are designed to respond solely to cluster-issued commands. Thus, they do not have the ability to extract data, such as credentials or other sensitive information, from the cluster.

Data in Transit Security

The data being transmitted to a Cohesity cluster or being transmitted from a Cohesity cluster to External Targets is encrypted for security. Examples of data movement are ingesting data from a primary site, replicating between remote offices or transmitting data to public cloud.

The agent encryption cipher in use can be viewed in the Pulse logs or the agent report per the UI changes.

Primary Site to a Cohesity cluster

When the Cohesity backup software ingests data from the primary storage, it first establishes a secure connection with the primary storage over HTTPS. Cohesity backup software determines which data blocks have changed from the previous backup run by communicating with the primary storage over the secure connection, and then transfers all the changed blocks over the HTTPS connection.

Communication between the Cohesity cluster and Cohesity backup service (agent) is secured using SSL/TLS integrated transport. They perform mutual authentication and all data exchanged is encrypted.

The encryption is done using the Advanced Encryption Standard-256 protocol. The cipher suites used for backups through agents are:

1. `TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384`
2. `TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA38`
3. `TLS_RSA_WITH_AES_256_GCM_SHA384.`

Replication from One Cohesity cluster to Another

A source Cluster starts a replication session by initiating a handshake with the target cluster over an HTTPS connection. Upon receiving the handshake request, the target Cluster obtains a session key from its local Key Management Server and sends it to the source cluster over the HTTPS connection.

The source Cluster stores the received session key in its local Key Management Server and completes the handshake. At this point, both the source and the target Clusters have the session key.

The source Cluster uses the session key to encrypt the data and transfer it securely for that replication session. The encryption uses Advanced Encryption Standard-256 protocol in Galois/Counter Mode (AES-256-GCM).

Data in Cloud Security

The cloud can be used:

- As another tier of storage (Cloud Tier)
- To store long-term retention copies (CloudArchive)

- Archive data directly to an external target without retaining a copy of the data on the cluster (CloudArchive Direct).

Cohesity supports all the major cloud vendors, including Amazon, Microsoft Azure, Google and Oracle, and any S3-compatible storage.

- You register the cloud storage as an External Target on the cluster and provide the cloud storage access keys. The access keys are encrypted and stored on the Cohesity cluster using AES-256 encryption in Galois/Counter Mode (AES-256-GCM). You can update the access keys from the Cohesity Dashboard or by using the Cohesity REST API. (Cohesity does not rotate the access keys.)
- Though the access keys are specific to the cloud storage provider, the Cohesity's key storage security is the same regardless of the cloud provider. Cohesity is FIPS certified and has an internal software-based key management system (KMS) that stores the key encryption key (KEK).
- Cohesity establishes a connection to the External Target *only* when making REST API calls to perform an archive or recovery operation.
- Cohesity does not include the External Target access keys in the API request. The request is signed using the External Target's access key and the signature is sent using the Authorization request header.
- Cohesity uses TLS 1.2 to encrypt in-transit data. Currently, Cohesity does not use mTLS (2-way SSL) in communication with External Targets.

CloudArchive and CloudArchive Direct use their own encryption, independent of data-at-rest encryption. The cipher suite used for encryption is `AES-256-GCM`.

- Cloud Archive encryption is on by default but can be turned off. Cohesity recommends keeping it on.
- Both the data encryption key (DEK) and KEK are encrypted, distributed for resiliency across the cluster and stored in SSD.
- The cluster creates a new DEK for each External Target. Cohesity provides two options. You can:
  - Store the data, metadata and encryption keys (DEK/KEK) in the External Target.
  - Store the data, metadata, and DEK only in the External Target. This requires the KEK to be downloaded and stored outside of the cluster. Without the downloaded keys, future CloudRetrieve operations will not be possible.

For Cloud Tier, encryption is always on and cannot be turned off.

Key Management

A Key Management Service (KMS) helps you manage the keys that encrypt data and secures it from unauthorized access. The Cohesity cluster has a built-in key manager or can

be configured to use external key managers - KMIP-based and Amazon Web Services (AWS) KMS - to manage encryption keys.

Ports Employed

For a list of firewall ports used by the Cohesity cluster,

Cluster Management Methods

The Cohesity cluster can be managed using the following methods:

- The Cohesity Dashboard web browser interface.
- The command line interface (CLI) available for Linux, Windows and iOS systems.
- The REST API endpoints on any platform using a REST client.

All access methods listed above require an SSL connection, and the Cohesity cluster prioritizes TLS 1.3. For backward compatibility, TLS 1.2 ciphers are also supported, but administrators can disable TLS 1.2 for enhanced security. The connection uses strong ciphers for the established session. To update the cipher list, see iris_cli cipher update. When the Cohesity cluster is created, a self-signed X.509 certificate (PEM format only) is generated for this purpose. The certificate must have the "Common Name" field set to the server's hostname (for example, a VIP's DNS name). Certificates are stored in the boot disk. They are replicated to other Nodes as part of Cluster formation using RPC calls. When the key expires, the web browser marks the session as invalid. Users can import new certificates to re-establish the session.

Users can overwrite this X.509 certificate according to their company policy.

Authentication

Authentication is required for all management methods (the Cohesity Dashboard, CLI and API). Only a user with an account on the Cluster can authenticate to the Cluster. Cohesity supports three types of accounts.

- **Local User Account**—A user account is created locally on the Cluster. This user can access only this Cluster. When the account is created, a password is assigned to the user and required to authenticate to the Cluster. This password is stored on the Cluster.
- **Active Directory**—A user account that exists on an Active Directory server. This user can access all the Clusters that have joined the Active Directory. The user uses the Active Directory password to authenticate to the Cluster. The Cluster authenticates the user with Active Directory. The password is not stored on the Cluster.
- **Single Sign-On** - A Single Sign-on (SSO) user account that uses the supported

Identity Provider (IdP) to authenticate to the Cohesity cluster. Cohesity supports major IdP vendors such as Okta, Duo, Ping, and Azure AD.

Protocols and Authentication

The Cohesity cluster can authenticate users defined locally in the Cluster and users defined in Active Directory. NFS uses allowlist-based access control. SMB uses Active Directory for authentication and authorization. Anonymous access, which doesn't require authentication, is not allowed for SMB.

Kerberos Authentication Protocol

Kerberos can be enabled for stronger authentication for SMB by joining the Cohesity cluster to Active Directory. Cohesity supports only Active Directory-based Kerberos authentication.

Client Side Protocols

Cohesity supports the SMB, NFS and S3 protocols.

SMB Protocol Security

Cohesity supports two types of authorization data on a file: Windows-style access control lists (ACLs) and POSIX mode bits (UNIX permissions). ACLs are used when a file is accessed from SMB. POSIX mode bits are used when a file is accessed via NFS.

Access Description	Supported	Notes
Access-control lists (ACLs)	Yes	Windows-style ACLs
Windows-style (NT) credentials for UNIX users	No	Not supported in NFS v3
SMB access of UNIX-created files	Yes	
NFS access of Windows-created files	Yes (with root access)	
Home directory permissions	Yes	Windows-style ACLs

NFS Protocol Security

- NFS access is controlled via IP addresses mentioned in the Allowlist. Client IP addresses that are mentioned in the Allowlist are allowed to mount an NFS share.
- The Allowlist is set at the Cluster level and View level override is available.
- Cohesity supports RPCSEC_GSS protocol for NFS.

Mixed SMB and NFS Environments

Beginning with version 6.0, support for mixed-permission environments is available. The supported scenarios are:

- A UNIX client can store and access a file over NFS.
- A Windows client can store and access a file over SMB.
- A UNIX client can connect by NFS to a file that was stored on the Cluster by a Windows client over SMB and access it based on the permissions.
- A Windows client can connect by SMB to a file that was stored on the Cluster by a UNIX client over NFS and access it based on the permissions.
- Data can be written at the same time to a file via NFS or SMB.

AWS S3

Cohesity supports:

- S3 server over HTTPs.
- Authentication with AWS Signature Version 2 and Version 4.
- AWS ACLs.
- Access controlled via allowed subnets.

Authorization

Authorization is implemented at two levels.

- The operation level, where operations are restricted to authorized users only.
- The object level, where objects are restricted to authorized users only.

The Cohesity cluster can also be added as an Active Directory domain.

Role Based Access Control (RBAC)

A role is a collection of operations, such as creating a View or deleting a Protection Group. A role grants authorization to perform one or more operations. Cohesity provides default roles such as Admin, Operator, Viewer, and Data Security. Customers can create custom roles. A user can have multiple roles but must have at least one role to log in to the Cluster.

A user can be assigned a set of objects on the Cluster. The user is authorized to access only those objects and perform operations on them allowed by the role assigned.

Accounting

Accounting is implemented at two levels.

- The operation level, where each operation is tracked.
- The file level, where each file access is tracked.

Audit Trail

Every user operation that changes the Cluster is audited and the audit log is saved. The log contains the original value and the value after the operation. For a list of logged operations, see Audit Logs. Cohesity stores audit logs on the Cohesity cluster. Users can read them using the standard NFS, SMB and S3 protocols and can export the logs to a syslog server.

Compliance

The following sections explain how Cohesity addresses various guidelines and specifications.

Federal Information Processing Standards (FIPS) Compliance

The Cohesity cluster is FIPS 140-2 certified. The encryption module has been validated on the Cohesity cluster with NIST for FIPS certification. The encryption module always operates in FIPS mode. You can find detailed information in the *Cohesity FIPS 140-2 Non-proprietary Security Policy* on the NIST website.

Common Criteria (EAL2+ Certification)

Common Criteria is an internationally recognized set of guidelines for evaluating IT security products. Common Criteria:

- is a catalog of criteria, and a framework for organizing a subset of the criteria, into security specifications
- is a methodology for evaluating security features
- can be applied to hardware, software, firmware or a combination thereof
- allows vendors to describe a product's security functionality with proof to support their claims

Cohesity realizes the value of being a Common Criteria participant. To view the CC certificate, see MyCC.

DoDIN APL Certification

Cohesity is DoDIN APL certified. The Department of Defense Information Network (DoDIN) Approved Products List (APL) is the single consolidated list of products that have completed Cybersecurity (CS) and Interoperability (IO) certification. DoD customers are allowed to select products for purchase from this list.

The DoDIN APL process is a rigorous security testing, validation, and certification process. This certification's security functional requirements come from a best practices guide called Security Technical Implementation Guides (STIG). It includes application security, OS hardening, web server security, and networking security as well. Cohesity adheres to these highest security standards.

As part of the DoDIN APL requirements, Cohesity provides the following security features:

- Login banner support
- Transfer audit logs to a Syslog server over a secure TLS connection.
- Certificate mapping-based authentication support
- Support to configure the classified or unclassified banner.
- Node-to-node encryption.

WORM (Write Once Read Many SEC 17a-4(f) Certification)

Long-term records retention is mandated by regulations and compliance rules, for example:

- In the financial services industry, SEC Rule 17a-4(f) specifies that "electronic records must be preserved exclusively in a non-rewriteable and non-erasable format."
- Other industries must meet similar requirements when they store mission-critical information.

WORM technology addresses these requirements by providing immutable locking and secure data retention capabilities.

Cohesity implements WORM as *DataLock* Views. DataLock Views are locked (read only) for a user-specified time period. Any user who has access to the View can clone a copy of the View as a DataLock View and set the lock retention time. During that time period, only users with Cohesity Data Security privileges can delete the cloned View, extend the lock period (it cannot be reduced) , add allowlisted IPs, change the QoS and change the description of the View. After the lock period expires, the View can be deleted by any user who has permission to delete it.

A replicated or archived DataLock View retains its DataLock properties. A DataLock View can be cloned to a regular or DataLock View.

General Data Protection Regulation (GDPR)

GDPR is an EU regulation designed to strengthen data protection for residents of the EU. It became effective on May 25th, 2018, and applies to any company controlling or processing Personally Identifiable Information (PII) of EU residents, regardless of the location of the company.

GDPR imposes a broad set of legal, governance and technical requirements on companies processing personal data. A subset of these requirements—those related to data protection and data management—are particularly relevant for storage platforms used to store personal data.

Cohesity has a strong vision to enable our customers to be at the top of their GDPR compliance. The tools and product functionality that Cohesity provides as part of its vision fall into the following categories:

Protect

- Mandate
  - GDPR mandates data protection by design and by default, making privacy by design an express legal requirement.
  - Organizations should also be able to demonstrate transparency when validating compliance.
- Features Offered
  - Encryption architecture, based on strong AES-256-GCM standard and has a FIPS-Certified mode, provides high end-to-end security while allowing optimal use of available resources.
  - Granular control through Role Based Access Control and strong Active Directory integration
  - File or view level WORM provides immutable locking and secure data retention capabilities

Minimize:

- Mandate
  - GDPR mandates data minimization as one of the main tenets to ensure that companies maintain reduced amounts of stored personal data.
  - Here, PII needs to be kept only for the time period relating directly to the original intent of capturing the data.
- Features offered
  - Cohesity architecture inherently minimizes data copies, reduces attack footprint, and tracks copies through centralized data management
  - Granular control over and automation of retention policies enables customers to keep PII only for intended periods
  - Effectively relocate files to on demand to minimize the spread of PII data

Locate:

- Mandate
  - GDPR mandates getting a 360-degree view of what PII is stored by an organization. In addition, the organization should be aware of:
    - What PII they store and why
    - Where does it come from
    - Where the data is stored, and the retention policy on the personal data
    - Who has access to the data
    - And, monitor the movement of the data

- Features Offered
  - Scheduled update to data maps that delineate the following:
    - Location and Movement Tracking (source & destination) of PII
    - Categories of PII stored
    - File containing PII
    - Retention policies of PII
    - Access rights to PII
  - Leverage Cohesity reports to complete Data Protection Impact Assessments (DPIAs), if needed.

Search:

- Mandate
  - GDPR mandates that any EU resident can request visibility of PII from a company.
  - They can also request for the PII to be deleted, modified/corrected, or exported out.
- Features offered
  - Search within unstructured data for multiple categories of PII
  - Input PII patterns and their variations, and file types (txt, doc, pdf, xls, zip, jpeg) to scan using templates
  - Inject custom code to run data processing jobs on stored data using in-place analytics tool
  - Report search results in txt file format or integrate with 3rd party data visualization or analytics tools

Monitor

- Mandate
  - GDPR mandates companies to monitor for and report security breaches.
  - Companies are obliged to communicate breaches to relevant supervisory authorities, and to affected individuals in certain cases.
  - Demonstrating appropriate reporting procedures post-identification of a breach can validate compliance.
- Features offered
  - Prevent portability of PII using Allowlists
  - Receive notifications or warnings when data is tiered, archived, or replicated to a non-Cohesity target
  - Receive a notification when data leaves EU while still on Cohesity
  - Ability to export cluster and system-level audit logs for additional analytics and breach detection

Payment Card Industry Data Security Standard (PCI DSS)

Cohesity adheres to the security benchmarks and requirements that are mandated by the PCI-DSS, including the following:

- authentication and access
- logging and auditing
- browser, plug-in and / or third-party software requirements
- management systems and software
- releases, patching and updates
- granular service controls
- exposed protocols
- monitoring, alerting and call home

Cohesity can provide details on demand.

Secure Government Clouds

Cohesity supports AWS GovCloud and Azure Government Cloud, and is working towards C2S support.

Trade Agreements Act (TAA)

All Cohesity appliances are compliant with the Trade Agreements Act (19 U.S.C. & 2501-2581) and ship from San Jose, CA.

Authorization to Operate (ATO)

Cohesity has the following:

- ATO for highly classified US Department of Defense (DoD) agency networks.
- DoD customers have created STIGs for Cohesity on DoD top-secret networks.
- ATO for highly classified Department of Energy networks.
- ATO for US Air Force networks that support mission-critical programs including the Air Force GPS ground systems.
- Support the US Intelligence Community on many programs.

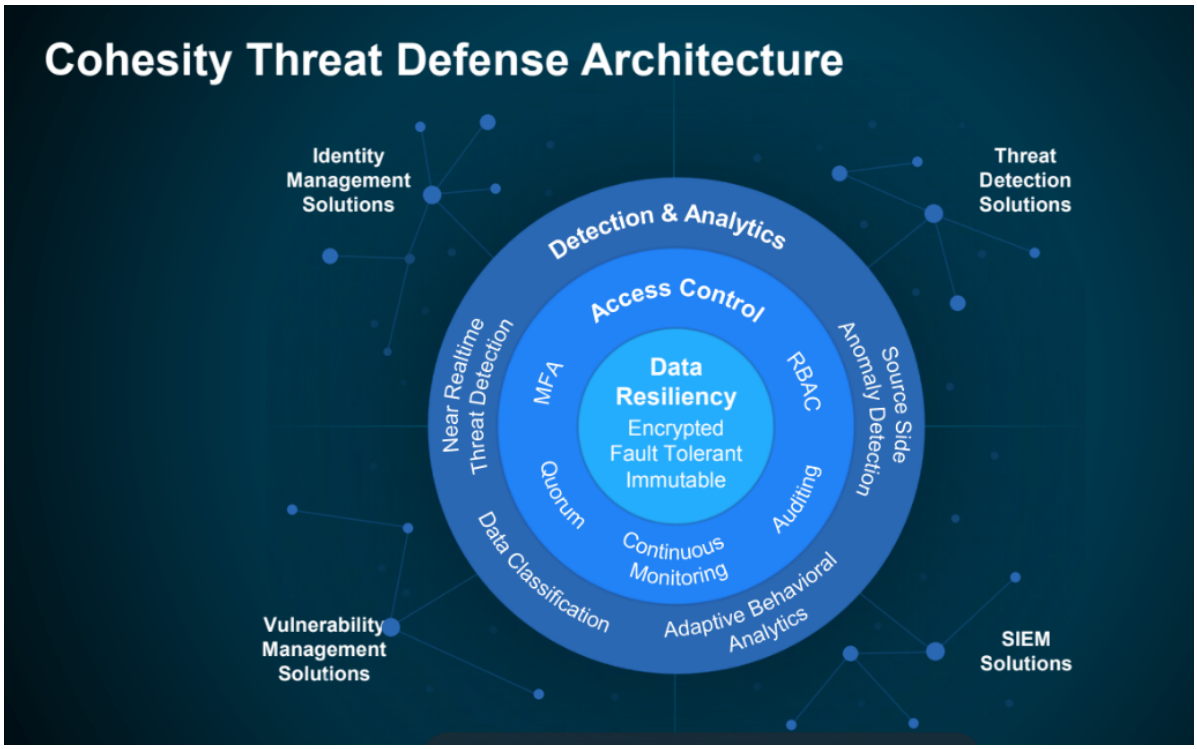
Secure Data from Ransomware Attacks

Threat Defense Architecture

Cohesity's Threat Defense architecture is designed to help you combat threats against your data in the cluster by enabling you to achieve outcomes related to data protection, compliance, operational resiliency, and defense against sophisticated attacks.

For instance, these outcomes include:

- An ability to rapidly recover from a ransomware attack.
- Resilience of the data against aggressive attacks that actively target the data protection platform.
- An ability to recover from both operational and data center failures.
- Compliance through immutable and tamper-resistant data archives.



Cohesity Data Cloud

At its core, Threat Defense architecture is about providing a highly resilient platform that ensures confidentiality, availability, and integrity of the data with encryption, fault tolerance, and immutability built into the Cohesity Data Cloud.

The Cohesity Data Cloud is built around a hardened, self-contained Linux-based operating system (CohesitySpanOS) specifically designed to serve as a data management platform.

> **Note:** Cohesity's data protection application does not run on general-purpose operating systems such as Windows.

The SpanOS kernel operates with SELinux extensions enabled in enforcing mode by default. This helps restrict privilege escalation and file modification, and confine access to services to ensure zero-trust security. Cohesity SpanOS is not accessible to users.

Services

Services and subsystems on the Cohesity Data Cloud remain isolated with established APIs and other secure communication mechanisms used for service-to-service communications. Services that are essential to the operation of the cluster are installed and enabled, and other services included in general-purpose Linux distributions are not included on the Cohesity Data Cloud. This helps minimize the attack surface area of the Cohesity Data Cloud.

Cohesity Data Cloud includes an in-built firewall that minimizes the network surface area of the cluster, therefore, only exposing ports and services necessary for cluster operation based on the configured operation.

Cohesity SpanFS

Cohesity SpanFS is an immutable file system. It ensures strict consistency of data across nodes within a cluster to provide data resiliency. Immutability ensures that WORM-protected data cannot be deleted or modified by any process or user including cluster administrators. Only the backup service running on the Cohesity cluster can write to the file system through trusted APIs.

DataLock

DataLock enables your storage to be WORM-compliant (Write-once-read-many) and restricts any modification of backup snapshots. You can refer to Create or Edit a Standard Policy to learn more about creating or editing policy that includes DataLock.

Data Operations

In a Cohesity cluster, data integrity is maintained through multiple integrity checks whenever data is read or written. Data is securely written to the Cohesity Data Cloud. This means data is always written in empty space and never overwritten.

> **Note:** Every read or write operation to internal views is sandboxed.

Encryption

Data at rest and data in-flight encryption using FIPS-validated cryptography are employed with support for external key management.

Air Gap Protection

Cohesity Data Cloud can be configured to achieve air-gap protection that allows you to maintain a physically isolated network. Refer to Cohesity's Solutions for Air Data Protection to learn more about air-gap protection.

Zero Trust Access Control

Data resiliency is further augmented with comprehensive access control capabilities that ensure that entities accessing the data management platform conform to Zero Trust

principles.

Authentication

Cohesity supports a wide range of user authentication options, including a local user store (with in-built support for multi-factor authentication), integration with external identity providers, and certificate-based authentication (including support for smart cards). Besides native, in-built support for multi-factor authentication, Cohesity can also integrate with SAML-based authentication providers.

Access Control

Administration relies on role, object, and tenant-level access controls to ensure that Cohesity users are provided with the least privilege on the system. Access to the shell via SSH is disabled by default and can be controlled with organizational security policies. By default, you have read-only permission. Multi-man approval protocols are required for sensitive operations such as escalating privileges. Cohesity Support cannot access a cluster for troubleshooting unless explicitly granted limited-time permission by a cluster administrator. By default, read-only permission is granted.

Credentials Management

Each locally managed credential on the Cohesity Data Cloud is securely stored as a cryptographic representation of the credential and not in plaintext format. Therefore, you can reset it from factory defaults. In addition, security policy, which is enabled by default, can enforce password length and complexity rules and force password changes regularly to minimize the risk of brute force attacks.

Access to API

User and API access to the Cohesity Data Cloud are strictly controlled. Cohesity conforms with Zero Trust principles. This means that a user can access the Cohesity cluster only if they have the required permissions on the objects and files, and have been authenticated through any authentication protocol in the cluster. You can additionally control access to Cohesity APIs with rotatable API access tokens and user credentials.

Auditing

User activity is recorded in an audit trail that can be automatically shipped to an external log repository.

Analytics and Detection

The Threat Defense architecture incorporates additional layers of protection, including AI-driven detection and analytics. It combines a set of advanced capabilities ranging from threat detection to data anomaly detection.

Threat Detection

The Cohesity Data Cloud detects threats and vulnerabilities in several ways.

- The Cohesity Data Cloud detects anomalies in your cluster and provides a dashboard to monitor it. Refer to Detect Anomalies for more information.
- The Cohesity Data Cloud integrates with anti-malware and next-gen antivirus engines to detect when data managed by the Cohesity may contain or be infected with ransomware.
- The CyberScan app that runs on the Cohesity Data Cloud provides live vulnerability scanning of protected workload snapshots.

The final layer of Cohesity Threat Defense is about ensuring the data management platform can be operated securely. This means integrating and inter-operating with security infrastructure from vendors. The supported security infrastructure ranges from SOAR to identity management and from vulnerability management to key management.

Prepare Your Deployment Against Ransomware Attacks

In a ransomware attack, attackers focus on compromising privileged accounts with weak authentication mechanisms to gain complete access to the cluster and eventually, data.

You can eliminate these risks by preparing your cluster for ransomware attacks. The preparation includes:

- Ensure the Cohesity cluster is upgraded to the latest release and updated with latest patches. You can find the latest version at the Cohesity Downloads portal.
- Change default passwords for each user account such as UI Admin, Support, Intelligent Platform Management Interface (IPMI) admin, and cohesity_console and applying the required password policies. For more information, see Users and Groups and Configure Account Security Settings.
- Maintain separate Active Directory (AD) or SSO protection groups for primary and disaster recovery cluster credentials
- Store privileged credentials securely in credential vaults.
- Enable two-factor authentication (2FA) or multi-factor authentication.
- Disable sudo access for the support user account.
- Ensure users are assigned roles with the least privilege to perform their jobs through role-based access control.
- Enable DataLock on Protection Policies applied to critical data.
- Enable centralized logging and auditing (External Syslog Server).
- Enable offsite backups such as replication or archival in an operationally independent environment.
- Enable firewall policy to restrict network access and manage inbound traffic on Cohesity cluster. Refer to the topic Manage Application-Based Firewall Rules to learn more about firewall rules.

- Protect your Active Directory. Ransomware attacks often target Active Directories to gain control over identity management systems associated with your cluster. You can refer to Active Directory to learn more about prerequisites, best practices, and recovery workflows.

Detect Anomalies

You can connect your Cohesity cluster to Cohesity Data Cloud and keep track of anomalous snapshots in your cluster. Ransomware detection in Helios is based on machine learning and statistical anomaly detection techniques to identify sudden changes in the data across snapshots over time. When these changes are detected, it might be indicative of ransomware compromising the data.

Cohesity Data Cloud constantly monitors the metrics, such as how many modified snapshots, and detects any anomalies. In addition, it uses machine learning algorithms to monitor change rates in the backup data continuously.

Cohesity's ransomware detection techniques can analyze changes in:

1. The volume of data read or written over time – noticing whether the volume of data protected from one protection job run to the next changed dramatically.

2. Analyzing changes in data entropy – very good for detecting when the contents of files may have changed dramatically due to encryption or compression

3. Changes in the nature of the file system – identifying when a large number of files has been added, deleted, or modified

If the rate is out of the normal range — based on daily and historical rates — Cohesity flags it as a potential ransomware attack. Refer to Detect Ransomware Attacks to learn more about how Cohesity Data Cloud detects anomalies.

Respond to Ransomware Attacks

In response to ransomware attacks, it's important to immediately take the required measures and limit the potential damage to your organization's digital assets. You can integrate Helios Security Orchestration, Automation, and Response (SOAR) platforms to receive alerts when ransomware has attacked your cluster.

You can refer to the View the Alert section in the Anti-ransomware topic to learn about how to check the alerts in your cluster. As a first step to limit the exposure of your cluster to the ransomware attack, you should:

1. Reset Passwords. For more information, see Users and Groups.

   > **Note:** For 6.6.0d and earlier, and 6.5.1 releases, you have to change the password of Linux users.

2. Disable accounts that are not configured with multi-factor authentication.
3. Inform your Technical Account Manager and the Cohesity account team.

4. Enable Legal Hold for critical workloads. It ensures that snapshots of protection groups will not be deleted until the Legal Hold is removed or disabled. For more information, see Add or Remove a Legal Hold to a Snapshot.
5. Stop the cluster through a CLI command cluster stop.

After limiting exposure to the ransomware, you have to start recovery from a clean snapshot, recover active directory objects, and initiate mass restoration of your critical workloads such as VMware virtual machines and network-attached storage backups. For more information, see the Cohesity white paper: Cohesity Ransomware Protection — Prepare and Recover.

Key Management

A Key Management Service (KMS) helps you manage the keys that encrypt data and secures it from unauthorized access. A Cohesity cluster has a built-in key manager or can be configured to use external key managers - KMIP-compliant or Amazon Web Services (AWS) KMS - to manage encryption keys.

Cohesity uses two types of keys for encryption.

- Data Encryption Keys (DEKs) - these keys are used to encrypt the data.
- Key Encryption Keys (KEKs) - these keys are used to encrypt the DEKs.

Data on the Cohesity cluster is encrypted using a FIPS-validated implementation of the Advanced Encryption Standard (AES) in Galois/Counter Mode using a 256-bit DEK.

A unique DEK is created for the following entities in your Cohesity cluster.

- Encryption-enabled Storage Domains
- External targets, such as
    - CloudArchive
    - CloudArchive Direct

Regardless of the entity type, DEKs are encrypted using a KEK and persisted on the cluster in an encrypted format as Encrypted DEKs (EDEKs). DEKs are never stored or exposed in a plain text format.

If the external targets are CloudArchive and CloudArchive Direct, then the EDEKs are also stored alongside the data in the cloud.

The encryption and decryption process is performed within the Cohesity cluster and is transparent to all inbound or outbound protocols and applications such as backup, archiving, and file services.

Security Measures

Cohesity prioritizes security and access control to ensure that customer data remains protected at all times. A key concern is whether Cohesity administrators can access customer Key Management Systems (KMS) or encryption keys, potentially exposing

protected data. These Security measures clarify why such access is not a risk within the Cohesity Cloud Services (CCS) Backup-as-a-Service (BaaS) solution.

- **Restricted Production Environment Access**: Cohesity enforces strict access controls, access to the production environment is limited to authorized personnel.
- **Encryption and Decryption Controls**: Cohesity does not provide any mechanism to decrypt customer data outside of normal product operations. Encryption and decryption occur within the secure system framework, adhering to strict security protocols.
- **Key Management and Secure Storage**: Key Encryption Keys (KEKs) are securely stored in a Key Management System (KMS), purpose-built for secure key storage and management. This ensures that keys are not exposed or accessible beyond their intended use.
- **Customer-Controlled Key Management**: Customers can configure an external KMS, ensuring full control over their encryption keys. In this case, Cohesity does not retain direct access to KEKs but only invokes them to decrypt Data Encryption Keys (DEKs) when required for standard operations.
- **Risk Mitigation**: In the unlikely event of a security breach, Customers utilizing an external KMS can revoke Cohesity's access to the KEK, preventing further decryption operations.

Internal Key Management Service

Cohesity provides an internal key management service (KMS) to generate Data Encryption Keys (DEKs) and Key Encryption Keys (KEKs) on your Cohesity cluster.

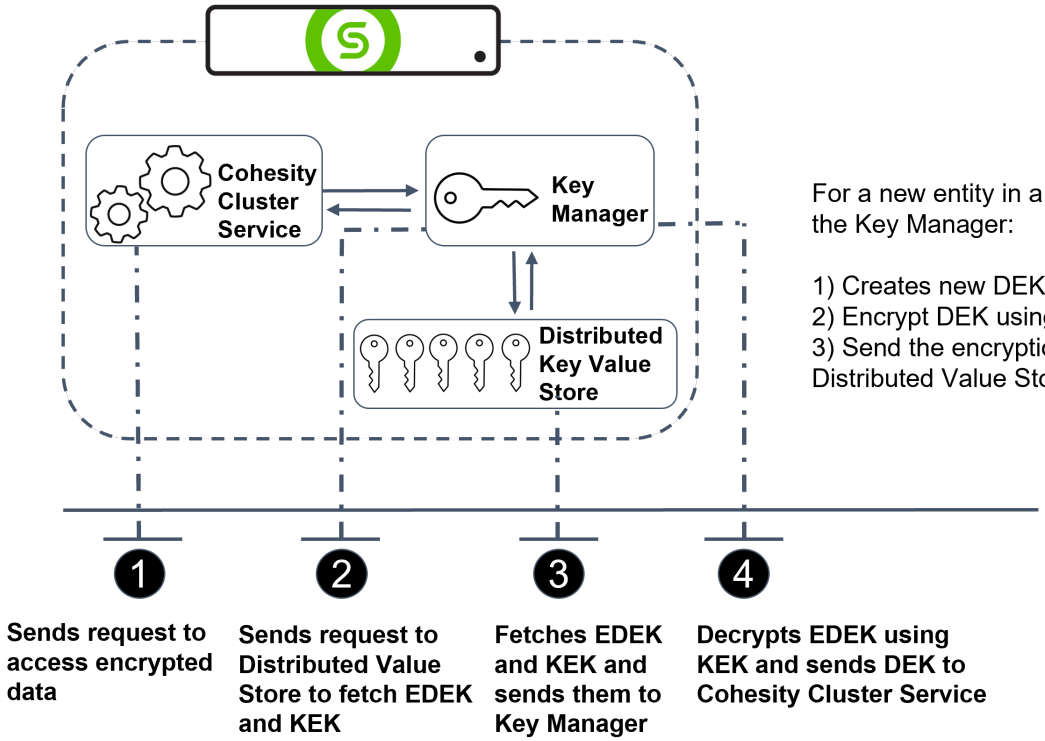
For example, when a new Storage Domain is added to the cluster, the internal KMS creates a new DEK and encrypts it with a KEK. Cohesity securely stores this DEK internally within the cluster's key store as an Encrypted DEK (EDEK).

To keep the encryption keys safe, Cohesity restricts the following actions:

- Export it from your cluster
- Expose it in a plain text format through any API or user interface

Key Rotation Policy

A Cohesity cluster rotates only KEKs and not DEKs. By default, the key rotation interval is 90 days and you can also configure it. See Set Key Rotation Policy.

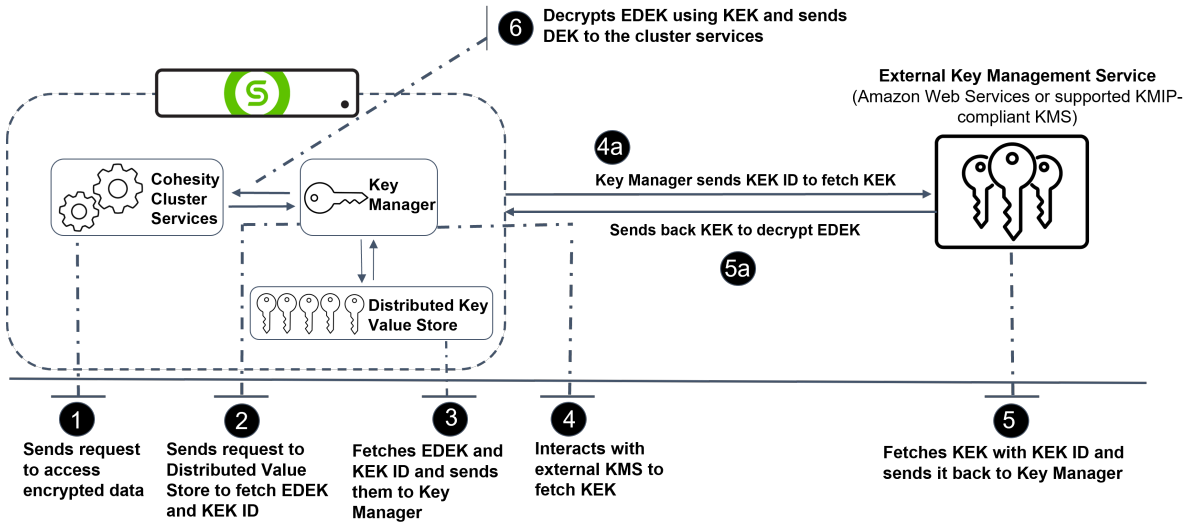


External Key Management Service

Cohesity supports Amazon Web Services-based KMS and Key Management Interoperability Protocol (KMIP) compliant KMS as external key management services. KMIP is used to facilitate communication between the Cohesity cluster and the key server of the external KMS. You can register multiple key management services.

When the Cohesity cluster is configured to use an external KMS, KEKs are generated and stored in the external KMS, though a KEK ID, a reference to the KEK, is maintained on the cluster. The cluster never persists a copy of the KEK, though the Cohesity cluster will persist the KEK ID as an identifier to fetch the KEK from the external KMS periodically.

> **Note:** The KEK ID does not contain any key material.



KMIP-based External KMS

When a KMIP-based external KMS is enabled, the Cohesity cluster will store both the EDEK and KEK ID locally. The external KMS will manage the KEK.

A Cohesity cluster interacts with an external KMS when a service on the cluster requests access to the encrypted data. After receiving this request, the Cohesity cluster sends a request to the external KMS for the KEK referenced using the KEK ID. When the external KMS responds with KEK, the Cohesity cluster uses it to decrypt the EDEK and derive the DEK. This DEK is sent to the service that requires the key to decrypt or encrypt the data for any read or write operations.

Cohesity allows caching of keys and it is implemented within various cluster services to ensure cluster throughput and minimize load on the external KMS. This allows the DEK to be cached in-memory on the cluster node for four hours before a call to external KMS must be made again to fetch the KEK and decrypt the EDEK.

> **Note:** If the external KMS is unavailable or unable to deliver the KEKs due to any reason, the data in the Storage Domains remains in an encrypted state and inaccessible.

By default, the key rotation interval is 90 days, though this is configurable.

Create a KMS Cluster

You can add multiple KMS and create a KMS cluster to ensure high availability of keys. A KMS cluster can include up to four key management services.

In a KMS cluster, every KMS node should share the same CA certificate and each Cohesity cluster node's certificate is shared internally. This means the additional KMS that is added must be connected to the same Cohesity cluster.

Follow the steps below to add a new KMS.

1. Go to **Settings** -> **Summary** and select **Key Management System** tab.
2. Select the edit icon against an existing KMS.

   The **Edit Key** dialog is displayed.
3. Enter a **Key Name**.
4. Under **Key Configuration**, select **KMIP Compliant** as the **Key Type**.

   KMIP Compliant: Select this option to add an external KMS. For more information, see External Key Management System.
5. Enter the following details.
   1. **Protocol Version**: Enter the KMIP version. If the version is KMIP 1.2, then enter KMIP1_2.
   2. **Server Address**: Enter the IP address of KMS. The IP address of each KMS node must belong to the same KMS cluster.

      > **Important:** The IP Address of the active KMS should be first on the list followed by the IP addresses of the secondary key management systems.

   3. **Port**: Enter the port number of KMS.
6. Under **Upload Certificates**, you have to upload the following keys and certificates.
   1. **Client Certificate**
   2. **Client Key**
   3. **CA Certificate**
7. Optionally, you can select the storage domain and external targets that must use this key for encryption. Ensure that encryption is enabled on the storage domain.
8. Select **Create**.

Validated External KMIP-based KMS

Cohesity supports KMIP versions 1.1 to 1.4, and the following KMIP-based KMS systems have been validated by the Cohesity cluster.

KMS	Documentation Reference
Entrust KeyControl	Cohesity and Entrust KeyControl Integration Guide
SafeNet KeySecure	Integration Guide - Cohesity and SafeNet AT KeySecure for Government

KMS	Documentation Reference
Vormetric Data Security Manager	Use Vormetric DSM to Manage Cohesity Encryption Keys
Fortanix KMS	Use Fortanix Self-Defending KMS to Manage Cohesity Encryption Keys
CipherTrust Manager	CipherTrust Manager Documentation Portal
IBM Security Guardium Key Lifecycle Manager	IBM SGKLM Documentation
Hashicorp Enterprise Vault	Manage Cohesity Encryption Keys Using HashiCorp Vault 1.4

AWS KMS

When a AWS KMS is enabled, the Cohesity cluster will store the KEK ID locally while the EDEK will be stored both on the cluster as well as alongside the data (in the case of CloudArchive and CloudArchive Direct).

A Cohesity cluster interacts with AWS KMS when a service on the cluster requests access to the encrypted data. After receiving this request, the Cohesity cluster will send a request to the AWS KMS for the Customer Managed Key (CMK). When you're using AWS KMS, the CMK acts as the KEK. When AWS KMS responds with the CMK, the Cohesity cluster uses it to decrypt EDEK and derive the DEK. This DEK is sent to the service that requires the key to decrypt or encrypt the data for any read or write operations.

If you are using AWS KMS as an external KMS, then

- DEKs are rotated every four hours
- KEKs, which is an AWS CMK, is rotated once every year by AWS

Caching of keys is implemented within various cluster services to ensure cluster throughput and minimize load on the external KMS. This allows the DEK to be cached in-memory on the cluster node for a limited period of time before a call to AWS KMS must be made again to fetch the KEK and decrypt the EDEK.

> **Note:** You can configure a HTTPS proxy on the Cohesity cluster and use it for communication with AWS KMS. This is an Early Access feature. Contact your Cohesity account team to enable the feature.

Configure AWS KMS

Perform the following steps in the Cohesity cluster to configure AWS KMS.

1. Navigate to **Settings** > **Summary**.
2. Select **Key Management System**.
3. Select .

   The **New Key** pop-up dialog is displayed.
4. Enter the **Key Name** in the **New Key** dialog box.
5. Go to **Key Configuration** > **AWS**.
6. Enter the following details.
   1. **Customer Managed Key ARN**: You can choose to have an Amazon CMK ID or Amazon Resource Name (ARN). You should not enter key aliases in this field.
   2. **Access Key ID**: Amazon access key ID.
   3. **Secret Access Key**: AWS secret access key.
7. Enable or disable **SSL verification** of the connection to the AWS KMS server. By default, **SSL verification** is enabled.
8. Optionally, you can select the storage domain and external targets that must use this key for encryption. Ensure that encryption is enabled on the storage domain.
9. Select **Create**.

You have configured AWS KMS as your cluster's external key management service.

Azure KMS

When Azure KMS is enabled, the Cohesity cluster stores the Key Encryption Key (KEK) ID locally. The Encrypted DEK (EDEK) is stored both on the cluster and alongside the data (for services like CloudArchive and CloudArchive Direct).

The Cohesity cluster interacts with Azure KMS when a service requests access to encrypted data. Upon receiving the request, the cluster uses the Azure C++ SDK to authenticate via Managed Identity and fetch the private key from Azure Key Vault. This private key acts as the KEK. The cluster then uses it to decrypt the EDEK and derive the DEK. The DEK is passed to the requesting service to perform encryption or decryption operations.

If you are using Azure KMS as an external KMS:

- DEKs are generated locally on the cluster and rotated periodically (similar to internal KMS behavior).
- KEKs (RSA-HSM keys in Azure Key Vault) are rotated every 365 days for Cohesity-managed keys.
- Key caching is implemented across cluster services to optimize performance and reduce load on Azure KMS. DEKs are cached in memory for a limited time before the cluster re-authenticates and re-fetches the KEK to decrypt the EDEK.

You can now configure an HTTP or HTTPS proxy for both new and existing Azure KMS configurations on a Cohesity cluster. This allows Azure KMS operations to run through the

web proxy already set up on the cluster. Contact Cohesity Support to configure proxy for Azure KMS.

Manage Key Management Service

After you have configured a key management service (KMS) for your Cohesity cluster, you can do the following to manage KMS.

- Restart the Cohesity Keychain Service: The keychain service creates and manages encryption keys in a Cohesity cluster. Restarting it is required after you have updated the KMS configuration.
- Set Key Rotation Policy: You can set the lifetime of encryption keys on the Cohesity cluster. By default, it is set to 90 days.
- Delete an External Key Management System: You can delete an external KMS that is configured to manage encryption keys on the Cohesity cluster.
- Add a Secondary External KMS: If you're using an external key management system, then you can add more than one KMS to your Cohesity cluster to ensure high availability of keys.

Restart the Cohesity Keychain Service

If you update the KMS configuration on the Cohesity cluster, you must restart the Cohesity keychain service on the Cohesity cluster for the configuration changes to take effect. If you configure KMS for the first time, you do not need to restart the keychain service.

To restart the keychain service on the Cohesity cluster:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.
2. Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command.
3. Provide a Cohesity cluster username and password.

```
./iris_cli -server 172.16.3.101 -username=admin
```

4. Run the following command to restart the Cohesity keychain service:

```
cluster restart service-names="keychain"
```

Example:

```
admin> cluster restart service-names="keychain"

Success: Restarting the cluster services [keychain] ...
```

Set Key Rotation Policy

After the Cohesity cluster is created, the key rotation policy, by default, is set to 90 days. This means that the Cohesity cluster uses new encryption keys every 90 days. After the time period has been reached, all the old encryption keys used by the Cohesity cluster are

replaced by a new set of keys and the data on the Cohesity cluster remains as it was originally encrypted.

You can change the period of time that new keys are generated by the Cohesity cluster using the CLI command listed below. Specify the time period in seconds.

To change the default key rotation period:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. Change the Key Rotation period. Specify the time period in seconds. For example to change the key rotation period to 30 days, enter the following CLI command:

   ```
   admin>cluster edit enc-key-rotation-period-secs=2592000
   ```

Delete an External Key Management System

You can delete an external KMS from the **Key Management System** page. Ensure that the external KMS is not used by a storage domain or external target.

> **Note:** If the external KMS is used by a storage domain or an external target, the delete icon does not appear.

To delete an external KMS, complete the following steps:

1. Go to **Settings** > **Summary**.
2. Click the **Key Management System** tab.
3. Hover over the key that you want to delete and click the delete icon.
4. Click **Delete**.

Add a Secondary External KMS

You can add a new KMS and create a KMS cluster to ensure high availability of keys. A KMS cluster can include up to four key management services.

In a KMS cluster, every KMS node should share the same CA certificate and each Cohesity Platform node's certificate is shared internally. This means the additional KMS that is added must be connected to the same Cohesity cluster.

Follow the steps below to add a new KMS.

1. Go to **Settings** -> **Summary** and select the **Key Management System** tab.
2. Select the edit icon against an existing KMS.

   The **Edit Key** dialog is displayed.
3. Enter a **Key Name**.
4. Under **Key Configuration**, select **KMIP Compliant** as the **Key Type**.

   KMIP Compliant: Select this option to add an external KMS. For more information, see External Key Management System.
5. Enter the following details.
   1. **Protocol Version**: Enter the KMIP version. For example, if the version is KMIP 1.2, then enter KMIP1_2.
   2. **Server Address**: Enter the IP address of KMS. The IP address of each KMS node must belong to the same KMS cluster.

      > **Important:** The IP Address of the active KMS should be first on the list followed by the IP addresses of the secondary key management systems.

   3. **Port**: Enter the port number of KMS.
6. Under **Upload Certificates**, you have to upload the following keys and certificates.
   1. **Client Certificate**
   2. **Client Key**
   3. **CA Certificate**
7. Optionally, you can select the storage domain and external targets that must use this key for encryption. Ensure that encryption is enabled on the storage domain.
8. Select **Create**.

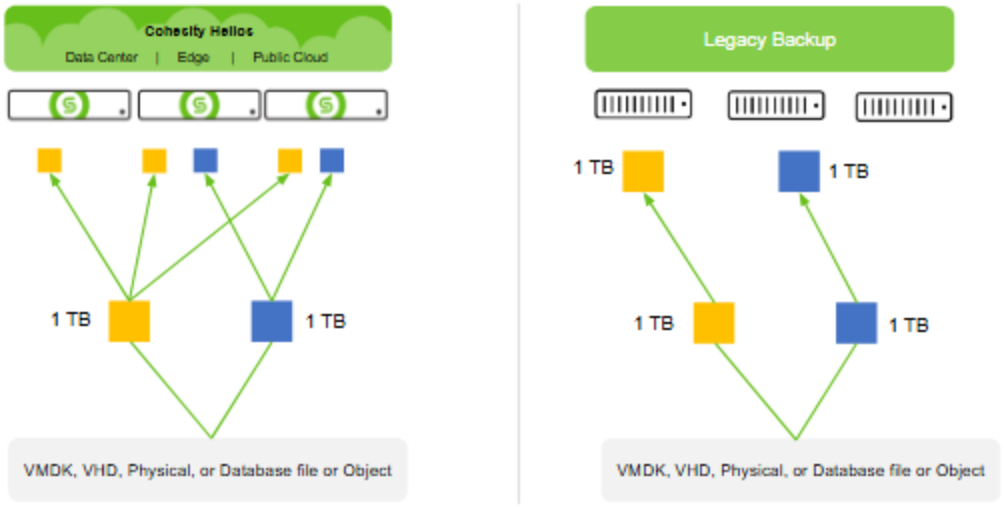
You've successfully added a new KMS.

To migrate from Internal KMS to External KMS, see Migrate from Internal KMS to External KMS.

MegaFile

Storage of large volumes of data such as large file systems can be challenging because they are often stored in a single storage container, delaying backup and recovery. The MegaFile feature alleviates this delay by dividing large files into smaller parts and distributing the smaller parts across multiple nodes of a Cohesity cluster, allowing parallel and hence faster backup and recovery.

The following example helps to understand the impact of MegaFile. In a four-node cluster, the data ingest of a 2 TB VMDK is split into four parts, each of which is 512 GB, reducing the ingest time by a factor of four. In an eight-node cluster, the data ingest of a 2 TB VMDK is split into eight parts, each of which is 256 GB, reducing the ingest time by a factor of eight. As the number of nodes in a Cohesity Cluster grows, the time to ingest decreases significantly.



> **Note:** The size of the smaller parts is determined by MegaFile and varies depending on many factors such as the size of the larger file, the number of nodes in the Cohesity cluster, and so on.

> **Note:** The MegaFile feature is built in a Cohesity Cluster and is enabled by default.

Example using MegaFile

In the example below, two sub-tasks are created by MegaFile and it splits the VMDK to a sub-task for every 256 GB offset:

```
<date, time>    Number of sub-tasks: 2, total amount of data to be read:
260.00 GB
```

```
<date, time>    Setting up VM files in preparation to copy the snapshot
```

```
<date, time>    Setting up files completed
```

```
<date, time>    Querying disk [key: 2000, path: [HDD-3TB(0)] name-blank/-
name-blank.vmdk] from 0 with change id: *
```

```
<date, time>    Requesting permit for sub-task 0
```

```
<date, time>    Requesting permit for sub-task 1
```

```
<date, time>    Permit granted to sub-task 0
```

```
<date, time>    Permit granted to sub-task 1
```

Example without using MegaFile

In the example below, only a single sub-task is created:

```
<date, time>  Number of sub-tasks: 1, total amount of data to be read:
260.00 GB
```

```
<date, time>  Setting up VM files in preparation to copy the snapshot
```

```
<date, time>  Setting up files completed
```

```
<date, time>  Querying disk [key: 2000, path: [HDD-3TB(0)] name-blank/name-
blank.vmdk] from 0 with change id: *
```

```
<date, time>  Requesting permit for sub-task 0
```

```
<date, time>  Permit granted to sub-task 0
```

MegaFile in Backup and Recovery

The following sections discuss the various backup and recovery flows that employ MegaFile:

Source	Supported Backup Workflows	Supported Recovery Workflows
Microsoft Hyper-V	• Full backups use MegaFile by default. • Incremental backups only if the previous backup used MegaFile.	• Linux and Windows VM recoveries in Cohesity DMaaS portfolios. • File recovery to Linux VMs on On-Prem.
Nutanix AHV	• Full backups use MegaFile by default. • Incremental backups only if the previous backup used MegaFile.	N/A
VMware	• Full backups use MegaFile by default. • Incremental backups use MegaFile only if the previous backup used MegaFile.	File recoveries streamed over a Cohesity agent on VMware Cloud use MegaFile. **Note:** MegaFile is not supported if a file recovery on VMware Cloud is based on VMware tools.

Source	Supported Backup Workflows	Supported Recovery Workflows
Physical Server	All file-based AND block (volume) based backups.	All file and folder recoveries.
SQL Server	All SQL Server backups.	All SQL Server recoveries.
Pure Storage (SAN)	• File backups use MegaFile by default. • Incremental backups use MegaFile only if the previous backup used MegaFile.	All Pure Storage recoveries.
Active Directory	Volume and File backups.	N/A
Exchange	Volume and File backups.	N/A
MongoDB physical	Full backups use MegaFile by default.	N/A

Data Retention for Audits

In planning for audits, keep in mind that the Cohesity cluster retains metadata for Protection Groups and Objects (VMs, physical servers, databases, etc.) differently, as described below.

Data Retention for Backup

Backup auditors need to verify that your organization's assets are backed up at regular intervals and that backups are available for recovery. For example, you might be asked to show evidence of successful backups for the past three months or more.

Protection Group Metadata

Protection Group metadata requires minimal overhead in the Cluster and is retained forever for reporting and compliance purposes, unless the Protection Group is deleted. There is no set retention period for this information. The information includes:

- the Protection Group name
- the protection run start and end date and time
- the names of the backed up Objects
- the total number of bytes read and written
- whether the protection run succeeded or failed

Note that the protection run is considered successful only if *all* its Objects are backed up successfully. For example, if a Protection Group is configured to back up 100 VMs, but one of the VMs gets deleted in vCenter, the protection run status indicates failure. The more VMs included in a Protection Group, the greater the probability of the protection run reporting a failure. As a result, it may be desirable to capture more granular success/failure metadata at the Object level.

Object Metadata

Object metadata is **not** retained forever in the Cluster. A single protection run can back up hundreds or thousands of Objects and the metadata can grow quickly and require overhead. Therefore the Object metadata is retained only for the retention period specified in the Protection Group's Policy. After that period, the Object metadata is permanently deleted from the Cluster and is no longer available. You can guard against gaps in the Object backup history by collecting the Object information on a regular basis and storing it outside the Cluster.

Getting Audit Data

You can get Protection Group and Object information by running the following reports in the Cohesity cluster:

- Backup Summary report
- Protection Details Per Object report
- Protection Summary by Object Type report
- Failed Objects report

You can customize the reports with filters including a date range, Protection Group names and object names. You can run the reports as needed, on a recurring schedule, download them as CSV files or email them to backup administrators to review and keep for auditors.

Data Retention for Recovery

Recovery metadata requires minimal overhead in the cluster and is retained forever for reporting and compliance purposes. There is no set retention period for this information.

Recovery Metadata Retention

The following information is retained:

- Recovery Task
- Start Time
- Status
- Duration

Object Metadata Retention

The following information is retained:

- Object name
- Recovered From
- Recovery Point
- Options

For recovery tasks performed in the last month, the following information is retained:

- Object name
- Recovered From
- Recovery Point
- Recovery Task
- Start Time
- Duration
- Options

Getting Audit Data

You can get recovery task and object information for VMs by running the Clone and Recover VM Tasks Summary report in the Cohesity cluster.

Data Retention for Clone

Clone metadata requires minimal overhead in the cluster and is retained forever for reporting and compliance purposes, unless the clone is deleted. There is no set retention period for this information.

Clone Metadata Retention

The following information is retained:

- Task Name
- Objects Cloned
- Start Time
- Task Duration
- Status

Object Metadata Retention

The following information is retained:

- Clone Options
- Object
- Snapshot Cloned

- Teardown Tries
- Status

Getting Audit Data

You can get recovery task and object information for VMs by running the Clone and Recover VM Tasks Summary report in the Cohesity cluster.

Sending Audit Data Outside the Cluster

Consider the following options for retaining backup information outside the Cluster:

- Email Cohesity reports on a recurring schedule to an external repository such as a SharePoint site, an email inbox or a log collection server such as Splunk. For a list of reports and how to email and schedule them, see Reports. For information on how to set up your repository to receive and store emails, see the documentation from the repository vendor.
- Write a script that calls the Cohesity REST API operations to generate and save reports to a location outside of the Cluster.

Dynamic Disk Support

This topic describes what dynamic disks are and captures details of the supported and unsupported workflows of the Dynamic Disk use case in ESXi VMs.

What are Dynamic Disks?

Dynamic disks provide features such as the ability to create volumes that span multiple disks (spanned and striped volumes) and the ability to create fault-tolerant volumes (mirrored and RAID-5 volumes). Like basic disks, dynamic disks can use the MBR or GPT partition styles on systems that support both styles. All volumes on dynamic disks are known as dynamic volumes. Dynamic disks offer greater flexibility for volume management because they use a database to track information about dynamic volumes on the disk and about other dynamic disks in the computer. Because each dynamic disk in a computer stores a replica of the dynamic disk database, for example, a corrupted dynamic disk database can repair one dynamic disk by using the database on another dynamic disk. The location of the database is determined by the partition style of the disk. On MBR partitions, the database is contained in the last 1 megabyte (MB) of the disk. On GPT partitions, the database is contained in a 1-MB reserved (hidden) partition.

Dynamic disks are a separate form of volume management that allows volumes to have non-contiguous extents on one or more physical disks. Dynamic disks and volumes rely on the Logical Disk Manager (LDM) and Virtual Disk Service (VDS) and their associated features. These features enable you to perform tasks such as converting basic disks into dynamic disks and creating fault-tolerant volumes. To encourage the use of dynamic disks,

multi-partition volume support was removed from basic disks and is now exclusively supported on dynamic disks.

The following operations can be performed on dynamic disks:

- Create and delete simple, spanned, striped, mirrored, and RAID-5 volumes.
- Extend a simple or spanned volume.
- Remove a mirror from a mirrored volume or break the mirrored volume into two volumes.
- Repair mirrored or RAID-5 volumes.
- Reactivate a missing or offline disk.

Are Dynamic Disks Recommended?

Cohesity supports dynamic disks while recommending against them as they complicate the disaster recovery process. Cohesity also advises against using dynamic disks as a system disk.

Physical Windows workflows back up at the volume level and create one VHD / VHDX file with one volume. Thus, there is no issue with supporting dynamic disks if the VM is treated as a physical server.

Supported Workflows in ESXi VMs

The following table lists supported and unsupported workflows of Dynamic Disk use cases in ESXi VMs.

Workflow	Backup	Indexing	File Restore to Source	VM Restore to Source	Recommended Approach
VM with simple Dynamic Disks	Supported	Supported	Supported	Supported	Treat VM as a Physical Server
VM with spanned Dynamic Disks	Supported	Supported	Download file is supported • Search to download • Browse to download	Supported	Treat VM as a Physical Server

Workflow	Backup	Indexing	File Restore to Source	VM Restore to Source	Recommended Approach
VM with SQL Dynamic Disks	Supported	Supported	Supported	VM restore is supported DB restore to same VM not supported. DB restore to alternate VM supported.	Treat VM as a Physical Server

Limitations

- Recovery to an alternate location is supported with the following restrictions:
  - The volume should be a simple volume. Dynamic disks may be created unintentionally after some P2V workflows.
  - The alternate machine should ideally not have any other dynamic disks. If there are any other disks already, then manual intervention is required to clean up the missing dynamic disks that result from the disks attached during restores.
  - Quiesced VM snapshots fail with missing dynamic disks. Thus, if the alternate machine has dynamic disks and is part of a job that takes quiesced snapshots of the VM, then the cleanup becomes mandatory.
- Indexing (and hence search and download) will work for Simple, Spanned, Striped and Mirrored volumes. It will not work for RAID-5 volumes. So, File Level Recoveries are not supported for RAID-5 volumes.
- Instant Volume mounts on Hyper-V are not supported for Dynamic Disks.
- VM with SQL DB will have the same behaviors as above.

Chapter 4: Cluster Administration

From the (**Settings > Summary**) page of the Cohesity cluster, you can view overall statistics about the Cohesity cluster, configure or upgrade the Cohesity cluster and manage the Support Channel. See the following topics for details.

- Initial Cluster Setup 220
- Configure Settings 220
- Customize Preferences 246
- Software Update 249
- Power Off and Power On a Cohesity Cluster 268
- Search the Cluster and Take Action 281
- Manage Storage Domains 283
- Manage Nodes 309
- Use Cohesity Data Cloud (Self-managed) in DoD Mode 353
- About Node-to-Node Encryption 362
- Quorum Protected Operations 365
- Antivirus Software to Protect Cluster Data 365
- Cohesity Licensing 370
- Manage Apps 380
- Networking Workflows 382

Initial Cluster Setup

The initial cluster Setup Guides, Quick Starts and Worksheet PDFs for all Cohesity platforms are available at Initial Cluster Setup.

Configure Settings

In addition to the settings initially entered while setting up the Cohesity cluster, you must provide the configuration information listed below if it is not already specified.

To continue the configuration of Cohesity cluster settings:

1. Navigate to **Settings > Summary**. The Summary page displays the following details:

Field	Description
Cluster Name	Displays the name of your cluster.
Cluster ID	Displays the unique ID of your cluster.
Creation Date	Displays when you created the cluster.

Field	Description
Software	Displays the cluster's Cohesity release version.
Hardware	Displays which hardware the cluster is on. For example, Virtual ROBO.
Software Encryption	Indicates whether encryption is enabled at the cluster level. **Note:** Encryption can be enabled at the cluster level only when creating the cluster and cannot be disabled or modified later. If Encryption is enabled at the Cluster level, all Storage Domains are encrypted. However, encryption can be enabled at the Storage Domain level after creating the cluster. For enhanced security, the 7.0.1 or later clusters use Galois/Counter Mode (GCM) encryption. Once you upgrade the Cohesity cluster to version 7.0.1, all data newly generated within the Cohesity cluster is automatically encrypted using GCM. Data that existed prior to the upgrade will remain encrypted using the previous method (CBC). You can apply GCM at the cluster level during cluster creation or at the storage domain level after the cluster is created.
Hardware Encryption	Indicates whether Encryption is enabled at the cluster hardware.
Storage Domain	Displays the total number of Storage Domains you have created and the encryption status. For details, see Manage Storage Domains.
Nodes	Displays the total number of nodes in the cluster. For details, see Manage Nodes.
Support Channel	Allows you to enable the Support Channel and copy the Support Channel token. For details, see Manage the Support Channel.
Storage Capacity for Metadata	Displays the total storage capacity available for the cluster's metadata.
Storage Used for Metadata	Displays the percentage of capacity utilized by the cluster.
Failure Domain	Displays the Failure Domain. For example, Node.

2. On the **Summary** tab, click **Configure**, and provide the following configuration information:

Required Settings

The following table lists the mandatory settings that are required for your Cohesity cluster to be up and running.

Settings	Description
Cluster Subnet Gateway	Specify the IP address of the Subnet Gateway for the Data (Primary) Network. You can either provide IPv4 or IPv6 addresses to configure the Cohesity cluster subnet gateway.
Domain Names	Enter the domain name(s) for the Cohesity cluster.

Optional settings

The following tables list the optional settings that are available for advanced Cohesity cluster configuration.

Web Proxy settings

Use an HTTP proxy server if the Cohesity cluster does not have direct internet connectivity to connect to Cohesity Data Cloud, the support channel, or to download upgrade software.

Settings	Description
Configure Web Proxy settings	Enable the **Configure Web Proxy settings** option, and enter the hostname or IP address and port number for the server. If the server requires a username and password, toggle on **Proxy Requires Password** and enter the username and password. You can either provide IPv4 or IPv6 addresses to configure the IP addresses or hostnames of the Web proxy server.

To configure Web Proxy using the CLI commands, see Use a Proxy Server.

> **Note:** To configure an HTTP proxy server for outbound internet connectivity from a Cohesity cluster to external targets, Office 365, AWS, and Azure Cloud Connector (for CloudSpin and native snapshot), see this KB article.

Security settings

Add an extra layer of security to your Cohesity cluster by changing the default password and enabling two-factor authentication.

Field	Description	Additional Notes
Enable Two-Factor Authentication	Enable this option for the users (belonging to the same AD domain to which Cohesity has joined) to sign in to the Cohesity cluster using a digital certificate instead of a password (Local users will continue to sign in with a password).	Changing this setting automatically restarts the web server.
Encryption	Encrypts metadata and data on the Storage Domain on the Cohesity cluster. > **Note:** The metadata encryption impacts Cohesity cluster performance. For example, the read/write operations could delay the backup/archival/replication run times.	This option is displayed only if the **Encryption** setting is turned on during Cohesity cluster creation. > **Note:** Once enabled during the Cohesity cluster creation, you cannot disable this option.
Key Management Service Type	Select the required Key Management Service Type. The available options in the drop-down are: • Internal Key Management Service • KMIP Compliant • AWS > **Note:** By default, Cohesity uses Internal Key Management Type. For **KMIP Compliant**, you need to select the key from the **KMIP Compliant Key** drop-down. For **AWS**, you need to select the key from the **AWS Key** drop-down.	At the cluster-level encryption, DEK (Data Encryption Key) rotation is not supported for AWS KMS. If multitenancy is enabled on the Cohesity cluster, Cohesity uses the same key to encrypt all tenants' metadata.

Storage Domain Configuration

Activate cloud tiering and set default disk-level fault tolerance for Storage Domains.

Settings	Description	Additional Notes
Cloud Tier	Set **Local Storage Utilization Threshold** to activate cloud tiering for configured storage domains.	This is a global setting for all the Storage Domains created on the Cohesity cluster. Setting up thresholds for cloud tiering at individual Storage Domains will take precedence over the global setting (overrides the global settings).
Custom Failure Domain	Specify a failure domain at the global cluster level: **Node**–Sets node as the failure domain and protects the Cohesity cluster against node failures. This is the default setting.	This is a global setting that sets the failure domain to configure fault tolerance for all the storage domains created on the Cohesity cluster.

Settings	Description	Additional Notes
Failures Tolerated	Select the number of node failures that can be tolerated: • **1 Failure**–Can tolerate one random node failure at any given point in time. The usable metadata capacity will be 50%. A minimum of three nodes in a Cohesity cluster is required to tolerate one node failure. • **2 Failures**–Can tolerate two random node failures in a Cohesity cluster simultaneously. The usable metadata capacity will be 33%. A minimum of five nodes in a Cohesity cluster is required to tolerate two node failures. For more details, see About Fault Tolerance.	• Applied to metadata and used as the default setting for Storage Domains. • This setting is not supported for single-node Virtual Edition. • A 2-node failure has a higher fault tolerance than a 1-node failure.

Email Configuration

Configure the connection to the SMTP Server and verify the SMTP settings when you save the Cohesity cluster configuration.

Settings	Description	Additional Notes
Enable SMTP Server	Enable the **Enable SMTP Server** option to configure the connection to the SMTP Server. Specify the following SMTP settings: • **SMTP Server**: Specify the name of an SMTP server that is used to send emails when Warning or Critical Alerts are generated by the Cohesity cluster. Cohesity recommends specifying an SMTP mail server. • **Port**: Specify the port number used to access the SMTP Server. • **SMTP Server uses SSL/TLS without STARTTLS (typically for port 465)**: Select this option if the SMTP Server uses SSL/TLS without STARTTLS. Typically, SSL/TLS without STARTTLS uses port 465. • **SMTP Username**: Specify the name of the account used to authenticate with the SMTP Server. • **Change SMTP Password**: Specify the password of the account used to authenticate with the SMTP Server. • **Sender Email Address**: The SMTP server uses the email address you enter in this field to send alert notification emails. **Note:** From release 6.6.0d_u3 CPD patch onwards, the email address you enter in this field will take precedence over the email address specified for the local System Admin account (admin) of the Cohesity cluster.	The SMTP Server is used to send emails when Warning or Critical Alerts are generated by the Cohesity cluster. Cohesity recommends that you configure the SMTP Server.
Test Email on Save	Enable the **Test Email on Save** option to verify the SMTP settings when you save the Cohesity cluster configuration. In the **Test Email Recipient** field, enter an email address to receive the test email.	

Multitenancy Settings

Configure multitenancy for the Cohesity cluster.

Settings	Description	Additional Notes
Enable Organizations	Enable the **Enable Organizations** option to configure multitenancy for the Cohesity cluster. Optionally, toggle on **Allow multiple organizations to use one Storage Domain** to reduce storage consumption in the Cohesity cluster by providing Cohesity deduplication across all the organizations using the Storage Domain. Organizations will be isolated from other organizations, whether this option is on or off.	Enabling multitenancy for a Cohesity cluster cannot be undone. You cannot revert the Cohesity cluster to a single tenancy state.

Apps Management

Manage applications from the Cohesity App MarketPlace in the Cohesity cluster.

Settings	Description

Enable Apps Management	Enable the **Enable Apps Management** option to manage applications from the Cohesity App MarketPlace in the Cohesity cluster. Provide the following details:
	• **Subnet**: Provide an unused subnet in a private address space between /12 (maximum size) and /22 (minimum size). The subnet will be used to create an overlay network on which to run the apps. Make sure the subnet is unused to avoid routing conflicts. The Internet Assigned Numbers Authority (IANA) reserves the following IP address blocks for use as private IP addresses:
	  • 10.0.0.0 to 10.255.255.255
	  • 172.16.0.0 to 172.31.255.255
	  • 192.168.0.0 to 192.168.255.255
	• **Allow external connectivity from apps**: Toggle on to allow the apps network access beyond the Cohesity cluster nodes. Not all apps require external connectivity. For example, a backup app that needs to access a database will require external connectivity, but the Cohesity Insight app, which searches Views on the Cluster, does not require external connectivity.

Statistics

Send anonymized data about product usage.

Setting	Description
Share Product Usage Statistics	Enable this option to send anonymized data about product usage. For more information, see this Google Analytics topic.

Product Documentation

Use the documentation help that is included directly on the Cohesity cluster without internet access.

Settings	Description	Additional Notes
Documentation	Select the **No internet access? Access Help directly from the Cluster** option to use the documentation help that is included directly on the Cohesity cluster without internet access.	The Cohesity cluster pages have context-sensitive links to the online help available from the Cohesity Documentation site or offline help from the Cohesity cluster. Click the icon in the upper right corner of the Cohesity cluster to open the help topic for the page you are currently viewing. Then, if prompted, enter your MyCohesity portal credentials.

Login Banner

Displays a login banner message on the Login screen.

Settings	Description
Enable Login Banner	Toggle on to see the configured login banner message on the Login screen. In the displayed text field, configure the login banner message.

Time Settings

Change the time zone for reports and audit logs.

Settings	Description
Time Zone	Click **Change Time Zone** and select a time zone from the drop-down to change the time zone for reports and audit logs.

Throttling Background System Activities

The activities, such as garbage collection, system checks, post-process storage optimization, and other system activities, run in the background on the Cohesity cluster. These system activities utilize the Cohesity cluster resources and impact the workloads, such as file shares and backups.

Schedule the throttling of the system activities to reduce the utilization of the Cohesity cluster resources.

Settings	Description
Background System Activity	Enable this option to schedule the throttling of the system activities running in the background. **Time Zone Settings** To change the time zone for throttling schedules, click **Change Time Zone** and select a time zone from the drop-down menu. By default, your current time zone is displayed. **Add Throttling Schedules** > **Important:** Cohesity recommends that you schedule the throttling in such a way that, on average, the background system activities utilize at least 50% of Cohesity resources in a week. To add schedules: 1. In the **Days** column, select one or more weekdays from the drop-down menu. You can also select **Everyday** to schedule throttling to run daily. 2. In the **Time** column, enter the time duration for throttling. 3. In the **Activity Level** column, select a level of throttling from the drop-down menu. • **No restriction**: The background system activities will run without any restriction. • **Moderate**: The background activities will utilize 66% of the Cohesity resources. This is the default option. • **Low**: The background activities will utilize 33% of the Cohesity resources. • **No activity**: Other than critical processes, all other background system activities will be completely stopped. The background activities will not utilize any of the Cohesity resources. 4. Click **Add**. 5. Optional. To configure multiple schedules for throttling the background system activities, repeat steps a to d.

Settings	Description
	Note: • If there is an overlap between the schedules added, then the latest added schedule will take precedence over other schedules. For example, you have added a schedule (say S1) for running the background activities on **every Monday** between **9.00 am to 5.00 pm** with **Activity Level** set to **Low**. Later, you added another schedule (say S2) for running the background activities every day between **1.00 am to 3.00** pm with **Activity Level** set to **Moderate**. In this scenario, on Monday from 1.00 am to 3.00 pm, there is an overlap between these two schedules. In such cases, the recently added schedule, S2, will take precedence during the overlap time. • Cohesity will perform throttling of the system activities running in the background only for the days and duration for which you have configured the throttling. Saving the Cohesity cluster configuration with this option disabled will clear all the existing throttling schedules. When you save the Cohesity cluster configuration, the following error message appears if the Cohesity resources utilization by the background system activities is less than 50%: `Error occurred while configuring background activity schedule. Background activity has been excessively throttled. Please relax the throttling conditions.` **Delete an Existing Throttling Schedule** To delete a throttling schedule, click the delete icon against the schedule.

3. Click **Save**.

Manage the Support Channel

The Cohesity Support Channel is a secure, simple, and effective way for Cohesity employees to provide on-demand assistance to customers. When the channel is enabled, a qualified Cohesity employee can log in to the Cohesity cluster to troubleshoot issues in a remote session. The following diagram illustrates how the Support Channel works.

The Support Channel server is located in the public cloud and has a secure login mechanism. The server is configured with a public key and accepts connections from the Cohesity cluster. The Cohesity cluster selects a master Node, which then establishes an SSH reverse tunnel with the Support Channel server on a TCP port. (For information on ports,

see Firewall Ports for Support Channel.) This setup ensures that all communication is encrypted between the Support Team and the Cohesity cluster.

The server configuration is limited to only certain Cohesity employees, and there are strict rules for user registration that are checked regularly.

Only a limited set of Cohesity employees can configure the Support Channel server, and a strict user registration policy is enforced and audited regularly.

Firewall Ports for Support Channel

The primary node in the Cohesity cluster initiates an SSH reverse tunnel with the Support Channel server on TCP port 443. To use the Support Channel server server, you need to configure the ports listed in the Cohesity Support Channel section in the Manage Firewall Ports topic before you enable the Support Channel server.

> **Note:** Make sure your network team has unblocked and is not monitoring the Cohesity support channel sites or ports for seamless connectivity and effective communication.

Enable Support Channels

Cohesity recommends that you enable the Support Channel when you need assistance from Cohesity employees. You can enable the Support Channel using the Cohesity Dashboard or the Cohesity CLI. When you enable the Support Channel, you must specify how long you want the Support Channel enabled. When the period you specified expires, the Support Channel turns off. You can also manually disable the Support Channel before the specified period expires.

> **Note:** Support Channels are disabled by default in Cohesity clusters.

Enable or Disable the Support Channel

To enable or disable the Support Channel:

1. Navigate to **Settings > Summary**.
2. Next to the **Support Channel** at the bottom of the page, click the edit icon ( ).
3. Select one of the following from the list:
   - **Off**—Disables the channel.
   - **Temporarily On**—Lets you enable the channel temporarily. Enter a number (1 to 30) and then select hours or days from the drop-down.
4. Click **Save**.

You can also manage the Support Channel with the Cohesity CLI. See the `iris_cli support support-channel` command.

Support Channel Tokens

Once the Support Channel is enabled, a Support Channel token is autogenerated. Cohesity employees require the Support Channel token to remotely log in to your Cohesity cluster using SSH. Copy the Support Channel Token and share it with the Cohesity employee. Support Channel tokens provide a more secure and hassle-free method than sharing the password with Cohesity employees.

Support Channel tokens are encrypted and are longer than the tokens in the previous Cohesity versions. Because encryption appends a random number, an encrypted token may appear different every time it is fetched. However, the token is still valid until the Support Channel expires or is disabled.

Support Channel tokens expire when the set time duration for the Support Channel expires, as a security enhancement. A new token is generated when you re-enable the Support Channel. Cohesity employees logging into Cohesity clusters require the new Support Channel token every time the Support Channel is enabled.

> **Note:** If you extend the Support Channel duration before it expires, the existing Support Channel token is retained. However, if you manually disable the Support Channel before its session expires, the Support Channel token also expires.

Copy the Support Channel Token

To copy the Support Channel token:

1. Navigate to **Settings > Summary**.
2. From the **Support Channel token** field, copy the Support Channel token using the copy icon.

Or, from the Cohesity CLI, run the following `iris_cli` command to copy the Support Channel token:

```
iris_cli user linux-bash-access
```

The following is a sample output of the command:

```
admin@127.0.0.1> user linux-bash-access

supportUserToken             :
JDEkTUhjQ0FRRUVJQ2VOLzR4QTBwUllJNWJEK1VyVEZGR2l0NXRkODRmZWwzTVB0WlgzaEZvS29
Bb0dDQ3FHU000OQpBd0VIb1VRRFFnQUVDWWJESDFoRVU2U0gvdkZ6a3pQcndaZU41aGNLZWdrdD
AvNzNpZktxL2NXODloWkJqbXgzCkJaZlFF
SEZmTzhjTEt1MllkbXRjNWxVbkh2cE0raUNBbGc9PQ==
```

Support UI User

When you enable a Support Channel, a Support UI user role (cohesity_ui_support_<clusterid>) is created by default and displayed along with the other user roles under the **Users & Groups** tab on the **Access Management** page. Cohesity employees remotely logging into the Cohesity cluster use this user role. By default, this user role will have viewer permissions and a secure password. The user role is automatically disabled and deleted if the Support Channel expires or if the Support Channel is manually disabled.

Migrate from Internal KMS to External KMS

This section describes the procedure to migrate the storage domain or metadata encryption from Internal KMS to External KMS.

> **Note:** Once you migrate from Internal KMS to External KMS, the change is irreversible. Migration from External back to Internal KMS is not supported.

Migrate Storage Domain Encryption from Internal KMS to External KMS

If encryption is already enabled and the storage domain uses **Internal KMS**, you can migrate from Internal KMS to AWS KMS or any KMIP-compliant KMS.

To migrate the storage domain encryption from Internal KMS, complete the following steps:

1. Go to **Settings > Summary**.
2. Click the **Storage Domains** tab.
3. In the **Storage Domains** page, hover over the storage domain, click ⋮ and select **Edit**.
4. In the **Encryption** section, from the **Key Management Service Type** drop-down list, select **AWS** or **KMIP Compliant**.
5. Click **Update Storage Domain**.

Migrate Metadata Encryption from Internal KMS to External KMS

If you enable encryption when creating a Cohesity cluster, by default, Cohesity uses **Internal KMS** for cluster-level encryption. After the Cohesity cluster is created, you can migrate from Internal KMS to AWS KMS or any KMIP-compliant KMS.

> **Note:** If encryption was not enabled when you created the Cohesity cluster, the **Encryption** option does not appear.

To migrate metadata encryption from Internal KMS, complete the following steps:

1. Go to **Settings > Summary**.
2. Click **Configure**.
3. In the **Encryption** drop-down list, select **AWS** or **KMIP Compliant**.
4. Click **Save**.

Set Key Rotation Policy for Encryption

After the Cohesity cluster is created, the key rotation policy, by default, is set 90 days. This means that the Cohesity cluster automatically creates and uses new encryption keys every 90 days. After the time period has been reached, all the old encryption keys used by the Cohesity cluster are replaced by a new set of keys and the data on the Cohesity cluster remains as it was originally encrypted. You can change the period of time that new keys are generated by the Cohesity cluster using the CLI command listed below. Specify the time period in seconds.

To change the default key rotation period:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. Change the Key Rotation period. Specify the time period in seconds. For example to change the key rotation period to 30 days, enter the following CLI command:

   ```
   admin>cluster edit enc-key-rotation-period-secs=2592000
   ```

Update SSL Certificates Using Cohesity CA or Customer CA certificate

Cohesity software packages ship with an auto-generated self-signed certificate. You must accept the self-signed certificate to access the Cohesity clusters. This topic describes two scenarios for updating the cluster certificate from the Cohesity cluster (User Interface):

- Load a Certificate Authority (CA) signed certificate.
- Refresh the factory shipped (Cohesity signed) certificate if it expires.

Important Notes on SSL Certificates

- Cohesity does not recommend using self-signed certificates.
- Cohesity cluster supports X.509 certificates in PEM format only.

- The certificate must have the "Common Name" field set to the server's hostname (for example, a VIP's DNS name). The Common Name must be the same as the name you plan to use to access the Cohesity cluster.
- Private Key Files must not be encrypted.
- If the certificate admin provides a single file, ensure to separate the file to obtain the certificate and key files.
- By default, OCSP validation is disabled. Contact your Cohesity account team to enable the feature.
- Cohesity does not support ECDSA certificates.

Examples

The following is a sample cert.pem file.

Configuring Cohesity Cluster with a CA Signed Certificate

A Certificate Authority (CA) signed certificate is a digital certificate issued by a trusted organization called Certificate Authority. It authenticates the identity of the entity (certificate holder) before digitally signing the certificate, thereby assuring users that they are interacting with a legitimate and secure entity.

You can replace the Cohesity cluster's self-signed certificate with a Certificate Authority (CA) signed certificate. Optionally you can use the Subject Alternative Name (SAN) field to specify additional host names (such as sites, IP addresses, and common names) to be protected by a single SSL certificate, such as a Multi-Domain or Extend Validation Multi-Domain Certificate.

This procedure applies to configuring the Cohesity cluster using SHA256 and SHA384 cryptographic hash algorithms. When configuring, update the default_md parameter in step 3 accordingly. To configure a Cohesity cluster with a CA certificate using SHA256 or SHA384:

1. Copy the following template to a text editor, replace the sample values in red color with actual values, and save the file in your local directory.
   Sample

```
#REQ FILE: cert_req.conf
#--------------------------
[ req ]
default_bits     = 2048
default_md       = sha384 (or sha256)
prompt           = no
```

```
encrypt_key     = no
distinguished_name = req_distinguished_name
req_extensions     = req_ext

[ req_distinguished_name ]
countryName          = "US"
stateOrProvinceName = "CA"
localityName         = "San Jose"
organizationName     = "Data Protection"
organizationalUnitName = "example Organization Name"
commonName           = "cluster1.example-domain.com"

[ req_ext ]
subjectAltName = @alt_names

[alt_names]
DNS.1 = cluster1.example-domain.com
DNS.2 = cluster1-vip.example-domain.com
IP.1 = 10.1.1.1
IP.2 = 10.1.1.3
IP.3 = 10.1.1.5
#---------------------------
```

2. Run the following command to the SCP file saved in the local directory to support user:

   ```
   scp "/path_to_file/filename" user@ip_address:"/Path to destination/"
   ```

   Example

   ```
   scp cert_req.conf support@111.1.1.1:/var/tmp/
   ```

3. Get the IP address for any Cohesity Cluster node (You can get the list of IP addresses by selecting Settings > Summary and then opening the Nodes tab). Use the IP address to log into that node as the support user.

   Command

   ```
   ssh support@<node IP address>
   ```

   Example

   ```
   ssh support@111.1.1.1
   ```

   When prompted, enter the password of the support user account.

   ```
   [support@111.1.1.1's password:
   ```

   Once your password is successfully authenticated, the prompt changes to the Secure Shell prompt.

```
[support@restricted-8888222f444 ~]\>
```

4. Generate the private key and certificate signing request files using cert_req.conf file:

```
openssl req -out cert_req.csr -newkey rsa:2048 -nodes -keyout cert_
key.key -config <path to file>/cert_req.conf
```

Example

```
openssl req -out cert_req.csr -newkey rsa:2048 -nodes -keyout cert_
key.key -config /var/tmp/cert_req.conf
```

> **Note:** Private key must not be encrypted.

5. Convert the cert_key.key to a PEM private key using the following command:

```
openssl rsa -in cert_key.key -out /var/tmp/key.pem
```

6. Make sure all users (owners, groups, others) have read permissions for the private key (key.pem) file:

To check the current permissions settings, run the following command:

```
ls -ltr <key.pem>
```

Run the following command to set the required permissions for all users:

```
chmod 600 <key.pem>
```

Sample Output:

```
[support@restricted-a121 ~]\> chmod 600 key.pem
```

```
[support@restricted-a121 ~]\> ls -ltr key.pem
```

```
-rw------. 1 support support 1704 Jun 13 08:23 key.pem
```

7. Run the following command to verify that the CSR file includes the Subject Alternative Name.

```
openssl req -text -noout -verify -in cert_req.csr
```

Sample Output

```
verify OK
Certificate Request:
Data:
Version: 0 (0x0)
Subject: C=XX, ST=PROVINCE, L=CITY, O=EXAMPLE, CN=HOST-A.EXAMPLE.COM
Subject Public Key Info:
Public Key Algorithm: rsaEncryption
Public-Key: (2048 bit)
```

```
Modulus:

   68:10:36:bf
```

8. Use WinSCP or SCP command to download the `cert_req.csr` file from the Cohesity node to your local computer and upload it to the Certificate Authority (CA) for

signature. Obtain the certificate in PEM format (`cert.pem`).

> **Important:** Submit a certificate request to the CA using the contents of the CSR file, following the CA's enrollment process.

> **Note:**
> - Cohesity cluster only supports X.509 certificates in PEM format only with Base64 encoded.
> - When you are getting the cert_req.csr certificate file signed to create the cert.pem file, ensure not to choose chain certificates.
> - If the certificate is in DER format, run the following command to convert it into PEM format:
>
>   ```
>   openssl x509 -in cert.cer -outform PEM -out cert.pem
>   ```
>
> - If the server certificate is signed by an intermediate CA then the `cert.pem` file must have the server certificate first and then the intermediate certificate.
>
>   Example
>
>   ```
>   -----BEGIN CERTIFICATE-----
>   Server Certificate
>   -----END CERTIFICATE-----
>   -----BEGIN CERTIFICATE-----
>   Intermediate CA Certificate
>   -----END CERTIFICATE-----
>   ```

9. After you obtain the certificate (cert.pem), copy it to the Cohesity cluster so you can update the cluster with the new certificate. Copy the file to a node on the cluster using the scp command on Linux systems as follows:

   ```
   scp cert.pem support@<Node IP Address>:/var/tmp
   ```

> **Note:** If you created the key pair on your enterprise certificate management tool, you must import both the files (signed certificate and key) on the Cohesity cluster. Copy the file to a node on the cluster using the scp command on Linux systems as follows:
>
> ```
> scp cert.pem key.pem support@<Node IP Address>:/var/tmp
> ```

10. Make sure all users (owners, groups, others) have read permissions for the self-signed certificate (cert.pem) file:

    To check the current permissions settings, run the following command:

    ```
    ls -ltr <cert.pem>
    ```

    Run the following command to set the required permissions for all users:

    ```
    chmod 600 <cert.pem>
    ```

11. Replace the Cohesity cluster's current SSL certificate with the new certificate you created in the previous steps:

    a. Start the Cohesity CLI using the following command:

    ```
    support@restricted-test-cluster-005056ba314a-node-1 ~]\> iris_cli
    ```

    When prompted, enter the Username and password you use to log into the Cohesity Cluster's User Interface. Once the password is successfully authenticated, the Cohesity CLI console opens.

    b. Replace the certificate by running the following command:

    ```
    cluster update-ssl-certificate ssl-certificate=<absolute path of the cert.pem file> ssl-cert-private-key=<absolute path of the key.pem file>
    ```

    Example

    ```
    admin@127.0.0.1>cluster update-ssl-certificate ssl-certificate=/var/tmp/cert.pem ssl-cert-private-key=/var/tmp/key.pem
    ```

    c. Restart the UI and REST API Services using the following command:

    ```
    admin@198.51.100.12>cluster restart service-names=iris
    ```

    > **Note:** It is recommended to wait a minute before proceeding with the next command.

d. Restart the I/O Operations service using the following command:

```
admin@198.51.100.12>cluster restart service-names=bridge
```

Configuring Cohesity Cluster with a Cohesity CA Issued Certificate

Before you Begin

You need Host Shell Access for the Cohesity cluster to run the last four commands in this procedure. For details, see Using the Secure Shell.

1. Get the IP address for any Cohesity Cluster node (You can get the list of IP addresses by selecting Settings > Summary and then opening the Nodes tab). Use the IP address to log into that node as the support user.

   Command

   ```
   ssh support@<node IP address>
   ```

   Example

   ```
   ssh support@111.1.1.1
   ```

   When prompted, enter the password of the support user account.

   ```
   [support@111.1.1.1's password:
   ```

   Once your password is successfully authenticated, the prompt changes to the Secure Shell prompt.

   ```
   [support@restricted-8888222f444 ~]\>
   ```

2. Run the following command to start Cohesity CLI.

   Command

   ```
   $ iris_cli
   ```

   When prompted, enter the Username and password you use to log into the Cohesity Cluster's User Interface. Once the password is successfully authenticated, the Cohesity CLI console opens.

   Example

   The following is a example of Cohesity CLI.

   iris_cli, Version: 6.8.2_release-20240317_97f56d9a

   Host: cork-clu-lts-005056ba9163-node-2, 127.0.0.1

   Cluster Server: 127.0.0.1:443

   admin@127.0.0.1>

3. Run the following command to generate Cohesity CA certificate.

   Command

   ```
   cert-manager new-cert city="San Jose" country-code=US organization-
   unit=IT organization="Cohesity Inc" state=California san-list="fqdn
   ```

```
ipaddresses comma separated" common-name="common-name" output-
dir=/home/support/
```

Certificate and Private Key will be written to following path:

- /home/support/new-cert/privateKey.pem
- /home/support/new-cert/certificate.pem

4. Run the following command to replace the certificate:

   Command

   ```
   cluster update-ssl-certificate ssl-certificate=<absolute path of the
   cert.pem file> ssl-cert-private-key=<absolute path of the key.pem file
   ```

   Example

   ```
   admin@127.0.0.1>cluster update-ssl-certificate ssl-
   certificate=/home/support/new-cert/certificate.pem ssl-cert-private-
   key=/home/support/new-cert/privateKey.pem
   ```

   Sample Output

   ```

5. Run the following command to restart bridge and iris services:

   Command

   ```
   iris_cli cluster restart service-names=bridge,iris
   ```

   Sample Output

   ```
   [support@stor1-525488a33cal-node-1 ~]$ iris cli cluster restart
   service-names-bridge, iris
   Username: admin
   'admin' Password:
   Success: Restarting the cluster services [bridge iris] ...
   ```

Related Topic

Generate SSL Certificates with a Subject Alternate Name

Enable File Modification Detection

The **Enable File Modification Detection** feature sends notifications to the user if a shared file or folder is modified. To enable this feature, contact Cohesity Support.

Update the Change Notification Events Limit

This feature enables you to update the number of events generated per file object within a given time interval. The default limit is 5 events in one minute (60000000 usecs).

To update the events notification, contact Cohesity Support.

Customize Preferences

The **Customization** page in the Cohesity cluster allows you to customize various settings and options to tailor your experience according to your personal preferences. You can modify settings related to your account, user interface, and interactions with the Cohesity cluster.

For example, you can hide the options on the left navigation that are not relevant to your environment, hide the options from the **Data Protection** menu, or select a favorite dashboard. You can customize the preferences both at the cluster level and user level.

> **Note:** The Customization feature is not available for tenant users.

Customize Preferences at the User Level

User-level customization of the Cohesity cluster applies to the logged-in user.

Perform the following steps for user-level customization:

1. Log in to the Cohesity cluster.
2. Navigate to **Settings > Customization**.
3. Mouse hover on the option and click the edit icon to customize the following:

User Interface Components	Description
Language	Set the default language. Cohesity supports the following languages: • English (US) • Japanese (JP)

Byte Scaling	Adjust the scale or size of data in terms of bytes. Cohesity offers the following byte scaling options: • Base 1024 (1 KiB = 1024) • Base 1000 (1 KB = 1000)
Recovery Location	Set the recovery location. Cohesity supports the following recovery locations: • Original Location • New Location
Default Dashboard	Set the default dashboard to view when you log in to the Cohesity cluster. The available options are: • Summary • Data Protection • SmartFiles • Cloud • MS SQL • Continuous Data Protection
Simple Create Workflows	Set the simple create workflows to display the quick protect or quick create pop-ups when creating a Protection Group, Policy, or View. Cohesity supports the following: • Protection • Policy • View
Time Format	Select how time must be represented in the Cohesity cluster: • 12-hour clock • 24-hour clock

Persist Snack Bars	Snack bars are brief notifications that appear at the bottom of the Cohesity cluster after an action is performed. Choose whether to keep messages, alerts, or notifications visible until you interact with them or let them disappear automatically: • **Persist Snackbar Messages** - Messages, alerts, or notifications stay visible until you acknowledge the message or dismiss it manually. • **Disappearing Snackbar Messages** - Messages, alerts, or notifications disappear automatically after a few seconds.

4. Click **Save**.

Customize Preferences at the Cluster Level

Cluster-level customization of the Cohesity cluster allows you to hide dashboards, navigational items, and protection adapters that do not apply to your environment.

> **Note:** The **Cluster** section is available to users only with the Manage Cluster privilege.

Perform the following steps for cluster-level customization:

1. Log in to the Cohesity cluster.
2. Navigate to **Settings > Customization**.

3. Mouse hover on the option and click the edit icon to customize:

User Interface Components	Description
Dashboards	Select the dashboards to be hidden from the drop-down menu on the **Dashboards** page. **Note:** A hidden dashboard at the cluster level is not available for the user to select at the user level.
Navigation Items	Select the options to be hidden from the left navigation pane. **Note:** You cannot hide **Settings** and **Customization**.
Protection Adapters	Select the adapters to be hidden from the **Protection**, **Recovery**, and **Sources** pages. **Note:** You cannot hide an adapter if it includes registered sources.

4. Click **Save**.

Software Update

Cohesity provides a comprehensive solution for managing software upgrades and patch installations within your cluster. The new design streamlines the update process, enabling you to upload and apply both upgrade and patch packages, perform necessary pre-checks, and initiate the upgrade or patch on all cluster nodes. When you download an upgrade package, you also have the option to download a corresponding patch, ensuring your cluster is fully updated. Additionally, Cohesity provides real-time tracking for both upgrades and patches, allowing you to monitor the status of each node, track completion times, and resolve any issues that may occur during the process.

Cohesity ensures a seamless and efficient way to maintain your cluster with the following key functions:

- Download Package
- Upgrade Cluster
- Apply Patch
- Upgrade with Patch

Before you begin, it is important to familiarize yourself with the following upgrade paths, prerequisites, and considerations to ensure a smooth upgrade and patching process.

Upgrading to 7.3.1

You can upgrade your Cohesity cluster from previous releases to 7.3.1. The following table provides details on supported upgrade paths.

Your Current Release	Upgrade Path to 7.3.1
• 7.3 • 7.2.2_u2 • 7.2.2_u1 • 7.2.2 • 7.2.1 • 7.2 • 7.1.2_u6 • 7.1.2_u4 • 7.1.2_u3 • 7.1.2_u2 • 7.1.2_u1 • 7.1.2 • 7.1.1 • 7.1	7.3.1 directly

> **Note:** Direct upgrades from 6.8.x to 7.3.1 are not supported. If your cluster is running any 6.8.x release (such as 6.8.1, 6.8.1_u1, or 6.8.2), a step upgrade is necessary. First, upgrade to 7.1.2_u6, and then proceed to 7.3.1.

Release Upgrade Policy

Policy	Example
Cohesity will support upgrades from the latest release of the prior LTS release branch, which includes all LTS designated releases within the branch, to the most recent release of the current LTS branch.	6.6.0d+ (LTS designated releases: 6.6.0d_u3, 6.6.0d_u4, 6.6.0d_u5, 6.6.0d_u6) to 6.8.2 LTS designated release will be supported.
Cohesity will not allow upgrades by default to any release that is older in time irrespective of the release branch. Exceptions are to be managed on a case-by-case basis.	6.5.1f_release-20210825_596bb917 is released after 6.6.0c_release-20210822_0d731348. Therefore, an upgrade from the 6.5.1f version to the 6.6.0c version is not supported. This policy is also applicable to patches. If you have upgraded your Cohesity cluster to a patch released after the LTS release, upgrading to that LTS release is not supported. However, you can upgrade to any LTS version released after the patch. For example, your Cohesity clusters were upgraded to 6.6.0d_u5 in July 2022. Cohesity released 6.8.1_u1 on Nov 2022 and the 6.6.0d-p32 patch on March 2023. If you've applied 6.6.0d-p32, you cannot upgrade to 6.8.1_u1. However, you can upgrade to the upcoming 6.8.1_u2 release.
Cohesity will support the release N-1 upgrade without an intermediate step. (N is defined as the current release branch).	7.2.x to 7.3.1 is supported. 7.3.1 is the current release branch.
Cohesity will support the release N-2 upgrade without an intermediate step. (N is defined as the current release branch).	7.1.x to 7.3.1 is supported. 7.3.1 is the current release branch.
When a specific release is declared LTS, Cohesity will support upgrading from the open LTS releases to the new LTS release. This will include the three most recent releases on the LTS branch to the new LTS release.	6.8.1, 6.8.1_u1, 6.8.1_u2, 6.8.1_u3, 6.8.1_u4, 6.8.1_u5, 6.8.1_u6, 6.8.1_u7 to 6.8.2.

Upgrade Considerations

Note the following about upgrading the Cohesity cluster to 7.3.1:

- Cohesity does not support rolling back to older versions.
- To upgrade the Cohesity cluster from a version that is no longer supported, Cohesity recommends you to upgrade to any of the supported versions mentioned in the Upgrade Paths, and then perform an upgrade to the latest release version. For information on Cohesity Products that have reached the end of support, see Cohesity Products End of Support.
- See Cohesity Feature Deprecation to review the list of features marked for deprecation for Cohesity 7.3.1 and later releases.
- Before performing the upgrade, ensure that the cluster data space and metadata space utilized is less than 85%. After the cluster upgrade, the Garbage Collection algorithms take 3 to 4 days to trigger. Hence, ensure that the cluster has enough space during this period. Space constraints may lead to backup and replication failures on the Cohesity cluster.
- If you are running remote adapter jobs and the cluster is upgraded, the jobs will be disrupted during the upgrade process. The jobs will be killed and restarted multiple times during the upgrade.
- Starting 6.8.2 and 7.1.2, the Cohesity indexing service is optimized to automatically identify and delete stale directories at regular intervals, which were created for indexing. After upgrading from a version without this optimization, the cluster indexing service will remove any stale directories identified, which may result in cluster-free space increase.
- Cohesity recommends upgrading the Cohesity Agent on Physical Servers and the Cohesity installed Agent on VMs to the latest release version of the Cohesity cluster.
- Cohesity recommends upgrading the Cohesity cluster first, followed by the Cohesity Agent. Upgrading an agent before the cluster is likely to impact the existing functionality and disruptions may be observed due to agent being on a higher version than the cluster. Cohesity also recommends the agents be on the same, latest major version as the Cohesity cluster to get the latest security fixes and benefit from newer features.
- After upgrading to the latest version, if there is an IP subnet conflict, the **Enable Apps Management** toggle in **Marketplace** > **My Apps** is turned off. Navigate to **Settings** > **Summary** > click **Configure** and specify a different IP address in the **Configure Apps management network** field and then turn on the **Enable Apps Management** option.
- If you are on a Cohesity Cloud Edition cluster and using Marketplace Apps, then when you upgrade the Cohesity Cloud Edition cluster to 7.3.1, connectivity among the Marketplace Apps could be impacted* due to Flannel moving to etcd v3 APIs. It is

recommended to pause any Marketplace Apps before the upgrade and resume them once the upgrade is complete.

*__Impact__: Running workloads, Protection Groups, or scans related to the Marketplace App might see network disruption during the upgrade.

- For pure PXG clusters, before upgrading from version 6.6 to 6.8.1 or above, make sure that your cluster usage is below 95%. After the upgrade, there is a known issue where the available data space may decrease. Even clusters that are using only 88% of disk space before the upgrade have experienced out-of-space errors afterward, which can lead to backup failures. To avoid disruptions, Cohesity strongly recommends reducing disk usage well below 95% before starting the upgrade process.

Databases

- The addition of the new Postgres database could cause UI slowness until the ETL process completes. The bootstrap run of the ETL process pulls the entire data set to populate the database. The initial run has a slight performance impact. In the case of upgrades, data population happens in the post-upgrade step. Subsequent upgrades will not be affected.
- After upgrading to the latest version, to display SAP HANA log backups in the Cohesity cluster, you need to modify the existing registered source and set the `et-log-backup` source registration parameter to `true`. Only the log backups triggered after enabling `et-log-backup` will be shown on the Cohesity cluster.

  > **Note:** After modifying the source configuration (with`-et-log-backup=true`), a full backup is mandatory. The initial full backup must be completed before any log backups appear on the Cohesity user interface.

- If you are upgrading to version 7.3.1 or later, you need to update the existing SAP HANA source configuration to enable auto-discovery and entity hierarchy. Set the `--entity-hierarchy` source registration parameter to "`true`." After updating the source configuration (with `--entity-hierarchy=true`), a full backup is mandatory.
- For **SQL log backups**, if you are upgrading the cluster to version 7.2 and above, ensure that the Cohesity cluster bridge node VIPs on port 11117 are reachable from the SQL source. In case of the multitenant environment, ensure that the Hybrid Extender IPs on port 11117 are reachable from the SQL Source.

  > **Note:** The SQL log backup will fail post-upgrade if the above-mentioned port requirement is not satisfied.

- If you have upgraded your cluster to Cohesity 7.3.1 from an earlier version and already have an AWS account registered, you must add new permissions to protect

the newly supported AWS workloads:

- Amazon RDS (Ingest-based protection)
- Amazon Redshift
- Amazon DocumentDB
- Amazon DynamoDB

Administration

- To generate a new SSH key after upgrading the Cluster, contact Cohesity Support.
- Cohesity Support Engineers require a Support Channel token to remotely log into the Cluster using SSH for on-demand assistance. From your Cohesity cluster, you need to copy the Support Channel token and provide it while raising a request for on-demand assistance.
- The Secure Shell restricts access to the host commands or scripts. After you upgrade to 6.7 or later version, the secure shell might have the following impact on your existing Cohesity Data Cloud deployments:
  - Access to the bash shell using SSH will be no longer available to the support user account without authorization from Cohesity.
  - If you run custom scripts using SSH on your Cohesity cluster, the scripts may fail. In this case, Cohesity recommends the following:
    - Verify if there is an alternate method to use Cohesity CLI commands or REST API and update your scripts accordingly.
    - Verify if a corresponding Cohesity CLI command is available in the supported list of CLI commands; if so, use the supported CLI command. If the CLI command is not available in the supported list of commands, contact Cohesity Support to enable the CLI command.
  - The private binary or tools running on the Cohesity nodes might fail. Contact Cohesity Support for options to install private binaries or tools.
  - Sudo access is disabled by default. For support channel access, enable the sudo access. For more information, see Enable or Disable Linux Sudo Access.
- If there is a source that is registered before the upgrade and assigned to an organization, then unassigning its root entity is not allowed. You can unassign the source if it is not assigned to an organization, and it will get assigned after the upgrade.

NoSQL and Hadoop

- To continue using Cohesity NoSQL & Hadoop services on the Cohesity cluster version 7.2.2, you must upgrade the NoSQL & Hadoop service to the 7.0.0 version available on Helios.

- If you are running NoSQL and Hadoop app, Cohesity recommends the following before upgrading the Cohesity cluster:
  - Pause the protection runs by navigating to **Data Protection > Protection** . From the Action Menu (⋮) of the required protection run, select **Pause Future Runs**.
  - Pause the NoSQL and Hadoop app by navigating to **Marketplace > My Apps** . From the Action Menu (⋮) of the app instance, select **Pause**.

  After upgrading the Cohesity cluster to the latest version, contact your Cohesity account team to check if the upgraded Cohesity cluster requires a new NoSQL and Hadoop app. If it requires a new version of the app, you must upgrade to the latest version of the NoSQL and Hadoop app. Once the cluster upgrade is complete, resume the app, and then the protection runs.

Microsoft 365

- If you upgrade your Cohesity cluster to 6.8.2 or later versions and currently backing up Microsoft 365, ensure that you add the required Microsoft Graph Permissions related to MS Groups to your custom application to continue using your existing Protection Groups and protect your Microsoft 365 data.
- After upgrading to the 7.3.1 version, if you are replicating the Mailbox data to a remote Cohesity cluster, then ensure that you upgrade the remote Cohesity cluster to the 7.3.1 version.

Single Node Cluster Upgrades

Single node cluster upgrades must be run when the upgrade will have the least impact. During the upgrade of a single node cluster, the node is rebooted and during the reboot, the cluster is unable to process Protection Groups, recover tasks, or any other workflow.

Virtual Edition Deployment

The following are the requirements for the Virtual Edition deployment for 6.8 and later versions:

- small (8 TB) configuration supports Virtual Machines with 12 vCPUs, 32 GB of memory, and 64 GB virtual disk to store the operating system.
- large (16 TB) configuration supports Virtual Machines with 24 vCPUs, 64 GB of memory, and 64 GB virtual disk to store the operating system.

For more information, see Virtual Edition for VMware Setup Guide and Virtual Edition for Clustered VMware Setup Guide.

Replication Environments

- If the cluster replication is configured, verify that the network connectivity is functioning properly during the upgrade to ensure the cluster replication relationship is successfully upgraded to use AES-256-GCM for encryption.
- In a replication setup, when you upgrade your Cohesity cluster to Cohesity 6.6 or later and you use the default System Admin password, you will be prompted to change the password. After changing the password, you must update the new password on the replication partner cluster.
- For information about using replication between Cohesity clusters running different versions, see Replication Compatibility.

  For the latest notes about replication compatibility, prerequisites and limitations, see the *Release Notes*.

Upgrade and Patch Workflows

If the Cohesity cluster is not running the newest software version, upgrade the Cohesity cluster. Only upgrade packages that are newer than the current version can be installed.

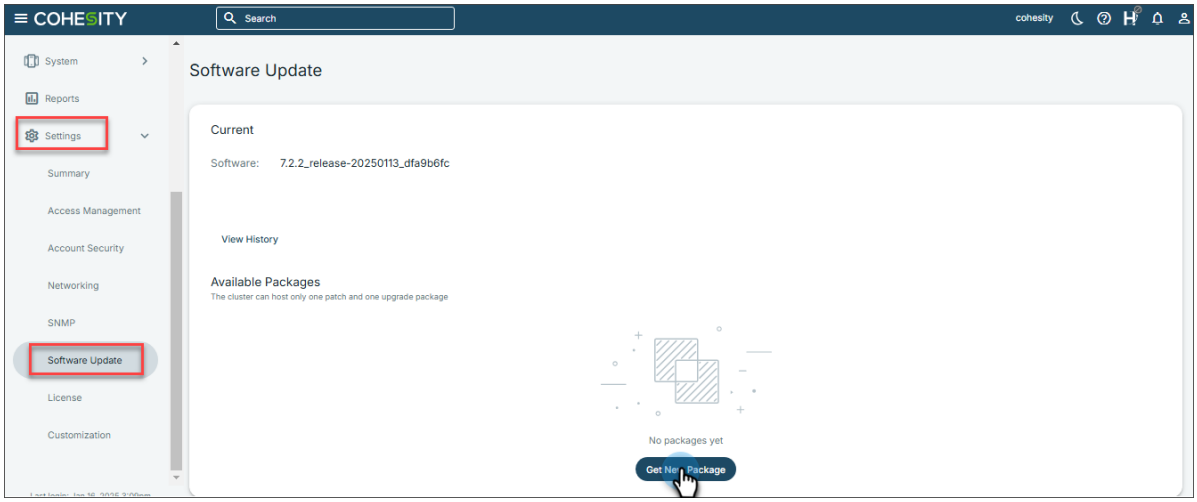
You can upgrade the software using the Cohesity cluster as described in the procedures below. You can use the same procedure and upgrade package to upgrade any Cohesity cluster, regardless of whether the Cohesity cluster is hosted on on-premises hardware, Cloud Edition or Virtual Edition.

Download Package

To download an upgrade or patch package, you can select the desired package type from either a URL or your local machine. Once the package is chosen, you can proceed with downloading, or opt to apply the upgrade or patch immediately.

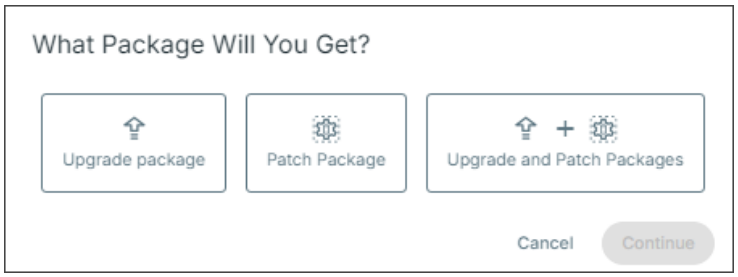
Perform the following steps to download the package:

1. Go to **Settings** > **Software Update** and click **Get New Package**.

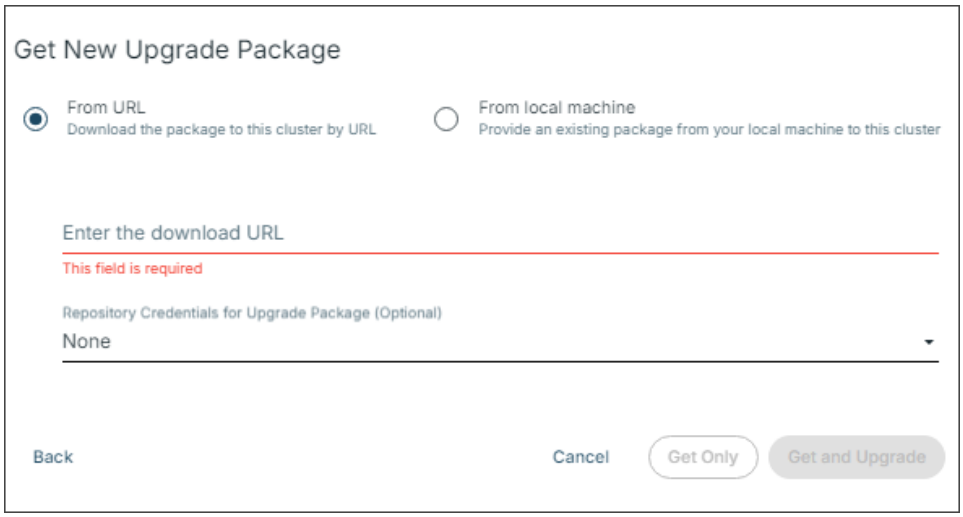


A dialog appears with the following package options:

1. **Upgrade Package**
2. **Patch Package**
3. **Upgrade and Patch Packages**



2. Select the required package and click **Continue**.
   A **Get New Upgrade Package** dialog appears.



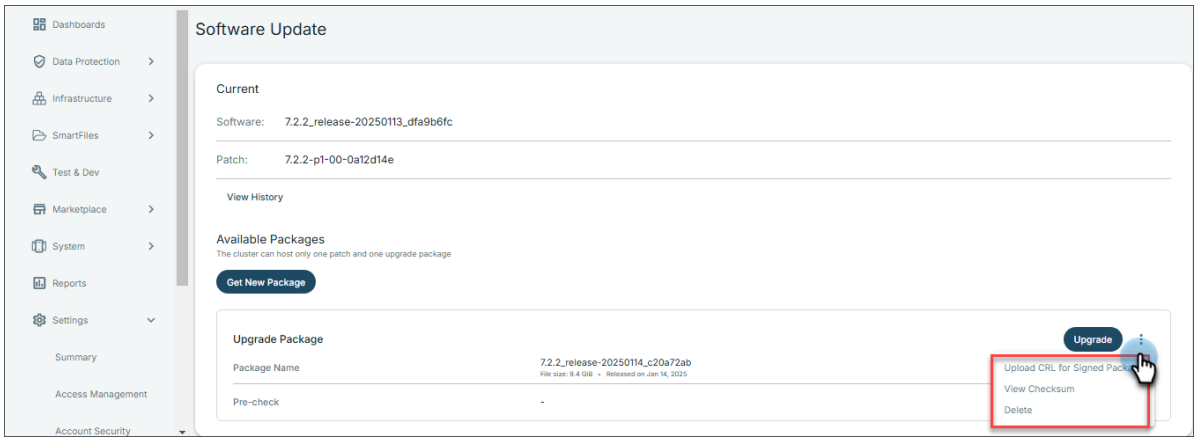
3. Choose one of the following options to download the package.

Option	Field	Description
From URL	**Enter the download URL**	Provide the package's URL
	Repository credentials for package (Optional)	Repository credentials can be used to download packages from secure repositories that require authentication to access the files. Choose one of the following options from the drop-down: **Basic** - Select this if your repository requires HTTP basic authentication. Enter the **Username** and **Password**. **Custom** - Select this if your repository requires custom authentication schemes and requires you to pass credentials as HTTP headers. Enter **Key** and **Value**. Key is the HTTP header name and Value is the HTTP header value.
From Local Machine	**Select File**	Browse and select the downloaded package from your local machine.

> **Note:**
> When you select the **Upgrade and Patch Package** option, you can either specify the download URLs of both upgrade and patch packages or you can upload the downloaded packages from your local machine to cluster.

4. Depending on your package selection, you can click:
    1. **Get Only** to download the package.
    2. **Get and Upgrade** to download and immediately upgrade the package.
    3. **Get and Apply** to download and apply the patch.

Once the package is downloaded, you can perform the following actions by clicking ⋮ on the package:

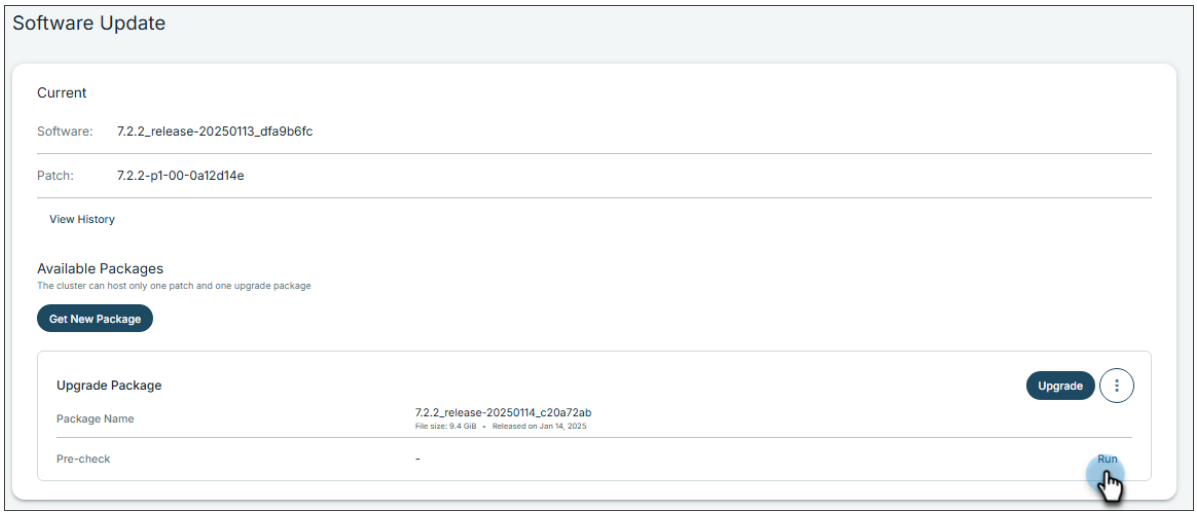


- **Upload CRL for Signed Package** - To upload Certificate Revocation List (CRL) for signed packages. CRLs are used to validate whether the certificate used for signing the package has been revoked after the package was downloaded to the Cohesity cluster.
- **View Checksum** - To view and verify the checksum of the package.
- **Delete** - To delete the package.

Run Pre-check

The pre-check option is available after the package download. It is important to run the pre-checks once the packages have been downloaded. Doing so in advance allows you to identify and resolve any issues, ensuring a smooth upgrade and patching process without any interruptions.

To run the pre-check on the downloaded package, click **Run**.



The pre-check will start and you can see the pre-check details by clicking **View Details**.

> **Note:** The cluster can host only one patch package and one upgrade package.

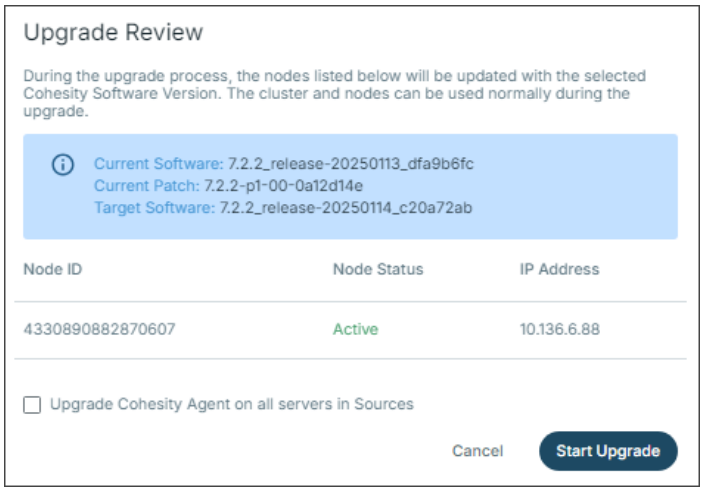
Upgrade Cluster

To upgrade the cluster, you can select the upgrade package and initiate the upgrade process after performing the pre-check. You can track the upgrade progress for all nodes until the operation is completed.

Perform the following steps to upgrade the cluster:

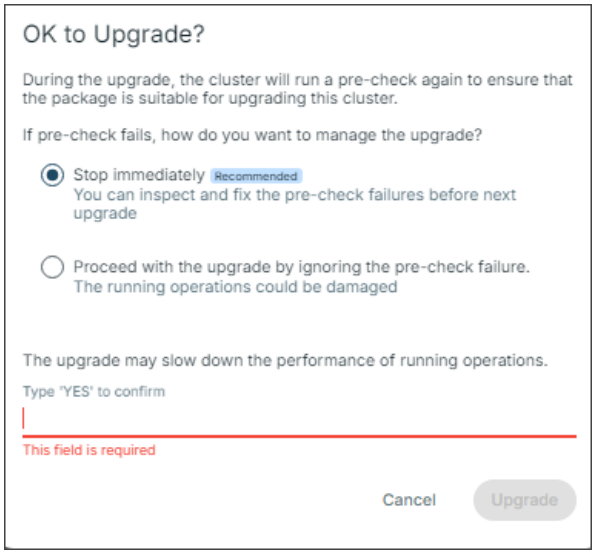
1. On the **Software Update** page, click **Upgrade**.

   The **Upgrade Review** dialog appears.



2. After reviewing the upgrade information, click **Start Upgrade**.

   The **Ok to Upgrade?** dialog appears.



3. If the pre-check fails, you can either:
   1. **Stop immediately** to stop the upgrade process (recommended). This allows you to review and address the pre-check failures before retrying the upgrade.
   2. **Proceed with the upgrade by ignoring pre-check failure** to continue the upgrade process despite the pre-check failure.
4. Enter **Yes** in the text field and click **Upgrade** to confirm and start upgrading.

The upgrading process will begin. You can observe the upgrading progress for all the available nodes in the cluster.

Apply Patch

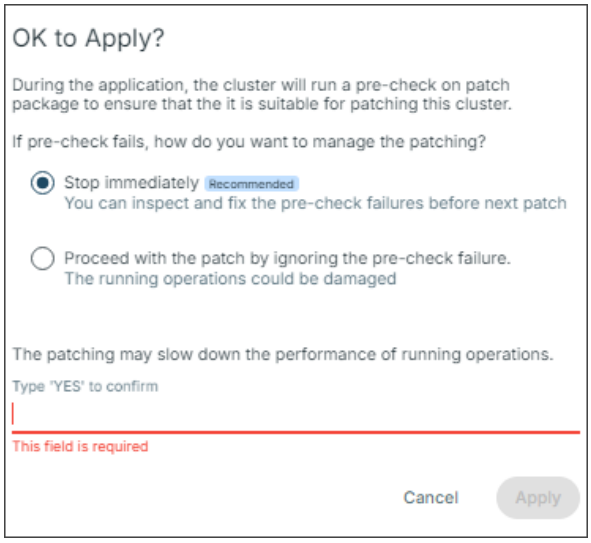
To apply a patch, select the patch package and begin the process after performing the pre-check. The patch will be applied across all nodes in the cluster, with progress tracked until

completion.

Perform the following steps to apply a patch:

1. On the **Software Update** page, click **Apply**.

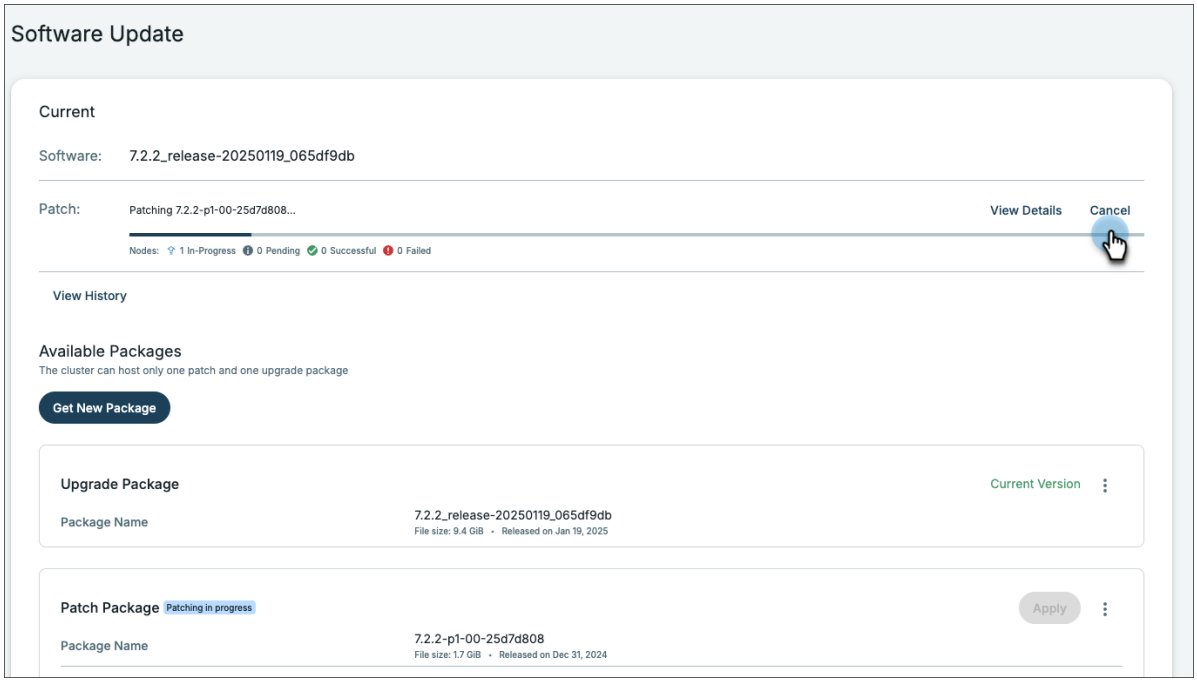
   The **OK to apply?** dialog appears.



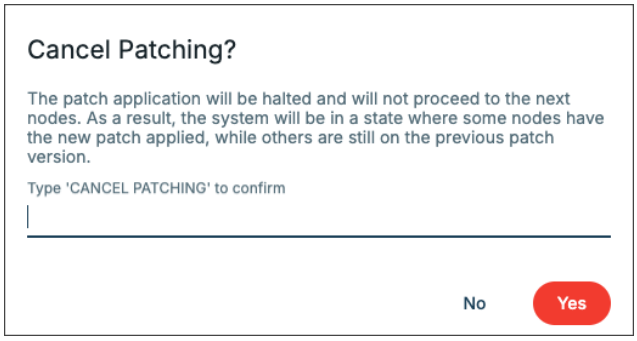
2. If the pre-check fails, you can either:
   1. **Stop immediately** to stop the patching process (recommended). This allows you to review and address the pre-check failures before retrying the patch.
   2. **Proceed with the patch by ignoring pre-check failure** to continue applying the patch despite the pre-check failure.
3. Enter **Yes** in the text field and click **Apply** to confirm and start applying the patch.

You can observe the patching progress for all the available nodes in the cluster. The patching process will begin after the pre-checks are completed on all nodes, starting with the node having the lowest ID.

To cancel the patching, click **Cancel**.



The **Cancel Patching?** dialog appears.



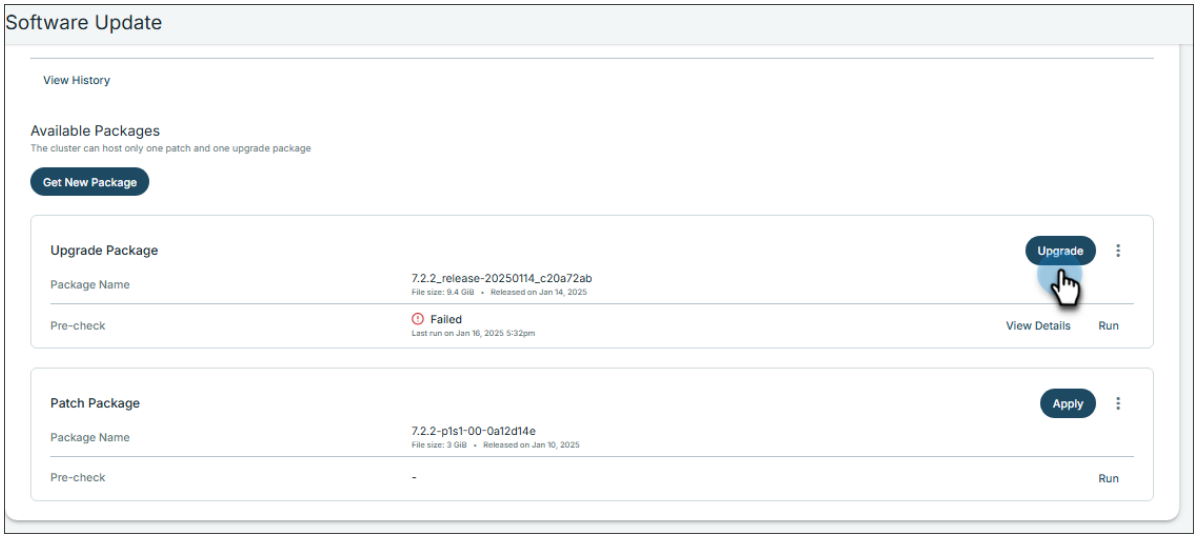
Enter **Cancel Patching** in the text field and click **Yes** to cancel the patching or **No** to continue the patching.

Upgrade with Patch

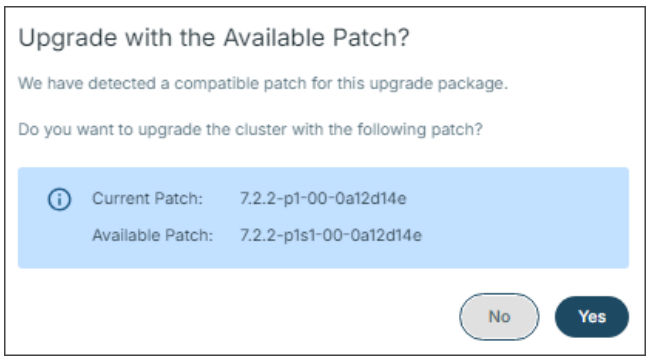
Upgrading with a patch allows you to apply both an upgrade and patch in one action. After downloading the upgrade and patch packages, you can proceed with the upgrade, including the patch, following a pre-check process.

Perform the following steps to upgrade with the available patch:

1. On the **Software Update** page, click **Upgrade**.

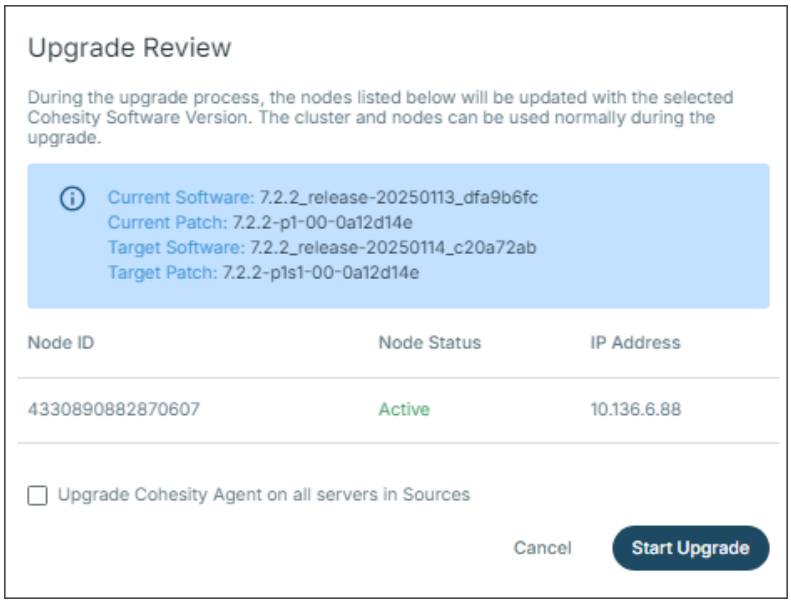


The **Upgrade with the Available Patch?** dialog appears.



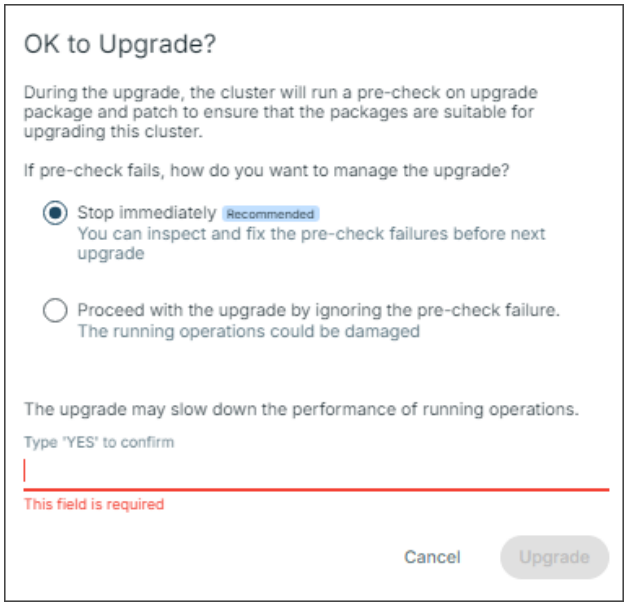
2. Click **Yes** to upgrade the cluster with the available patch.

   The **Upgrade Review** dialog appears.



3. After reviewing the upgrade information, click **Start Upgrade**.

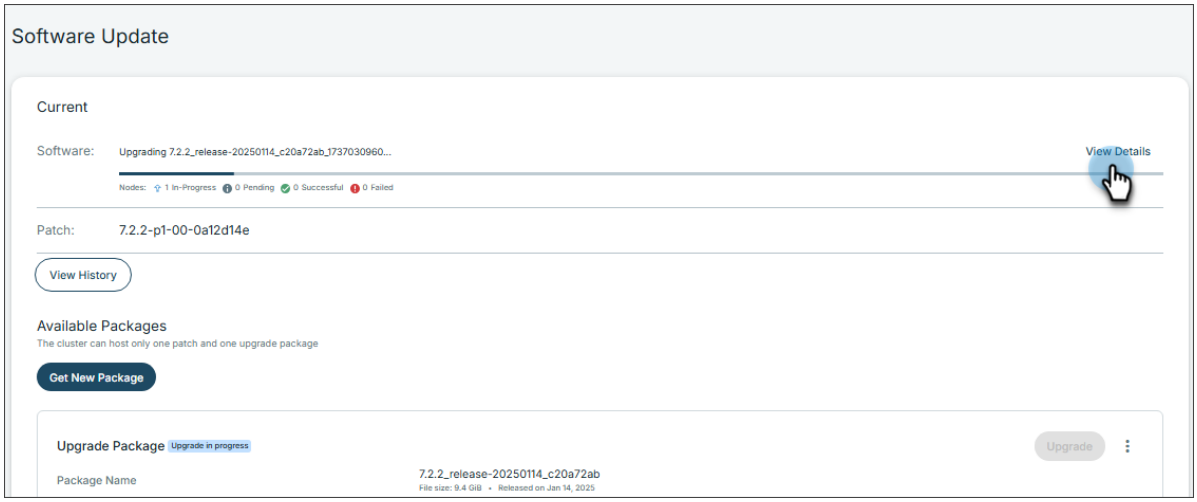
   The **Ok to Upgrade?** dialog appears.



4. If the pre-check fails, you can either:
   1. **Stop immediately** to stop the upgrade process (recommended). This allows you to review and address the pre-check failures before retrying the upgrade.
   2. **Proceed with the upgrade by ignoring pre-check failure** to continue the upgrade process despite the pre-check failure.
5. Enter **Yes** in the text field and click **Upgrade** to confirm and start upgrading.

The upgrading process will begin. You can observe the upgrading progress for all the available nodes in the cluster.

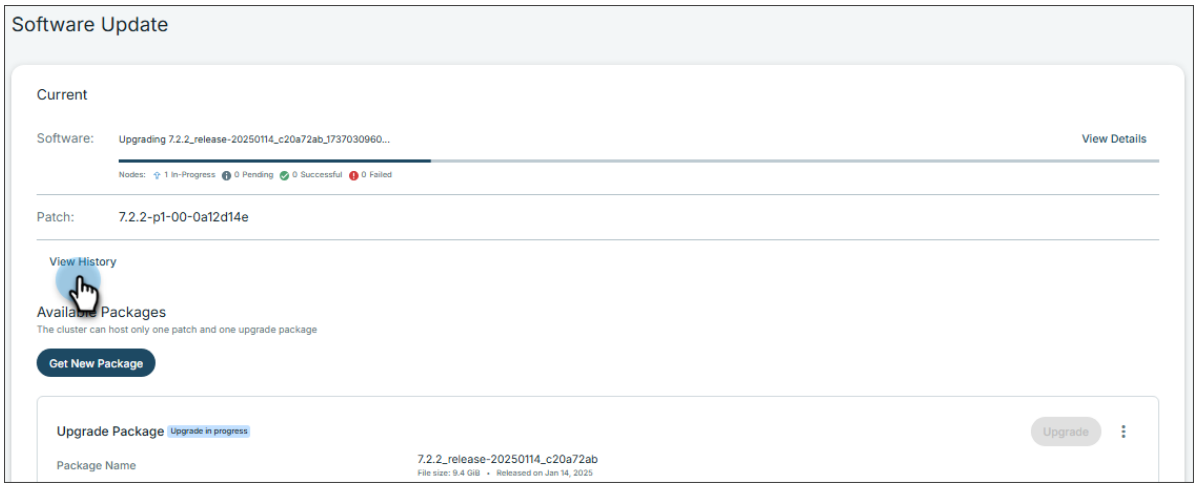
To monitor upgrading progress, click **View Details**.



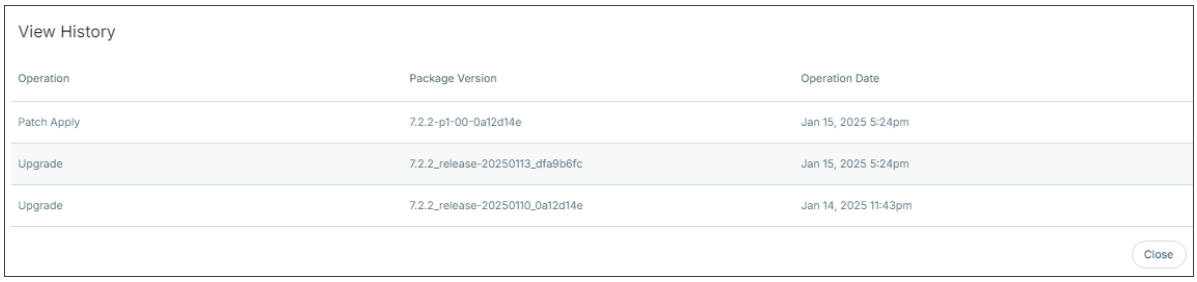
The **Upgrading the Cluster** page appears, showing the following information:

- Target version for upgrading
- Node Status
    - In-progress
    - Pending
    - Successful
    - Failed
- Node IP Address
- Upgrading Duration
- Upgrading Completion Time

To view the upgrade and patch history, click **View History**.



The **View History** dialog appears, where you can see the following information:



- **Operation** - Displays the type of operation you performed.
- **Package Version** - Displays the package version used during the operation.
- **Operation Date** - Displays the date and time when the operation was completed.

Cancel Upgrade

Cancel Upgrade in a Single Node Cluster

Run the following command to cancel the upgrade in a single node Cohesity cluster:

```
iris_cli cluster upgrade cancel=true
```

Sample Output

```
Username: admin
```

```
'admin' Password:password123
```

```
Success: Aborted upgrade.
```

When running the CLI command to cancel the upgrade of a Single Node Cohesity Cluster, all upgrades, including ongoing upgrades on its nodes, are canceled.

Cancel Upgrade in a Multinode Cluster

Run the following command to cancel the upgrade in a multinode Cohesity cluster:

```
iris_cli cluster upgrade cancel=true
```

Sample Output

```
Username: admin
```

```
'admin' Password:password123
```

```
Success: upgrade cancellation is requested.
```

If upgrade cancellation is requested when an upgrade is in progress on one of its nodes, the Cohesity cluster allows the upgrade to complete on that node. Once the ongoing upgrade is completed, subsequent upgrades on its remaining nodes are aborted. While the approach improves cluster stability, it may lead to nodes on different versions. You can resolve this by upgrading the remaining nodes to ensure all the nodes are of the same version.

Verify an Upgrade is Canceled

To verify the upgrade is canceled in a single or multinode Cohesity cluster, Cohesity recommends that you run the `cluster status` command:

- To check the current version of the nodes in the output.
- To verify there are no ongoing upgrades on the cluster by ensuring that `CLUSTER ACTIVE OPERATION` is empty.

```
admin> cluster status
```

Sample Output

```
Username: admin
'admin' Password:Password123
CLUSTER ID                    : 1111111
CLUSTER NAME                  : LocalCluster
SERVICE STATE SYNC            : DONE
CLUSTER ACTIVE OPERATION      :
CLUSTER HEAL STATUS           : NORMAL
```

If a node (irrespective of whether it's the first or last node of that cluster) becomes inoperable during an upgrade, cancel the upgrade, delete the node, and restart the upgrade.

Power Off and Power On a Cohesity Cluster

This topic describes the following:

- How to power off a Cohesity cluster or Node.
- How to power on a Cohesity cluster or Node.

Power off a Cohesity cluster or a Cohesity Node

1. Login to the Cohesity CLI.

   If your default username and password is not admin, then login to Cohesity CLI using the `iris_cli -username=XXXX` command. For more information, see Using the Cohesity CLI and List of Cohesity CLI Commands.

2. Stop all IOs from the Clients, and wait for 2-3 minutes.

   Skip this step when powering off a single node on a Cohesity cluster.

3. Run the following commands:

   To stop the Cohesity cluster, use the command:

```
cohesity>cluster stop
```

To stop a single node on a Cohesity cluster, on the Linux CLI, run the:

`node_stop.sh script`

The `node_stop.sh script` is located at: `/home/cohesity/bin/node_stop.sh`

You can also use the following command to power off the cluster:

This command will disconnect the secure shell and come back to normal in a few minutes.

Then provide `shutdown.sh` to stop the cluster services and the linux kernel.

> **Note:** Enable Host Shell to run the node_stop.sh command as Cohesity restricts custom scripts to the host operating system shell. For more information, see Enable Host Shell Access.

4. Wait for 5 minutes for the services to stop and run the status command to the view service status.

   In case of aCohesity cluster, use command:

   ```
   cohesity>cluster status
   ```

   In case of a Cohesity node, use command:

   ```
   cohesity>node status
   ```

   For Cohesity cluster, output similar to the following is expected:

   ```
   NODE ID                        : 101954678100000
   NODE IPS                       : <Node IP>
   SOFTWARE VERSION               : <Software Version>
   ACTIVE OPERATION               :
   SERVICE NAME                   :
   alerts                      :
   apollo                      :
   athena                      :
   atom                        :
   bifrost                     :
   bifrost_broker              :
   bridge                      :
   bridge_proxy                :
   compass                     :
   eagle_agent                 :
   elrond                      :
   etl_server                  :
   ```

```
gandalf                    : 25981, 25988

yoda                       :
```

For a Cohesity node, output similar to the following is expected:

```
[support@hpe-apollo-4510-2m282800yf-node-1 ~]$ iris_cli node status
```

```
E0726 10:47:16.470086 32855 handle_rest.go:676] Client.Do Error:Post
https://127.0.0.1:443/login: dial tcp 127.0.0.1:443: connect:
connection refused after making /login request.
```

```
Unable to connect to server 127.0.0.1:443.
```

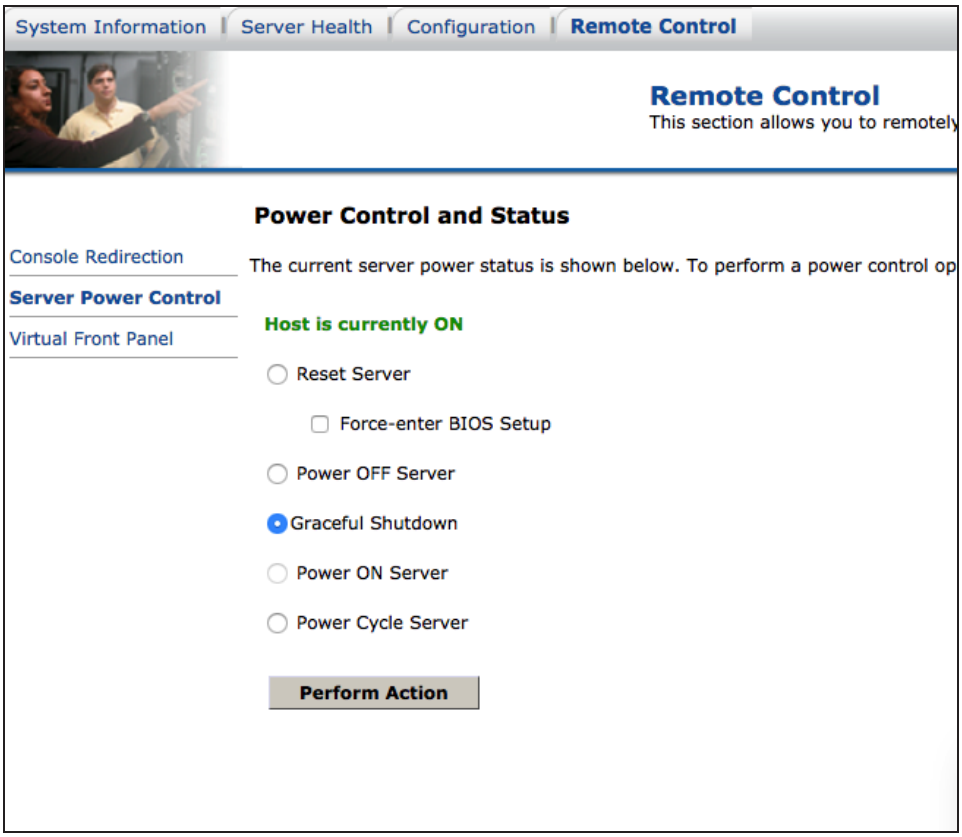
> **Note:** The numbers for each Cohesity cluster service may differ for each node or Cohesity cluster.

5. Based on the hardware or hypervisor, perform the following:

   C2000 Series

   Log in to the IPMI and power off each node by performing the steps below:

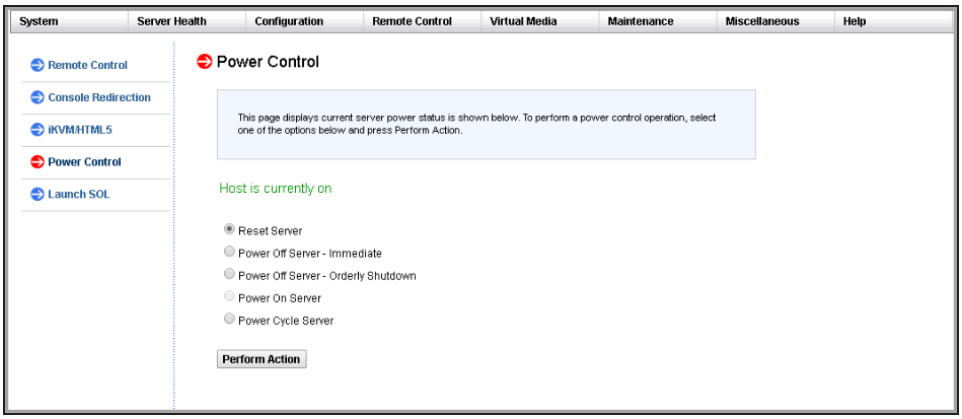
1. Click the **Remote Control** tab.
2. In the left-hand pane, select **Server Power Control** > **Power OFF Server** or **Graceful Shutdown**> **Perform Action**.



C3500

Log in to the IPMI and power off each node by performing the steps below:

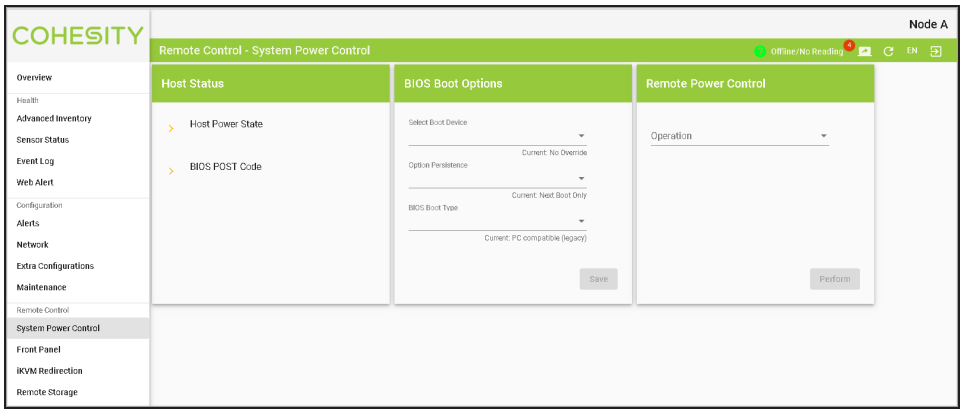
1. Click the **Remote Control** tab.
2. In the left-hand pane, select **Power Control** > **Power Off Server - Immediate** or **Power Off Server - Orderly Shutdown** > **Perform Action**.



C4000 Series

Log in to the IPMI and power off each node by performing the steps below:

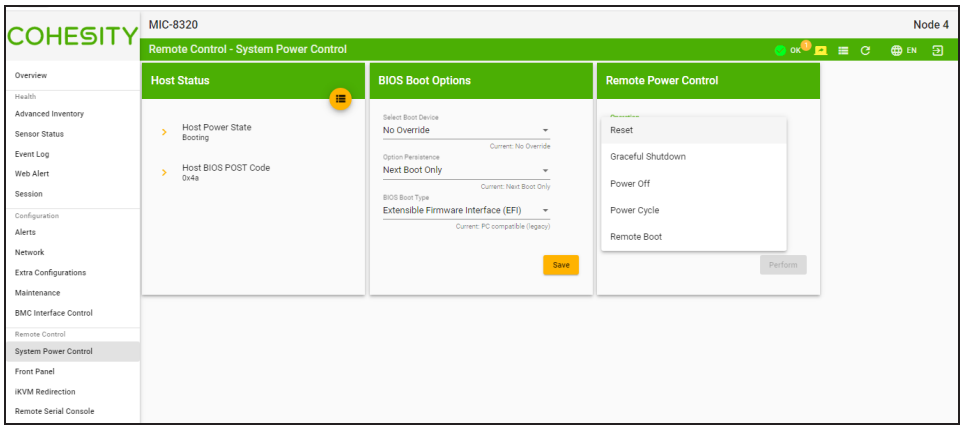
1. In the left-hand pane, select **System Power Control**.
2. In the **Remote Power Control** section, from the **Operation** drop-down, select **Power Off**.
3. Click **Perform**.



C5000

Log in to the IPMI and power off each node by performing the steps below:

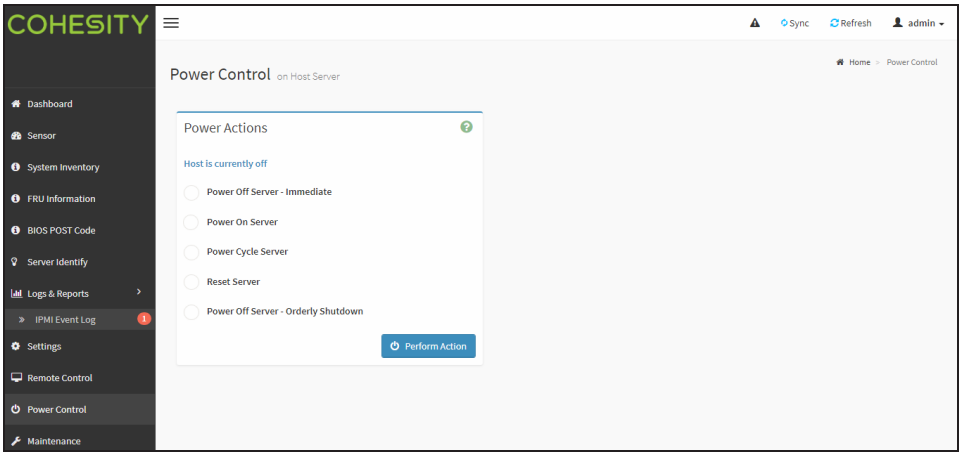
1. In the left-hand pane, select **System Power Control**.
2. In the **Remote Power Control** section, from the **Operation** drop-down, select **Power Off**.
3. Click **Perform**.



C6000 Series

Log in to the IPMI and power off each node by performing the steps below:

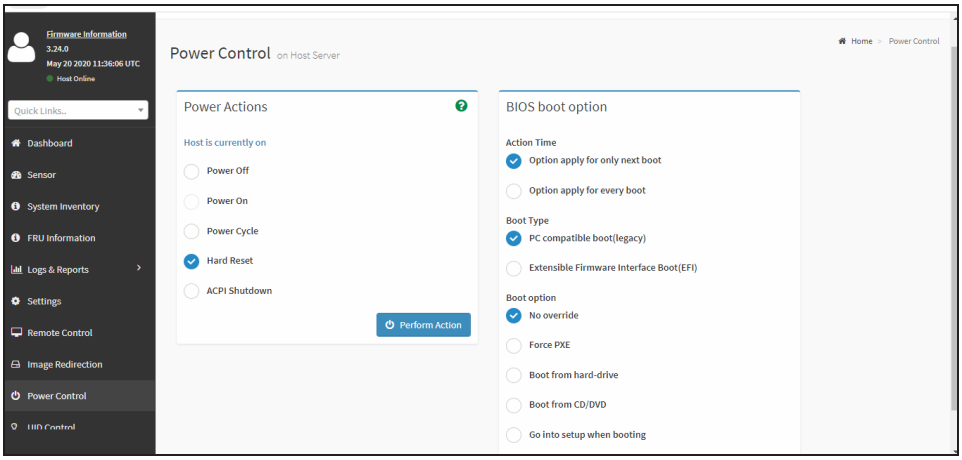
1. In the left-hand pane, select **Power Control**.
2. Under **Power Control** > **Power Actions**, select either **Power Off Server - Immediate** or **Power Off Server - Orderly Shutdown.**
3. Click **Perform Action**.



CX8000 Series

Log in to the IPMI and power off each node by performing the steps below:

1. In the left-hand pane, select **Power Control**.
2. Under **Power Control** > **Power Actions**, select **Power Off**.
3. Click **Perform Action**.



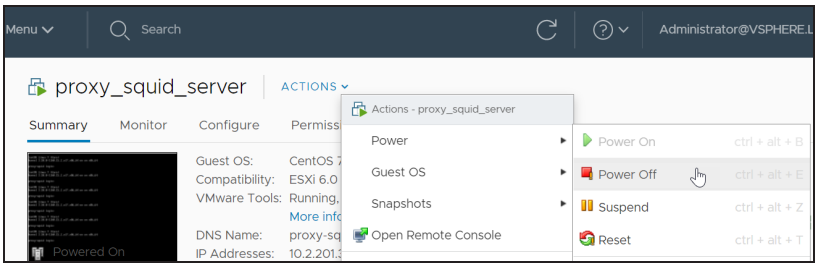
Virtual Edition Cluster

1. Log into your Hypervisor's Management Console to power on the node. For details on how to do this, see the documentation of your Hypervisor.

   For example, if you are using a VMware VM:

1. Log into the vCenter Server using the vSphere Web Client.
2. Follow these steps to power on each VM in the Cohesity cluster:
   - From the **Hosts and Clusters** tab, right-click the VM and select **Power** > **Power Off**.

     (or)
   - Click the **Summary** tab of the VM, and from the **ACTIONS** menu, select **Power** >**Power Off**.



Cloud Edition Cluster

You can stop your cloud instance using the Cloud Management Console of your Cloud Service Provider. For details on how to stop a cloud instance, using the:

- **AWS**: Amazon EC2 console or the AWS CLI.
- **Azure**: Azure portal.
- **GCP**: Google Cloud console or the gcloud CLI.

Power on a Cohesity cluster or a Cohesity Node

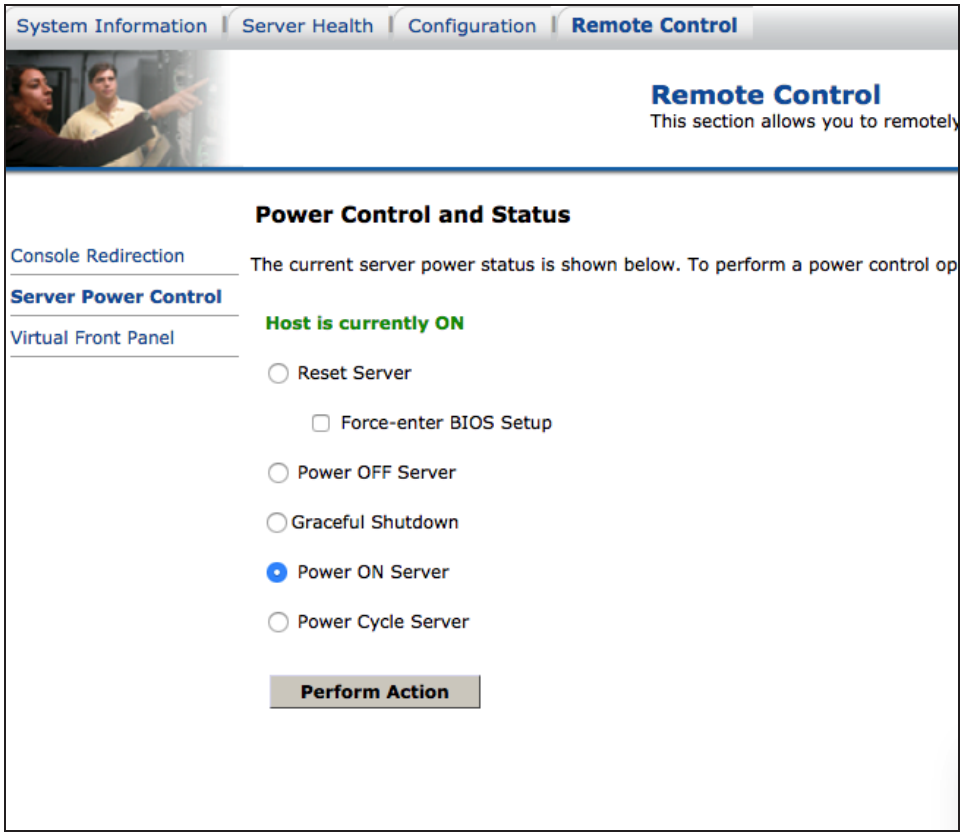
1. Based on the hardware, perform the following:

   C2000 Series

   Log in to IPMI and power on each node by performing the steps below:

   1. Click the **Remote Control** tab.
   2. In the left-hand pane, select **Server Power Control** > **Power ON Server** >

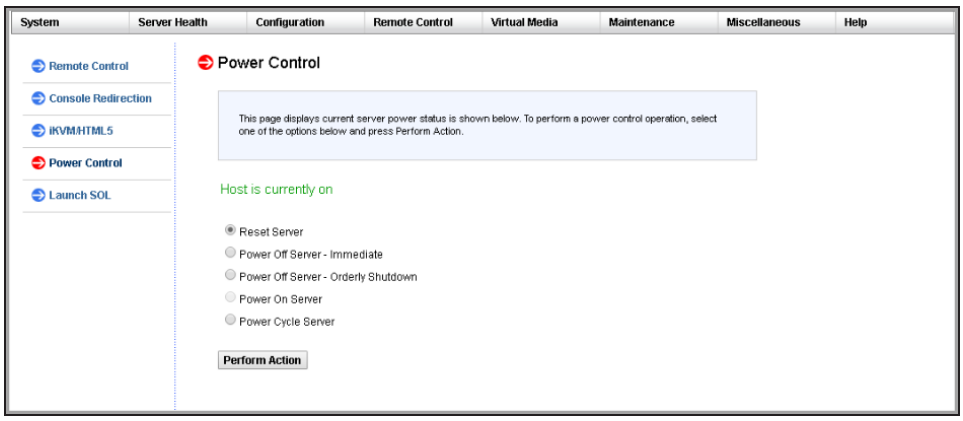
Perform Action.



C3500

Log in to the IPMI and power on each node by performing the steps below:

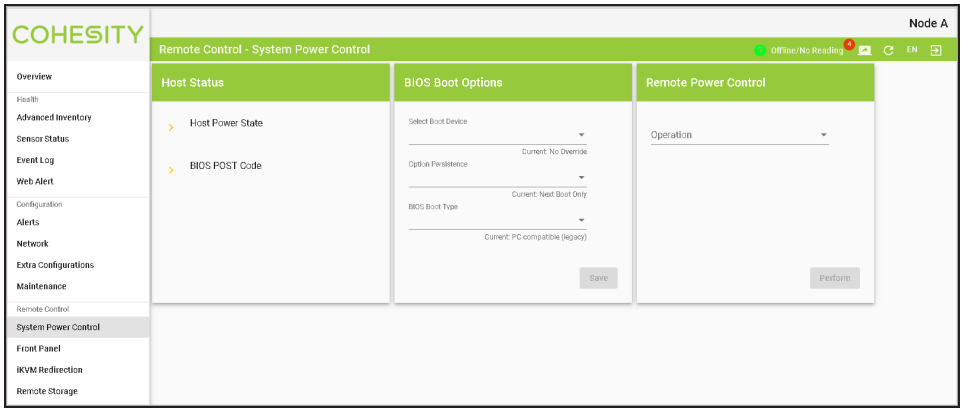
1. Click the **Remote Control** tab.
2. Select **Power Control** > **Power On Server** > **Perform Action**.



C4000 Series

Log in to the IPMI and power on each node by performing the steps below:

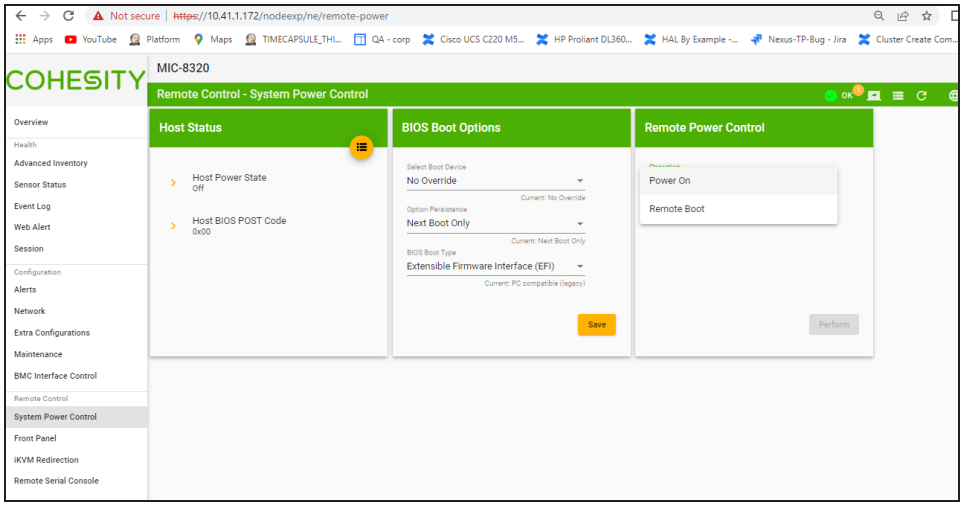
1. In the left-hand pane, select **System Power Control**.
2. In the **Remote Power Control** section, from the **Operation** drop-down, select **Power On**.
3. Click **Perform**.



C5000

Log in to the IPMI and power on each node by performing the steps below:

1. In the left-hand pane, select **System Power Control**.
2. In the **Remote Power Control** section, from the **Operation** drop-down, select **Power On**.
3. Click **Perform**.

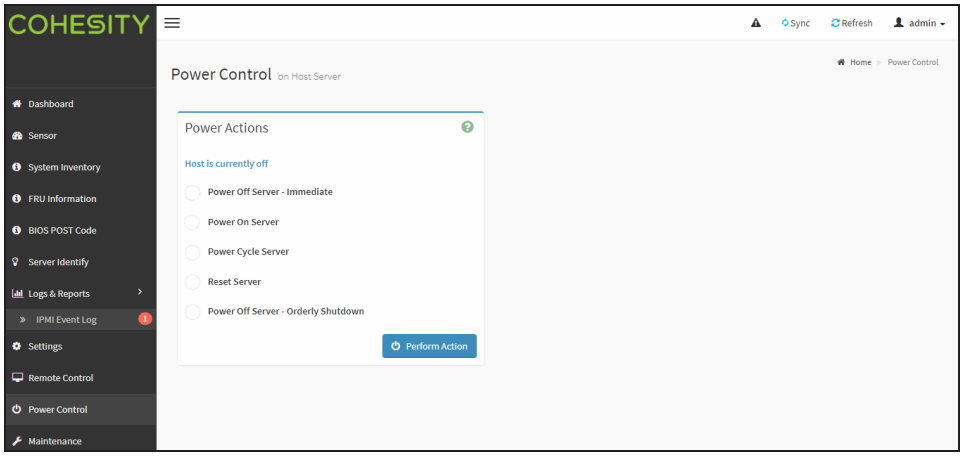


C6000 Series

Log in to the IPMI and power off each node by performing the steps below:

1. In the left-hand pane, select **Power Control**.
2. Under **Power Control** > **Power Actions**, select **Power On Server.**

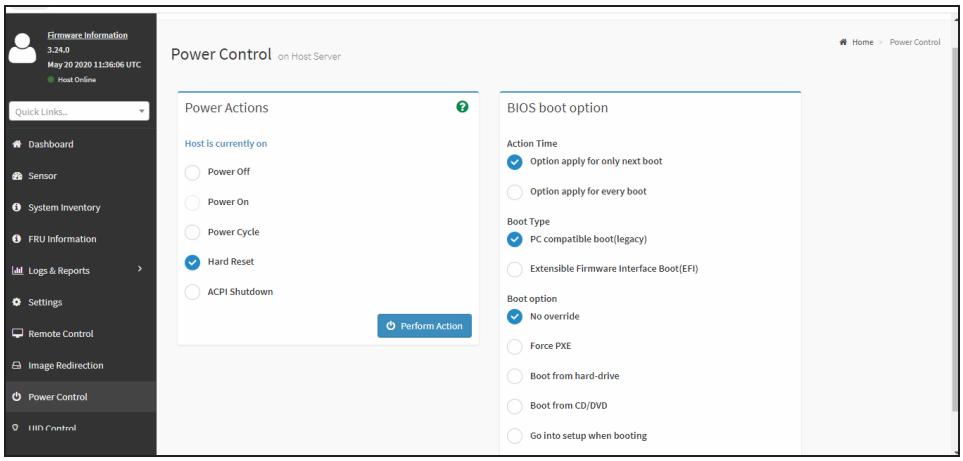
3. Click **Perform Action**.



CX8000 Series

Log in to the IPMI and power off each node by performing the steps below:

1. In the left-hand pane, select **Power Control**.
2. Under **Power Control** > **Power Actions**, select **Power On**.
3. Click **Perform Action**.



Virtual Edition Cluster

Log into your Hypervisor's Management Console to power on the node. For details on how to do this, see the documentation of your Hypervisor.

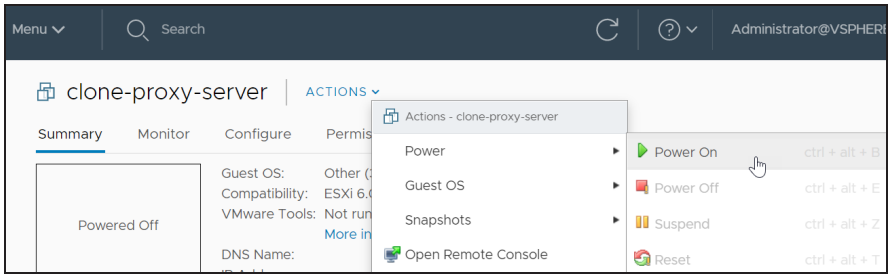
For example, if you are using a VMware VM:

1. Log into the vCenter Server using the vSphere Web Client.
2. Follow these steps to power on each VM in the Cohesity cluster:

- From the **Hosts and Clusters** tab, right-click the VM and select **Power** > **Power On**.

  (or)

- Click the **Summary** tab of the VM, and from the **ACTIONS** menu, select **Power** > **Power On**.



3. Repeat step 2 for all the nodes in the Cohesity cluster.

Cloud Edition Cluster

You can start your cloud instance using the Cloud Management Console of your Cloud Service Provider. For details on how to start a cloud instance, using the:

- **AWS**: Amazon EC2 console or the AWS CLI.
- **Azure**: Azure portal.
- **GCP**: Google Cloud console or the gcloud CLI.

2. Login to the Cohesity CLI.

   If your default user name and password are not admin, then login to Cohesity CLI using the `iris_cli -username=XXXX` command. For more information, see Using the Cohesity CLI and List of Cohesity CLI Commands.

3. Run the following command:

   To start a Cohesity cluster, use the command:

   ```
   cohesity>cluster start
   ```

   To start a single node on a Cohesity cluster, on the Linux CLI, run the:

   `node_start.sh script`

   The `node_start.sh script` is located at: `/home/cohesity/bin/node_start.sh`

4. Wait for 5 minutes for the services to start and run the status command to the view service status.

   In case of a Cohesity cluster, use command:

   ```
   cohesity>cluster status
   ```

   In case of a Cohesity node, use command:

   ```
   cohesity>node status
   ```

For Cohesity cluster, output similar to the following is expected:

```
NODE ID                          : 101954678100000
NODE IPS                         : <Node IP>
SOFTWARE VERSION                 : <Software Version>
ACTIVE OPERATION                 :

> **Note:** The numbers for each Cohesity cluster service may differ for each node or Cohesity cluster.

Search the Cluster and Take Action

You can search the Cohesity cluster for objects, such as VMs, storage volumes and databases, refine the search results and then perform actions on the objects. You can find and protect unprotected objects, investigate failed Protection Groups, or recover or clone snapshots, all from the search results page. The actions launch the same familiar Cohesity workflow pages, but help is available for each page if you need it.

Example: Find and Protect with a Job

The following example demonstrates how to find unprotected VMs and protect them by creating a Protection Group.

1. Type `vm` in the search box at the top of the dashboard and press enter. You can search for any partial name or type an asterisk * wildcard.

   The Search page displays a list of objects that contain `vm` in the name.

2. Optionally, refine the list by selecting checkboxes in the left pane.

a. Under **Type**, select the **Virtual Infrastructure** checkbox. Additional options are displayed based on the infrastructure you select.
b. Under **Virtual Infrastructure Type**, select the **VMware** checkbox.
c. Under **Status**, select the **Unprotected** checkbox.

The list of objects automatically updates to display only unprotected VMware VMs.

3. Select a VM in the center pane.

   Details about the VM display in the right pane.
4. Click **Protect** and select **Protection Group**.
5. Click **New Job**.
6. The New Job page is displayed and you can create a job to protect the VM.

> **Tip:** For an explanation of the options on the New Job page, click the help icon (?) in the top right corner of the dashboard.

7. When you are finished configuring the Protection Group, click **Protect** to create the job and return to the Search page.

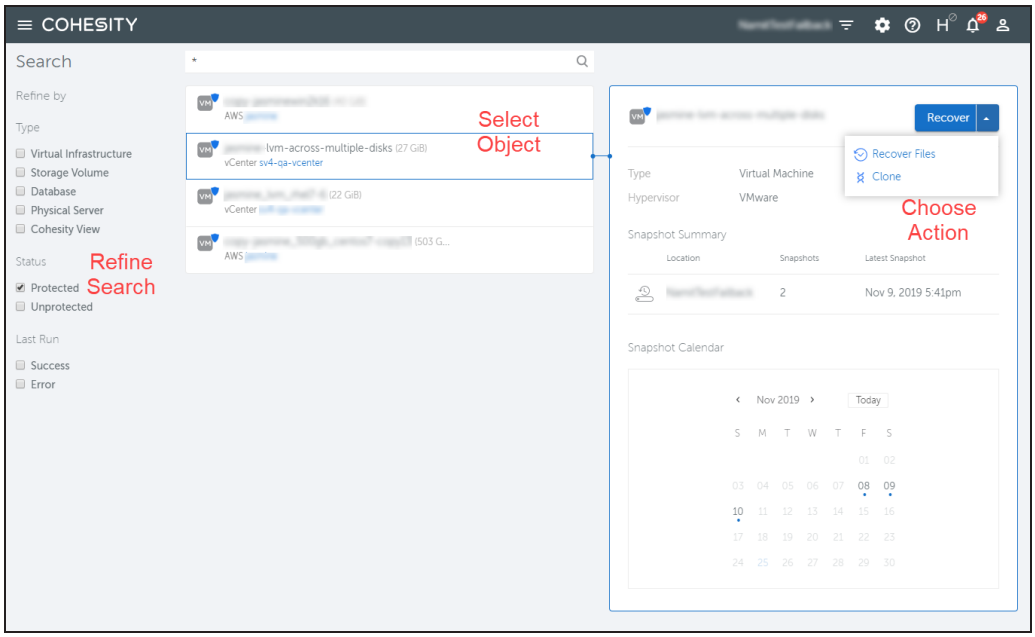
Example: Clone or Recover a Snapshot

To clone or recover a snapshot previously created by a Protection Group:

1. Type a partial job name or * in the search box at the top of the dashboard and press enter.

   The Search page is displayed with a list of objects.
2. Select the **Protected** check box in the left pane.
3. Select a job from the center pane.

   Details about the job are displayed in the right pane.
4. Click the actions icon in the right pane and select **Clone** or **Recover**.



5. Depending on which action you click, the **Clone** or **Recover** page is displayed.

> **Tip:** For an explanation of the options on the **Clone** or **Recover** page, click the help icon (?) in the top right corner of the dashboard.

6. When you finish configuring the clone or recovery options, click **Finish** to run the task and return to the Search page.

Manage Storage Domains

From the Manage Storage Domains page, you can view, add and manage the Storage Domains that have been created on the Cohesity cluster. For detailed instructions, see Create or Edit Storage Domains.

The columns for the table displayed on the Manage Storage Domains page are described below.

Column Name	Description / Action
Storage Domain Name	Drill-down on this link to view the details and statics about the Storage Domain. You can also edit the Storage Domain from the linked page.
Organization	Drill-down on this link to get details of the organization that is associated with the Protection Group.

Column Name	Description / Action
Physical Used	The size of the data physically stored on the Cohesity cluster, after the data has been reduced by change block tracking, compression and deduplication, including the disk space used for data resiliency (fault tolerance and erasure coding).
Physical Quota	The maximum physical capacity of the Storage Domain if its Physical Quota option is on. If the option is off, the field indicates `n/a`.
Logical Managed	The logical data managed, as computed by the Cohesity cluster without reduction by change-block tracking, compression and deduplication.
Redundancy	The Storage Domain's redundancy, either Redundancy Factor (RF2 or RF3) or Erasure Coding (EC) and the number of data stripes : number of failures to tolerate.
Deduplication	Indicates if Deduplication is on for the Storage Domain and when the deduplication occurs. If Deduplication is on, the Cohesity cluster eliminates duplicate blocks of repeating data stored on the Cohesity cluster, thus reducing the amount of storage space needed to store data. If Inline Deduplication is on, deduplication occurs when the Cohesity cluster writes the data to the Cohesity View. If Inline Deduplication is off, deduplication occurs after the Cohesity cluster writes the data to the Cohesity View.
Compression	Indicates if Compression is on for the Storage Domain and when the compression occurs. If Compression is on, the Cohesity cluster compresses all the data stored in the Storage Domain, thus reducing the amount of storage space needed to store the data. If Inline Compression is on, compression occurs when the Cohesity cluster saves the blocks to the Cluster. If Inline Compression is off, compression occurs after the Cohesity cluster writes the data to the Cohesity cluster.
Encryption	Indicates if Encryption is on for the Storage Domain. > **Note:** Encryption can be enabled at the cluster level only when creating the cluster and cannot be disabled or modified later. If Encryption is enabled at the Cluster level, all Storage Domains are encrypted. However, encryption can be enabled at the Storage Domain level after creating the cluster.
Cloud Tier	If Cloud Tier is on, the Cohesity cluster moves cold (rarely accessed) data to the designated External Target. Once Cloud Tier is on, it cannot be turned off.

Column Name	Description / Action
Actions	To manage an existing Storage Domain, select one of the following options: For a Multitenancy Cohesity cluster, you can only modify the objects that belong to your organization. • **Edit** ( )–Configure the settings of the existing Storage Domain. For detailed instructions, see Create or Edit Storage Domains. • **Create View in this Storage Domain** ( )–Create a new View in this Storage Domain. For details instructions, see Create or Edit Storage Domains.

Create or Edit Storage Domains

A Storage Domain, formerly known as a View Box, is a named storage location on a Cluster. A Storage Domain defines the policy and frequency for deduplication among other configurations such as Compression, Erasure Coding, and Replication Factor. A Storage Domain contains Views. When you configure a Protection Group, you specify a Storage Domain, and during a Protection Group Run, the Cohesity cluster stores the Snapshots in that Storage Domain.

To create or edit a Storage Domain:

1. Navigate to **Settings > Summary** and select the **Storage Domains** tab.
2. On the Storage Domains page, complete one of the following actions:
   - Click **Add Storage Domain** located at the top right of the page.
   - Edit an existing Storage Domain by clicking the Actions Menu (⋮) and selecting **Edit** ( ).
3. **Storage Domain Name:** Enter a name for the Storage Domain.
4. **Associated External Target**: Select the external target to be associated with the Storage Domain. This associated external target stores all the data landing on this Storage Domain. Each Storage Domain can only be associated with one external target and vice versa. Once set, the associated external target cannot be changed.

   NOTE: This field is only available for GCP Next-Gen Cloud Edition.
5. **Authentication Provider:** You can map the Storage Domain to an AD domain if the Cohesity cluster, version 6.5.1d or higher, is AD domain-joined. Mapping to a specific AD domain means that users from only that AD domain have permission to view the Storage Domain's contents when accessing through SMB. By default, a Storage Domain is accessible to users from all joined AD domains.

6. **Deduplication:** Optionally toggle on. If Deduplication is on, the Cohesity cluster eliminates duplicate blocks of repeating data stored on the Cohesity cluster, thus reducing the amount of storage space needed to store data.

   > **Note:** Toggling **Deduplication** on for a non-Deduplication Storage Domain that uses Cloud Tier may result in a large number of reads from the Cloud Tier if Storage Domain data has already been sent to the Cloud Tier.

   Inline Deduplication: Optionally toggle on. If Inline Deduplication is on, deduplication occurs when the Cohesity cluster writes the data to the Cohesity View. If Inline Deduplication is off, deduplication occurs after the Cohesity cluster writes the data to the Cohesity View.

7. **Compression:** Optionally toggle on. If Compression is on, the Cohesity cluster compresses all the data stored in the Storage Domain, thus reducing the amount of storage space needed to store the data. If Compression is on and then turned off later, the current data on the Storage Domain is not decompressed, but any new data stored on the Storage Domain is not compressed.

   Inline Compression: Optionally toggle on. If Inline Compression is on, compression occurs when the Cohesity cluster saves the blocks to the Cluster. If Inline Compression is off, compression occurs after the Cohesity cluster writes the data to the Cohesity cluster.

   > **Note:** If both Compression and Inline Deduplication are on, Cohesity recommends you turn **Inline Compression** on.

8. **Encryption:** Toggle to enable encryption for the Storage Domain. Encryption can be enabled only when you are creating the Storage Domain. Once the Storage Domain is created, the options to enable encryption or modify its encryption settings are disabled in the Cohesity cluster.

   By default, Cohesity uses **Internal KMS** for encryption. If encryption is enabled at the cluster level, then data within the Storage Domains is also encrypted, and you don't have to enable encryption for each Storage Domain. You can register an external KMS and select one of the following from the drop-down list:

   - AWS
   - KMIP Compliant

   For more information, see External Key Management Service.

9. Expand **Show Advanced Settings** to see the list of additional View settings.

10. **Physical Quota:** Optionally toggle on to limit the Storage Domain's physical capacity and then set the capacity. The capacity must be a whole number.

    Toggle **Alert** on to trigger an Alert when the Storage Domain reaches the specified threshold.

11. **Logical Quota:** Optionally toggle on to set a default logical capacity limit for Views created in this Storage Domain and set the capacity. Logical data is fully hydrated and expanded.

    Toggle **Alert** on to trigger an Alert when the View reaches the specified threshold.

12. **Cloud Tier:** Optionally toggle on. If Cloud Tier is on, the Cohesity cluster moves cold (rarely accessed) data to the designated External Target. Once Cloud Tier is on, it cannot be turned off.

    To turn Cloud Tier off, contact Cohesity Support to disable the feature.

    If Cloud Tier is on, select an External Target or register a new External Target.

    Set the coldness of data to tier.

    > **Note:** If the **Physical Quota** toggle is off, the cluster's default capacity and space utilization threshold are used for tiering.

    Optionally, toggle on **Override Cluster Threshold** and set the **Space Utilization Threshold** to activate cloud tiering for the Storage Domain.

13. **Fault Tolerance:** Select the number of hard drive, node, chassis, or rack failures that can occur before a Cluster Health Alert is triggered. The available choices are determined by the number of nodes, chassis, or racks in the Cluster. The Cluster's global **Custom Failure Domain** setting determines the failure domain (Node, Chassis or Rack) and the number of failures tolerated at the Storage Domain level. For more details about global cluster level failure domain settings, see Configure Cluster Settings.

    > **Note:** Fault Tolerance is not available for single node Cohesity cluster (ROBO). By default, the Storage Domain is configured with RF1.

    The following table provides the fault tolerance options you can select based on the failure domain set at the cluster level and the number of components available in the Cohesity cluster.

Minimum Failures Tolerated	Description
0D:0N	No hard disk failure or node failure can occur without triggering the alert. This option provides Redundancy Factor 1 (RF1). If you select this option, you are opting for no replication and indicating that you trust the underlying datastore medium's resiliency. This option is available only in the Virtual Edition clusters. **Note:** If you select this option, Erasure Coding will be disabled. If RF1 is enabled on a multi-node Virtual Edition Cluster, during the cluster upgrade, data will be temporarily unavailable until the associated node comes online.
1D:0N	Tolerate failure of 1 drive. No node failure is tolerated. This is only available on physical ROBO clusters, it provides RF2 like redundancy and is set by default.
1D:1N	Tolerate failure of 1 drive or 1 node. The available options to select are RF2 or EC x:1.
2D:1N	Tolerate failure of 2 drives or at least 1 node. The available options to select include RF3 and EC x:2. This option is available only if the Cluster has three or more nodes. Cohesity will always make the best effort to place each EC stripe unit to be on separate nodes when sufficient nodes are available. Only when sufficient nodes are not present the EC stripe units will be placed within the same node but on separate disks.

Minimum Failures Tolerated	Description
2D:2N	Tolerate failure of 2 drives or 2 nodes. This setting is only available if there are at least four nodes. With this setting, the available options are RF3 or EC x:2. Cohesity will always try to place each EC stripe unit on separate nodes when sufficient nodes are available. **Note:** You cannot change the fault tolerance setting to 2D:2N if the metadata usage is >=50% of the available storage. For more information, see the Cohesity white paper: Cohesity Fault Tolerance – Data Integrity for Modern Web-scale Environments. **Note:** The Erasure Coding (EC) setting is not recommended for Clusters with fewer than five nodes because the data cannot be healed after one Node failure. Your data will be at risk until the failed Node is replaced.
3D:1N	Tolerate failure of 3 drives or 1 node. This setting is only available if there are at least three nodes. With this setting, the available options are RF4, EC x:3, or EC x:4.
3D:2N	Tolerate failure of 3 drives or 2 nodes. This setting is only available if there are at least seven nodes. With this setting, the available options are RF4, EC x:3, or EC x:4.
0D:0C	No hard disk failure or chassis failure can occur without triggering the alert. This option provides Redundancy Factor 1 (RF1). If you select this option, you are opting for no replication and indicating that you trust the underlying datastore medium's resiliency. This option is available only in the Virtual Edition clusters. If you select this option, Erasure Coding will be disabled. If RF1 is enabled on a multi-node Virtual Edition Cluster, during the cluster upgrade, data will be temporarily unavailable until the associated chassis comes online.
1D:1C	Tolerate failure of 1 drive or 1 chassis. This setting is only available if there are at least three chassis. With this setting, the available options are RF2 or EC x:1.

Minimum Failures Tolerated	Description
2D:1C	Tolerate failure of 2 drives or 1 chassis. This setting is only available if there are at least three chassis. With this setting, the available options are RF3 or EC x:2.
2D:2C	Tolerate failure of 2 drives or 2 chassis. This setting is only available if there are at least four chassis. With this setting, the available options are RF3 or EC x:2.
3D:1C	Tolerate failure of 3 drives or 1 chassis. This setting is only available if there are at least three chassis. With this setting, the available options are RF4, EC x:3, or EC x:4.
3D:2C	Tolerate failure of 3 drives or 2 chassis. This setting is only available if there are at least seven chassis. With this setting, the available options are RF4, EC x:3, or EC x:4.
1D:1R	Tolerate failure of 1 drive or 1 rack. This setting is only available if there are at least three racks. With this setting, the available options are RF2 or EC x:1.
2D:1R	Tolerate failure of 2 drives or 1 rack. This setting is only available if there are at least three racks. With this setting, the available options are RF3 or EC x:2.
2D:2R	Tolerate failure of 2 drives or 2 racks. This setting is only available if there are at least four racks. With this setting, the available options are RF3 or EC x:2.
3D:1R	Tolerate failure of 3 drives or 1 rack. This setting is only available if there are at least three racks. With this setting, the available options are RF4, EC x:3, or EC x:4.
3D:2R	Tolerate failure of 3 drives or 2 racks. This setting is only available if there are at least seven racks. With this setting, the available options are RF4, EC x:3, or EC x:4.

The 2D in 2D:1N or 2D:2N has several effects at the same time:

- 2D allows selecting higher EC X:Y levels with fewer nodes. For example, an X+Y complete EC unit can be formed from n/2 nodes (assuming 2 disks per node taken for the single EC unit).
- Survive 2 simultaneous disk (HDD) failures OR 2 simultaneous node failures with 2D:2N with EC X:2. The disk failures are per cluster and not per node.
- Data stripe units from a single EC stripe are spread across as many nodes as possible. For example, if there are 10 nodes and EC 5:2 has been configured, the EC stripes will be spread across 7 separate nodes even if the protection level is 2D:1N. If there are 4 nodes, the EC 5:2 bits will be spread across 4 nodes

with a 2D:1N protection level, with 3 of the 4 nodes having 2 stripe units each on separate disks.

- 2 node failures can be tolerated with EC X:2 if the number of nodes is at least X+2.
- Tolerate SSD (metadata) failures of up to 2.

For more information, see the Cohesity white paper: Cohesity Fault Tolerance — Data Integrity for Modern Web-scale Environments.

14. **Erasure Coding:** Toggle on for better fault tolerance and capacity utilization. You can also select an Erasure Coding setting from the drop-down list. The available choices are determined by the **Fault Tolerance** setting and the number of nodes, chassis, or racks in the Cohesity cluster. The settings indicate the ratio of the data stripes to the code stripes, expressed as x:y. For example, 2:1, 2:2, 3:1, 3.2, 4:1, 4:2, 4:3, 5:1, 5:2, or 5.3.

    Node Resilience Settings

    The following table shows possible EC settings that can be set for the required resiliency of hard drives and nodes. The table indicates the number of failures tolerated in disks *or* nodes at any EC or RF level. For example, if a 5-node Cohesity cluster is set to EC4:2, failures are tolerated in 2 disks or 1 node.

    For more details on Cohesity Erasure Coding, see the Cohesity-White-Paper-Fault-Tolerance-Data-Integrity.pdf.

    > **Note:** From Cohesity 6.6 onwards, you can use EC 8:2 for Azure, AWS, GCP, Imanis, MS SQL file-based, Physical Server, VMware, NAS, and SAN backup workloads.

Number of Nodes in the Cluster	Number of Failures Tolerated		Storage Domain Resilience Settings	
	Disks (D)	Nodes (N) or SSD	EC	RF (IF EC is Disabled)
3	1	1	2:1	RF2
	2	1	2:2, 3:2, 4:2	RF3
	3	1	3:3, 4:3, 5:3	RF4

Number of Nodes in the Cluster	Number of Failures Tolerated		Storage Domain Resilience Settings	
	Disks (D)	Nodes (N) or SSD	EC	RF (IF EC is Disabled)
4	1	1	2:1, 3:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
5	1	1	2:1, 3:1, 4:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
6	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2, 4:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
7	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2, 4:2, 5:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
	3	2	3:3, 4:3, 5:3	RF4

Number of Nodes in the Cluster	Number of Failures Tolerated		Storage Domain Resilience Settings	
	Disks (D)	Nodes (N) or SSD	EC	RF (IF EC is Disabled)
8	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2, 4:2, 5:2, 6:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
	3	2	3:3, 4:3, 5:3	RF4
9	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2, 4:2, 5:2, 6:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
	3	2	3:3, 4:3, 5:3	RF4
10+	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
	3	2	3:3, 4:3, 5:3	RF4

Chassis Resilience Settings

The following table shows possible EC settings that can be set for the required resiliency of chassis.

> **Note:** From Cohesity 6.6 onwards, you can use EC 8:2 for Azure, AWS, GCP, Imanis, MS SQL file-based, Physical Server, VMware, NAS, and SAN backup workloads.

Number of Chassis in the Cluster	Number of Failures Tolerated		Storage Domain Resilience Settings	
	Disks (D)	Nodes (N) or SSD	EC	RF (IF EC is Disabled)
3	1	1	2:1	RF2
	2	1	2:2, 3:2, 4:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
4	1	1	2:1, 3:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
5	1	1	2:1, 3:1, 4:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
6	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2, 4:2	RF3
	3	1	3:3, 4:3, 5:3	RF4

Number of Chassis in the Cluster	Number of Failures Tolerated		Storage Domain Resilience Settings	
	Disks (D)	Nodes (N) or SSD	EC	RF (IF EC is Disabled)
7	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2, 4:2, 5:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
	3	2	3:3, 4:3, 5:3	RF4
8	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2, 4:2, 5:2, 6:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
	3	2	3:3, 4:3, 5:3	RF4
9	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2, 4:2, 5:2, 6:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
	3	2	3:3, 4:3, 5:3	RF4

Number of Chassis in the Cluster	Number of Failures Tolerated		Storage Domain Resilience Settings	
	Disks (D)	Nodes (N) or SSD	EC	RF (IF EC is Disabled)
10+	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
	3	2	3:3, 4:3, 5:3	RF4

Rack Resilience Settings

The following table shows possible EC settings that can be set for the required resiliency of racks.

> **Note:** From Cohesity 6.6 onwards, you can use EC 8:2 for Azure, AWS, GCP, Imanis, MS SQL file-based, Physical Server, VMware, NAS, and SAN backup workloads.

Number of Racks in the Cluster	Number of Failures Tolerated		Storage Domain Resilience Settings	
	Disks (D)	Racks (R)	EC	RF (IF EC is Disabled)
3	1	1	2:1	RF2
	2	1	2:2, 3:2, 4:2	RF3
	3	1	3:3, 4:3, 5:3	RF4

Number of Racks in the Cluster	Number of Failures Tolerated		Storage Domain Resilience Settings	
	Disks (D)	Racks (R)	EC	RF (IF EC is Disabled)
4	1	1	2:1, 3:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
5	1	1	2:1, 3:1, 4:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
6	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2, 4:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
7	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2, 4:2, 5:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
	3	2	3:3, 4:3, 5:3	RF4

Number of Racks in the Cluster	Number of Failures Tolerated		Storage Domain Resilience Settings	
	Disks (D)	Racks (R)	EC	RF (IF EC is Disabled)
8	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2, 4:2, 5:2, 6:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
	3	2	3:3, 4:3, 5:3	RF4
9	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2, 4:2, 5:2, 6:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
	3	2	3:3, 4:3, 5:3	RF4
10+	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
	3	2	3:3, 4:3, 5:3	RF4

Post Processing Only: Toggle OFF to write erasure coding as data comes to the Cohesity cluster. When this option is ON, erasure coding is done post-process due to which data ingest performance rate is higher. .

ECX:4 is available only as a post processing option where the data is initially ingested as RF3 and then converted to X:4. Changing the viewbox configuration for EC X:Y (with Y < 4) to EC 12:4 or EC 16:4 is not permitted and not displayed in the viewbox editing page. However, you can switch from EC12:4 to EC16:4 and back, but the configuration only takes effect for any new data.

> **Note:** EC12:4 and EC16:4 are Early Access features. Contact Cohesity Support to enable the feature.

For more information, see the Cohesity white paper: Cohesity Fault Tolerance — Data Integrity for Modern Web-scale Environments.

15. Click **Create Storage Domain**.

Storage Domain Details

The **Storage Domain** details page has been redesigned to improve the user experience. This page provides granular details about the storage domain.

From the storage domain details page, you can do the following:

- Click the Actions menu (⋮) and select **Edit** to go to the **Edit Storage Domain** page.
- Click the Actions menu (⋮) and select **Create View in Storage Domain** to create a new view that uses this storage domain.

To view the storage domain details page:

1. Navigate to **Settings > Summary** and click the **Storage Domains** tab.
2. On the **Storage Domains** page, click a storage domain to navigate to the corresponding storage domain details page. This page displays the following details:

- **Storage**—Displays the current total quota, data consumed, space available, and the space saved owing to data deduplication and data compression:
- **Performance**—Displays the performance statistics of the selected storage domain:
  - **Throughput**—Amount of data transferred through external network interfaces in the cluster.
  - **IOPS**—Average number of read, write, or metadata operations serviced per second.
  - **Latency**—Average response time for read and write operations for views configured with TestAndDev High QoS policy.
- Partition details
- Authentication provider details
- Type of deduplication enabled on the storage domain—Inline or Post Process
- Type of compression enabled on the storage domain—Inline or Post Process
- Encryption status
- Quota and alert threshold details for the storage domain

- Quota and alert threshold details for views created in this storage domain
- Cloud Tier status

Delete Storage Domains

You can delete a Storage Domain to free up storage space if required. When deleting a Storage Domain, Cohesity clusters also delete the following entities associated with the Storage Domain:

- Protection groups and snapshots
- Recoveries in progress
- Views
- Dev/test clones

> **Note:** Cohesity cluster cannot delete views that have DataLock enabled or snapshots (and their owning protection groups) that have legal hold.

Before you Begin

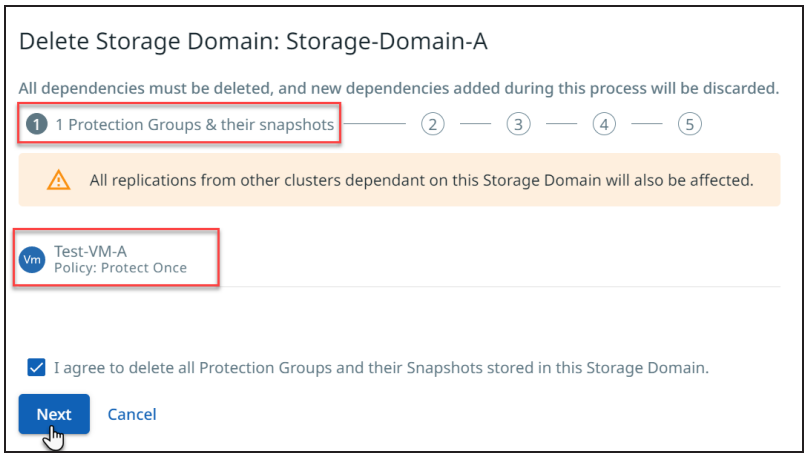
Ensure the following prerequisites are met before you delete the Storage Domain:

- In a multitenant environment:
  - Only the Service Provider administrators can delete Storage Domains, not Tenants.
  - Service Provider administrators must remove all tenants associated with the Storage Domain before deleting the Storage Domains.
- If cloud archival is set up, delete the archive policy before deleting the Storage Domain.

To delete a Storage Domain:

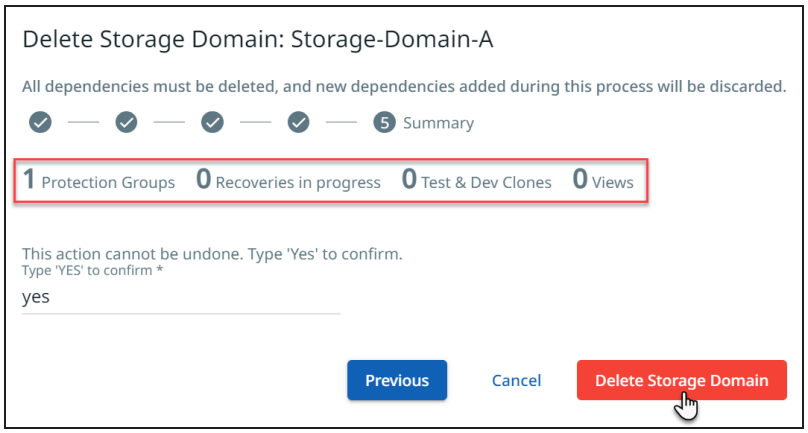
1. Navigate to **Settings** > **Summary**.
2. Select the **Storage Domain** tab.
3. Click the Actions menu (⋮) of the Storage Domain you want to delete and click **Delete**.
4. The **Delete Storage Domain** dialog displays the list of Protection Groups, Recoveries, Clones, and Views that are dependent on the Storage Domain on separate pages one after another.

   Review the list of dependent objects on each page, select the check box to confirm the deletion, and click **Next**.



> **Note:** Once you click **Delete Storage Domain** in the next step, you cannot undo the action, associate entities to that Storage Domain, or restore the deleted data.

5. The last page in the **Delete Storage Domain** dialog displays the summary of the dependent objects. To delete the Storage Domain, enter **Yes** and click **Delete Storage Domain**.



The Storage Domain deletion starts. The duration of the deletion process depends on the size of the Storage Domain.

When the delete succeeds, the Storage Domain and associated objects are deleted and no longer displayed under the Storage Domain tab. Cohesity clusters generate alerts (such as CE02806012) if the deletion fails or is unresponsive.

> **Note:** When you delete a storage domain with CloudTier enabled, the cold data moved to the external target is deleted along with the hot data in the storage domain.

Disk and Node Resilience Settings

Cohesity provides the following protection levels for disk or node resiliency that can be set separately for each storage domain. The allowed values depend on the fault tolerance setting chosen. Cohesity supports node and disk failures, and the number of failures tolerated depends on the configured resiliency. The user selects the minimum failures to tolerate and the system adjusts the available options for RF and EC accordingly.

The following table shows possible EC settings that can be set for the required resiliency of hard drives and nodes. The table indicates the number of failures tolerated in disks *or* nodes at any EC or RF level. For example, if a 5-node Cohesity cluster is set to EC4:2, failures are tolerated in 2 disks or 1 node.

For more details on Cohesity Erasure Coding, see the Cohesity-White-Paper-Fault-Tolerance-Data-Integrity.pdf.

> **Note:** From Cohesity 6.6 onwards, you can use EC 8:2 for Azure, AWS, GCP, Imanis, MS SQL file-based, Physical Server, VMware, NAS, and SAN backup workloads.

Number of Nodes in the Cluster	Number of Failures Tolerated		Storage Domain Resilience Settings	
	Disks (D)	Nodes (N) or SSD	EC	RF (IF EC is Disabled)
3	1	1	2:1	RF2
	2	1	2:2, 3:2, 4:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
4	1	1	2:1, 3:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2	RF3
	3	1	3:3, 4:3, 5:3	RF4

Number of Nodes in the Cluster	Number of Failures Tolerated		Storage Domain Resilience Settings	
	Disks (D)	Nodes (N) or SSD	EC	RF (IF EC is Disabled)
5	1	1	2:1, 3:1, 4:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
6	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3

	2	2	2:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
5	1	1	2:1, 3:1, 4:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
6	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2, 4:2	RF3
	3	1	3:3, 4:3, 5:3	RF4

Number of Chassis in the Cluster	Number of Failures Tolerated		Storage Domain Resilience Settings	
	Disks (D)	Nodes (N) or SSD	EC	RF (IF EC is Disabled)
7	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2, 4:2, 5:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
	3	2	3:3, 4:3, 5:3	RF4
8	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2, 4:2, 5:2, 6:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
	3	2	3:3, 4:3, 5:3	RF4
9	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2, 4:2, 5:2, 6:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
	3	2	3:3, 4:3, 5:3	RF4
10+	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
	3	2	3:3, 4:3, 5:3	RF4

Rack Resilience Settings

Cohesity provides the following protection levels for rack resiliency that can be set separately for each storage domain. The allowed values depend on the fault tolerance setting chosen. The user selects the minimum failures to tolerate and the system adjusts the available options for RF and EC accordingly.

The following table shows possible EC settings that can be set for the required resiliency of racks.

Number of Racks in the Cluster	Number of Failures Tolerated		Storage Domain Resilience Settings	
	Disks (D)	Racks (R)	EC	RF (IF EC is Disabled)
3	1	1	2:1	RF2
	2	1	2:2, 3:2, 4:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
4	1	1	2:1, 3:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2	RF3
	2	2	2:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
5	1	1	2:1, 3:1, 4:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
6	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2, 4:2	RF3
	3	1	3:3, 4:3, 5:3	RF4

Number of Racks in the Cluster	Number of Failures Tolerated		Storage Domain Resilience Settings	
	Disks (D)	Racks (R)	EC	RF (IF EC is Disabled)
7	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2, 4:2, 5:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
	3	2	3:3, 4:3, 5:3	RF4
8	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2, 4:2, 5:2, 6:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
	3	2	3:3, 4:3, 5:3	RF4
9	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2, 4:2, 5:2, 6:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
	3	2	3:3, 4:3, 5:3	RF4
10+	1	1	2:1, 3:1, 4:1, 5:1	RF2
	2	1	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	2	2	2:2, 3:2, 4:2, 5:2, 6:2, 8:2	RF3
	3	1	3:3, 4:3, 5:3	RF4
	3	2	3:3, 4:3, 5:3	RF4

Manage Nodes

The nodes summary displays the details about all the hardware and cloud nodes that are part of the Cohesity cluster. You can assign nodes to one or more chassis on the nodes summary dashboard and set the node status.

The following topics provide guidance to help you manage hardware and cloud nodes:

Configure a Rack

Using the Cohesity Dashboard or the Cohesity CLI, you can:

- Add a rack and assign it to one or more chassis
- Edit a rack configuration
- View a list of racks, chassis, and nodes

> **Note:** After adding a rack, you cannot delete it. You can edit the rack configuration.

Add a Rack

You can add a rack and associate it with one or more chassis.

> **Note:** Every available chassis must be assigned to a rack to set the rack as a failure domain at the global cluster level. For more details about setting rack as the failure domain, see Configure Cluster Settings.

To add a rack and assign it to one or more chassis:

1. Navigate to **Settings > Summary** and click the **Nodes** tab.
2. On the **Nodes** page, click **Configure Rack**.

   Alternatively, select **Settings > Summary** and click **Configure** to display the Edit Cluster Setting page. Under Custom Failure Domain, click **Configure Rack**.
3. In the Assign Racks page, click **Add** and enter the following information:
   - **Name:** Name of the rack.
   - **Location:** Location of the rack.
   - **Chassis:** Select one or more chassis from the drop-down menu.
4. Click **Assign**.

   The rack is assigned successfully to the selected chassis.

Edit a Rack Configuration

You can edit a rack name and location. After a rack is associated with a chassis, you cannot remove a chassis or associate the chassis with another rack. You cannot delete a rack after you add and assign it to one or more chassis.

To edit or update a rack configuration:

1. Navigate to **Settings > Summary** and click the **Nodes** tab.
2. On the **Nodes** page, click **Configure Rack**.

   Alternatively, select **Settings > Summary** and click **Configure** to display the Edit Cluster Setting page. Under Custom Failure Domain, click **Configure Rack**.
3. In the Assign Racks page, edit or update the following information:
   - **Name:** Name of the rack.
   - **Location:** Location of the rack.
4. Click **Assign**.

   The rack configuration is updated.

View a List of Racks

To view a list of racks and the associated chassis and nodes:

1. Select **Settings > Summary**.
2. Click the **Nodes** tab.

   You can view the chassis and the rack names. You can also view a list of nodes that are part of the chassis.

You can also use Cohesity CLI to add, edit, and view rack details. For more information, see the Cohesity CLI Reference Guide.

Manage Hardware Nodes

A Cohesity node contains CPU with spinning disk or flash storage that is preinstalled with the Cohesity software. When you initially set up a Cohesity cluster that is hosted on hardware natively, the setup process assigns the nodes you selected to the Cohesity cluster. A Cohesity cluster hosted directly on supported hardware must have at least three nodes. A Cohesity cluster Virtual Edition only supports a single node. Additional nodes cannot be added. For more information about supported hardware, see Initial Cluster Setup.

When you connect an additional chassis, nodes will be detected automatically on the Cohesity cluster.

Using the nodes summary dashboard, you can do the following:

- Adding Nodes to the Cohesity cluster
- Removing Nodes from the Cohesity cluster

- Removing HDD Disk from a Hardware Node
- Adding HDD Disk to a Hardware Node
- Removing SSD Disk from a Hardware Node
- Adding SSD Disk to a Hardware Node

Adding Nodes to the Cohesity cluster

To add Nodes to the Cohesity cluster:

> **Note:**
> - If Cluster usage is above 85%, Cohesity recommends adding multiple Nodes to the Cohesity cluster.
> - VLAN VIPs need to be provisioned first before adding the nodes. Typically one per node in each VLAN. VLAN VIPs need not be added for Primary Interface VLAN.
> - You must ensure connectivity to all the existing sources on the newly added nodes.

1. Navigate to **Settings > Summary** and select the **Nodes** tab.
2. Click **Add Node**. The Cohesity cluster looks for Nodes to add to the Cohesity cluster and displays the Node list in the Cohesity Dashboard. You assign Nodes from the list to the Cohesity cluster.

   > **Note:** The cluster can accommodate a maximum of 8 nodes when adding them at the same time.

   To know the software version on the new node, SSH to the node and run the following command:

   iris_cli node status

   A Cohesity cluster Virtual Edition only supports a single node. Additional nodes cannot be added. The **Add Node** option is only available for Cohesity clusters that are hosted directly on supported hardware.

   a. Select the node(s) you want to add to the Cohesity cluster and click **Next**.
   b. Specify IP addresses and IPMI IP addresses for each of the new Nodes and click **Next**. You must open specific ports in the firewall to allow the Cohesity cluster for backup and recovery operations. For more information, see Manage Firewall Ports.

> **Note:** If a Node's software version is different from the Cohesity cluster's software version, the Node's software is automatically updated to the Cohesity cluster's version when you add the Node. Also, the IPMI configuration is optional. You can configure IPMI after adding nodes to the Cohesity cluster using the Cohesity CLI or the Cohesity Dashboard.

Removing Nodes from the Cohesity cluster

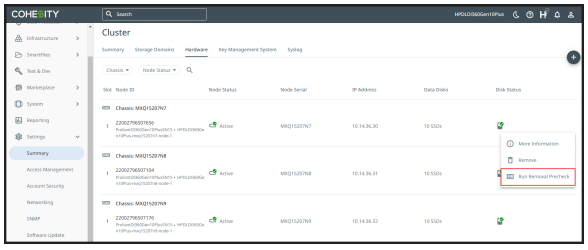
A Cohesity cluster node may have multiple Cohesity services such as Data Protection service, I/O operations service, and Indexing service running. Removing the node without gracefully handling these existing services may result in data loss. To prevent this, Cohesity recommends a pre-check of the nodes. During this pre-check process, the resources used by a service running on that node are optimally redistributed to other available nodes, and then the service is stopped. After all the services have stopped, the node is removed, thereby handling the node removal in an orderly manner.

Before you Begin:

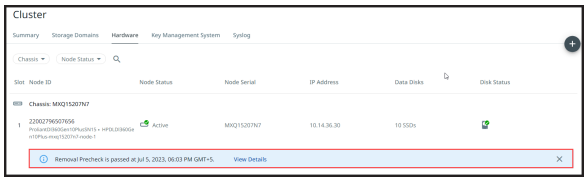
- Do not remove drives from the Cohesity cluster unless it is required to fix a verified issue such as a failed drive as described later in this topic.
- Do not upgrade your Cohesity cluster while replacing the drive.
- Do not add new nodes while replacing the drive.

To remove nodes from the Cohesity cluster:

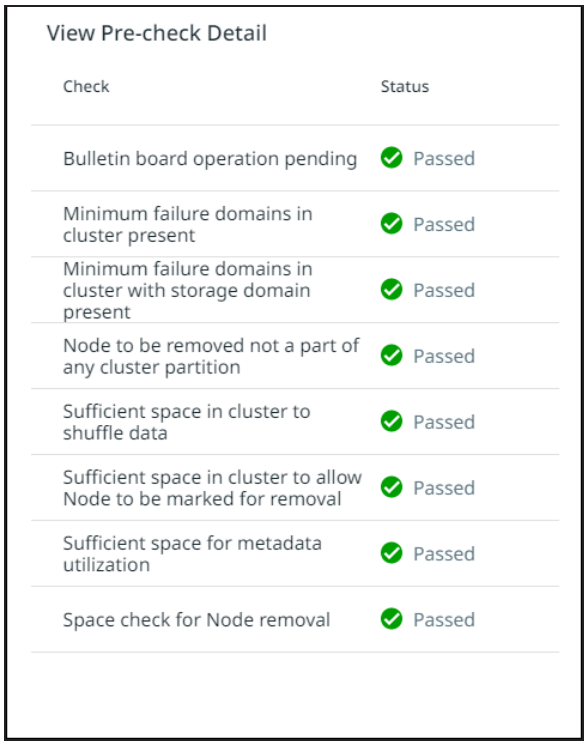
1. Navigate to **Settings > Summary** and click the **Hardware** tab.
2. Select the node you want to remove, click the **Actions** menu (⋮) next to the node, and click **More Information** to view the node information.
3. Click **Run Removal Precheck** to pre-check the nodes before removal.



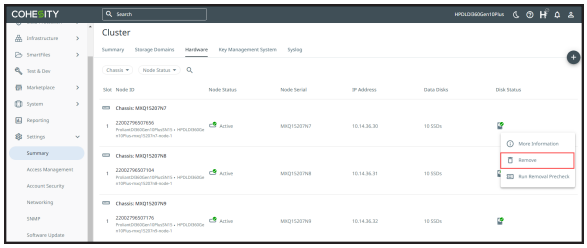
The status of the removal pre-check is displayed, as shown below.



4. Click **View Details** and see the pre-check details.

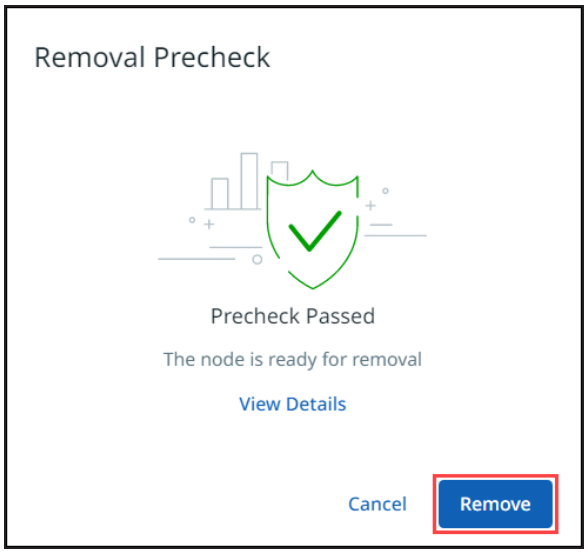


5. Verify the node information and click **Remove**.



The nodes are pre-checked before the removal to ensure that they are not stopped abruptly.

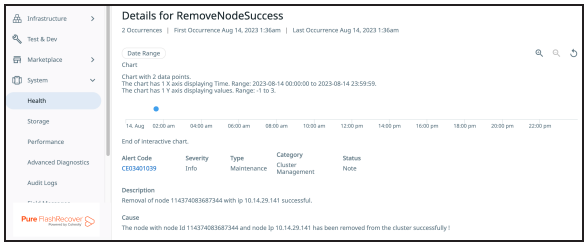
6. Once the pre-check is passed and the nodes are ready for removal, click **Remove**.



> **Note:** Node will be unusable once it is marked for removal.

After you confirm the node removal, the `NodeMarkedForRemoval` label is observed.

Once the node is removed, the `RemoveNodeSuccess` label is displayed with the details, as shown below.



Removing HDD Disk from a Hardware Node

Before you Begin:

- Do not remove drives from the Cohesity cluster unless it is required to fix a verified issue such as a failed drive as described later in this topic.
- Do not upgrade your Cohesity cluster while replacing the drive.
- Do not add new nodes while replacing the drive.

To remove the HDD disk from a hardware node:

1. Navigate to **Settings > Summary > Hardware**.
2. Select a node to see the HDD disks associated with the node.

3. Identify the failed disk by lighting the disk LED. Select **Settings > Summary> Nodes**, and click **LED On** in the Actions menu (⋮) to identify the disk. Once turned on, "**LED turned on successfully**" notification will be observed.
4. Select the HDD disk you want to remove and click the Actions menu (⋮) next to the HDD disk.
5. Click **Run Removal Precheck** to pre-check the nodes before removal.
6. Verify the information and click **Remove**.

   > **Note:** The HDD disk will be unusable once it is marked for removal.

   The disk status is marked as **Removing**.

   `MarkDiskForRemoval` alert is generated and displayed on the Health page in the Cohesity cluster.

   After the disk is removed, the HDD disk will be marked as **Ready for Physical Removal**.

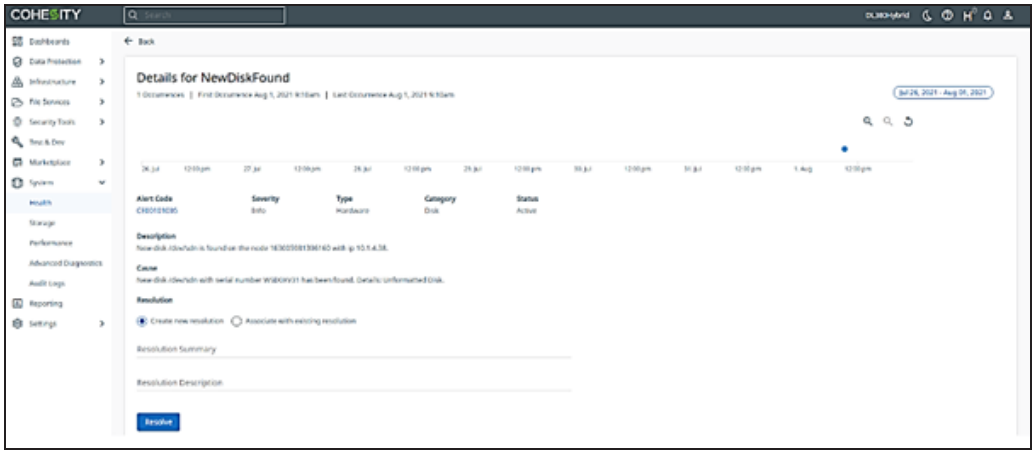
   Once the removal is finished, `DiskOkToRemove` alert is generated and displayed on the Health page in the Cohesity cluster.

   Once the disk is removed physically, `DiskRemoved` alert is generated and displayed on the Health page in the Cohesity cluster.

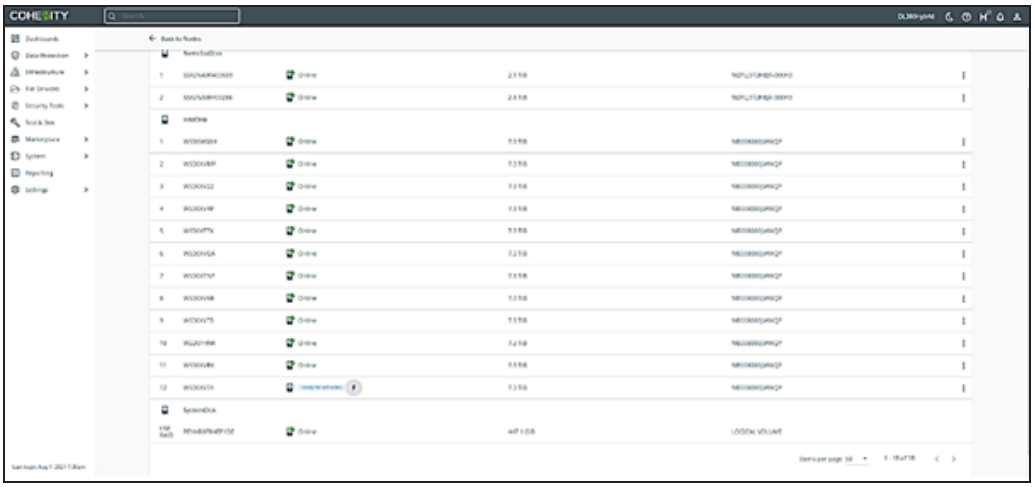
Adding HDD Disk to a Hardware Node

To add HDD disk to a hardware node:

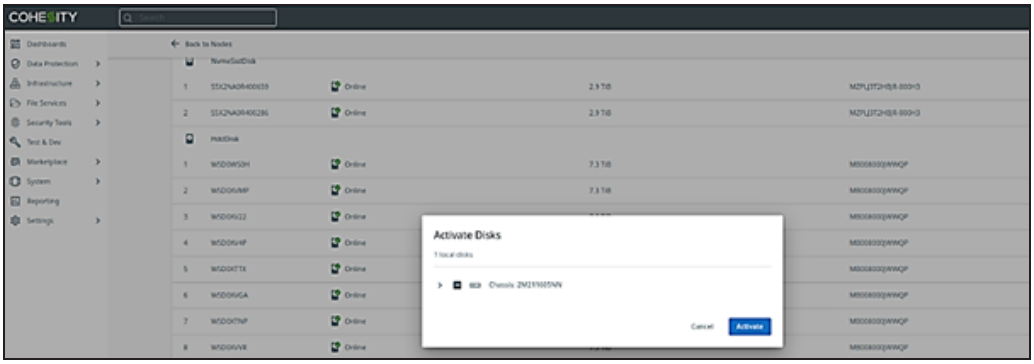
1. Physically install the new hard drive and insert the new HDD disk to a node on the Cohesity cluster.
2. The `NewDiskFound` alert is generated and displayed on the Health page in the Cohesity cluster.



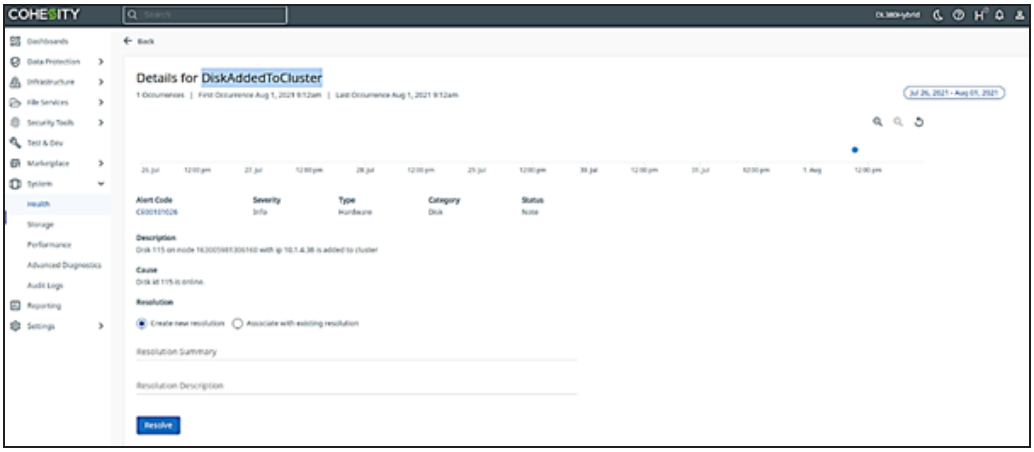
3. Navigate to **Settings > Summary** and click the **Nodes** tab.
4. Select a node to which you have added the new HDD disk. The status of the newly added disk is displayed as **Ready for Activation**.



5. Select the newly added HDD disk and click the Actions menu (⋮) next to the HDD disk and click **Activate**.



Once the disk activation is completed, the `DiskAddedToCluster` alert is displayed on the Health page in the Cohesity cluster.



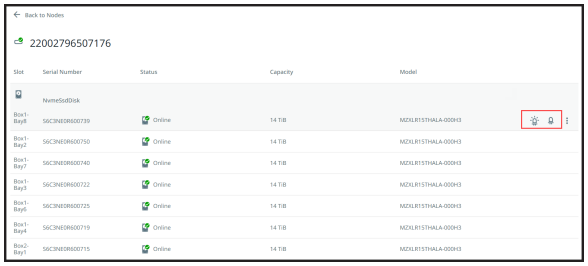
Removing SSD Disk from a Hardware Node

Before you Begin:

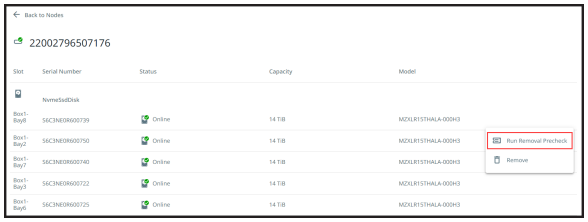
- Do not remove drives from the Cohesity cluster unless it is required to fix a verified issue such as a failed drive as described later in this topic.
- Do not upgrade your Cohesity cluster while replacing the drive.
- Do not add new nodes while replacing the drive.

To remove SSD disk from a hardware node:

1. Navigate to **Settings > Summary > Hardware**.
2. Select a node to see the SSD disks associated with the node.
3. Identify the failed disk by lighting the disk LED. Navigate to **Settings > Summary> Hardware**, and click **LED On** in the Actions menu (⋮) to identify the disk. Once turned on, "**LED turned on successfully**" notification will be observed.

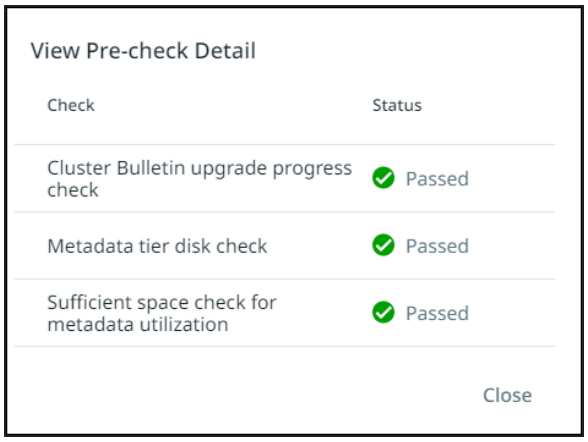


4. Select the SSD disk you want to remove and click the **Actions** menu (⋮) next to the SSD disk.
5. Click **Run Removal Precheck** to pre-check the nodes before removal.

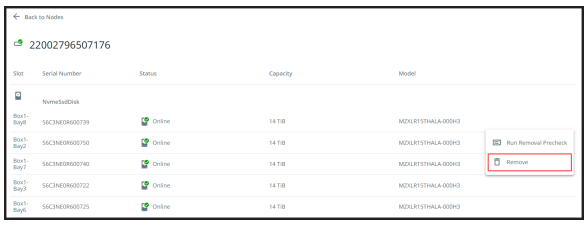


The status of the removal pre-check is displayed, as shown below.

6. Click **View Details** and see the pre-check details.

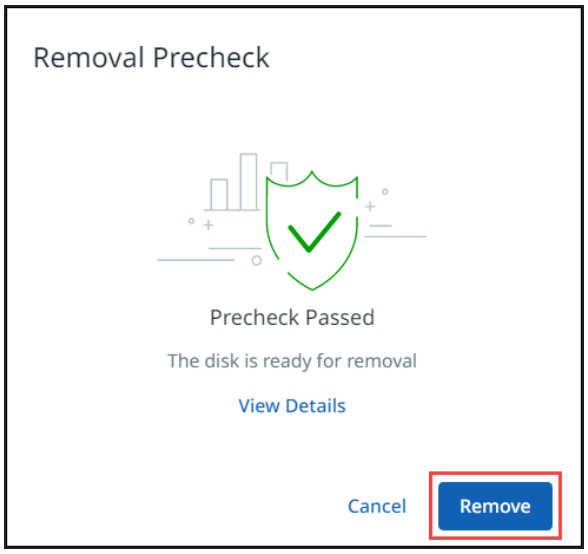


7. Verify the information and click **Remove**.

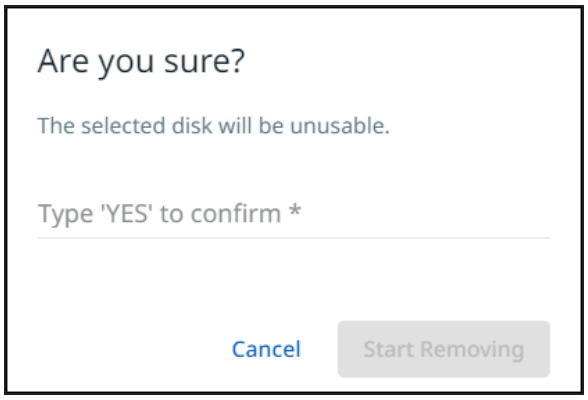


The disks are pre-checked before the removal to ensure that they are not stopped abruptly.

8. Once the pre-check is passed and the disks are ready for removal, click **Remove**.

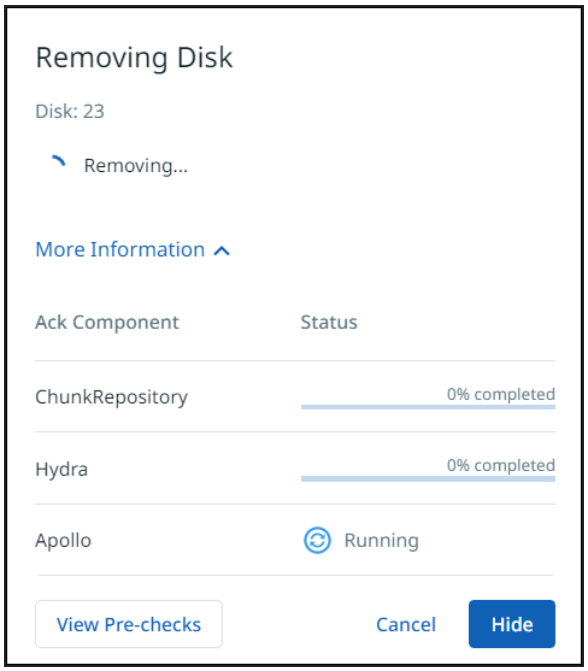


9. Enter '**Yes**' to confirm removal and click '**Start Removing**'.

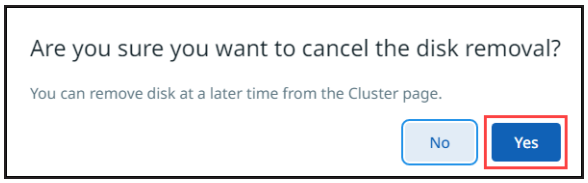


The status changes to 'Removing initiated' with the timestamp.

10. Click the status to view more information on the disk removal. The component information and the status of removal appear, as shown below.



11. Click **Hide** to hide the information.
12. To cancel the disk removal, click **Cancel** and click **Yes**.



> **Note:** The SSD disk will be unusable once it is marked for removal.

The disk status is marked as **Removing**.

`MarkDiskForRemoval` alert is generated and displayed on the Cohesity cluster UI.

After the disk is removed, the SSD disk will be marked as **Ready for Physical Removal** on the Cohesity cluster.

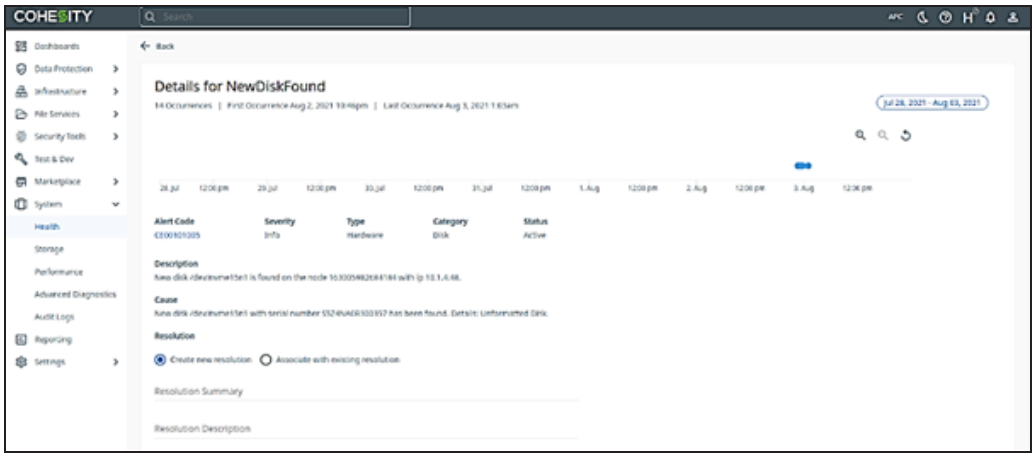
Once the removal is finished, `DiskOkToRemove` alert is generated and displayed on the Cohesity cluster.

Once the disk is removed physically, `DiskRemoved` alert is generated and displayed on the Health page in the Cohesity cluster.

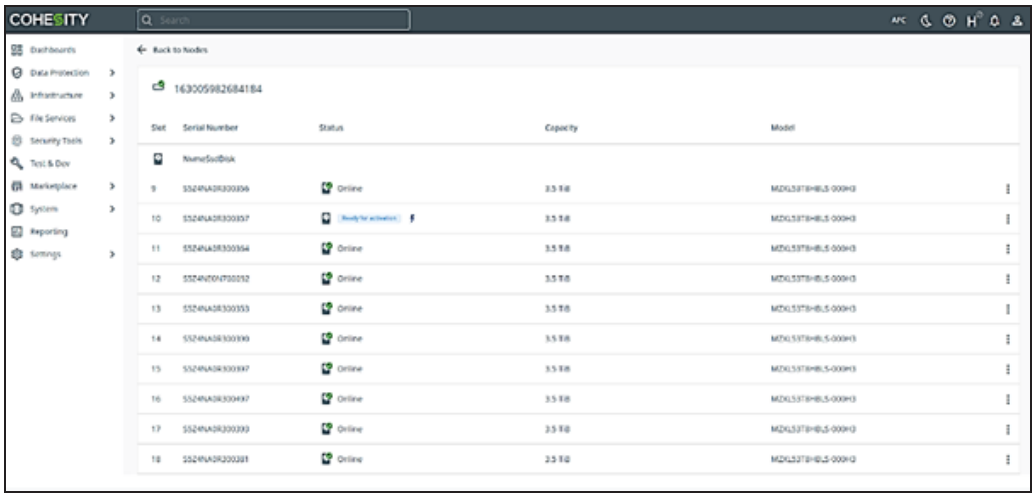
Adding SSD Disk to a Hardware Node

To add SSD disk to a hardware node:

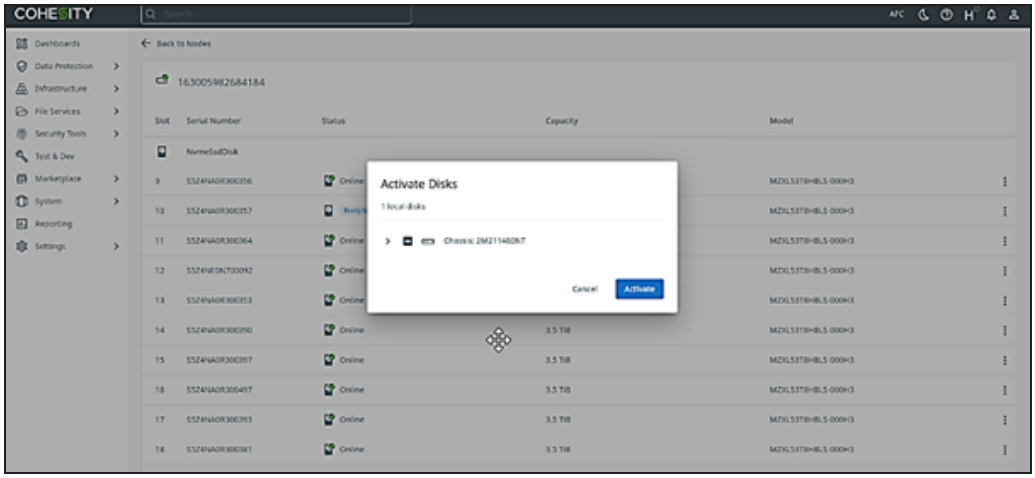
1. Physically install the new hard drive and insert the new SDD disk to a node on the Cohesity cluster.
2. After the scanning is completed, the `NewDiskFound` alert is displayed on the Health page in the Cohesity cluster.



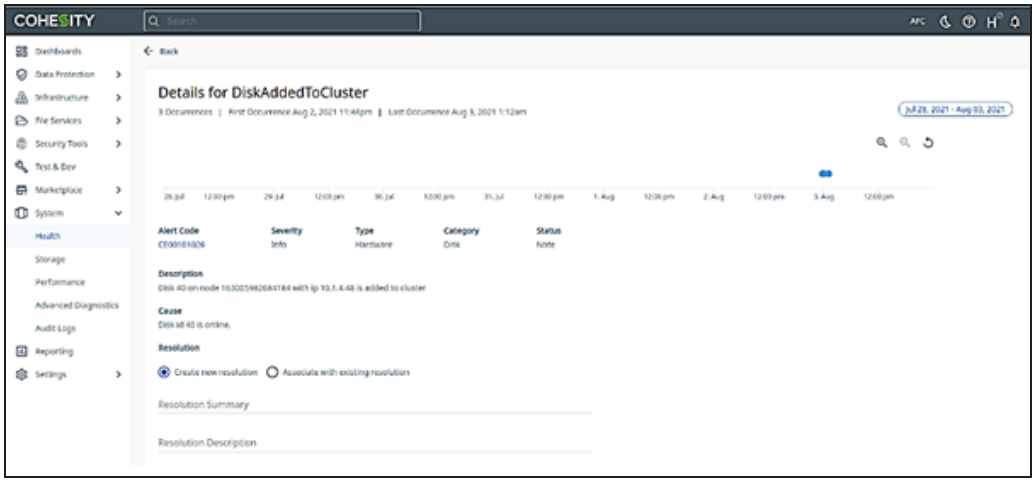
3. Navigate to **Settings > Summary** and click the **Nodes** tab.
4. Select a node to which you have added the new SSD disk. The status of the newly added disk is displayed as **Ready for Activation**.



5. Select the newly added SSD disk and click the Actions menu (⋮) next to the SSD disk and click **Activate**.



After the new disk is added to the node, the `DiskAddedtoCluster` alert is displayed on the Health page in the Cohesity cluster.



Manage Multi-Node Virtual Edition

A Cohesity Virtual Edition(VE) node is a virtual machine with disk storage that is preinstalled with the Cohesity software. When you initially set up a Cohesity cluster that is hosted on a hypervisor, the setup process assigns the nodes you selected to the Cohesity cluster. A Cohesity Virtual Edition multi-node (8TB and 16TB) cluster must have at least three nodes.

> **Note:** A Cohesity Virtual Edition single-node cluster only supports a single node. Additional nodes cannot be added.

Add Nodes to the Multi-Node Virtual Edition Cluster

To add a new node to the Virtual Edition multi-node cluster, the new node must be deployed with the same product model OVA used for the Virtual Edition cluster.

For example:

- For 8TB Virtual Edition cluster, deploy the new node with 8 TB OVA/vmdk image
- For 16TB Virtual Edition cluster, deploy the new node with 16 TB OVA/vmdk image.

The new node and the cluster nodes must be accessible to each other through a network.

> **Note:** If cluster usage is above 85%, Cohesity recommends adding multiple nodes to the Cohesity cluster.

You can add new nodes either using the Cohesity Dashboard or Cohesity CLI.

Perform the following steps to add nodes using Cohesity Dashboard:

1. Select **Settings > Summary** and select the **Nodes** tab.
2. Click **Add Node**. The Cohesity cluster looks for Nodes to add to the Cohesity cluster and displays the Node list in the Cohesity Dashboard. You assign Nodes from the list to the Cohesity cluster.

   To know the software version on the new node, SSH to the node and run the following command:

   ```
   iris_cli node status
   ```

   A Cohesity Virtual Edition single-node cluster only supports a single node. Additional nodes cannot be added. The **Add Node** option is only available for clusters that are hosted directly on supported hardware and Virtual Edition multi-node (8TB and 16TB) clusters. For more information about supported hardware, see Initial Cluster Setup.
3. Select the node(s) you want to add to the Cohesity cluster and click **Next**.
4. Specify IP addresses for each of the new nodes and click **Next.**

> **Note:** If a node's software version is different from the cluster's software version, the node's software is automatically updated to the cluster's version when you add the node. Also, the IPMI configuration is optional. You can configure IPMI after adding nodes to the Cohesity cluster using the Cohesity CLI or the Cohesity Dashboard.

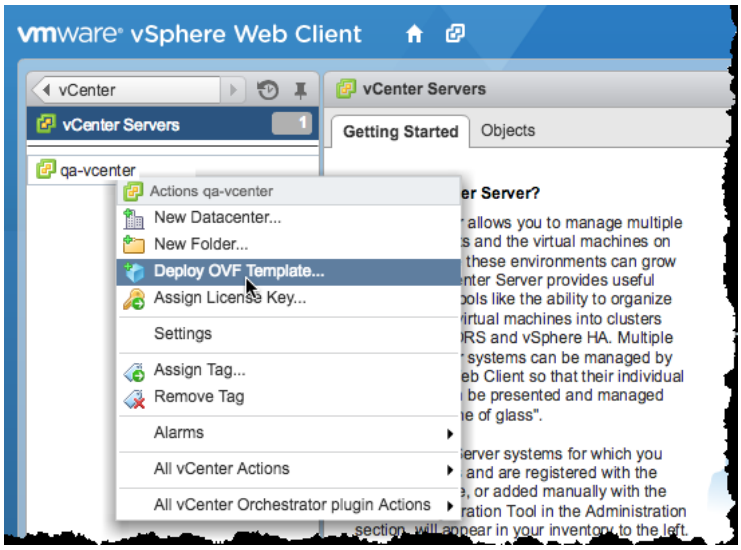
5. Enter new VIPs if any and click **Finish**.

Perform the following steps to add nodes using Cohesity CLI:

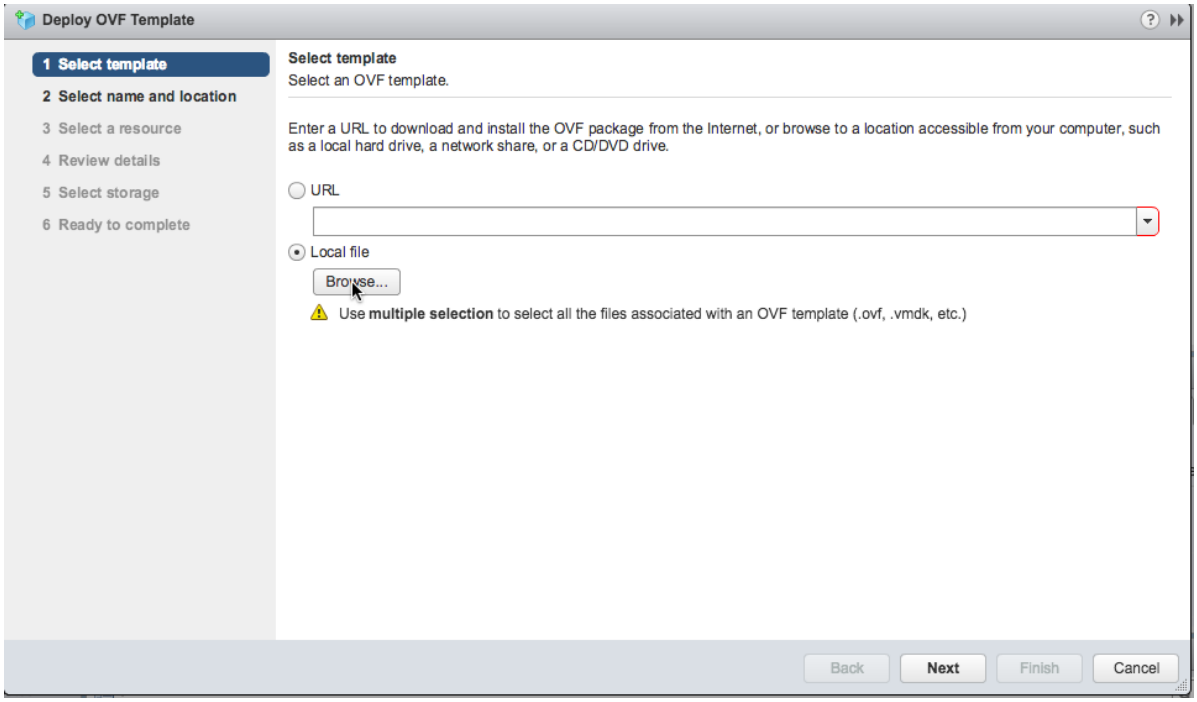
Use the vSphere Web Client 6.5.0 to deploy and configure the Virtual Edition cluster.

> **Note:** The procedure you use may be different depending on the vSphere release and the vSphere Client type.

1. Obtain the Clustered Virtual Edition for VMware OVA file from the Cohesity Download Site. The OVA package file contains the Virtual Edition OVF template and VMDK file. It can be imported into a vCenter Server like an OVF template file. For more information, see Cohesity Support.
2. Using a VMware vSphere Web Client, log in to a vCenter Server that will host the Virtual Edition Virtual Machines:
    1. Enter the IP address or host name of the vCenter Sever into the address bar of a browser.
    2. If prompted, select the **vSphere Web Client (Flash)** option.
3. In the Inventory located in the left panel, navigate to your vCenter server, right-click on the vCenter root, and select **Deploy OVF Template...**.



4. Under Local file, click **Browse** and find the CohesityVirtual Edition OVA file and click **Next** and **Open**.



5. In the **Select name and location** panel, enter a unique name for the Virtual Machine such as `Virtual_Edition1` in the **Name** field. Get the unique Virtual Machine names that were saved in the Worksheet. When you create a new Virtual Machine, you must specify a unique Virtual Machine name for each node in the cluster. Each name must be unique to distinguish it from the existing VMs in the parent folder or Datacenter, and must not exceed 80 characters.
6. **Click Next**.
7. In the **Select a resource** panel, select where the VM should run and click **Next**.
8. In the **Review details** panel, click **Next**.
9. From the deployment **Configuration** drop-down, select an appropriate deployment configuration provided by Cohesity:
    - The small (8 TB) configuration supports Virtual Machines with 4 vCPUs, 32 GB of memory and 64 GB of virtual disk to store the operating system as the minimum configuration.
    - The large (16 TB) configuration supports Virtual Machines with 8 vCPUs, 64 GB of memory and 64 GB of virtual disk to store the operating system as the minimum configuration.

      The Metadata drive size must be smaller than the Data Tier drive size. A single Virtual Cohesity cluster must contain all nodes of small configurations or all nodes of large configuration only.

10. Click **Next**.
11. In the **Select storage** panel, select a VMFS datastore to store the new virtual machine files. Set the **Thick Provision Lazy Zeroed** virtual disk format. Click **Next**.
12. In the **Select networks** panel, for the **Destination** drop-down, select networks. Select the type of IP Address allocation, either dynamic **DHCP** or **Static - Manual**.
13. Click **Next**.
14. In the **Customize template** panel, if you are using static (manual) networking, provide values for the following Data Network Properties:
    - Network IP Address
    - Network Netmask
    - Default Gateway—If a Secondary Network interface is configured using the Cohesity CLI during the Virtual Edition installation procedure, the Secondary Network is used as the default gateway for the Cohesity cluster.

    If you are using DHCP networking, leave these three fields blank.

    > **Note:** If the VM is deployed over ESXi without vApp support, then the network information such as IP address, gateway, netmask for both primary and secondary network provided cannot be applied to the VM.

15. In the **Customize template** panel, you can optionally specify a Secondary Network interface. To configure a Secondary Network, you must specify a static manual settings for the following properties:
    - Network IP Address
    - Network Netmask
    - Default Gateway—If a Secondary Network interface is configured using the Cohesity CLI during the Virtual Edition installation procedure, the Secondary Network is used as the default gateway for the Cohesity cluster.

    If you are using DHCP networking, leave these three fields blank.
16. Click **Next**.
17. Click **Next** and then **Finish**.

    The process to deploy the VM starts.
18. Wait until the VM is deployed before continuing to the next procedure. Wait until all the following tasks are completed:
    - Upload disk
    - Reconfig VM
    - Import VAPP
19. Run the following command:

```
cluster add-nodes node-ips=<list of node_ips to be added>
```

Manage DataProtect for Cloud (Legacy) Nodes in AWS

DataProtect for cloud nodes in AWS is an AWS EC2 Instance with Cohesity software installed on it. Nodes are assigned to a Partition and the Partition uses the Nodes to store data.

When you initially set up a cluster, you specify the number of nodes and cluster size: small, medium or large. Small is 2TB HDD, medium is 6TB HDD and large is 12TB HDD. SSD and instance sizes remain the same for all cluster sizes.

> **Important:** To add a new node to a Cohesity cluster, both the node and Cohesity cluster must have Cohesity 6.0 or later installed. Upgrade the Cohesity cluster to at least 6.0x before adding a new Node.

Adding Nodes to DataProtect for Cloud (Legacy) in AWS

1. Determine unique IP addresses for *each* new Node that will be the added to the existing cluster.

   All IP addresses must be available and must be in the private (VPN-only) subnet of the AWS Virtual Private Cloud (VPC).

2. Log in to the Control VM.
   a. Open a terminal window on your machine.
   b. Ssh to the Control VM instance:

      ```
      $ ssh cohesity@<control_vm_ip_address>
      ```

      Enter the password for the `cohesity` account provided by Cohesity.
   c. If prompted, answer `yes` to continue connecting.
3. Change to the following directory.

   ```
   cd /home/cohesity/data/aws
   ```

4. Make a copy of the configuration file `cluster_config_params.json` that was used to create the cluster, for example:

   ```
   $ cp cluster_config_params.json copy_cluster_config_params.json
   ```

5. Edit the copied file with a Linux editor, such as `vi`.

   ```
   $ vi copy_cluster_config_params.json
   ```

6. Update the following parameters and save the file:

Property in JSON File	Description
`cohesity_aws_num_vms`	The number of additional nodes you are adding to the existing cluster.
`cohesity_aws_vm_ip_addresses`	The same number of IP addresses as the number of nodes specified. Provide the same number of IP addresses as the number of nodes specified (cohesity_aws_num_vms). All IP addresses must be available and must be in the private (VPN-only) subnet of the AWS Virtual Private Cloud (VPC). Specify these IP addresses in a comma separated list.
`cohesity_aws_s3_bucket_name`	An existing S3 bucket name is required for larger clusters. If you are creating a cluster (or adding nodes to an existing cluster), and the resulting cluster will have: • 20 or fewer nodes, the cluster will be deployed using the inline, default CloudFormation template, which is limited to 64KB and 200 resources. No bucket name is required. Specify two quotes "" with no space between them. • 21 or more nodes, provide the name of an existing S3 bucket. The Cohesity software will prepare a CloudFormation template with sufficient resource limits, upload the template to the bucket, deploy it from the bucket, and then delete the template after successful deployment.

7. Create the new Node VMs. Run the Setup Utility with the `create_vms` option.

```
/home/cohesity/software/bin/cohesity_aws_setup create_vms -cohesity_
aws_params_file=/home/cohesity/data/aws/copy_cluster_config_params.json
```

If the Control VM uses an HTTP proxy server to connect to the internet, provide the server information by adding the following options to the above command.

```
-http_proxy_ip=<proxyServerIP> -http_proxy_port=<proxyServerPort>
-http_proxy_username=<serverUsername> -http_proxy_
password=<serverPassword>
```

Wait until the process is completed. During the process, the IP addresses of the VMs are displayed in the output.

For more information about the commands to manage Cohesity cluster, see Commands to Manage Cohesity Cloud Edition Cluster.

8. Start the Cohesity CLI remotely or locally as described in Using the Cohesity CLI.
9. Use the following command to add the new VMs to the cluster:

```
admin> iris_cli cluster cloud-join node-ips=<ip1,ip2,...>
```

Specify the IP addresses that you specified in the `cohesity_aws_vm_ip_addresses` JSON property.

Do not specify any spaces between the comma-separated IP addresses.

Commands to Manage DataProtect for Cloud (Legacy) in AWS

The following commands are available in both Control VM and Cohesity node.

Description	Command
To validate the `cohesity_aws_params_file`	`validate_cluster -cohesity_aws_params_file=<required>`
To start a cluster	`start_cluster -cohesity_aws_params_file=<required>`
To stop a cluster	`stop_cluster -cohesity_aws_params_file=<required>`
To create a cluster	`create_cluster -cohesity_aws_params_file=<required>`
To restart a cluster	`restart_cluster -cohesity_aws_params_file=<required>`
To delete a cluster	`destroy_cluster -cohesity_aws_params_file=<required>` Alternatively, you can delete a cluster from the Amazon AWS console; select the CloudFormation service, select the stack that has the name specified on the `cohesity_aws_cluster_name` property in the params file, and select **Delete**.
To create new nodes to be added to a cluster	`create_vms -cohesity_aws_params_file=<required>`
To delete VMs that have been removed from the cluster	`delete_vms -cohesity_aws_params_file=<required>`
Note: If the Control VM uses an HTTP proxy server to connect to the internet, provide the server information with the following options on the above commands. `-http_proxy_ip=<proxyServerIP> -http_proxy_port=<proxyServerPort> -http_proxy_username=<serverUsername> -http_proxy_password=<serverPassword>`	

Syntax to run the command in the Control VM:

```
/home/cohesity/software/bin/cohesity_aws_setup <command> -cohesity_aws_params_file=<customer_config_params.json>
```

An example to stop a cluster from the Control VM is as follows:

```
/home/cohesity/software/bin/cohesity_aws_setup stop_cluster -cohesity_aws_
params_file= /home/cohesity/data/aws/awsce.json
```

Syntax to run the command on a Cohesity node:

```
/home/cohesity/bin/tools/cohesity_aws_setup <command> -cohesity_aws_params_
file=<customer_config_params.json>
```

An example to stop a cluster on a Cohesity node is as follows:

```
/home/cohesity/bin/tools/cohesity_aws_setup stop_cluster -cohesity_aws_
params_file=awsce.json
```

Manage DataProtect for Cloud (Legacy) Nodes in Azure

DataProtect for Cloud (Legacy) nodes in Azure is a Microsoft Azure VM that has the Cohesity software installed on it. A Partition and Storage Domain are created during the initial Cohesity cluster creation.

When you initially set up a cluster, you specify the number of nodes and cluster size: small, medium or large. Small is 2TB HDD, medium is 6TB HDD and large is 12TB HDD. SSD and instance sizes remain the same for all cluster sizes.

> **Important:** To add a new node to a Cohesity cluster, both the node and Cohesity cluster must have Cohesity 6.0 or later installed. Upgrade the Cohesity cluster to at least 6.0x before adding a new Node.

Adding Nodes to DataProtect for Cloud (Legacy) in Azure

1. Determine unique IP addresses for *each* new Node that will be the added to the existing cluster.

   All IP addresses must be available and must be in the VPN subnet of the VPN network.

2. Log in to Control VM that was used during initial cluster setup. This VM must have Internet access so the Cohesity utility can call the Cloud Service APIs to create new Nodes.

   a. Open a terminal window on your machine.

   b. Ssh in to the Control VM:

      ```
      $ ssh cohesity@<control_vm_ip_address>
      ```

      Enter the password for the `cohesity` account provided by Cohesity.

   c. If prompted, answer `yes` to continue connecting.

3. Change to the following directory.

   ```
   cd /home/cohesity/software
   ```

4. Make a copy of the configuration file `params.json` that was used to create the cluster, for example:

```
$ cp params.json copy_params.json
```

5. Edit the copied file with a Linux editor, such as `vi`.

```
$ vi copy_params.json
```

6. Update the following parameters and save the file.

JSON Property	Description
`cohesity_azure_num_vms`	The number of additional nodes you are adding to the existing cluster.
`cohesity_azure_vm_ip_addresses`	The IP addresses to assign to the nodes (VMs) of the Cohesity cluster. Provide the same number of IP addresses as the number of nodes specified. All IP addresses must be available and must be in the VPN subnet of the VPN network. Separate the IP addresses with commas.

7. Run the Setup Utility with the `validate` option to validate the Azure credentials. This is a dry run of the command and the Node VMs are not created.

```
/home/cohesity/software/cohesity_azure_setup validate -cohesity_azure_
setup_params_file=/home/cohesity/software/copy_params.json
```

8. If no errors are reported and utility reports the Azure credentials as successfully validated, run the Setup Utility to create the VMs.

```
/home/cohesity/software/cohesity_azure_setup create_vms -cohesity_
azure_setup_params_file=/home/cohesity/software/copy_params.json
```

   If the Control VM uses an HTTP proxy server to connect to the internet, provide the server information by adding the following options to the above command. (Password protected proxy servers are not supported.)

```
-http_proxy_ip=<proxyServerIP> -http_proxy_port=<proxyServerPort>
```

   Wait until the process completes. During the process, the IP addresses of the VMs are displayed in the output. In addition, the name of the Cohesity cluster and the resource group that contains the Cohesity cluster are displayed in the output.

9. Start the Cohesity CLI remotely or locally as described in Using the Cohesity CLI.
10. Using the following command to add the new VMs to the cluster:

```
admin> iris_cli cluster cloud-join node-ips=<ip1,ip2,...>
```

Specify the IP addresses that you specified in the `cohesity_azure_vm_ip_addresses` JSON property.

Do not specify any spaces between the comma-separated IP addresses.

Commands to Manage DataProtect for Cloud (Legacy) in Azure

The following setup utility commands are available on both the Control VM and nodes in the cluster.

Description	Command
To validate the `cohesity_azure_params_file`	`validate -cohesity_azure_setup_params_file=<required>`
To create a cluster	`create_cluster -cohesity_azure_setup_params_file=<required>`
To delete a cluster	`destroy_cluster -cohesity_azure_setup_params_flle=<required> -cohesity_azure_resource_group=<required>`
To start a cluster	`startup_cluster -cohesity_azure_setup_params_file=<required> -cohesity_azure_resource_group=<required>`
To stop a cluster	`shutdown_cluster -cohesity_azure_setup_params_file=<required> -cohesity_azure_resource_group=<required>`
To delete node (VMs) that have been removed from the cluster	`delete_vms -cohesity_azure_setup_params_file=<required> -cohesity_azure_resource_group=<required> -cohesity_azure_vm_list_csv=<required>`
To create new nodes (VMs) to be added to a cluster	`create_vms -cohesity_azure_setup_params file=<required>`
Note: If the Control VM uses an HTTP proxy server to connect to the internet, provide the server information by adding the following options to the above commands. (Password protected proxy servers are not supported.) `-http_proxy_ip=<proxyServerIP> -http_proxy_port=<proxyServerPort>`	

Manage DataProtect for Cloud (Legacy) Nodes in GCP

DataProtect for Cloud (Legacy) nodes in GCP is a Google Compute Engine instance that has the Cohesity software installed on it.

When you initially set up a cluster, you specify the capacity of the Cohesity cluster as small, medium or large. Small is 2TB HDD, medium is 6TB HDD and large is 12TB HDD. SSD and instance sizes remain the same for all cluster sizes.

> **Important:** To add a new node to a Cohesity cluster, both the node and Cohesity cluster must have Cohesity 6.0 or later installed. Upgrade the Cohesity cluster to at least 6.0x before adding a new node.

Adding Nodes to DataProtect for Cloud (Legacy) in GCP

1. Determine unique IP addresses for *each* new Node that will be the added to the existing cluster.

   All IP addresses must be available and must be in the VPC subnet of your VPC network.

2. Log in to Control VM. The VM must have internet access so the Cohesity utility can call the Cloud Service APIs to create new nodes.
   a. Open a terminal window on your machine.
   b. Ssh in to the Control VM:

      ```
      $ ssh cohesity@<control_vm_ip_address>
      ```

      Enter the password for the `cohesity` account provided by Cohesity.
   c. If prompted, answer `yes` to continue connecting.

3. Change to the following directory.

   ```
   cd /home/cohesity/data/gcp
   ```

4. Make a copy of the configuration file `cluster_config_params.json` that was used to create the cluster, for example:

   ```
   $ cp cluster_config_params.json copy_cluster_config_params.json
   ```

5. Edit the copied file with a Linux editor, such as `vi`.

   ```
   $ vi copy_cluster_config_params.json
   ```

6. Update the following parameters and save the file:

Property in JSON File	Description
`gcp_num_vms`	The number of additional nodes you are adding to the existing cluster.
`gcp_vm_ip_addresses`	Specify the IP addresses to assign to the new nodes (VMs) to add to the Cohesity cluster. All IP addresses must be available and must be in the VPC subnet of your VPC network. Separate the IP addresses by commas.

7. To create the new node VMs to add to the Cohesity cluster, run the Setup Utility with the `create_vms` option.

   ```
   /home/cohesity/software/bin/cohesity_gcp_setup create_vms -cohesity_gcp_params_file /home/cohesity/data/gcp/copy_cluster_config_params.json
   ```

   Wait until the process completes. During the process, the IP addresses of the VMs are displayed in the output.
8. Start the Cohesity CLI remotely or locally as described in Using the Cohesity CLI.
9. Using the following command to add the new VMs to the Cohesity cluster:

   ```
   admin> iris_cli cluster cloud-join node-ips=<ip1,ip2,...>
   ```

   Do not specify any spaces between the comma-separated IP addresses.

   Specify the IP addresses that you provided in the `cohesity_gcp_vm_ip_addresses` JSON property.

Commands to Manage DataProtect for Cloud (Legacy) in GCP

The following setup utility commands are available on both the Control VM and nodes in the Cohesity cluster.

Description	Command
To create a cluster	`create_cluster -cohesity_gcp_params_file=<required>`
To start a cluster	`start_cluster -cohesity_gcp_params_file=<required>`
To stop a cluster	`stop_cluster -cohesity_gcp_params_file=<required>`
To restart a cluster	`restart_cluster -cohesity_gcp_params_file=<required>`

Description	Command
To delete a cluster	`destroy_cluster -cohesity_gcp_params_flle=<required>` **Note:** Your service account requires the `compute.addresses.deleteInternal` permission to delete and free the static IP addresses associated with the node VMs.
To create new nodes (VMs) to be added to a cluster	`create_vms -cohesity_gcp_setup params file=<required>`
To delete node (VMs) that have been removed from the cluster	`delete_vms -cohesity_gcp_params_file=<required> -cohesity_gcp_vm_list_csv=<required>`

Manage DataProtect for Cloud Nodes in AWS

When you initially set up DataProtect for cloud in AWS, you specify the number of nodes. Once the cluster is deployed, you can add or remove nodes as per your requirement.

Add Data Nodes to DataProtect for Cloud in AWS

Perform the following steps to add data nodes to DataProtect for cloud in AWS:

1. Determine unique IP addresses for *each* new Node that will be the added to the existing cluster.

   All IP addresses must be available and must be in the private (VPN-only) subnet of the AWS Virtual Private Cloud (VPC).

2. Log in to the Control VM.
   a. Open a terminal window on your machine.
   b. Ssh to the Control VM instance:

      ```
      $ ssh cohesity@<control_vm_ip_address>
      ```

      Enter the password for the `cohesity` account provided by Cohesity.
   c. If prompted, answer `yes` to continue connecting.
3. Change to the following directory.

   ```
   cd /home/cohesity/data/aws
   ```

4. Make a copy of the configuration file `ngce_cluster_config_params.json` that was used to create the cluster, for example:

```
$ cp ngce_cluster_config_params.json copy_ngce_cluster_config_
params.json
```

5. Edit the copied file with a Linux editor, such as `vi`.

```
$ vi copy_ngce_cluster_config_params.json
```

6. Update the following parameters and save the file:

Property in JSON File	Description
`cohesity_aws_num_vms`	The number of additional nodes you are adding to the existing cluster.
`cohesity_aws_vm_ip_addresses`	The same number of IP addresses as the number of nodes specified. Provide the same number of IP addresses as the number of nodes specified (cohesity_aws_num_vms). All IP addresses must be available and must be in the private (VPN-only) subnet of the AWS Virtual Private Cloud (VPC). Specify these IP addresses in a comma separated list.
`cohesity_aws_s3_bucket_name`	An existing S3 bucket name is required for larger clusters. If you are creating a cluster (or adding nodes to an existing cluster), and the resulting cluster will have: • 20 or fewer nodes, the cluster will be deployed using the inline, default CloudFormation template, which is limited to 64KB and 200 resources. No bucket name is required. Specify two quotes "" with no space between them. • 21 or more nodes, provide the name of an existing S3 bucket. The Cohesity software will prepare a CloudFormation template with sufficient resource limits, upload the template to the bucket, deploy it from the bucket, and then delete the template after successful deployment.

7. Create the new Node VMs. Run the Setup Utility with the `create_vms` option.

```
/home/cohesity/software/bin/cohesity_aws_setup create_vms -cohesity_
aws_params_file=/home/cohesity/data/aws/copy_ngce_cluster_config_
params.json
```

If the Control VM uses an HTTP proxy server to connect to the internet, provide the server information by adding the following options to the above command.

```
-http_proxy_ip=<proxyServerIP> -http_proxy_port=<proxyServerPort>
-http_proxy_username=<serverUsername> -http_proxy_
password=<serverPassword>
```

Wait until the process completes. During the process, the IP addresses of the VMs are displayed in the output.

For more information about the commands to manage Cohesity cluster, see Commands to Manage Cluster.

8. Start the Cohesity CLI remotely or locally as described in Using the Cohesity CLI.
9. Use the following command to add the new nodes to the cluster as data nodes:

```
admin> iris_cli cluster cloud-join node-ips=<ip1,ip2,...>
```

Specify the IP addresses that you specified in the `cohesity_aws_vm_ip_addresses` JSON property.

Do not specify any spaces between the comma-separated IP addresses.

Add Compute Nodes to DataProtect for Cloud in AWS

Perform the following steps to add compute nodes to DataProtect for cloud in AWS:

1. Determine unique IP addresses for *each* new Node that will be the added to the existing cluster.

   All IP addresses must be available and must be in the private (VPN-only) subnet of the AWS Virtual Private Cloud (VPC).
2. Log in to the Control VM.
   a. Open a terminal window on your machine.
   b. Ssh to the Control VM instance:

   ```
   $ ssh cohesity@<control_vm_ip_address>
   ```

   Enter the password for the `cohesity` account provided by Cohesity.
   c. If prompted, answer `yes` to continue connecting.
3. Change to the following directory.

   ```
   cd /home/cohesity/data/aws
   ```
4. Make a copy of the configuration file `ngce_cluster_config_params.json` that was used to create the cluster, for example:

   ```
   $ cp ngce_cluster_config_params.json copy_ngce_cluster_config_
   params.json
   ```
5. Edit the copied file with a Linux editor, such as `vi`.

   ```
   $ vi copy_ngce_cluster_config_params.json
   ```

6. Update the following parameters and save the file:

Property in JSON File	Description
`cohesity_aws_num_vms`	The number of additional nodes you are adding to the existing cluster.
`cohesity_aws_vm_ip_addresses`	The same number of IP addresses as the number of nodes specified. Provide the same number of IP addresses as the number of nodes specified (cohesity_aws_num_vms). All IP addresses must be available and must be in the private (VPN-only) subnet of the AWS Virtual Private Cloud (VPC). Specify these IP addresses in a comma separated list.
`cohesity_aws_s3_bucket_name`	An existing S3 bucket name is required for larger clusters. If you are creating a cluster (or adding nodes to an existing cluster), and the resulting cluster will have: • 20 or fewer nodes, the cluster will be deployed using the inline, default CloudFormation template, which is limited to 64KB and 200 resources. No bucket name is required. Specify two quotes "" with no space between them. • 21 or more nodes, provide the name of an existing S3 bucket. The Cohesity software will prepare a CloudFormation template with sufficient resource limits, upload the template to the bucket, deploy it from the bucket, and then delete the template after successful deployment.

7. Create the new Node VMs. Run the Setup Utility with the `create_vms` option.

```
/home/cohesity/software/bin/cohesity_aws_setup create_vms -cohesity_
aws_params_file=/home/cohesity/data/aws/copy_ngce_cluster_config_
params.json
```

If the Control VM uses an HTTP proxy server to connect to the internet, provide the server information by adding the following options to the above command.

```
-http_proxy_ip=<proxyServerIP> -http_proxy_port=<proxyServerPort>
-http_proxy_username=<serverUsername> -http_proxy_
password=<serverPassword>
```

Wait until the process completes. During the process, the IP addresses of the VMs are displayed in the output.

For more information about the commands to manage Cohesity cluster, see Commands to Manage Cohesity Cluster.

8. Start the Cohesity CLI remotely or locally as described in Using the Cohesity CLI.
9. Use the following command to add the new nodes to the cluster as compute nodes:

   ```
   admin> iris_cli cluster cloud-join node-ips=<ip1,ip2,...> use-as-compute-nodes=true
   ```

   Specify the IP addresses that you specified in the `cohesity_aws_vm_ip_addresses` JSON property.

   Do not specify any spaces between the comma-separated IP addresses.

Commands to Manage DataProtect for Cloud in AWS

The following commands are available in both Control VM and Cohesity node.

Description	Command
To validate the `cohesity_aws_params_file`	`validate_cluster -cohesity_aws_params_file=<required>`
To start a cluster	`start_cluster -cohesity_aws_params_file=<required>`
To stop a cluster	`stop_cluster -cohesity_aws_params_file=<required>`
To create a cluster	`create_cluster -cohesity_aws_params_file=<required>`
To restart a cluster	`restart_cluster -cohesity_aws_params_file=<required>`
To delete a cluster	`destroy_cluster -cohesity_aws_params_file=<required>` Alternatively, you can delete a cluster from the Amazon AWS console; select the CloudFormation service, select the stack that has the name specified on the `cohesity_aws_cluster_name` property in the params file, and select **Delete**.
To create new nodes to be added to a cluster	`create_vms -cohesity_aws_params_file=<required>`
To delete VMs that have been removed from the cluster	`delete_vms -cohesity_aws_params_file=<required>`
Note: If the Control VM uses an HTTP proxy server to connect to the internet, provide the server information with the following options on the above commands. `-http_proxy_ip=<proxyServerIP> -http_proxy_port=<proxyServerPort> -http_proxy_username=<serverUsername> -http_proxy_password=<serverPassword>`	

Syntax to run the command in the Control VM:

```
/home/cohesity/software/bin/cohesity_aws_setup <command> -cohesity_aws_
params_file=<customer_config_params.json>
```

An example to stop a cluster from the Control VM is as follows:

```
/home/cohesity/software/bin/cohesity_aws_setup stop_cluster -cohesity_aws_
params_file= /home/cohesity/data/aws/awsce.json
```

Syntax to run the command on a Cohesity node:

```
/home/cohesity/bin/tools/cohesity_aws_setup <command> -cohesity_aws_params_
file=<customer_config_params.json>
```

An example to stop a cluster on a Cohesity node is as follows:

```
/home/cohesity/bin/tools/cohesity_aws_setup stop_cluster -cohesity_aws_
params_file=awsce.json
```

Manage DataProtect for Cloud Nodes in Azure

When you initially set up DataProtect for cloud in Azure, you specify the number of nodes. Once the cluster is deployed, you can add or remove nodes as per your requirement.

Add Data Nodes to DataProtect for Cloud in Azure

Perform the following steps to add data nodes to DataProtect for cloud in Azure:

1. Determine unique IP addresses for *each* new Node that will be the added to the existing cluster.

   All IP addresses must be available and must be in the VPN subnet of the VPN network.
2. Log in to Control VM that was used during initial cluster setup. This VM must have internet access so the Cohesity utility can call the Cloud Service APIs to create new Nodes.
   a. Open a terminal window on your machine.
   b. Ssh in to the Control VM:

      ```
      $ ssh cohesity@<control_vm_ip_address>
      ```

      Enter the password for the `cohesity` account provided by Cohesity.
   c. If prompted, answer `yes` to continue connecting.
3. Change to the following directory.

   ```
   cd /home/cohesity/software
   ```
4. Make a copy of the configuration file `params_nextGen.json` that was used to create the cluster, for example:

   ```
   $ cp params_nextGen.json copy_params_nextGen.json
   ```
5. Edit the copied file with a Linux editor, such as `vi`.

```
$ vi copy_params_nextGen.json
```

6. Update the following parameters and save the file.

JSON Property	Description
`cohesity_azure_num_vms`	The number of additional nodes you are adding to the existing cluster.
`cohesity_azure_vm_ip_addresses`	The IP addresses to assign to the nodes (VMs) of the Cohesity cluster. Provide the same number of IP addresses as the number of nodes specified. All IP addresses must be available and must be in the VPN subnet of the VPN network. Separate the IP addresses with commas.

7. Run the Setup Utility with the `validate` option to validate the Azure credentials. This is a dry run of the command and the Node VMs are not created.

```
/home/cohesity/software/cohesity_azure_setup validate -cohesity_azure_
setup_params_file=/home/cohesity/software/copy_params_nextGen.json
```

8. If no errors are reported and utility reports the Azure credentials as successfully validated, run the Setup Utility to create the VMs.

```
/home/cohesity/software/cohesity_azure_setup create_vms -cohesity_
azure_setup_params_file=/home/cohesity/software/copy_params_
nextGen.json
```

   If the Control VM uses an HTTP proxy server to connect to the internet, provide the server information by adding the following options to the above command. (Password protected proxy servers are not supported.)

```
-http_proxy_ip=<proxyServerIP> -http_proxy_port=<proxyServerPort>
```

   Wait until the process completes. During the process, the IP addresses of the VMs are displayed in the output. In addition, the name of the Cohesity cluster and the resource group that contains the Cohesity cluster are displayed in the output.

9. Start the Cohesity CLI remotely or locally as described in Using the Cohesity CLI.
10. Use the following command to add the new nodes to the cluster as data nodes:

```
admin> iris_cli cluster cloud-join node-ips=<ip1,ip2,...>
```

    Specify the IP addresses that you specified in the `cohesity_azure_vm_ip_addresses` JSON property.

    Do not specify any spaces between the comma-separated IP addresses.

Add Compute Nodes to DataProtect for Cloud in Azure

Perform the following steps to add compute nodes to DataProtect for cloud in Azure:

1. Determine unique IP addresses for *each* new Node that will be the added to the existing cluster.

   All IP addresses must be available and must be in the VPN subnet of the VPN network.

2. Log in to Control VM that was used during initial cluster setup. This VM must have internet access so the Cohesity utility can call the Cloud Service APIs to create new Nodes.

   a. Open a terminal window on your machine.

   b. Ssh in to the Control VM:

   ```
   $ ssh cohesity@<control_vm_ip_address>
   ```

   Enter the password for the `cohesity` account provided by Cohesity.

   c. If prompted, answer `yes` to continue connecting.

3. Change to the following directory.

   ```
   cd /home/cohesity/software
   ```

4. Make a copy of the configuration file `params_nextGen.json` that was used to create the cluster, for example:

   ```
   $ cp params_nextGen.json copy_params_nextGen.json
   ```

5. Edit the copied file with a Linux editor, such as `vi`.

   ```
   $ vi copy_params_nextGen.json
   ```

6. Update the following parameters and save the file.

JSON Property	Description
`cohesity_azure_num_vms`	The number of additional nodes you are adding to the existing cluster.
`cohesity_azure_vm_ip_addresses`	The IP addresses to assign to the nodes (VMs) of the Cohesity cluster. Provide the same number of IP addresses as the number of nodes specified. All IP addresses must be available and must be in the VPN subnet of the VPN network. Separate the IP addresses with commas.

7. Run the Setup Utility with the `validate` option to validate the Azure credentials. This is a dry run of the command and the Node VMs are not created.

   ```
   /home/cohesity/software/cohesity_azure_setup validate -cohesity_azure_
   setup_params_file=/home/cohesity/software/copy_params_nextGen.json
   ```

8. If no errors are reported and utility reports the Azure credentials as successfully validated, run the Setup Utility to create the VMs.

   ```
   /home/cohesity/software/cohesity_azure_setup create_vms -cohesity_
   azure_setup_params_file=/home/cohesity/software/copy_params_
   nextGen.json
   ```

   If the Control VM uses an HTTP proxy server to connect to the internet, provide the server information by adding the following options to the above command. (Password protected proxy servers are not supported.)

   ```
   -http_proxy_ip=<proxyServerIP> -http_proxy_port=<proxyServerPort>
   ```

   Wait until the process completes. During the process, the IP addresses of the VMs are displayed in the output. In addition, the name of the Cohesity cluster and the resource group that contains the Cohesity cluster are displayed in the output.

9. Start the Cohesity CLI remotely or locally as described in Using the Cohesity CLI.
10. Use the following command to add the new nodes to the cluster as compute nodes:

    ```
    admin> iris_cli cluster cloud-join node-ips=<ip1,ip2,...> use-as-
    compute-nodes=true
    ```

    Specify the IP addresses that you specified in the `cohesity_azure_vm_ip_addresses` JSON property.

    Do not specify any spaces between the comma-separated IP addresses.

Commands to Manage DataProtect for Cloud in Azure

The following setup utility commands are available on both the Control VM and nodes in the cluster.

Description	Command
To validate the `cohesity_azure_params_file`	`validate -cohesity_azure_setup_params_file=<required>`
To create a cluster	`create_cluster -cohesity_azure_setup_params_file=<required>`

Description	Command
To delete a cluster	`destroy_cluster -cohesity_azure_setup_params_flle=<required> -cohesity_azure_resource_group=<required>`
To start a cluster	`startup_cluster -cohesity_azure_setup_params_file=<required> -cohesity_azure_resource_group=<required>`
To stop a cluster	`shutdown_cluster -cohesity_azure_setup_params_file=<required> -cohesity_azure_resource_group=<required>`
To delete node (VMs) that have been removed from the cluster	`delete_vms -cohesity_azure_setup_params_file=<required> -cohesity_azure_resource_group=<required> -cohesity_azure_vm_list_csv=<required>`
To create new nodes (VMs) to be added to a cluster	`create_vms -cohesity_azure_setup_params file=<required>`
Note: If the Control VM uses an HTTP proxy server to connect to the internet, provide the server information by adding the following options to the above commands. (Password protected proxy servers are not supported.) `-http_proxy_ip=<proxyServerIP> -http_proxy_port=<proxyServerPort>`	

Manage DataProtect for Cloud Nodes in GCP

When you initially set up DataProtect for cloud in GCP, you specify the number of nodes. Once the cluster is deployed, you can add or remove nodes as per your requirement.

Adding Nodes to DataProtect for Cloud in GCP

1. Determine unique IP addresses for *each* new Node that will be the added to the existing cluster.

   All IP addresses must be available and must be in the VPC subnet of your VPC network.

2. Log in to Control VM. The VM must have internet access so the Cohesity utility can call the Cloud Service APIs to create new nodes.

   a. Open a terminal window on your machine.

   b. Ssh in to the Control VM:

   ```
   $ ssh cohesity@<control_vm_ip_address>
   ```

Enter the password for the `cohesity` account provided by Cohesity.

c. If prompted, answer `yes` to continue connecting.

3. Change to the following directory.

```
cd /home/cohesity/data/gcp
```

4. Make a copy of the configuration file `ngce_cluster_config_params.json` that was used to create the NGCE cluster, for example:

```
$ cp ngce_cluster_config_params.json copy_ngce_cluster_config_
params.json
```

5. Edit the copied file with a Linux editor, such as `vi`.

```
$ vi copy_ngce_cluster_config_params.json
```

6. Update the following parameters and save the file:

Property in JSON File	Description
`gcp_num_vms`	The number of additional nodes you are adding to the existing cluster.
`gcp_vm_ip_addresses`	Specify the IP addresses to assign to the new nodes (VMs) to add to the Cohesity cluster. All IP addresses must be available and must be in the VPC subnet of your VPC network. Separate the IP addresses by commas.

7. To create the new node VMs to add to the Cohesity cluster, run the Setup Utility with the `create_vms` option.

```
/home/cohesity/software/bin/cohesity_gcp_setup create_vms -cohesity_
gcp_params_file /home/cohesity/data/gcp/copy_ngce_cluster_config_
params.json
```

Wait until the process completes. During the process, the IP addresses of the VMs are displayed in the output.

8. Start the Cohesity CLI remotely or locally as described in Using the Cohesity CLI.

9. Using the following command to add the new VMs to the Cohesity cluster:

```
admin> iris_cli cluster cloud-join node-ips=<ip1,ip2,...>
```

Do not specify any spaces between the comma-separated IP addresses.

Specify the IP addresses that you provided in the `cohesity_gcp_vm_ip_addresses` JSON property.

Commands to Manage DataProtect for Cloud in GCP

The following setup utility commands are available on both the Control VM and nodes in the Cohesity cluster.

Description	Command
To create a cluster	`create_cluster -cohesity_gcp_params_file=<required>`
To start a cluster	`start_cluster -cohesity_gcp_params_file=<required>`
To stop a cluster	`stop_cluster -cohesity_gcp_params_file=<required>`
To restart a cluster	`restart_cluster -cohesity_gcp_params_file=<required>`
To delete a cluster	`destroy_cluster -cohesity_gcp_params_flle=<required>` **Note:** Your service account requires the `compute.addresses.deleteInternal` permission to delete and free the static IP addresses associated with the node VMs.
To create new nodes (VMs) to be added to a cluster	`create_vms -cohesity_gcp_setup params file=<required>`
To delete node (VMs) that have been removed from the cluster	`delete_vms -cohesity_gcp_params_file=<required> -cohesity_gcp_vm_list_csv=<required>`

Manage Compute Nodes

Compute Nodes are special nodes in the Cohesity cluster that provide dedicated CPU and memory to run resource-intensive apps and services. These nodes do not store any data and do not require disks other than the boot disk. Nodes are automatically detected as compute nodes or can be designated as compute nodes at the time of adding nodes to a Cohesity cluster. Compute nodes are only required if you are running resource-intensive applications.

You can run multiple applications or multiple instances of a single application on a compute node.

System Requirements

The following are the system requirements for a compute node:

- System Disk : 1 x 240GB
  - Must be SSD (HDD not supported)
  - Recommended to have 2 system disks with the same capacity for high availability.

    > **Note:** Do not configure any hardware RAID on the two system disks, if the system disks are connected to a RAID controller. You must configure the RAID controller and both the system disks as JBOD mode in the hardware system setup.

  - System disk must be less than 800 GB
  - Any additional drives must be removed from the system
- Memory : 128 GB (minimum)
- Intel CPU 32 Cores (minimum) with each core at 2.1GHz or above

Supported Hardware Platforms

Cohesity also extends support for hardware platforms from the following partners as long as they meet the minimum system requirements.

Cohesity certified platforms	Reference Links
C5K CNG2 Compute Node	C5000 Series Setup Guide
Bring your own Hardware (BYOH)	HPE, Cisco, DELL, Fujitsu, or Lenovo - any x86 that meets compute node requirements.

Bring Your Own Hardware (BYOH)	Minimum Specifications*
CPU	2 x 16 Cores (Intel or AMD), min 2.0GHz
Memory	128GB
Boot drives	2 x 240GB SATA/NVMe M.2 SSDs Note: Boot SSD drive size should not be more than 800GB (max limit)
NIC	4 x 10/25GbE (BaseT, SFP, SFP+, etc)

*The requirements can be more unless explicitly specified.

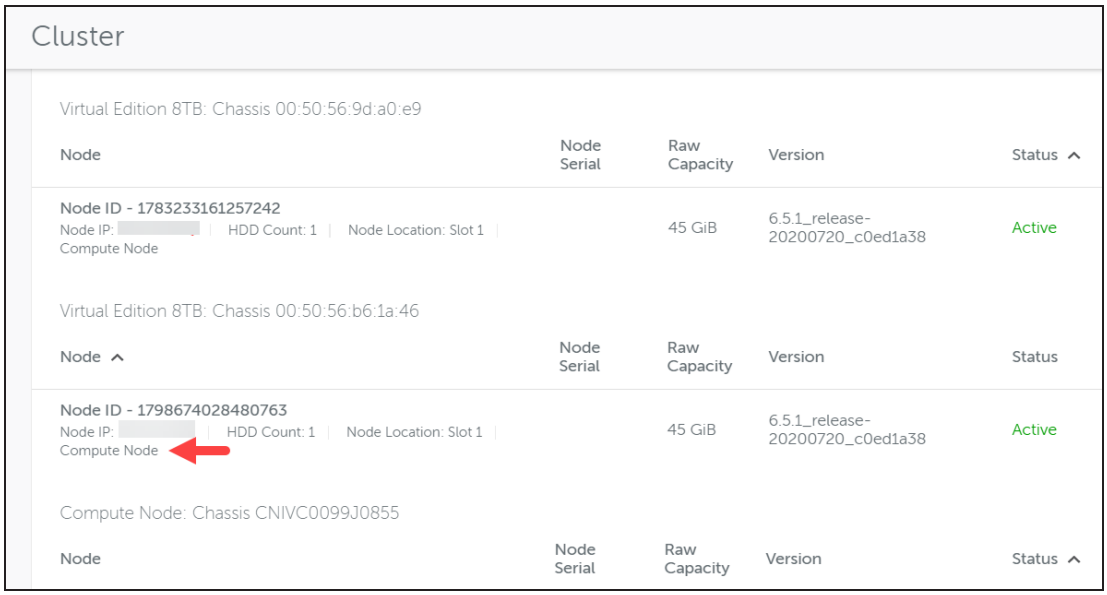
> **Note:** If you use a hardware model other than the Cohesity-certified platforms, it is recognized as 'Product Name : Unknown Platform' and supported as long as it meets the minimum system requirements.

Manage Compute Nodes

> **Note:** Nodes configured with VIPs cannot be designated as or automatically added as compute nodes.

Automatic Addition of Compute Nodes

Adding a physical compute node is seamless for the user with no additional configuration. If a physical node is added, and it meets the minimum specifications for a compute node, it will be automatically added as a Compute Node, unless it is a pre-certified data node platform.



Delete Compute Nodes

Deleting a compute node is like deleting any other node. For more information, see node delete.

Gracefully Remove Nodes from the Cohesity Cluster

A Cohesity cluster node may have multiple Cohesity services such as Data Protection service, I/O operations service, and Indexing service running. Removing the node without gracefully handling these existing services may result in data loss. To prevent this, Cohesity recommends that you remove a node gracefully. During graceful removal, the resources

used by a service running on that node are optimally redistributed to other available nodes, and then the service is stopped. After all the services have stopped, the node is removed, thereby handling the node removal in an orderly manner.

A node is gracefully removed by using the web UI or by running a Cohesity CLI command. The CLI command output displays the progress of the redistribution of resources used by each service. The output helps you understand how long you have to wait for the graceful removal to complete.

> **Note:** Physical Hardware nodes, Virtual Edition nodes, and Cloud Edition nodes can be gracefully removed.

Prerequisites

- You need CLUSTER_MANAGEMENT privilege to perform the graceful removal of nodes.
- Any ongoing upgrade must be canceled before initiating graceful removal. For details on how to cancel an upgrade, see Cancel Upgrade.

Gracefully Remove a Node

To gracefully remove a node from the Cohesity cluster:

1. To view the list of nodes in a Cohesity cluster and identify the unique ID of the node, do the following:
    1. Log into the Cohesity cluster.
    2. Navigate to **Settings** > **Summary**.
    3. Select the **Hardware** tab. The details of all the nodes in the Cohesity cluster are displayed. Make a note of the ID of the node you want to delete.
2. To remove the node, do one of the following:
    1. Using the web UI
        1. Hover over the node you want to remove and click the kebab menu and select **Remove**.
        2. In the **Removal Precheck** dialog, click **Remove** to confirm.
    2. Using the Cohesity CLI
        1. Start the Cohesity CLI. For details on how to do this, see Using the Cohesity CLI.
        2. Run the following command to mark a node in the Cohesity Cluster for removal using the ID of the node you made a note of in Step 1:

```
admin@127.0.0.1>node rm id=<ID of the node>
```

Example

```
admin@127.0.0.1>node rm id=1111222255
```

Sample Output

```
Success: Node ID:1111222255 marked for removal successfully.
```

Check Removal Status

Run the following command to check the removal status of the node.

```
node ls ids=<node id> include-marked-for-removal=true show-stats=true
```

Sample Command Output:

```
node ls ids=1111222255 include-marked-for-removal=true show-stats=true

NODE ID                          : 1111222255

NODE IP                          : 1.11.11.111

REMOVAL STATE                    : MARKED FOR REMOVAL

REMOVAL REASON                   : GRACEFUL REMOVAL

SERVICES ACKED                   : Athena, Librarian, Gandalf, Yoda, Magneto,
Groot, All

SERVICES NOT ACKED               : Hydra,ChunkRepository,Scribe,Apollo

DATA HEALING STATUS              :

Hydra                        : Number of epochs 4

ChunkRepository              : 3.84 MiB(2 files) remaining

Scribe                       : Number of buckets per entity 814
```

The output of the CLI command displays the progress of the node removal as follows:

- REMOVAL STATE— Displays MARKED FOR REMOVAL if removal is in progress. Changes to "OK TO REMOVE" after all the services have stopped and then to "REMOVED" when graceful removal is complete.
- REMOVAL REASON— Is always GRACEFUL REMOVAL.
- SERVICES ACKED—Indicates which services have successfully redistributed the resources and acknowledged the removal.
- SERVICES NOT ACKED—Indicates which services are yet to successfully redistribute the resources and acknowledge the removal.
- DATA HEALING STATUS— Indicates the progress of the ongoing redistribution of the resources for each service. For example, ChunkRepository indicates the progress of the reallocation of files used by the I/O service.

Cancel Removal of a Node

You can still cancel the removal of a node if one or more cluster services are in progress with the redistribution of the resources and are yet to send the acknowledgment.

Run the following command to cancel removal of a node:

```
node rm id=<node-id> cancel=true
```

Example

```
node rm id=1111222255 cancel=true
```

Sample Output

```
Success: Node ID:1111222255 marked-for-removal is cancelled
```

Gracefully Remove Disks from the Cohesity Cluster

A Cohesity cluster node from which you are removing an HDD or SSD disk may have multiple Cohesity services such as Data Protection service, I/O operations service, and Indexing service running. Removing the disks from such nodes without gracefully handling these existing services may result in data loss. To prevent this, Cohesity recommends that you remove a disk gracefully. During graceful removal, the resources used by a service running on the node from which the disk is removed are optimally redistributed to other available nodes. Then the disk is available for removal, thereby facilitating the disk removal in an orderly manner.

A disk is gracefully removed by running a Cohesity CLI command. The CLI command output displays the progress of the redistribution of resources used by each service. The output helps you understand how long you have to wait for the graceful removal to complete.

Prerequisites

- You need CLUSTER_MANAGEMENT privilege to perform the graceful removal of a disk.
- Any ongoing upgrade must be canceled before initiating graceful removal. For details on how to cancel an upgrade, see Cancel Upgrade.

Gracefully Remove a Disk

To gracefully remove a disk from the HDD or SSD disk from the Cohesity cluster:

1. Start the Cohesity CLI. For details on how to do this, see Using the Cohesity CLI.
2. To view the list of disks in a Cohesity cluster and identify the unique ID of the disk, run the following:

   ```
   disk ls
   ```

   From the command output, make a note of the ID of the disk you want to delete.
3. Run the following command to remove the HDD or SSD disk:

```
admin@127.0.0.1>disk remove disk-id=<disk ID>
```

Example

```
admin@127.0.0.1>disk remove disk-id=16
```

Sample Output

```
Success: Disk ID:16 marked for removal.
```

The reallocation of resources starts immediately. The disk is removed once all the services have successfully redistributed the resources and acknowledged the removal.

Check Removal Status

Run the following command to check the removal status of the disk.

```
disk ls ids=<disk id> include-marked-for-removal=true show-stats=true
```

Sample Command Output:

```
disk ls ids=16 include-marked-for-removal=true show-stats=true

DISK ID                          : 16

CURRENT NODE ID                  : 128635482687442

CURRENT NODE IP                  : 10.1.1.11

REMOVAL STATE                    : MARKED FOR REMOVAL

REMOVAL REASON                   : GRACEFUL REMOVAL

SERVICES ACKED                   : Groot, Gandalf, Magneto, All, Athena

SERVICES NOT ACKED               : ChunkRe-
pository,Scribe,Apollo,Yoda,Hydra,Librarian

DATA HEALING STATUS              :

ChunkRepository             : 490.95 MiB(38 files) remaining

Scribe                      : Number of buckets per entity 768
```

The output of the CLI command displayed the progress of the disk removal as follows:

- REMOVAL STATE— Displays MARKED FOR REMOVAL if removal is in progress. Changes to “Removed” when graceful removal is complete.
- REMOVAL REASON— Is GRACEFUL REMOVAL or HEALTHFAIL. The removal reason is HEALTHFAIL when the disks are removed if a disk is found inoperable during a self-initiated health check.
- SERVICES ACKED—Indicates which services have successfully redistributed the resources and acknowledged the removal.

- SERVICES NOT ACKED—Indicates which services are yet to successfully redistribute the resources and acknowledge the removal.
- DATA HEALING STATUS— Indicates the progress of the ongoing redistribution of the resources for each service. For example, ChunkRepository indicates the progress of the reallocation of files used by the I/O service.

> **Note:** Upon completion of the scribe shuffle, the newscribe process may experience a crash. This is a normal occurrence on nodes when the scribe shuffle enables them to utilize the new buckets. However, this does not result in a restart of all services on the node.

Cancel Removal of a Disk

You can still cancel the removal of a disk if one or more cluster services are in progress with the redistribution of the resources and are yet to send the acknowledgment.

Run the following command to cancel the removal of a disk:

```
disk remove disk-id=<disk-id> cancel=true
```

Example

```
disk remove disk-id=16 cancel=true
```

Sample Output

```
Success: Disk ID:16 marked-for-removal is cancelled
```

Hardware Node Detection Issues

If you encounter issues while creating Nodes, read the following sections for possible resolutions:

Verify the following:

- Multicast is enabled on the network switch that the Cohesity cluster Nodes are connected to.
- All of the following are reachable from the 10GbE switch:
  - Default gateway
  - DNS server
  - NTP server

No Node is Detected

Possible cause

The network switch configuration prevented mDNS from being received/transmitted.

Resolution

Attempt to connect the laptop to another Node's management port to narrow down which network cable, switch port, or Node network port has an issue so you can resolve it.

Some Nodes are Not Displayed

Possible cause

The Node’s network connection has an issue.

Resolution

Check the Node’s cable connection, network switch port or the Node’s network interface. Checking indicator lights may help you identify the issue.

Use Cohesity Data Cloud (Self-managed) in DoD Mode

Cohesity Data Cloud (Self-managed) is DoDIN APL certified.

To use Cohesity Data Cloud (Self-managed) as per DoDIN APL requirements and recommendations, you need to enable DoD mode in the Cohesity cluster.

As part of the DoDIN APL requirements, Cohesity provides the following security features:

- Login banner support
- Transfer audit logs to a Syslog server over a secure TLS connection.
- Certificate mapping-based authentication support.
- Support to configure the banner on the Cohesity Dashboard.
- Server-side session management.
- Node-to-node traffic encryption.
- Certificate path validation.

Enable DoD Mode

You can enable DoD mode using the Cohesity CLI.

> **Warning:** Once you have enabled DoD mode, you cannot disable it. For node-to-node traffic encryption, you must configure the required certificates before enabling DoD mode. For more information, see Node-to-Node Encryption.

When you enable DoD mode, by default:

- The **cohesity** user is disabled, and you cannot use the **cohesity** user account to access the Cohesity bash shell using SSH. Instead, you need to use the support user account to log into the Cohesity bash shell using SSH.
- You can change the **support** user password only once within a day.

- The **support** user can run the "`sudo`" prefixed commands only after providing the **support** user password. The sudo session is valid for 15 minutes, and you will be prompted to enter the password again.
- The **cohesity_console** account is disabled, and instead, you can use the root account to log into the console.
- The data transfer between the nodes in the Cohesity cluster is encrypted.

Prerequisites

Dedicated partitions are required to support DODIN RHEL STIG requirements for Operating System partitions. Before you enable the DOD mode, you must run a script provided by the Cohesity Data Cloud (Self-managed) to check if the system disk on the Cohesity node contains the dedicated partitions. To run the script:

1. Log on to the Cohesity node bash shell using SSH.
2. Run the following script:

   ```
   /home/cohesity/bin/validate_dodin_compliant_partitions.sh
   ```

The script validates if the following dedicated partitions are present in the the system disk on the Cohesity node:

- `/var`
- `/spare/var`
- `/var/log/audit`
- `/cohesity_users_home`

If the validation fails, it implies that the Cohesity node does not contain the dedicated partitions. Therefore, you need to perform ISO installation on the Cohesity node to get all the security benefits listed by DODIN RHEL STIG for Operating System partitions.

Enable DOD Mode

To enable DoD mode:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.
2. Run the following command to enable DoD mode:

   ```
   $iris_cli security-config update-security-mode security-mode-dod=true
   Configuring security mode...Success: Security mode DOD will be turned
   on after rolling reboot.
   ```

   The Cohesity cluster goes into a rolling reboot. Wait until the rolling reboot is complete.
3. Verify if the DoD mode is enabled. Run the following command:

   ```
   $iris_cli cluster info
   ```

Node-to-Node Encryption

By default, when you enable DoD mode on the Cohesity cluster, the user data exchanged between the nodes are encrypted.

> **Note:** Internal data such as statistics data or other non-critical data is not encrypted.

Before you enable DoD mode you need to configure the nodes to use certificates to encrypt the data exchanged between the Cohesity cluster nodes.

Configure Certificate for Node-to-Node Encryption

To use a certificate for node-to-node encryption, you must manually create a certificate signing request, generate the certificate, and import the certificate on each node in the Cohesity cluster.

Prerequisites

Before you configure a certificate for node-to-node encryption, ensure the following prerequisites:

- Verify if the domain name is set for your Cohesity cluster using the following command:

  ```
  $ cluster ls-domains
  ```

  For example:

  ```
  $ cluster ls-domains
  CLUSTER ID                : 4759089959284457
  CLUSTER NAME              : cohesity
  DOMAIN NAMES              : eng.cohesity.com, corp.cohesity.com
  ```

- Update the hostnames of the nodes in the Cohesity cluster using the following command:

  ```
  $ node-csr update-hostnames node-ids=<node_id1,node_id2> host-
  names=<hostname_1, hostname_2>
  ```

  Where:

  - `node-ids` - The node id of the nodes in the Cohesity cluster. Provide a comma separated list of the node ids.
  - `host-names` - Define the hostnames for the nodes in the Cohesity cluster. Provide a comma separated list of the hostnames for the node ids.

Step 1: Create a Certificate Signing Request

Perform the following to create a certificate signing request (CSR) on each node in the Cohesity cluster.

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.
2. Run the following command to create a certificate signing request:

```
$node-csr create city=<city_name> state=<state_name> country=<country_
name> organization=<org_name> organization-unit=<org_unit_name> dns-
names=<dns_name>
```

Sample Output:

```
CSR :-----BEGIN CERTIFICATE REQUEST-----
MIIC5TCCAc0CAQAwVTELMAkGA1UEBhMCVVMxETAPBgNVBAoMCENvaGVzaXR5MRIw
EAYDVQQLDAlDb3JlSW5mcmExCzAJBgNVBAgMAkNBMRIwEAYDVQQHDAlDdXBlcnRp

KzyUXKkcY/Md/n/k2EHDrF5thGX8X8qugw==
-----END CERTIFICATE REQUEST-----
```

The following table lists the attributes required to create the certificate signing request:

Attribute	Required/Optional	Description
city	Required	Identifies the city where the company is located.
common-name	Optional	Specifies a context for the certificate. For example, the name of the node to which the certificate must be assigned.
country	Required	Identifies the country where the state is located. You can specify it as two letter code defined by the ISO standard.

Attribute	Required/Optional	Description
dns-names	Optional	Concatenate the hostname with the first domain name. For more information, see Prerequisites. For example: `cohesity-0050568931e8-node-2.eng.cohesity.com` Though `dns-names` attribute is optional. Cohesity recommends that you use the `dns-names` attribute.
email-address	Optional	An alternative subject name component that must be included in the certificate.
host-ip	Optional	An alternative subject name component to be included in the certificate. It is used to uniquely identify the node.
organization	Required	Specifies the name of the company.
organization-unit	Required	Specifies the department or business unit in the company that owns the node.
state	Required	Identifies the state where the city is located.

Step 2: Sign the CSR with a CA

You can sign the CSR using a third-party Certificate Authority (CA) or a self-signed CA using OpenSSL commands.

Step 3: Verify the CA Certificate

Run the following command to check if the CA certificate is valid. The CA certificate is valid if the output is OK.

```
openssl verify -verbose -CAfile <path to ca cert>  <path to signed cert>
```

Example

```
openssl verify -verbose ca.crt server.crt
```

Sample Output for a valid CA certificate

```
ca.crt: C = US, ST = CA, L = SJ, CN = Cohesity Inc Server, O = Cohesity
```

```
OK
```

Sample Output for an invalid CA certificate

```
server.crt: C = US, ST = CA, L = SanJose, CN = localhost, O = Cohesity
```

```
error 20 at 0 depth lookup:unable to get local issuer certificate
```

Step 4: Import the Signed Certificates to the Nodes

After the certificate signing request (CSR) corresponding to the node is signed, import the signed certificate and the CA certificate onto each node in the Cohesity cluster.

Perform the following on all the nodes in the Cohesity cluster:

1. SCP or copy the signed certificate to node in the Cohesity cluster. Enter that you copy both the signed and CA certificates to the node.
2. Change the certificate file permission to 644.
3. Import the signed and CA certificates to the node using the following command:

   $node-csr import signedcert-path=<signed_cert_path> cacert-path=<ca_cert_path>

   Where:

   - `<signed_cert_path>` - The absolute path of the signed certificate file that must be imported to the node.
   - `<ca_cert_path>` - The absolute path of the CA certificate that was used to sign the CST for the node.

Certificate Path Validation

Certificate path validation is necessary to confirm if the certificate path is valid so that the Cohesity node can accept the end entity certificate. Cohesity uses Online Certificate Status Protocol (OCSP) for obtaining the revocation status of an X.509 digital certificate. Issuer certificate is required to recreate OCSP request for certificate path validation.

> **Note:** Cohesity supports only HTTP protocol URL for issuer certificates.

Configure a Login Banner

You can customize the login banner of Cohesity Dashboard to present a statement to users during the login process, requiring them to acknowledge and agree to the message before logging in.

When you configure the login banner, the message will appear before the user logs on to the Cohesity Dashboard. To configure a login banner, see ***Optional Settings*** in Configure Settings.

Configure Banner Message

You can present a banner message to a user who is using the Cohesity Dashboard. You can configure the banner and the message using the Cohesity CLI.

To configure the banner message:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.
2. Run the following command to configure the banner and the message:

```
$iris_cli security-config update is-data-classified=true classified-
data-msg="This is a sample message"
DATA CLASSIFICATION       :
IS DATA CLASSIFIED        : true
CLASSIFIED DATA MSG       : This is a sample message
```

Certificate Mapping-Based Authentication

If the Cohesity cluster is joined to an Active Directory (AD) domain, Active Directory (AD) users can authenticate to the Cohesity cluster using certificate mapping-based authentication.

In certificate mapping-based authentication, the AD user is authenticated based on the attribute mappings you have configured for the certificate and AD. In the Cohesity cluster, you can define the following attributes of the certificate and AD that must map for the user authentication:

- Certificate Attributes:
  - CommonName
  - EmailAddress
  - UserPrincipalName
- Active Directory Attributes:
  - SamAccountName
  - UserPrincipalName

For more information, see Certificate Mapping-Based Authentication.

Server-Side Session Management

Cohesity provides various session management related settings for server-side session security.

The following table lists the settings:

Settings	Description	Example
Session absolute timeout	A timeout after which a session is closed no matter whether there is user activity or not. You can specify the absolute session expiration time in seconds. The default value is 86400 seconds and the DoD mode value is 3600.	`$iris_cli security-config update session-absolute-timeout=3600` `SESSION CONFIGURATION : SESSION ABSOLUTE TIMEOUT : 3600`
Session inactivity timeout	A timeout after which a session is closed if the user is inactive. You specify the inactivity time in seconds after which the session expires. The default value is 3600 seconds and the DoD mode value is 600.	`$iris_cli security-config update session-inactive-timeout=600` `SESSION CONFIGURATION : SESSION INACTIVITY TIMEOUT : 600`
Limit sessions	Restrict the number of active sessions allowed per user and system-wide. The default value is set to false.	`$iris_cli security-config update limit-sessions=true` `SESSION CONFIGURATION : LIMIT SESSIONS : true`
Session limit per user	The maximum number of active sessions allowed per user. The default value is set to 10. **Note:** Ensure that you have enabled limit sessions.	`$iris_cli security-config update session-limit-per-user=40` `SESSION CONFIGURATION : SESSION LIMIT PER USER: 40`
Session limit system-wide	The maximum number of active sessions allowed system-wide. The default value is set to 100000 and the DoD mode value is 60000. **Note:** Ensure that you have enabled limit sessions.	`$iris_cli security-config update session-limit-system-wide=60000` `SESSION CONFIGURATION : SESSION LIMIT SYSTEM WIDE: 60,000`

Settings	Description	Example

Revoke active sessions	Revoke all the active sessions of a user or all active system-wide sessions.	If you provide the user-sid of the user, all active sessions of the user are revoked.
		For example:
		`$iris_cli user delete-sessions user-sid="S-1-100-21-86254287-1950289-11"`
		`Success: Deleted all active sessions of user with sid S-1-100-21-86254287-1950289-11`
		If you do not provide the user-sid of the user, then system-wide active sessions are revoked.
		For example:
		`$iris_cli user delete-sessions`
		`Success: Deleted system wide all active user sessions`

> **Note:**
> These are the two APIs used to get and update the session related settings.
>
> 1. GET /v2/security-config
> 2. PUT /v2/security-config
>
> For more information, see Create Session.

Securely Transfer Audit Logs to an External Syslog Server

You can add a Syslog server to the Cohesity cluster and securely transfer the following logs to an external Syslog server:

- Cluster audit logs
- Operating System audit logs

- Filer audit logs
- Web Server audit logs

The logs are transferred over a TLS connection from the Cohesity cluster to the external Syslog server.

You can add a Syslog server to the Cohesity cluster using the Cohesity CLI.

To securely transfer logs to an external Syslog server:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.
2. Run the following command to add a Syslog server:

   ```
   $iris_cli syslog add address=<ip_address/hostname> port=<port>
   protocol=<tcp/udp> ca-certificate-path=<certificate-absolute-path>
   ```

   Where:

   - `<ip_address/hostname>` - The IP address or hostname of the Syslog server.
   - `<port>` - The port for data transfer.
   - `<tcp/udp>` - The protocol used for the data transfer. The supported values are TCP or UDP.
   - `<certificate-absolute-path>` - The absolute path of the CA certificate on the Syslog server.

   > **Note:** The Syslog server CA certificate file path can be local to the current node.

About Node-to-Node Encryption

The Zero Trust Architecture of the Cohesity Data Cloud (Self-managed) is strengthened with certificate-based authentication for communications between services on a Cohesity cluster. Cohesity provides X509 certificates that are used to:

- Authenticate services for communication with another service
- Encrypt the user data exchanged between the nodes on a Cohesity cluster.

The communication between services of the same or different nodes happen through TLS and Mutual TLS (mTLS).

> **Important:** In new Cohesity cluster from 7.1.1 deployments, node-to-node encryption is enabled by default. However, if you are upgrading your existing Cohesity clusters from version 6.8 or later, you need to manually enable node-to-node encryption. For details, refer to Upgrade Scenarios.

This applies when a service communicates with another service on the same or a different node, it first verifies the other service through certificates and then encrypts the data before communication.

> **Note:** If node-to-node-encryption is enabled on your Cohesity cluster before upgrade, then it will remain enabled after upgrade. For details, refer to Upgrade Scenarios.

Each service on a Cohesity node is assigned a unique X509 certificate that holds the private key for authentication during a TLS handshake. This certificate is rotated every 12 hours automatically .

> **Note:** The mTLS-based node-to-node encryption is not enabled by default when you create a new cluster. Once you enable node-to-node encryption on your Cohesity cluster, it cannot be disabled.

Upgrade Scenarios

Cohesity Cluster Version	DoD Mode	Node-to-node Encryption	Post-Cluster Upgrade Actions
Latest patch update for 6.8.1 or any earlier version	Disabled	Disabled	Follow the steps to Enable Node-to-node Encryption
Latest patch update for 6.8.1 or any earlier version	Disabled	Enabled	Run the command on Cohesity CLI to enable mTLS-based node-to-node encryption: `iris_cli cluster tpenc enable-encryption=true`

Cohesity Cluster Version	DoD Mode	Node-to-node Encryption	Post-Cluster Upgrade Actions
Latest patch update for 6.8.1 or any earlier version	Enabled	Enabled	Run the command on Cohesity CLI to enable mTLS-based node-to-node encryption: `iris_cli cluster tpenc enable-encryption=true` For more information, see *Node-to-Node Encryption* in Use Cohesity Data Cloud (Self-managed) in DoD Mode.

Enable Node-to-node Encryption

> **Important:** By default, new Cohesity clusters deployed with version 7.1.1 or later have node-to-node encryption enabled. However, when upgrading a Cohesity cluster from version 6.8 or later to version 7.1.1 or above, only Gandalf RPC encryption is enabled by default. You need to manually enable internode traffic encryption. This ensures that all internode data traffic is encrypted, making the Cohesity Platform compliant with Zero Trust principles.

To enable node-to-node encryption:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. Run the following command to enable node-to-node encryption:

   ```
   $iris_cli cluster stop
   $iris_cli cluster tpenc enable-encryption=true
   $iris_cli cluster start
   ```

Verify Service and Node-to-node encryption is Enabled

You can run the following commands on Cohesity CLI to check:

1. Services on your Cohesity cluster are associated with X509 certificates.
2. Node-to-node encryption is enabled on your Cohesity cluster.

Command 1

```
iris_cli -username=<Value> -password=<Value> service-identity status
```

Sample Response

```
[cohesity@cluster-bqkp45044016-node-3 ~]$ iris_cli service-identity status
Username: admin
'admin' Password:
GLOBAL-ENABLED : true
[cohesity@cluster-bqkp45044016-node-3 ~]$
```

Quorum Protected Operations

Quorum approval on Helios is an authorization model that ensures that a predefined quorum of approvers must approve sensitive or privileged operations requested by Helios before those operations are executed.

Quorum approvals help you eliminate the risk associated with a unitary, highly-privileged administrator - specifically to prevent a rogue, poorly trained, or compromised administrator from performing sensitive or privileged operations on the Cohesity platform without authorization or oversight.

Any Cohesity cluster-related operations that are quorum-protected in Helios cannot be initiated from the Cohesity Platform UI or CLI. Instead, you need to initiate these operations from Helios. For more information on Quorum Approvals on Helios, see Quorum Approvals.

> **Important:** If you disconnect the Cohesity cluster from Helios, the quorum-protected cluster operations continue to be restricted from initiation from the Cohesity Platform UI or CLI.

Antivirus Software to Protect Cluster Data

You can enable antivirus software to protect your data on the Cohesity cluster from viruses. Once an antivirus software scans a file and detects a threat, the Cohesity cluster reports the threat on the Cohesity Dashboard. The administrators can either quarantine, unquarantine, reset, or delete the infected file.

Perform the following steps to enable antivirus scanning and manage threats:

1. Add an Antivirus Provider
2. Enable Antivirus Scan on a View
3. View and Manage Threats

Add an Antivirus Provider

To perform an antivirus scanning on your data in the Cohesity cluster, you must first add the antivirus software to the Cohesity cluster. You can add the software in one of the following ways:

- Register External Antivirus Software
- Install the Antivirus App from the Cohesity Marketplace

Register External Antivirus Software

1. Navigate to **SmartFiles > Antivirus** and click the **Providers** tab.
2. Click **Add External Provider** in the upper-right corner of the page.
3. In the **New External Provider** field, enter the name of the antivirus software provider of your choice.
4. (Optional) Describe the provider.
5. Enter the ICAP Server URL in the following format: `icap://<server>:<port>/<uri>`

Option	Description
icap	Indicates the required protocol identifier that enables communication with external servers hosting third-party antivirus software.
server	Specifies the domain name or IP address of the external server (ICAP server) hosting the third-party antivirus software.
port	Specifies the port that the external server monitors for incoming requests. If not specified, the default icap port, 1344 will be used.
uri	Specifies the path of the ICAP service.

6. (*Optional*) Click **Add** to register more than one external ICAP server.
7. Click **Check ICAP Server Connection Status** to check the status of the external antivirus software.

   If the connection is not successful, ensure that you have provided the correct ICAP URL and the external server is up and running.
8. Click **Add**.

   The antivirus software is registered on the Cohesity cluster.

Install the Antivirus App from the Cohesity Marketplace

1. Navigate to **SmartFiles > Antivirus** and click the **Providers** tab.
2. Click **Install Antivirus App** at the top right of the page.

You will be directed to the Cohesity App Marketplace.

3. Click **GET APP** for the Antivirus App you want to install on the Cohesity cluster.

   You will be directed to the Helios login page.

4. Log in to Cohesity Helios, select the Cohesity cluster on which you want to install the Antivirus App, and click **Install**. You also have the option to install the App later.
5. Go back to the Cohesity cluster and go to **Marketplace > My Apps**.

   The page displays the list of Apps that are available on the Cohesity cluster.

6. Click **Run App** to create an instance of the Antivirus App.

   The instance created will be displayed as an Antivirus provider on the **Providers** tab.

Enable Antivirus Provider

1. Navigate to **SmartFiles > Antivirus** and click the **Providers** tab.

   The page displays the list of antivirus providers that can be enabled for antivirus scanning.

2. From the Action menu, toggle on the **Enable** option.

   You can enable only one antivirus provider group at a time.

Enable Antivirus Scan on a View

Once you install the antivirus software on the Cohesity cluster, you can enable the antivirus scan on a View.

To enable antivirus scan on a view:

1. Navigate to **SmartFiles > Antivirus** and click the **Secured Views** tab.
2. Click **Add a View** at the top right of the page.
3. From the View drop-down list, select a view for which you want to perform the scanning of files.

   Antivirus scanning is supported only on Views with SMB protocol. Therefore, the drop-down list displays the Views which support SMB protocol.

4. Provide the following details either by clicking **Edit All** or by clicking the **Edit** option

for each scan settings option:

Option	Description
Scan on	Antivirus scans can be configured to send the files for scanning when they are closed, opened, or both. In each case, all the files to be scanned are added in a queue and sent to the antivirus provider(s) for scanning, as per the queue order. • **Close**: Files are scanned after they are closed (Default) With this configuration, you can access the files without any delay as file scanning is done after the user's file operation. This type of scanning is faster but less secure. • **Open**: Files are scanned before they are opened. With this configuration, you can access the files once they are scanned. You must wait for the file scan to complete. This type of scanning is slower but more secure. • **Open and Close**: Scans the files before they are opened and after they are closed. This type of scanning is the slowest and most secure, as the scanning queue includes all the live files (opened and closed). Cohesity recommends scanning the file after they are closed as this configuration ensures that the files are accessible even if the antivirus provider(s) or scanning network is down, unavailable or unreachable.
Files to Scan	• **All Files**: Select this option to scan all the files in the View. • **All Files Except**: Select this option to exclude files in the view from scanning. You can specify the file extensions (comma-separated) to be excluded in the **File extensions to skip** field. • **Only These Files**: Select this option to scan only the selected files. You can specify the file extensions (Comma-separated) to be included in the **File extensions to scan** field.
	Exclude files based on file size: Enable this option to exclude files based on the file size. In the **Max File Size** field, you can specify the file size limit for scanning. The default file size limit is 50 MB. The maximum file size limit is 125 MB.
Scan Timeout	Set the maximum amount of time (in seconds) that a scan can take before timing out.
If Scan Cannot Be Completed	Blocks file access if the antivirus servers are unavailable or are unable to scan the file due to any issue. This option is disabled by default to ensure that the files stay accessible even if the antivirus provider(s) or scanning network is down, unavailable, or unreachable.

5. Click **Add**.

You can also enable antivirus scan while creating a View or by editing an existing View.

View and Manage Threats

After you enable the antivirus scan on the View, you can view the scanned report from the **Threats** page and take action on the infected files.

To view the scanned report:

Navigate to **SmartFiles > Antivirus** to view the **Threats** page.

Alternatively, on the **Secured Views** page, click the view for which you want to view the reports.

The Threats page displays the following details:

- The total number of quarantined files
- The total number of unquarantined files
- The total number of views that are affected by the virus
- Option to filter the report based on the status of the file and View
- Information on the files that are affected:

Field	Description
Filename	The files that are infected, along with the file path. A lock icon will be displayed along with the file name if you have enabled the **File DataLock** option while creating the View.
View	The View name of the files. A lock icon will be displayed along with the View name if you have cloned the View as DataLock.
Threat	The threat type or virus signature along with the ICAP server URL that detected the threat.
Provider Name	The antivirus software provider that detected the threat.
Scan Time	The time at which the file is scanned for viruses.
Status	The status of the threat: • **Quarantine**: The file is determined to be unsafe. All access to the file is blocked until the administrator manually changes the file state. • **Unquarantine**: Allow file access. The file is not scanned again until the file state is reset.

Manage Threats

You can manage threats by performing the following actions from the **Threats** page:

Action	Description	How to
Unquarantine Files	Move the files from the quarantined state to allow file access. Unquarantined files are not scanned again.	Select the checkbox next to file names and then click **Unquarantine Files**.
Delete Files	Deletes the quarantined files. You cannot delete unquarantine files.	Select the checkbox next to file names and then click **Delete Files**.
Reset Files	Reset the unquarantine files. You cannot reset quarantine files	Select the checkbox next to file names and then click **Reset Files**.

Cohesity Licensing

The Cohesity Licensing system helps customers and partners ensure that Cohesity software is being used in accordance with the terms and conditions of the license and the usage is in compliance with the entitlement. The Cohesity licensing model gives the flexibility to use certain features or services of the Cohesity software, depending on which license(s) the customer is entitled to.

All Cohesity clusters must be licensed. License usage is metered on each Cohesity cluster and the usage is aggregated in Cohesity Helios. Alerts are triggered or GUI notifications are displayed in one of the following scenarios:

- License usage violation—If the aggregate metered usage is nearing the entitlement or has exceeded the entitlement
- A cluster is set up without a license
- Clusters are not reporting their usage information to Helios
- The license file on a particular cluster has expired or is about to expire

You must set up licensing on the Cohesity cluster. For more information on setting up licensing on each cluster, follow the instructions below.

You can monitor the license usage and view entitlement details in Helios. For more information, see View License Usage and Entitlements.

View License Usage and Entitlements

Starting from the Cohesity 6.6.0c release, details about license usage and entitlement are displayed only on the **License** page in Helios. On the Cohesity cluster, the **License** page does not display details about the license usage and entitlement.

To view details about license usage and entitlement:

1. Log in to Helios.
2. Select **All Clusters** on the upper-right corner of the page.

3. Navigate to **Settings > License**.

   For more information, see View License Usage and Entitlements.

License Modes

Before you start using the Cohesity licensing feature, use the descriptions in the following table to decide which Licensing Mode is suitable for your business requirement:

Cohesity cluster State	How Licensing Works	How Audits are Conducted
Manage in Cohesity Data Cloud (SaaS)– Cluster remains connected with Helios at all times. All usage data is automatically shared with Helios.	License is automatically generated in Helios. The license is then reflected in the connected cluster automatically. There is no need for any manual intervention of operations. For details on how to configure this mode, see Choose the Licensing Mode .	Audit reports are automatically uploaded to Helios on a daily basis. **Note:** The audit report contains details such as cluster ID, timestamp, license usage data, and entitlements.

Cohesity cluster State	How Licensing Works	How Audits are Conducted
Manage on Cluster–If you are unable to share cluster management information with Cohesity Data Cloud (SaaS) or if you cannot connect your cluster to the internet for security reasons, you can consider keeping your cluster disconnected from Helios. Cohesity provides the following options: • Manually license your cluster–Every 180 days, you must manually download the audit report from the Cohesity cluster, upload the audit report on Helios, generate the new license file on Helios, and upload the new license file on the Cohesity cluster. • Helios Smart Licensing - Enabling Helios Smart Licensing may enable transmitting some telemetry data to Cohesity. For details on turning off this feature, see page 6 in Cohesity Cluster Secure Phone-Home Channel Security Brief.	**Manual Licensing**–Cluster remains disconnected from Helios and you manage the licenses manually. Perform the following steps: 1. Download the audit report which captures the license usage information from the cluster and upload it to Helios on a monthly basis. 2. Download the updated license files from Helios and upload them to the cluster. For details on how to configure this mode, see Configure Manual Licensing Mode.	Generate and download the license file from Helios. The license file allows usage on the cluster for up to 180 days. Every month, Cohesity recommends that you: 1. Retrieve the audit report from the cluster. 2. Upload it manually to Helios. 3. Generate a new license file. 4. Apply the new license file on the designated cluster.
	Helios Smart Licensing–You connect your cluster with Helios for licensing purposes. If you wish to keep your cluster connected with Helios only for licensing purposes, you can avoid the above steps, and the licensing data between your cluster and Helios is automatically synchronized. For details on how to configure this mode, see Configure Helios Smart Licensing Mode .	Audit reports are automatically uploaded.

Configure License During Cluster Creation

During the initial setup of the Cohesity cluster, upon logging in for the first time, you are presented with the End User License Agreement (EULA). Following the acceptance of the EULA, a prompt to configure the license appears. You can opt to configure the license immediately or defer it for later configuration. Regardless of the chosen timing, it is advisable to explore the available licensing modes and select a mode aligned with your business needs before initiating the license configuration.

> **Note:** If the Cohesity cluster is disconnected from Helios, the LicenseAboutToExpire alert is triggered when the license is about to expire. For more information, see the KB article.

Choose the Licensing Mode

Follow these steps to choose between configuring the license immediately by selecting a license mode or deferring the license configuration for a later time:

1. Log in to the Cohesity Cluster.
2. Read the **EULA License Agreement** and click **Agree**.
3. Do one of the following:
   - If you want the cluster to remain connected with Helios and automatically synchronize operations such as downloading audit reports and uploading license files, perform the following:

     1. Click on **Manage in Helios SaaS** and then on **Connect to Helios SaaS**.
     2. On the **Connect with Helios** page, select the appropriate access permission—**Full Access** or **View Only** and click **Continue**.
     3. You will be redirected to the Helios login page.
     4. Enter valid Helios credentials and click **Connect** to establish connection with Helios.

        Once the clusters are connected with Helios successfully, all operations such as generating the license file in Helios, downloading the license file on the cluster, and uploading this license file in Helios are all performed automatically. No manual intervention is required.

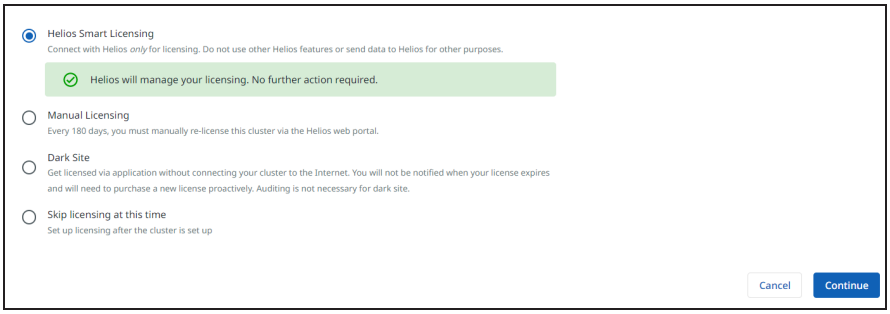
        You can access the **License** page on Helios to check the license usage against the purchased entitlement.

   - If you are unable to share cluster management information with Cohesity Data Cloud (SaaS) or if you cannot connect your cluster to the internet for security

reasons and are considering keeping your cluster disconnected from Helios, perform the following:

1. Click **Manage on Cluster**. Only the **Single-Cluster Management** icon remains enabled.
2. Click on **Connect to Cluster**.
3. On the **License** page, select one of the following licensing modes: Helios Smart Licensing, Manual Licensing, and Dark Site.

   To manage the licenses later, select **Skip licensing at this time**. For details on how to configure the license at a later point in time, see Configuring the License After Cluster Creation.



Configure Helios Smart Licensing Mode

Perform the following steps to configure Helios Smart Licensing:

1. Follow the steps in Choose the Licensing Mode section and select Helios Smart Licensing at Step 3.
2. On the **Management Options** page that appears, select the **Connect to Helios only for licensing** option.
3. Click **Continue**.

   You will be redirected to the Helios page to enter credentials to log in.

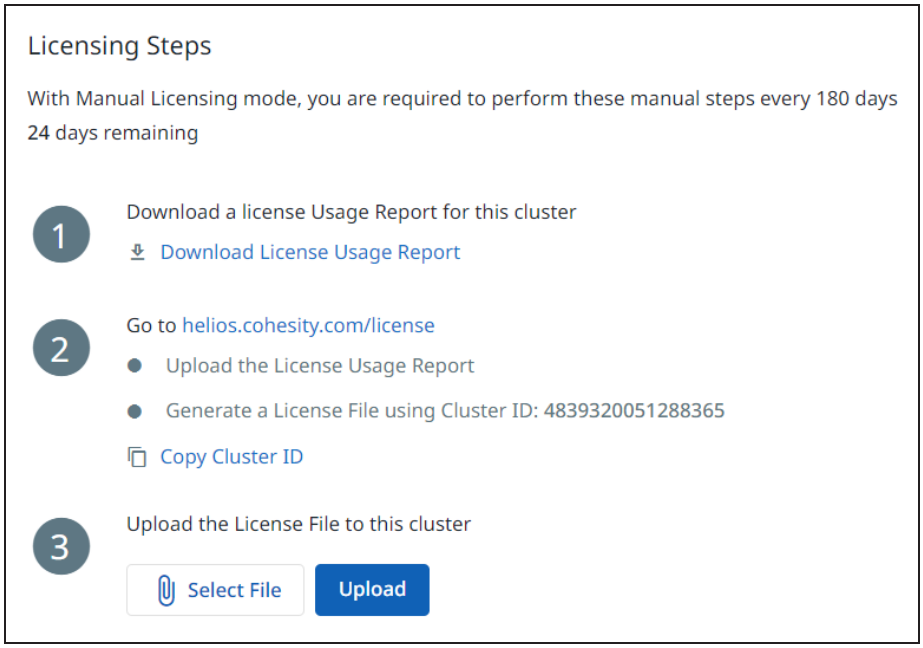
4. Click **Connect** to establish the connection with Helios.

   Only the licensing information is shared with Helios.

Configure Manual Licensing Mode

Configuring the Manual Licensing Mode requires you to download the License Usage Report from the Cohesity cluster and upload it to Helios. You must also generate the License File in Helios and upload it to the Cohesity cluster. As these steps require switching between the Cohesity cluster and Helios, Cohesity recommends that you remain logged in to both the Cohesity cluster and Helios till you complete the Manual License configuration.

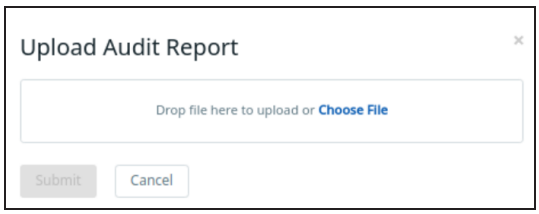
Perform the following steps to configure Manual Licensing:



1. Follow the steps in Choose the Licensing Mode section and select Manual Licensing at Step 3.
2. On the **Licensing Steps** dialog box, click on **Download License Usage Report**.

   The License Usage Report file or the Audit Report is downloaded to your local. The Audit Report contains details such as cluster ID, timestamp, license usage data, and entitlements.
3. To upload the Audit Report:
   1. Log in to Helios and navigate to **Settings** > **License**. The license summary of all clusters connected to Helios is displayed.
   2. Click **Upload Audit Report**.
   3. In the **Upload Audit Report** dialog box, upload the Audit Report downloaded at step 2.

4. Click **Submit**.



4. To generate the License File:
    1. In your Cohesity cluster, navigate to **Settings** > **License**. On the **Licensing Steps** page, select **Copy Cluster ID**.
    2. In Helios, click **Generate License File**.

       The **Generate License File** dialog box appears and prompts for the Cluster ID.
    3. Paste the Cluster ID copied in Step 4 (a) and click **Generate**.

       The License File is downloaded to your local.

5. To upload the License File:
    1. In your Cohesity cluster, navigate to **Settings** > **License**.
    2. On the **Licensing Steps** page, click **Select File**.
    3. Browse to select the License File downloaded at Step 4 (c) and click **Upload**.

Once Manual Licensing is configured, you must download the audit report from the Cohesity cluster and upload it on Helios every 180 days.

Configuring the License After Cluster Creation

Before you configure the license for your Cohesity cluster, Cohesity recommends that you learn about the licensing modes (in the License Modes section) and choose a Licensing mode suitable for your business requirement *before* you configure the license.

Choose a Licensing Mode after Cluster Creation

If you chose **Skip License** when you created the cluster, perform the following to configure licensing for your Cohesity cluster:

1. Log in to the Cohesity cluster.
2. Navigate to **Home** > **License Usage**.

   If you have not configured the license, the **License** page displays the Configure License link and the number of days within which you must configure the license. License must be configured within 180 days of creating the cluster.
3. To configure the license, click on **Configure License**.
4. In the floating menu that appears, select on of the following modes and click **Apply**:
   1. Helios Smart Licensing
   2. Manual Licensing
   3. Dark Site

      Follow the procedures below to configure a license mode.

Configure Helios Smart Licensing Mode

Perform the following steps to configure **Helios Smart Licensing**:

1. Follow the steps in the Choose a Licensing Mode after Cluster Creation section and select **Helios Smart Licensing** as the Licensing Mode.
2. On the **Management Options** page that appears, select the **Connect to Helios only for licensing** option.
3. Click **Continue**.

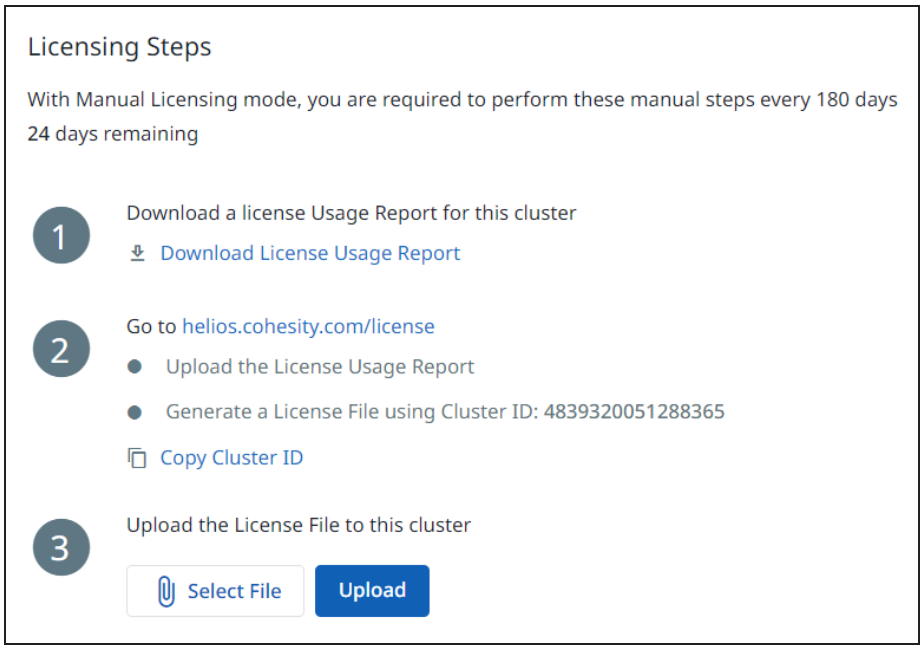
   You will be redirected to the Helios page to enter credentials to log in.
4. Click **Connect** to establish the connection with Helios.

   Only the licensing information is shared with Helios.

Configure Manual Licensing Mode

Configuring the Manual Licensing Mode requires you to download the License Usage Report from the Cohesity cluster and upload it to Helios. You must also generate the License File in Helios and upload it to the Cohesity cluster. As these steps require switching between the Cohesity cluster and Helios, Cohesity recommends that you remain logged in to both the Cohesity cluster and Helios till you complete the Manual License configuration.

Perform the following steps to configure Manual Licensing:



1. Follow the steps in the Choose a Licensing Mode after Cluster Creation section and select Manual Licensing as the Licensing Mode.
2. On the **Licensing Steps** dialog box, click on **Download License Usage Report**.

   The License Usage Report file or the Audit Report is downloaded to your local. The Audit Report contains details such as cluster ID, timestamp, license usage data, and entitlements.
3. To upload the Audit Report:
   1. Log in to Helios and navigate to **Home** > **License Usage**. The license summary of all clusters connected to Helios is displayed.
   2. Click **Upload Audit Report**.
   3. In the **Upload Audit Report** dialog box, upload the Audit Report downloaded at step 2.
   4. Click **Submit**.
4. To generate the License File:
   1. In your Cohesity cluster, navigate to **Home** > **License Usage**. On the **Licensing Steps** page, select **Copy Cluster ID**.
   2. In Helios, click **Generate License File**.

      The **Generate License File** dialog box appears and prompts for the Cluster ID.
   3. Paste the Cluster ID copied in Step 4 (a) and click **Generate**.

      The License File is downloaded to your local.
5. To upload the License File:

1. In your Cohesity cluster, navigate to **Home** > **License Usage**.
2. On the **Licensing Steps** page, click **Select File**.
3. Browse to select the License File downloaded at Step 4 (c) and click **Upload**.

Once Manual Licensing is configured, you must download the audit report from the Cohesity cluster and upload it on Helios every 180 days.

Configure Dark Site Mode

To set up a cluster as a dark site, you must contact your Cohesity Representative.

To setup the dark site:

1. Follow the steps in the Choose a Licensing Mode after Cluster Creation section and select Dark Site as the Licensing Mode.
2. To copy the license key from Helios:
    1. Log in to Helios and navigate to **Home** > **License Usage.** The alpha-numeric license key is displayed in the License page.
    2. Copy the License key.
3. Log in to your Cohesity cluster.
4. Navigate to **Home** > **License Usage**.
5. On the **Licensing Steps** page, paste the license key copied from Helios, and click **Upload**.
   The message **License Activated** is displayed. This message indicates that the license has been activated on that cluster.

Troubleshooting Licenses Managed on the Clusters

Cohesity Platform Smart Licensing and Manual Licensing Issues

The following are some of the notifications for sites that are not connected to Cohesity Platform:

Notification	Scenario	Steps to Resolve
`Unregistered cluster`	The cluster has not been registered with Cohesity Platform within 30 days of creation.	1. Go to Cohesity Platform and enter your cluster ID. 2. Once the License file is downloaded, upload the license file on your cluster, and click **Submit**. The following message is displayed: `License file uploaded successfully.`

Notification	Scenario	Steps to Resolve
`Cluster pending audit report upload`	The audit report has not been uploaded within 90 days from the last upload.	Generate a new audit report: 1. Download the audit report from your cluster. 2. Log in to Helios and upload the audit report.

Dark Site Issues

If the license activation was unsuccessful for Dark Site, see the points listed below for possible corrective actions:

- Invalid cluster ID—Confirm the cluster ID for which you have generated the license key. Reconfirm if you have applied this cluster ID while generating the license key. Otherwise, generate the license again using the correct cluster ID.
- License key expired—If the license key has expired, you must generate the license key again. The validity of the license key is 30 days from the time of license generation. You can also confirm if the cluster node time is not more than 30 days from the Helios time.
- Invalid license key—If the license key is invalid, reconfirm the correct license key and enter it correctly.

Manage Apps

Apps are purpose-built applications developed by Cohesity or other third party vendors. You can run the apps directly on the Cohesity cluster to leverage data stored on clusters. For example, the Cohesity Insight app lets you search data stored in views on a cluster. Running apps directly on the Cohesity cluster lets you:

- Get business insights from your backup and unstructured data.
- Analyze data in place; no need to copy data from Cohesity cluster to another infrastructure for analysis.
- Achieve business-critical goals around compliance, eDiscovery and security.

After an app is installed on the Cohesity cluster, users who are assigned the Admin role with the Apps privilege can run the app. The Apps privilege can also be assigned to other roles.

Running an app automatically creates an app instance on the cluster. You can have several instances of the app running at the same time. For example, you might run multiple instances that access data in different views.

Prerequisites

- Marketplace Apps use ports 61001 through 63786 on the Cohesity cluster. Be sure to open this port range if you are using a firewall.
- Before you can install and run apps, the cluster must be enabled to support apps management. Navigate to **Marketplace** > **My Apps**. Click on the **My Apps** tab, click **App Settings** located at the top right of the page and toggle on **Enable Apps Management**.
  - **Allow external connectivity from apps**: Toggle on to allow the apps network access beyond the Cohesity cluster Nodes. Not all apps require external connectivity. For example, a backup app that needs to access a database will require external connectivity, but the Cohesity Insight app, which searches Views on the Cluster, does not require external connectivity.
- Enabling apps management requires each node to have a minimum of 12 CPUs and 55GB RAM. If the cluster does not meet the requirements, you may encounter an error about insufficient memory when you attempt to enable apps management.

Note:

- For clusters running on 6.8.1 and above, the supported subnet size is between /12 (maximum size) and /22 (minimum size).
- The private IP ranges supported are 10.0.0.0/8, 172.16.0.0/12, and 192.168.0.0/16. The default IP range is 192.168.0.0/16.
  The RF6598 range of 100.64.0.0/10 is also supported. For more information, contact Cohesity Support.
- The alerts 'AppsModeDisabledDueToSubnetClash' or 'NodeNotPresnetInKubernetesCluster' are generated if the apps subnet is the same as the cluster subnet. If they are the same, then update the default app subnet to another private subnet to enable/disable apps management from cluster UI.

Consideration

- Only admin users can launch apps. System services such as Runbook, NoSQL and Hadoop Services, CyberScan cannot be launched by the non-admin user.
- Currently, Marketplace apps are not supported on Cloud Edition and Virtual Edition clusters.

> **Note:**
> - Only the CyberScan and Insights apps are supported on Virtual Edition clusters.
> - NoSQL app is supported from 6.8.1 on GCP.

Browse Apps

You can browse the apps in:

- App Marketplace— Scroll down the Marketplace page to view all the available apps. From the **Filter by** drop-down, select a category to view the apps specific to the selected category.
- Helios—Select **All Clusters** in the top left corner, select **More > Apps** and then click the **Browse Apps** tab.

Install and Run Apps

For information about installing and running apps, see the Marketplace Apps documentation.

Networking Workflows

Cohesity provides two methods to configure Cohesity settings: the Cohesity configure_network.sh script and the iris_cli. In general, using the iris_cli is the preferred method if available. The iris_cli, however, does not currently support all networking workflows. For more information, see Cohesity CLI Reference Guide.

For details about various networking deployment configurations, see Cohesity Networking Quick Start Guide. For details about network design choices, see Optimal Network Designs with Cohesity.

> **Note:** Cohesity recommends using the `configure_network.sh` script only for the initial cluster setup. To change the IP address of the node, contact Cohesity Support.

configure_network.sh

The configure _network.sh script is located at:

```
~/bin/network/configure_network.sh
```

Example from running the script:

```
[cohesity@mycluster-node-1 ~]$ ~/bin/network/configure_network.sh
1) Configure IPMI interface                7) Set Bond Mode
2) Configure IP Address on interface       8) Update Interface Gateway
3) Show Interface config                   9) Configure Default Gateway
4) Show IPMI Config                       10) Configure VLAN interface
5) Check Connectivity                     11) Configure Static Route
6) Remove IP Config                       12) Quit
Please enter your choice:
```

configure_network.sh Option	iris_cli Steps
1) Configure IPMI Interface	N/A
2) Configure IP Address on Interface	Configure Interfaces
3) Show Interface Config	Configure Interfaces
4) Show IPMI Config	Manage IPMI Configuration
5) Check Connectivity	N/A
6) Remove IP Config	Configure Interfaces
7) Set Bond Mode	Bonding Mode
8) Update Interface Gateway	Configure Interfaces
9) Configure Default Gateway	Configure Interfaces
10) Configure VLAN Interface	Configure a Non-native VLAN for Cohesity cluster Creation and Expansion
11) Configure Static Route	Add a Static Route

Cohesity Networking Quick Start Guide.

Bonding Mode

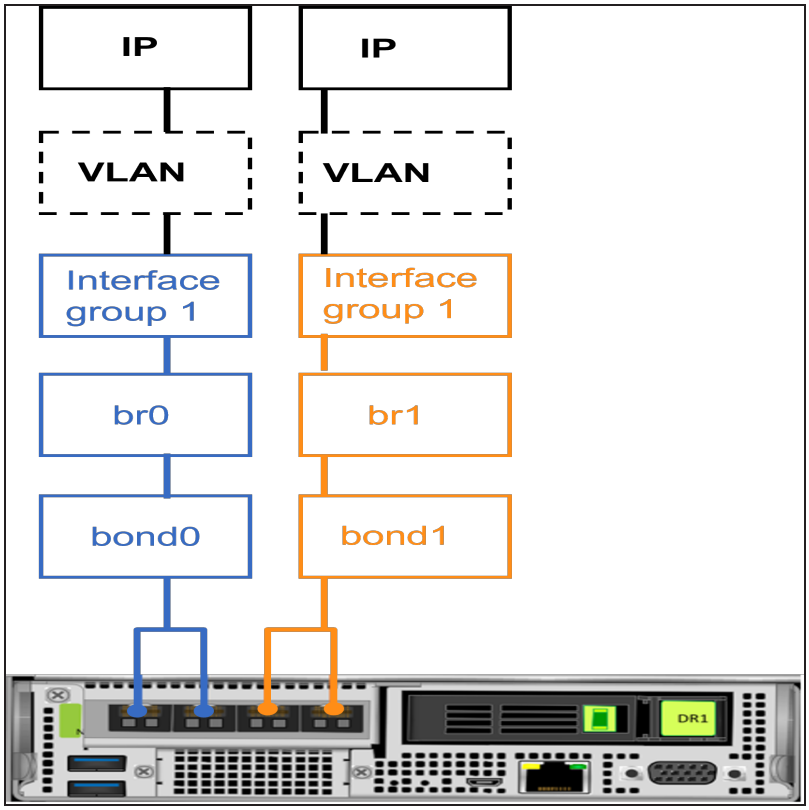
You can edit the bonding mode of the Cohesity cluster bond interfaces. The Cohesity cluster supports these bonding modes:

- **Bonding mode 1 (active-backup):** Places one of the interfaces into a backup state. If the active interface fails, the interface in the backup state becomes active.

This mode provides fault tolerance. By default, bonding mode 1 is configured on the Cohesity cluster bond interfaces.

- **Bonding mode 4 (LACP 802.3ad):** This mode is also known as Dynamic Link Aggregation mode. It creates aggregation groups with the same speed and duplex settings.

The physical and logical networking components in Cohesity cluster are illustrated in this image.



Edit the Bonding Mode

This section provides you steps to change the Cohesity cluster configuration and local ifcfg files to set the bonding mode to LACP.

On the Free Node

Perform these steps on the free node:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. Run this command:
   - To update the bonding mode from 1 to 4:

     ```
     iris_cli interface update interface-name=bond0 bonding-mode=4
     xmit-hash-policy=1
     ```

   - To update the bonding mode from 4 to 1:

     ```
     iris_cli interface update interface-name=bond0 bonding-mode=1
     ```

3. To verify the node configuration and connectivity, perform these steps:
   - Run this command and verify the output if bonding mode is configured on the bond interface:

     ```
     cat /proc/net/bonding/bond<x>
     ```

     Where x is the bond interface.

     Example:

     ```
     cat /proc/net/bonding/bond0
     ```

   - Ping the gateway IP as follows:

     ```
     ping <gateway IP address>
     ```

On the Cohesity cluster

Perform these steps on one of the nodes in the Cohesity cluster:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. Stop the cluster services running on the nodes before you edit the bonding mode:

   ```
   admin> cluster stop
   ```

3. Check the cluster status:

   ```
   admin> cluster status
   ```

   Verify the cluster status in the command output:

   ```
   SERVICE STATE SYNC: DONE
   CLUSTER ACTIVE OPERATION:
   CLUSTER HEAL STATUS: NORMAL
   ```

4. Set the existing bonding mode:

```
iris_cli interface update interface-name=<interface_group_name>
bonding-mode=<x> xmit-hash-policy=1
```

Example:

```
iris_cli interface update interface-name=intf_group1 bonding-mode=4
xmit-hash-policy=1
```

or

```
iris_cli interface update interface-name=intf_group1 bonding-mode=1
```

5. Change the upstream switch ports to LACP or move the network cable connections to LACP configured ports and wait for LACP on the switch and bond0 interface to come up.
6. To verify the node configuration and connectivity, perform these steps:
   - Run this command and verify the output if bonding mode is configured on the bond interface:

     ```
     cat /proc/net/bonding/bond<x>
     ```

     Where x is the bond interface.

     Example:

     ```
     cat /proc/net/bonding/bond0
     ```

   - Ping the gateway IP as follows:

     ```
     ping <gateway IP address>
     ```

7. Start the cluster services:

   ```
   admin> cluster start
   ```

8. Check the cluster status:

   ```
   admin> cluster status
   ```

   Verify the cluster status in the command output:

   ```
   SERVICE STATE SYNC: DONE
   CLUSTER ACTIVE OPERATION:
   CLUSTER HEAL STATUS: NORMAL
   ```

9. Verify the updated bonding mode:

   ```
   admin> interface list
   ```

Create Cross-Bonding Interface

Create Cross-Bonding for a Primary Interface

Perform these steps on one of the nodes in the cluster:

1. Connect the node in the Cohesity cluster to the IPMI interface via the IPMI Console. For details on how to configure IPMI, see Manage IPMI Configuration.
2. Run the following command in the IPMI console to get a list of all the connected NIC ports and check the 10GbE link.

```
list_all_nic_ports.sh
NODE ID : 181140266786854
NODE IP : 10.1.4.16
```

Sample Output

```
PORT NAME STATE MAC
I/O Module Slot Port 1 ens802f0 UP a4:bf:01:41:a0:26
I/O Module Slot Port 2 ens802f1 UP a4:bf:01:41:a0:27

Port Type: 1GbE
=====================================================
PORT NAME STATE MAC
Embedded 1G NIC Port 1 eno1 DOWN a4:bf:01:21:7e:c8
Embedded 1G NIC Port 2 eno2 DOWN a4:bf:01:21:7e:c9
================================
```

3. Run the following command to stop a single node on a Cohesity cluster:

```
node_stop.sh script
```

The node_stop.sh script is located at */home/cohesity/bin/*

4. In the **ifcfg-ens1f1** file, replace **MASTER=bond0** with **MASTER=bond1**.

To change the bonding master for ens1f1 from bond0 to bond1, you can use one of the following methods:

a. Using nmcli command:

To change the bond master using nmcli, run the following command:

```
sudo nmcli connection modify ens1f1 master=bond1
```

b. Using ens1f1.nmconnection file:

To change the bond master using ens1f1.nmconnection file:

Replace master=bond0 with master=bond1.

> **Note:** If the master field is not available, check for the controller field and update controller=bond0 to controller=bond1.

The ens1f1.nmconnection file is located at /etc/NetworkManager/system-connections/.

5. In the ifcfg-ens7f1 file, replace **MASTER=bond0** with **MASTER=bond1**.

   To change the bonding master for ens7f1 from bond0 to bond1, you can use one of the following methods:

   a. Using nmcli command:

      To change the bond master using nmcli, run the following command:

      ```
      sudo nmcli connection modify ens7f1 master=bond1
      ```

   b. Using ens7f1.nmconnection file:

      To change the bond master using ens7f1.nmconnection file:

      Replace master=bond0 with master=bond1.

      > **Note:** If the master field is not available, check for the controller field and update controller=bond0 to controller=bond1.

      The ens7f1.nmconnection file is located at /etc/NetworkManager/system-connections/.

6. Restart the node.
7. Use the following command to verify that the cross-bonding for the primary interface has been successfully created.

   ```
   List_all_nic_ports.sh
   ```

   Sample Output

   ```
   Port Type: 10GbE
                                                 ==========================================

8. Repeat steps 1 to 7 for all the nodes in the Cohesity cluster.

Create Cross-Bonding for a Secondary Interface

Follow these steps to create Cross-Bonding for a secondary interface. Perform these steps on one of the nodes in the cluster:

1. Run the following command in the IPMI console to get a list of all the connected NIC ports and check the 10GbE link.

   ```
   list_all_nic_ports.sh
   NODE ID : 181140266786854
   NODE IP : 10.1.4.16
   ```

   Sample Output

   ```
   Port Type: 10GbE
   ====================================================
   PORT    NAME    STATE   MAC
   Network Card Slot Port 1        eno1    UP
   Network Card Slot Port 2        eno2    UP
   Network Card Slot Port 3        eno3    DOWN
   Network Card Slot Port 4        eno4    UP

   Port Type: 1GbE
                                                        ==============================
   PORT    NAME    STATE   MAC
   PCIe Slot 1 Port 1     enp59s0f0       DOWN
   PCIe Slot 1 Port 2     enp59s0f1       DOWN
   ```

2. Run the following command to verify the bond interface and its associated physical interface:

   ```
   ip addr
   ```

   In this sample output, eno1 and eno2 are bond slaves of bond0, and eno3 and eno4 are bond slaves of bond1.

   Sample Output

```
4: eno1: <BROADCAST,MULTICAST,SLAVE,UP,LOWER_UP> mtu 1500 qdisc mq
master bond0 state UP group default qlen 1000
link/ether e4:43:4b:2f:f7:10 brd ff:ff:ff:ff:ff:ff
5: eno2: <BROADCAST,MULTICAST,SLAVE,UP,LOWER_UP> mtu 1500 qdisc mq
master bond0 state UP group default qlen 1000
link/ether e4:43:4b:2f:f7:10 brd ff:ff:ff:ff:ff:ff
6: eno3: <NO-CARRIER,BROADCAST,MULTICAST,SLAVE,UP> mtu 1500 qdisc mq
master bond1 state DOWN group default qlen 1000
link/ether e4:43:4b:2f:f7:12 brd ff:ff:ff:ff:ff:ff
7: eno4: <BROADCAST,MULTICAST,SLAVE,UP,LOWER_UP> mtu 1500 qdisc mq
master bond1 state UP group default qlen 1000
link/ether e4:43:4b:2f:f7:12 brd ff:ff:ff:ff:ff:ff
```

3. Remove the bond interface_group.

```
iris_cli interface-group delete group-name=<name of the interface
group>
```

4. Remove the bond to free the interfaces.

```
iris_cli bond delete bond-interface=<name of the bond>
```

5. Place the node in maintenance mode.

```
iris_cli node update id=<ID of the node> maintenance-mode=true
```

6. Use the following CLI command to update the cross-bonding interface for bond0 and bond1.

```
iris_cli bond update bond-interface=<name of the bond interface> bond-
slave-interface=<name of the bond slave interface>
```

   Example:

   Commands that set eno1 and eno3 as salve-interface bond0 and eno2 and eno4 as slave-interface for bond1:

```
iris_cli bond update bond-interface=bond0 bond-slave-interface=eno1
```

```
iris_cli bond update bond-interface=bond1 bond-slave-interface=eno4
```

```
iris_cli bond update bond-interface=bond0 bond-slave-
interface=eno1,eno3
```

```
iris_cli bond update bond-interface=bond1 bond-slave-
interface=eno2,eno4
```

7. Identify the ports that need to be part of the respective bond interface and create bond interfaces using the following command:

```
iris_cli bond create bond-interface=<name of the bondinterface> bond-
slaveinterface=<name of the bond slave interface>
```

Example

```
iris_cli bond create bond-interface=bond0 bond-slaveinterface=eno3,eno4
```

```
iris_cli bond create bond-interface=bond1 bond-slaveinterface=eno1,eno2
```

Delete Cross-Bonding Interface

To delete the cross-bonding interfaces:

1. Run the following command to delete the interface groups that are associated with the cross-bonding interfaces:

   ```
   iris_cli interface-group delete group-name=<name of the interface group>
   ```

   > **Note:** Deleting an interface group fails if the underlying network bonding interface has static IPs, VIPs or VLANs configured.

2. Run the following commands to delete the cross-bonding interfaces:

   ```
   iris_cli bond delete bond-interface=<name of the bond interface>
   ```

   Example

   ```
   iris_cli bond delete bond-interface=bond1
   ```

3. To verify the delete is successful, check if the ifcfg-bond<x> file is deleted/not present in the */etc/sysconfig/network-scripts/* folder.

   Example: Ensure the ifcfg-bond1 file (where 1 is the bond number) is not in the network-scripts folder.

4. Run the following command to remove the node from the maintenance node:

   ```
   iris_cli node update id=<ID of the node> maintenance-mode=false
   ```

Configure Interfaces

Use the iris_cli to configure an interface. To edit the bonding mode, see Bonding Mode.

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

```
./iris_cli -server 172.16.3.101 -username=admin
```

2. Run any of the following commands to perform the desired task.

> **Note:** You can change the IP address of the node on the Cohesity cluster. To change the IP address, contact Cohesity Support.

Configure the IP Address for an Interface in an Existing Cohesity cluster

Run the following command to set the IP address (IPv4 or IPv6) for the respective Secondary Interface.

For IPv4

```
iris_cli ip config interface-name=<interface_name> interface-ips=<ip_
addresses> node-ids=<node_ids> subnet-gateway=<gateway> subnet-mask-bit-
s=<subnet_mask>
```

Example:

```
iris_cli ip config interface-name=intf_group2 interface-ips=10.1.1.1 node-
ids=1234 subnet-gateway=10.1.1.100 subnet-mask-bits=24
```

For IPv6

```
iris_cli ip config interface-name=<interface_name> interface-ips=<ip_
addresses> node-ids=<node_ids> subnet-gateway=<gateway> subnet-mask-bit-
s=<subnet_mask> family=<ip address_family>
```

Example:

```
iris_cli ip config interface-name=intf_group2 interface-ips=2001::100 node-
ids=1234 subnet-gateway=2001::1 subnet-mask-bits=64 family=
```

> **Note:** The preceding commands cannot be used to update the IPv4 or IPv6 addresses of a Primary Interface.

Configure the IP Address for an Interface in a Free Node

Run the following command to set the IP address (IPv4 or IPv6) for the respective Secondary Interface (and not in a node in a Cohesity cluster).

```
iris_cli ip config interface-name=<interface_name> interface-ips=<ip_
addresses> subnet-gateway=<gateway> subnet-mask-bits=<subnet_mask>
```

Example:

```
iris_cli ip config interface-name=bond0 interface-ips=10.1.1.1 subnet-gate-
way=10.1.1.100 subnet-mask-bits=24
```

Update the IP address of a Primary Interface

If you are using Cohesity cluster 6.6 or later, run the configure_network.sh script to change the Primary Interface on the VLAN:

```
~/bin/network/configure_network.sh
```

Sample Output:

```
(1) Configure IPMI interface                 7) Set Bond Mode
2) Configure IP Address on interface        8) Update Interface Gateway
3) Show Interface config                     9) Configure Default Gateway
4) Show IPMI Config                         10) Configure VLAN interface
5) Check Connectivity                       11) Configure Static Route
6) Remove IP Config                         12) Quit
Please enter your choice:
IPv4 selected.
Enter the interface to configure [Default=bond0]:bond0
Choose interface:bond0
Enter the vlan id to configure:100
Creating the vlan interface file ...
Created the vlan interface file successfully
Do you want to set bond0.100 as primary interface? y
Setting the primary interface on bond-.100.
Do you want to configure IP info on this VLAN?: Y
Enter the IP address to configure: 20.1.5.18
Enter the interface Prefix: [Default=32]: 20
Do you want to configure the gateway? y
Enter the gateway to configure: 20.1.0.1
Enter the MTU to configure: 1500
--------MESSAGE--------------
Following is your configuration
DEVICE=xy0.200
```

```
TYPE=ABBridge
DEVICETYPE=ovs
ONBOOT=yes
ZONE-public
IPADDR=20.1.5.18
PREFIX= 20
GATEWAY=20.1.0.1
MTU=1500
Do you want to make config active? y
----------MESSAGE----------
Reset interface
----------MESSAGE----------
Restarting Cohesity service....
```

> **Note:** The configure_network.sh prompts for information from you as it runs. The preceding example depicts what follows when you enter "y"(yes) when the script prompts you to configure an IP address on the VLAN. If you do not want to configure the IP address on the VLAN, enter "n"(no) when prompted by the script.

Update the IP address of a Secondary Interface

Configure the Secondary Interface VLAN IP

Follow these steps to configure the Secondary VLAN IP:

1. Run the following command to create the Secondary VLAN IP using Virtual IP:

   ```
   iris_cli vlan create id=<vlan number> interface-group=<name of the interface group> subnet-ip=<IP address of the subnet> subnet-mask-bits=<subnet mask bits> vlan-ips=<comma separated values of the VLAN IPs> subnet-gateway=<subnet gateway>
   ```

   Example

   ```
   iris_cli vlan create id=200 interface-group=intf_group2 subnet-ip=200.1.0.0  subnet-mask-bits=20 vlan-ips=200.1.4.15,200.1.4.16,200.1.4.17 subnet-gateway=200.1.0.1
   ```

2. Run the following command to verify if the Secondary VLAN IP has been created successfully:

```
cluster linux cmd="ifconfig | grep -A 1 <name of the interface>"
```

Example

```
cluster linux cmd="ifconfig | grep -A 1 br1.200"
```

Sample Output

```
Username: admin
'admin' Password:

Configure the Secondary Interface IP (without VLAN)

Follow these steps to configure the Secondary Interface IP without using the VLAN IP:

1. Run the following command to create the Interface Group for the new bond interface:

   ```
   interface-group create group-name=<name of the interface group>
   interface-name=<name of the interface> node-ids=<comma separated values
   of the node ids>
   ```

   Example:

   ```
   interface-group create group-name=intf_group2 interface-name=bond1
   node-ids=181140264822986,181140266786854,181140263920230

   Success: Interface group created successfully.
   ```

2. Run the following command to check if the Interface Group is created in all the nodes of the Cohesity cluster:

   ```
   interface-group ls
   ```

   Sample Output

   ```
   INTERFACE GROUP NAME          : intf_group1

   INTERFACE GROUP ID            : 1

   INTERFACE GROUP TYPE          : Vlan

   NODE ID                    : 181140264822986

   INTERFACE NAME             : bond0

   NODE ID                    : 181140266786854

   INTERFACE NAME             : bond0

   NODE ID                    : 181140263920230

   INTERFACE NAME             : bond0

   INTERFACE GROUP MTU           : 1500
   ```

```
INTERFACE GROUP BONDING MODE  : 4
BONDING XMIT HASH POLICY      : 1
BONDING LACP RATE             : 0
INTERFACE GROUP NAME          : intf_group2
INTERFACE GROUP ID            : 2
INTERFACE GROUP TYPE          : Vlan
NODE ID                   : 181140264822986
INTERFACE NAME            : bond1
NODE ID                   : 181140266786854
INTERFACE NAME            : bond1
NODE ID                   : 181140263920230
INTERFACE NAME            : bond1
INTERFACE GROUP MTU           : 1500
INTERFACE GROUP BONDING MODE  : 1
```

3. Run the following command to assign an IP address to the interface:

```
ip config interface-ips=<comma separated IP address of the interface>
node-ids=<comma separated values of the node IDs> subnet-
gateway=<subnet gateway> subnet-mask-bits=<subnet mask bits> interface-
name=<name of the interface>
```

Example

```
ip config interface-ips=20.1.4.15,20.1.4.16,20.1.4.17 node-
ids=181140264822986,181140266786854,181140263920230 subnet-
gateway=20.1.0.1 subnet-mask-bits=20 interface-name=intf_group2
```

Remove an IP Configuration

Run the following command to unconfigure an interface.

For IPv4

```
iris_cli ip delete interface-name=<interface_name> node-ids=<node_ids>
```

Example:

```
iris_cli ip delete interface-name=intf_group2 node-ids=1234
```

For IPv6

```
iris_cli ip delete interface-name=<interface_name> node-ids=<node_ids> fam-
ily=<ip address_family>
```

Example:

```
iris_cli ip delete interface-name=intf_group2 node-ids=1234 family=2
```

Update the Interface Gateway

Run the following command to update an interface gateway.

```
iris_cli ip config interface-name=<interface_name> interface-ips=<ip_
addresse> node-ids=<node_ids> subnet-mask-bits=<subnet_mask> subnet-gate-
way=<gateway>
```

Example:

```
iris_cli ip config interface-name=intf_group2 node-ids=1234 subnet-mask-bits-
s=24 subnet-gateway=10.1.1.100
```

Use the preceding command to change the gateway if the primary interface is not involved. If traffic routes through the primary interface to reach the default gateway, use the following command instead:

```
iris_cli route add dest-network=<subnet>/<mask> interface-group=<intf_group>
next-hop=<gateway_ip_address>
```

Example:

If the subnet is 10.0.0.0/24, the interface group associated with this subnet is intf_group1, and the gateway address is 10.1.2.1:

```
iris_cli route add dest-network=10.0.0.0/24 interface-group=intf_group1
next-hop=10.1.2.1
```

Show the Configuration for Interfaces in a Cohesity cluster

Run the following command to show interface configurations in a Cohesity cluster.

```
iris_cli interface list
```

Configure Interface Group

The Interface Group can be configured only through Cohesity CLI. Run the following commands to configure and manage an interface group that will be mapped to different bonds. Once an interface group is created through CLI, it can also be managed (edit, remove, and so on) using the iris_cli.

Operation	Command

To create an Interface Group in the Cohesity cluster	`iris_cli interface-group add group-name=<interface_group_name>`
	or
	`iris_cli interface-group create group-name=<name of the interface group> interface-name=<name of the interface> node-ids=<comma separated values of the node ids>`

To list all the Interface Groups in the Cohesity cluster	`iris_cli interface-group list`
To delete an existing Interface Group **Note:** Deletion of an interface group fails if the underlying network bonding interface have static IPs, VIPs or VLANs configured	`iris_cli interface-group delete group-name=<interface_group_name>`
To edit an Interface Group	`iris_cli interface-group edit group-name=<interface_group_name>`

Add Secondary Interface Groups to New Nodes in Existing Cohesity cluster

If you add a new node to an existing 7.1.2 or later Cohesity cluster, the secondary interface group is not automatically added for the new node. Run these commands to add the secondary interface group to the new node:

Add new nodes and associate them with the existing secondary interface group

Run this command to add a new node to an existing Cohesity cluster and to also associate the new node with an existing secondary interface group:

Command

```
interface-group update group-name=<name of the existing interface group> interface-name=<name of the existing interface>  add-node-ids=<comma separated values of the new node ids>
```

Example

```
interface-group update group-name=intf_group2 interface-name=bond1 add-node-ids=181140264822986,181140266786854,181140263920230
```

Sample Output

```
Success: Interface group updated successfully.
```

Add a new secondary interface group to a new node

Run this command to add a new secondary interface group to a new node already added to a Cohesity cluster:

Command

```
interface-group create group-name=<name of the new interface group> inter-
face-name=<name of the interface> node-ids=<comma separated values of the
node ids>
```

Example

```
interface-group create group-name=intf_group3 interface-name=bond1 node-ids-
s=181140264822986,181140266786854,181140263920230
```

Sample Output

```
Success: Interface group created successfully.
```

Configure the 1G Interface for Cluster Creation

You can configure the 1G interfaces on free nodes and create a Cohesity cluster for testing or validation purposes. Cohesity recommends you to use the 10G interfaces for production deployments.

This topic describes how to configure the 1G interface on a free node and use it to set up a Cohesity cluster.

To configure the 1G interface:

1. Connect to the IPMI console using the GUI or ipmitool command. Log in using the default username and password. After you log in, the Cohesity shell prompt appears.

   ```
   cohesity_shell#
   ```

2. Enter the `shell` command to access the shell and enter the password.

   ```
   cohesity_shell# shell
   Enter password for user 'cohesity'
   Password:
   Last login: Mon Aug 5 01:43:52 PDT 2019 from 192.168.100.10 on pts/0
   [cohesity@node-1 ~]$
   ```

3. To get a list of interfaces that are up and running, run the following command:

   ```
   [cohesity@node-1 ~]$ list_all_nic_ports.sh
   Port Type: 1GbE
   ======================================================
   PORT NAME STATE MAC
   Embedded 1G NIC Port 1 eno1 UP a4:bf:01:50:75:ca
   Embedded 1G NIC Port 2 eno2 UP a4:bf:01:50:75:cb
   ```

```
Port Type: 10GbE
=====================================================
PORT NAME STATE MAC
I/O Module Slot Port 1 ens802f0 UP a4:bf:01:29:66:1e
I/O Module Slot Port 2 ens802f1 UP a4:bf:01:29:66:1f
```

4. To determine if a bond interface contains 1G interfaces, run the following command:

```
[cohesity@node-1 ~]$ cat /proc/net/bonding/bond1 |egrep -i
"interface|speed"

Slave Interface: eno1
Speed: 1000 Mbps
Slave Interface: eno2
Speed: 1000 Mbps
```

5. To configure the 1G bond interface (bond1) as the primary interface, run the following command on all the free nodes:

```
[cohesity@node-1 ~]$ iris_cli ip config interface-name=bond1 interface-
role=primary
```

6. To verify if the bond1 interface is configured as the primary interface, run the following command on all the free nodes:

```
[cohesity@node-1 ~]$ primary_interface_name.sh

bond1[cohesity@node-1 ~]$
```

7. To restart the services, run the following commands on all the free nodes:

```
[cohesity@node-1 ~]$ sudo service nexus restart
[cohesity@node-1 ~]$ nexus_proxy.sh stop && nexus_proxy.sh start
[cohesity@node-1 ~]$ gandalf.sh stop && gandalf.sh start
```

8. To configure the IP address on the bond1 interface, run the following command:

```
[cohesity@node-1 ~]$ iris_cli ip config interface-name=<interface_name>
iface-ips=<ip_addresses> subnet-gateway=<subnet_gateway> subnet-mask-
bits=<subnet_mask_bits>
```

   Example:

```
[cohesity@node-1 ~]$ iris_cli ip config interface-name=bond1 iface-
ips=10.5.1.5 subnet-gateway=10.5.0.1 subnet-mask-bits=20
```

9. Using a web browser, connect to the node IP configured in **Step 8** and run the cluster setup:

```
http://<node-ip>
```

Example:

```
http://10.5.1.5
```

For more information about the initial cluster setup, see Initial Cluster Setup.

Set Up the Secondary Interface for Replication

This topic explains how to configure the Cohesity cluster's secondary interface for remote replication. You must perform all steps in this topic on both the local and remote Clusters.

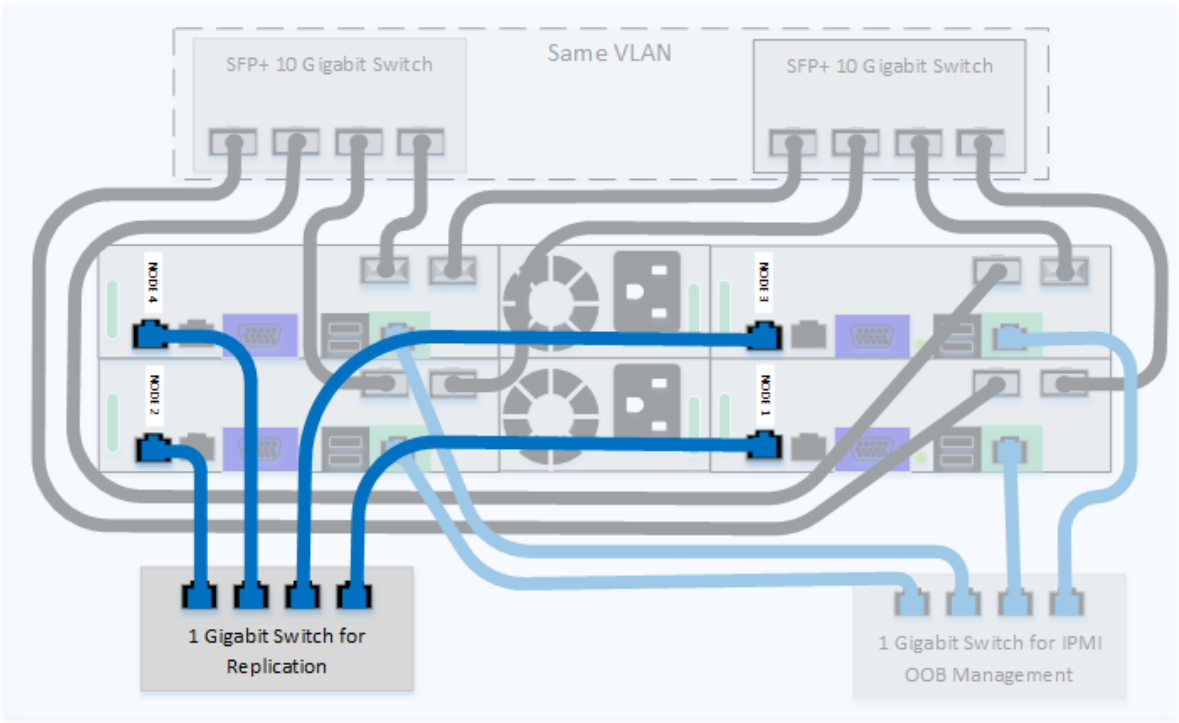
1. Verify connectivity to the IPMI interface of all Nodes.

   This is needed for cases where misconfiguration might cause loss of connectivity to the bond0 IP address.

   Connect the secondary interface on all Cohesity cluster Nodes.

   On each Node, connect the 1G interface from the same port group.

   The following diagram illustrates cabling for Haswell with SFP+ ports. When cabling for replication over the secondary interfaces, it is the same for all hardware types (Haswell with SFP+ ports, Haswell with RJ45 ports and Ivy Bridge).



Haswell with SFP+ Ports

2.

3. Verify secondary interfaces are up by using the following command:

```
iris_cli interface list
```

Example:

```
[cohesity@mycluster-node-1 ~]$ iris_cli interface list
CHASSIS NAME                  : BQKP63000000
NODE SLOT                     : 4
    INTERFACE ID              : 130592912804
    INTERFACE NAME            : bond0
    INTERFACE GROUP           : intf_group1
    BONDING MODE              : 4
    BOND SLAVE                : ens802f0, ens802f1
    BOND SLAVE SLOT           : 3, 4
    INTERFACE MAC ADDRESS     : 00:1e:67:f1:b5:a4
    INTERFACE IP              : 10.2.2.15
    INTERFACE SUBNET          : 10.2.32.0/20
    INTERFACE MTU             : 1500
    INTERFACE GATEWAY         : 10.2.32.1
    DEFAULT ROUTE             : true
    INTERFACE ROLE            : primary
    INTERFACE SPEED           : 10Gbit/s
    INTERFACE LINK UP         : true
    INTERFACE SERVICES        : ClusterDataService

    INTERFACE ID              : 130590912508
    INTERFACE NAME            : bond1
    INTERFACE GROUP           : intf_group2
    BONDING MODE              : 1
    BOND SLAVE                : enp8s0f0, enp8s0f1
    BOND SLAVE SLOT           : 1, 2
    INTERFACE MAC ADDRESS     : 00:1e:67:d3:2f:fc
    INTERFACE IP              :
    INTERFACE SUBNET          :
    INTERFACE MTU             : 1500
    INTERFACE GATEWAY         :
    INTERFACE ROLE            : secondary
    INTERFACE SPEED           : 1Gbit/s
    INTERFACE LINK UP         : true
```

> **Note:** bond1 is typically the 1G interface in a Cohesity 6.x release. You can verify by checking “INTERFACE_SPEED”.

4. Find the Cohesity IDs for all interfaces in the group.

Use the following command to find all interface id from interface name. Interface id is used as input for replication CLI input.

```
iris_cli cluster status
```

5. Configure the VIP, subnet, and gateway using the following command.

   ```
   iris_cli vlan add
   ```

   Configuring mtu is optional. For more information, see Set MTU.

6. Check the configured parameters.

   Use the following command to check the VIP parameters on 1G interface name that were configured.

   ```
   iris_cli vlan ls
   ```

7. Configure remote replication over the 1G interface.

   a. Add a static route

   > **Note:** Adding a static route is required only if the 1G interface for the local and remote Cohesity clusters are not in same network.

   A static route enables the local Cohesity cluster and remote Cohesity cluster to reach each other. Use the following command to add a static route on both Clusters:

   ```
   iris_cli route add
   ```

   For more information, see Add a Static Route.

   Example for adding a static route:

   ```
   cohesity@mycluster-node-4 ~]$ iris_cli route add desc="inside
   cluster route" dest-network=10.2.55.0/22 interface group=intf_
   group2 next-hop=10.1.0.1
   Success: Static route add successfully.
   ```

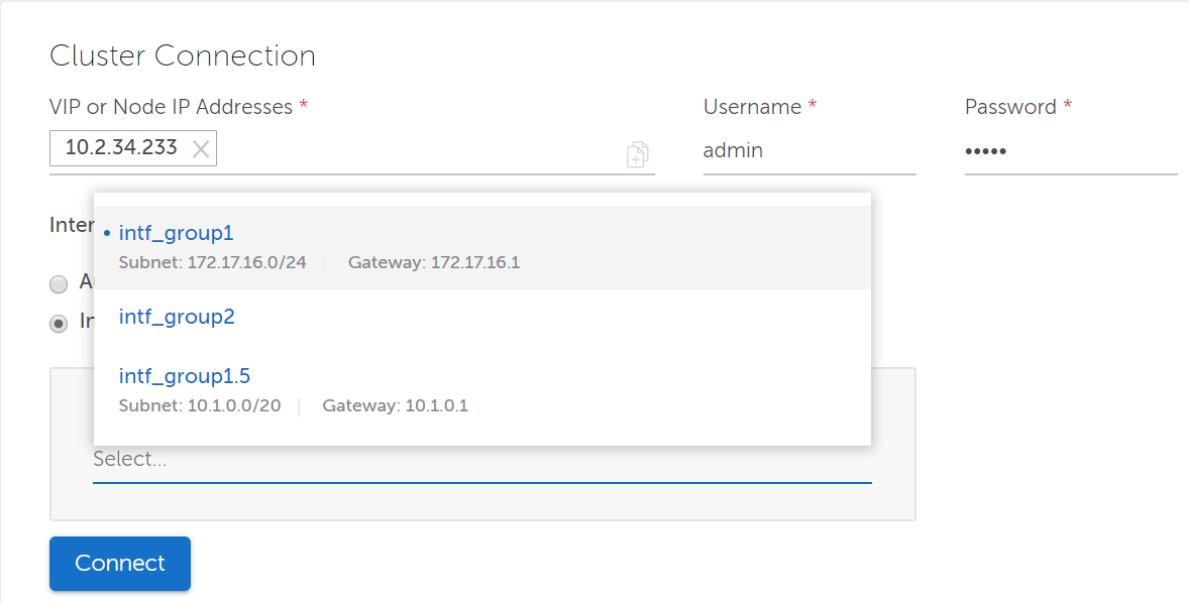
   In above example, bond1 is the 1G interface, you can get this information from `iris_cli cluster ls-ifaces`.

   ```
   [cohesity@mycluster-node-4 ~]$ iris_cli route ls
   DEST NETWORK : 100.2.32.0/24
   NEXT HOP : 10.2.32.1
   INTERFACE GROUP NAME : intf_group1
   DESCRIPTION : inside cluster route
   ```

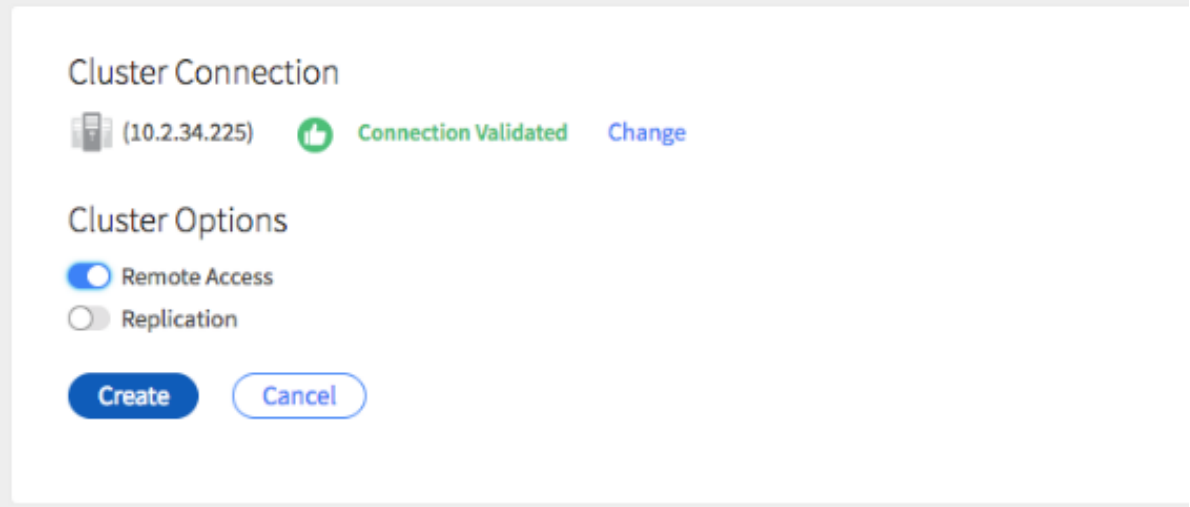
   b. Add a remote Cluster pair using the Cohesity UI.

   Select **Infrastructure > Remote Clusters > Add Cluster**.

Select **Interface Group** and choose the corresponding interface group.



Select **Connect > Replication > Create**.



> **Note:** Perform all steps in this topic on both the local and remote Cohesity cluster.

Add a Static Route

This topic describes how to configure a static route on an interface. It also explains how to configure and move the default route from the primary interface to another configured interface on a Cohesity cluster.

Configure a Static Route using Cohesity Dashboard

To configure a static route using the Cohesity Dashboard:

1. In the Cohesity Dashboard, select **Settings > Networking** and then select the **Routes** tab.
2. Click **+Add** and provide the following details:
   a. **Interface Group**: Select one of the pre-configured interface groups from the drop-down menu.
   b. **Destination Network**: Provide the destination network's IP/prefix. For example, 10.0.0.0/24
   c. **Next Hop**: Next hop to the destination network.
   d. **Description (Optional)**: Optional description.
3. Click **Save**.

Configure a Static Route using Cohesity CLI

To configure a static route:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. To add a static route, use the following command:

   ```
   iris_cli route add dest-network=<subnet>/<mask> interface-group=<intf_
   group> next-hop=<gateway_ip_address>
   ```

   Example:

   If the subnet is 10.0.0.0/24, the interface group associated with this subnet is `intf_group1` and the gateway address is 10.1.2.1:

   ```
   iris_cli route add dest-network=10.0.0.0/24 interface-group=intf_group1
   next-hop=10.1.2.1
   ```

3. To verify the configured routes, use the `route list` command.

   In the following example, the `route list` command output shows that the primary interface (intf_group1) of a cluster is configured with a static route.

   ```
   iris_cli route list

   DEST NETWORK                  : 10.0.0.0/24
   NEXT HOP                      : 10.1.2.1
   INTERFACE GROUP NAME          : intf_group1
   ```

> **Note:** Removal of static entry may not work if it overlaps with the primary interface's subnet. For more information, see the Recovering from incorrect static route config KB article.

Configure the Default Route

By default, the primary interface (intf_group1) is configured with the default route. To configure and move the default route to another configured interface, perform the steps provided in this section.

> **Note:** If you configure the default route on a non-primary physical interface (for example, bond1), configure the bond1 interface on the free node in the same subnet as the non-primary interface of the cluster node before you add the free node to the cluster.

To configure the default route:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. By default, the primary interface (intf_group1) is configured with the default route. To configure and move the default route to another configured interface, run the following command:

   ```
   iris_cli route add dest-network=0.0.0.0/0 interface-group=<intf_group>
   next-hop=<gateway_ip_address>
   ```

   Example 1: Moving the default route to a configured physical interface

   If the interface group is intf_group2 and the gateway address is 10.2.32.1:

   ```
   iris_cli route add dest-network=0.0.0.0/0 interface-group=intf_group2
   next-hop=10.2.32.1
   ```

   Example 2: Moving default route to a configured VLAN interface

   If the interface group is intf_group1.100 and the gateway address is 10.1.100.1:

   ```
   iris_cli route add dest-network=0.0.0.0/0 interface-group=intf_
   group1.100 next-hop=10.1.100.1
   ```

3. To verify the configured routes, use the `route list` command.

In the following example, the `route list` command output shows that the secondary interface (intf_group2) of a cluster is configured with the default route.

```
iris_cli route list

DEST NETWORK                    : 0.0.0.0/0
NEXT HOP                        : 10.2.32.1
INTERFACE GROUP NAME            : intf_group2
```

In the following example, the `route list` command output shows that the VLAN interface (intf_group1.100) of a cluster is configured with the default route.

```
iris_cli route list

DEST NETWORK                    : 0.0.0.0/0
NEXT HOP                        : 10.1.100.1
INTERFACE GROUP NAME            : intf_group1.100
```

Delete a Static Route using the Cohesity Dashboard

1. In the Cohesity Dashboard, select **Settings > Networking** and then select the **Routes** tab.
2. Hover your mouse over the static route you want to delete and then click the delete icon .
3. Click **Delete**.

Delete a Static Route using the Cohesity CLI

To delete the static route:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. To see the list of configured routes, run the `route list` command:

   ```
   iris_cli route list
   ```

   Sample Output

   ```
   DEST NETWORK                    : 10.0.0.0/24
   ```

   ```
   NEXT HOP                        : 10.1.2.1
   ```

   ```
   INTERFACE GROUP NAME            : intf_group1
   ```

In the preceding example, the output shows that the primary interface (intf_group1) has been configured with a static route (10.0.0.0/24).

3. To delete the static route, run the `route delete` command:

```
iris_cli route delete dest-network=<IP address of the static route>
interface-group=<name of the interface group>
```

Example

```
iris_cli route delete dest-network=10.0.0.0/24 interface-group=intf_
group1
```

Manage IPMI Configuration

IPMI configuration for the Cohesity cluster is optional. For ease of managing the nodes remotely, you can either configure IPMI while creating the cluster or after you have created the Cohesity cluster.

The IPMI configuration includes:

- IPMI credentials (username and password).
- IPMI subnet and subnet gateway.
- IPMI address for each node in the cluster.

After you have created the Cohesity cluster, using the Cohesity dashboard, you can:

- Configure IPMI for the Cohesity cluster, if you have not configured IPMI while creating the Cohesity cluster.
- View the IPMI address configured for the nodes in the cluster.
- Edit the IPMI configuration, such as IPMI subnet, subnet gateway, and IPMI address for each node in the cluster.

> **Note:** IPMI communication is required for certain systems to facilitate a proper call-home or dial-home functionality. Please refer to the Setup guides for more information.

Configure IPMI

If you have not configured IPMI while creating the Cohesity cluster, you can set up the IPMI credentials and IPMI addresses at the cluster level using the Cohesity Dashboard.

To configure IPMI:

1. In the Cohesity Dashboard, select **Settings > Networking** and then select the **IPMI** tab.
2. In the **IPMI** tab, click **Setup IPMI**.

> **Note:** The **Setup IPMI** option is available only if you have not configured IPMI while creating the Cohesity cluster.

3. On the **Setup IPMI** page, in the **User** section, perform the following:
    1. In the **Username** field, enter the IPMI or iRMC username to connect to the IPMI or iRMC interface for each node in the Cohesity cluster.
        - The username length should not exceed 16 characters.
        - Requirements for IPMI credentials may differ according to the hardware platform. For more information, see the Comment column in the Knowledge Base article.
        - The Cohesity cluster supports only one IPMI user.
        - The IPMI user configured on the Cohesity cluster is enabled.

        > **Note:** If the IpmiUserUpdateFailed alert is triggered, check if the node BMC has reached the maximum number of IPMI users. If, yes, delete unwanted users.

    2. In the **New Password** and **Confirm Password** fields, enter and confirm the IPMI or iRMC password to connect to the IPMI or iRMC interface for each node in the Cohesity cluster.
        - The password must not be the same as the username.
        - The password must not be the reverse of the username.
        - The password can be 8 to 16 characters. It must include at least three characters of the following:
            - Upper case
            - Lower case
            - Numbers
            - Special characters: _, -, @, #, ^, &, !, +, ~.
4. In the **Networking** section, perform the following:
    1. In the **Subnet** field, enter the subnet for the IPMI or iRMC network interfaces.
    2. In the **Gateway** field, enter the subnet gateway for the IPMI or iRMC network interfaces.
5. In the **IPMI Address** section, enter the IPMI IP address for each node in the Cohesity cluster.
6. Click **Save**.

View the IPMI Address of the Nodes

Using the Cohesity Dashboard, you can view the IPMI address that you have configured for each node in the Cohesity cluster.

To view the IPMI addresses:

In the Cohesity Dashboard, select **Settings > Networking** and then select the **IPMI** tab. The **IPMI** tab displays the nodes, node IP addresses, and IPMI address configured for the nodes in the cluster.

Edit the IPMI Configuration

You can update the IPMI addresses that you have configured for the nodes in the Cohesity cluster. It provides you options to change:

- The IPMI address configured for the node.
- The IPMI subnet configured for the node, in case if you plan to move the node to a different subnet from the common subnet configured for the Cohesity cluster.
- The subnet gateway IP address.

To edit the IPMI addresses:

1. In the Cohesity Dashboard, select **Settings > Networking** and then select the **IPMI** tab.
2. Click the **Edit** icon next to the node.
3. In the **Edit IPMI Settings** page, update the IPMI address, IPMI subnet, and subnet gateway address for the node as per your requirement.

Manage IPMI Configuration Using the Cohesity CLI

You can update IPMI credentials, list IPMI users, and view IPMI addresses using the iris_cli.

Update IPMI Credentials at the Cluster Level

You can change IPMI credentials at the Cohesity cluster level. For more information on IPMI specific commands, see the ipmi topic in the Using the Cohesity CLI.

To update the IPMI credentials:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. Run the following command on the node:

   ```
   iris_cli ipmi cluster-update-users ipmi-password=<new_password> ipmi-username=admin
   ```

Sample:

```
cohesity@mycluster-node-1:$ iris_cli ipmi cluster-update-users ipmi-
password=Admin@123 ipmi-username=admin
Success: Updated IPMI credentials.
```

Update the IPMI Credentials at the Node Level

If you want a node or set of nodes to use different IPMI credentials than other nodes in the cluster, you can change the IPMI credentials for a node in the cluster. For more information on IPMI specific commands, see the ipmi topic in the Using the Cohesity CLI.

To update the IPMI credentials at node level:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. Run the following command on the node:

   ```
   iris_cli ipmi cluster-update-users node-ipmi-password=<new_password>
   node-ipmi-username=admin node-ips=<comma_separated_IP_addresses_of_the_
   nodes>
   ```

   Sample:

   ```
   cohesity@mycluster-node-1:$ iris_cli ipmi cluster-update-users node-
   ipmi-passwords=Admin@123,Admin@1234 node-ipmi-usernames=admin,admin1
   node-ips=10.1.1.9,10.1.1.11
   Success: Updated IPMI credentials.
   ```

Update IPMI Subnet and Gateway Configuration

You can change IPMI subnet and gateway configuration at the Cohesity cluster level. For more information on IPMI specific commands, see the ipmi topic in the Using the Cohesity CLI.

To update the IPMI subnet and gateway configuration:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. Run the following command on the node:

```
iris_cli ipmi cluster-update-lan-info ipmi-subnet-gateway=<gateway_IP>
ipmi-subnet-mask=<subnet_IP>
```

Sample:

```
cohesity@mycluster-node-1:$ iris_cli ipmi cluster-update-lan-info ipmi-
subnet-gateway=172.17.16.1 ipmi-subnet-mask=255.255.240.0
```

Update IPMI Subnet and Gateway Configuration and Node IP addresses

Simultaneously, you can change IPMI subnet, gateway configuration, and IP addresses of the nodes in the Cohesity cluster at the cluster or node level. For more information on IPMI specific commands, see the ipmi topic in the Using the Cohesity CLI.

Update IPMI Subnet and Gateway Configuration and Node IP address at Cluster Level

To update the IPMI subnet, gateway, and node IP addresses:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

```
./iris_cli -server 172.16.3.101 -username=admin
```

2. Run the following command on the node:

```
iris_cli ipmi cluster-update-lan-info ipmi-subnet-gateway=<gateway_IP>
ipmi-subnet-mask=<subnet_IP> node-ips=<comma_separated_IP_addresses_of_
the_nodes> node-ipmi-ips=<comma_separated_IPMI_IP_addresses_of_the_
nodes>
```

> **Note:** IPMI addresses are from the same subnet.

   Sample:

```
cohesity@mycluster-node-1:$ iris_cli ipmi cluster-update-lan-info ipmi-
subnet-gateway=172.17.16.1 ipmi-subnet-mask=255.255.240.0 node-
ips=10.1.2.235,10.1.2.236 node-ipmi-ips=172.17.16.200,172.17.16.201
```

Update IPMI Subnet and Gateway Configuration and Node IP addresses at Node Level

To update the IPMI subnet, gateway, and node IP addresses:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

```
./iris_cli -server 172.16.3.101 -username=admin
```

2. Run the following command on the node:

```
iris_cli ipmi cluster-update-lan-info node-ipmi-subnet-
gateways=<gateway_IP> node-ipmi-subnet-masks=<subnet_IP> node-
ips=<comma_separated_IP_addresses_of_the_nodes> node-ipmi-ips=<comma_
separated_IPMI_IP_addresses_of_the_nodes>
```

Sample:

```
cohesity@mycluster-node-1:$ iris_cli ipmi cluster-update-lan-info node-
ipmi-subnet-gateways=172.17.16.1,172.17.16.1 node-ipmi-subnet-
masks=255.255.240.0,255.255.240.0 node-ips=10.1.2.235,10.1.2.236 node-
ipmi-ips=172.17.16.200,172.17.16.201
```

View Network Configuration of the Cluster

You view the IPMI subnet, gateway and the IP addresses of the nodes in the Cohesity cluster. For more information on IPMI specific commands, see the ipmi topic in the Using the Cohesity CLI.

To view the network configuration:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

```
./iris_cli -server 172.16.3.101 -username=admin
```

2. Run the following command on the node:

```
iris_cli ipmi cluster-get-lan-info
```

Sample:

```
cohesity@mycluster-node-1:$ iris_cli ipmi cluster-get-lan-info
                                ipmiSubnetMask               :
255.255.240.0
  ipmiGateway                 : 10.2.160.1
                                  nodesIpmiInfo

nodeIp                      : 10.2.162.53
                                nodeIpmiIp                 :
10.2.162.54
```

```
                                    nodeIp                      :
10.2.162.51
    nodeIpmiIp                  : 10.2.162.52

nodeIp                      : 10.2.162.49
                                  nodeIpmiIp                :
10.2.162.50

                                    nodeIp                      :
10.2.162.55
    nodeIpmiIp                  : 10.2.162.56
```

View Network configuration of the Node

You view the network configuration of the node or a particular node in the Cohesity cluster. For more information on IPMI specific commands, see the ipmi topic in the Using the Cohesity CLI.

To view the network configuration:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. Run the following command on the node:

   ```
   iris_cli ipmi get-lan-info
   ```

   Sample:

   ```
   cohesity@mycluster-node-1:$ iris_cli ipmi get-lan-info
                                  ipmiLanInfo

   Channel                     : 3
                                  IpSrc                       : Static
   Address                                                         ip
                           : 10.2.162.56
                                subnetMask                  :
   255.255.240.0
      defaultGatewayIp           : 10.2.160.1
                                     DefaultGatewayMac
   ```

View the IPMI Users in the Cluster

You can view the IPMI users in the Cohesity cluster. For more information on IPMI specific commands, see the ipmi topic in the Using the Cohesity CLI.

To view IPMI users in the cluster:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. Run the following command on the node:

   ```
   iris_cli ipmi cluster-list-users
   ```

   Sample:

   ```
   cohesity@mycluster-node-1:$ iris_cli ipmi cluster-list-users
                                clusterIpmiUser              : admin
   ```

View the IPMI Users in the Node

You can view detailed information about the IPMI users and IPMI channel used in the node or a particular node in the Cohesity cluster. For more information on IPMI specific commands, see the ipmi topic in the Using the Cohesity CLI.

To view IPMI users in the node:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. Run the following command on the node:

   ```
   iris_cli ipmi list-users
   ```

   Sample:

   ```
   cohesity@mycluster-node-1:$ iris_cli ipmi list-users
                                ipmiUserList

   Channel                   : 3
                                MaxUserId                 : 4
   ```

```
UserList
                                  Id                          : 2
                                                                  name
                    : root
                          CallIn                      : false
                                                          LinkAuth
              : true
                     IpmiMsg                    : true
                                                   Priv
        : 4

                                                 Id
  : 3
         name                        : admin
                                        CallIn                     :
true
     LinkAuth                  : true
                                      IpmiMsg                    : true

Priv                        : 4

                                                                  Id
                    : 4
                          name                        : ADMIN
                                                          CallIn
              : true
                     LinkAuth                   : false
                                                   IpmiMsg
        : false
               Priv                        : 4
```

Reset Networking Configuration Settings

Cohesity supports resetting the network configuration (IP configuration, bonding modes, VLANs, etc) from the Networking Dashboard. This is particularly helpful during the movement of the Cohesity cluster from one network to another network. In other words, when you want to move your data center to a different location or when you are reconfiguring the whole network settings. There will be no effect on the data in the cluster.

When you reset the network configuration settings, ensure the following:

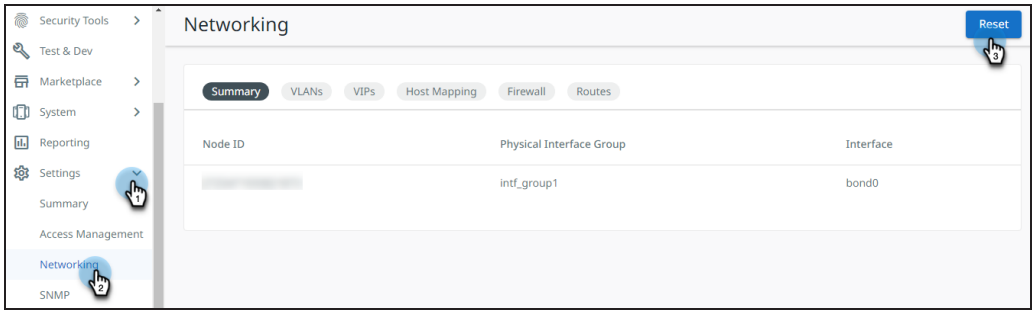
- The Cohesity cluster is not running backup or restore jobs.
- No new nodes are added to the Cohesity cluster.
- No nodes are removed from the Cohesity cluster.

> **Note:** This functionality is not supported on the virtual ROBO and cloud clusters.

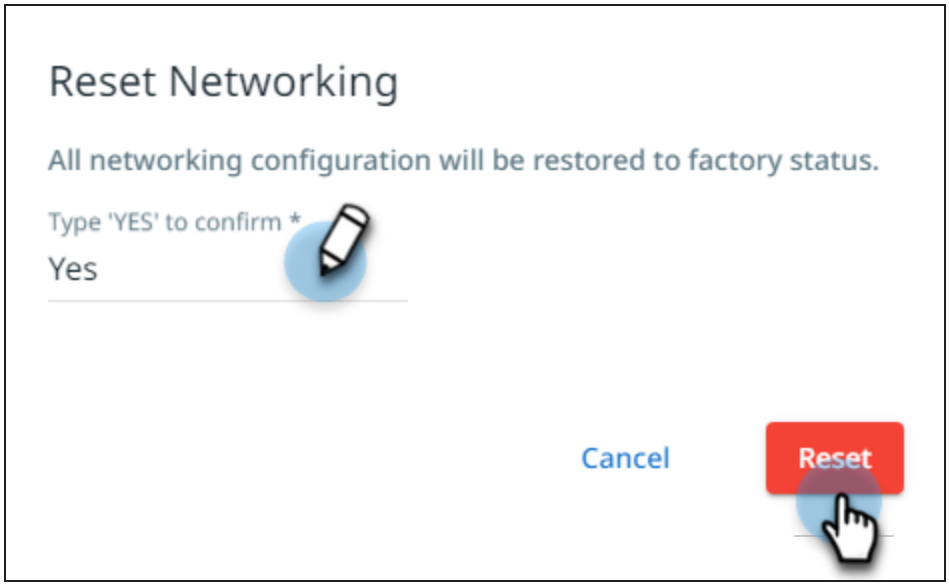
> **Note:** This functionality does a cluster-wide reset only.

To reset the networking configuration settings:

1. Log in to the Cohesity cluster.
2. Navigate to **Settings > Networking**.
3. Click **Reset**.

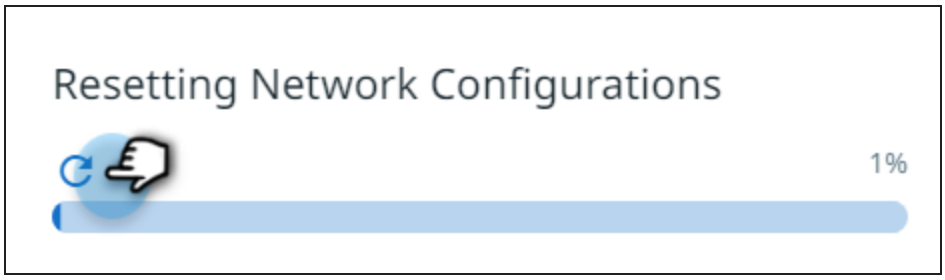


4. On the **Reset Networking** pop-up, type **YES** to confirm and click **Reset**.



You can see the progress bar in the **Resetting Network Configurations** pop-up.

The progress will automatically be updated. Optionally, you can click the **Refresh**( ) icon to see the real-time progress of resetting the network configurations.

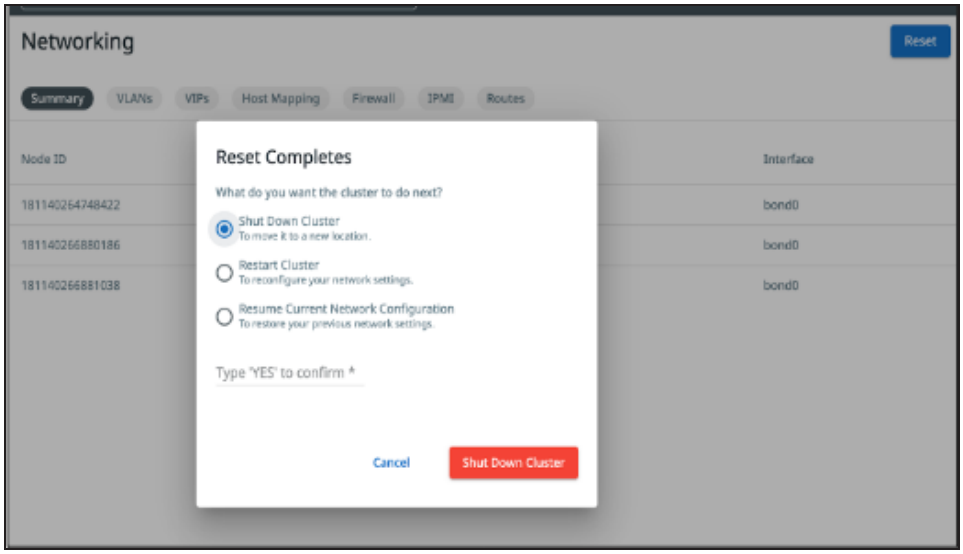


5. After the network configurations reset completes, select one of the following options in the **Reset Completes** pop-up:
   - **Shut Down Cluster**: Select this option to shut down the cluster. You may choose this option when moving the Cohesity cluster to a new location. For more information on powering on a Cohesity cluster, see Power Off and Power On a Cohesity Cluster.
   - **Restart Cluster**: Select this option to reconfigure the network settings on the cluster. For more information on configuring cluster settings, see Configure Settings.
   - **Resume Current Network Configuration**: Select this option to restore your previous network settings.
6. Type **YES** to confirm your selection. Based on your section in step 4, one of the following buttons will be displayed.
   - **Shut Down Cluster**: Click this button to shut down the cluster.
   - **Restart Cluster**: Click this button to restart the cluster.

     Resume: Click this button to restore the previous network settings.

     > **Note:** It is recommended to click the **Resume** button, instead of **Cancel**. If you want to restore your previous network settings. If you click the **Cancel** button after you reset the network settings, this can

leave the Cohesity cluster in an unstable state.



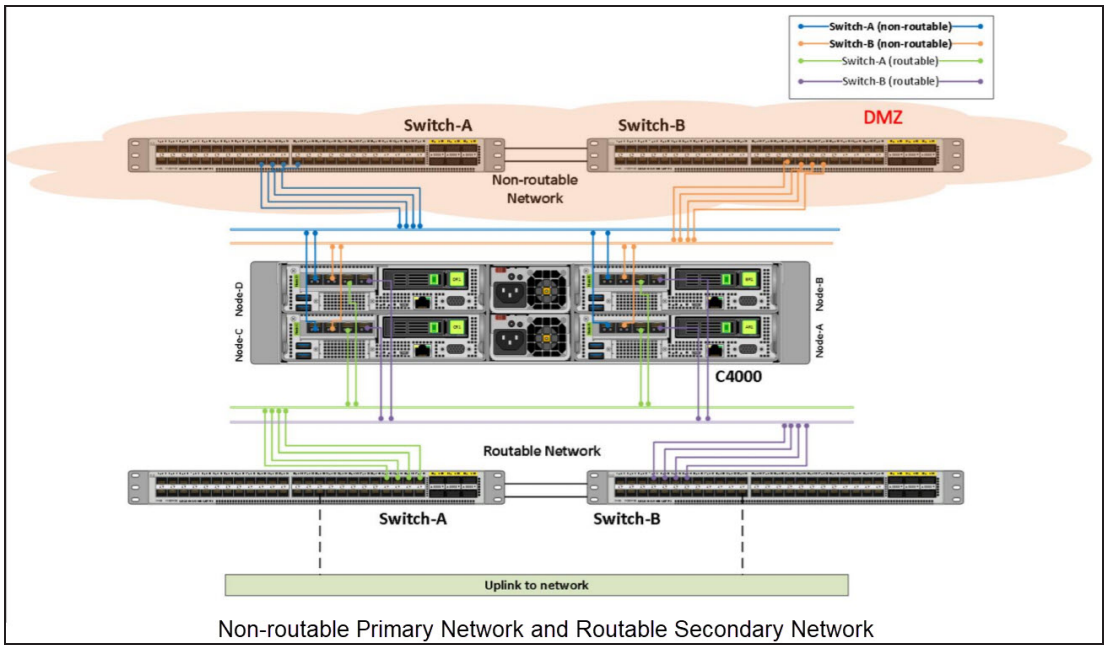
When you select **Shutdown** or **Restart Cluster** in step 5, you need to go through the cluster creation process again and recreate your cluster. You have to re-configure the network configuration on at least one node, update the bonding mode to match the new network, or create a non-native VLAN primary interface. For more information, see Initial Cluster Setup.

Refer to the Setup guide, depending on the hardware model from the Initial Cluster Setup Help.

Note: After you update the node IP addresses of Cohesity Virtual Edition clusters protecting VMware VMs, you must enable the Promiscuous mode in all the ESXi hosts before you rebuild the cluster. For information on how to enable the Promiscuous mode in the vCenter, see the VMware article.

Configure a Non-routable Primary Network for Cluster Creation and Expansion

A few customer environments have a dedicated storage network where the traffic is not routed outside of that network. In such a scenario, you can use the instructions in this topic to deploy Cohesity cluster data traffic on an isolated (non-routable) primary network and use the secondary interface for replication traffic.



Non-routable Primary Network and Routable Secondary Network

> **Important:** In cases where data traffic is isolated on a primary interface, the gateway is configured on the secondary interface. Ensure that NTP and other ports are reachable via the secondary interface.

Creating a Cohesity cluster

1. Install 6.6 on Cohesity cluster nodes.
2. Launch all cluster nodes' IPMI remote console. (ssh to nodes is not possible.)
3. To create a cluster, you can use one of the following steps on each node:
    a. Use the following command to configure the IP on a routable secondary interface.

    ```
    iris_cli ip config interface-name=<primary_interface_name> iface-ips=xx subnet-gateway=yy subnet-mask-bits=zz mtu=qq(optional)
    ```

    Example:

    ```
    Iris_cli ip config interface-name=bond1 interface-ips=10.1.1.19 subnet-gateway=10.1.0.1 subnet-mask-bits=20
    ```

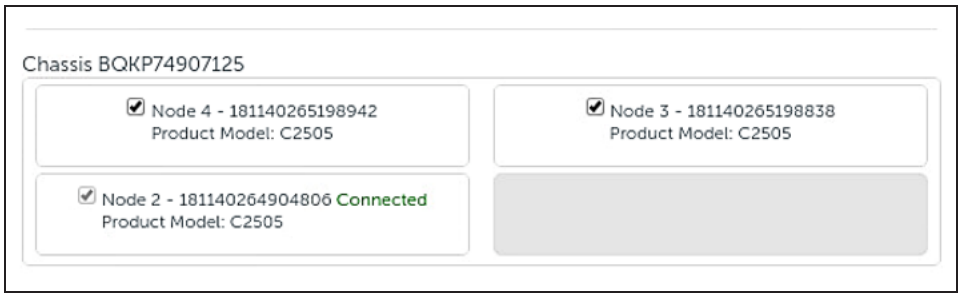
    b. Use the following command to set the secondary interface used as the default route:

    ```
    Iris_cli route add dest-network=0.0.0.0/0 interface-name=xx next-hop=yy
    ```

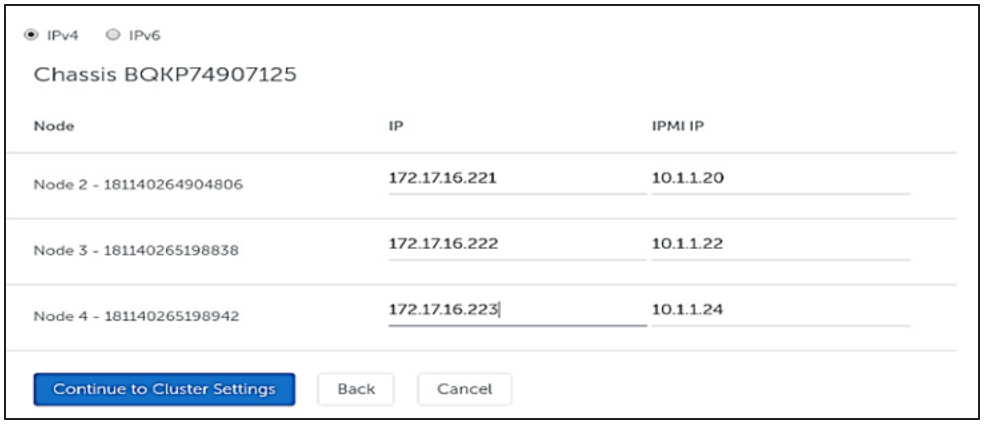
    Example

```
Iris_cli route add dest-network=0.0.0.0/0 interface-name=bond1
next-hop=10.1.0.1
```

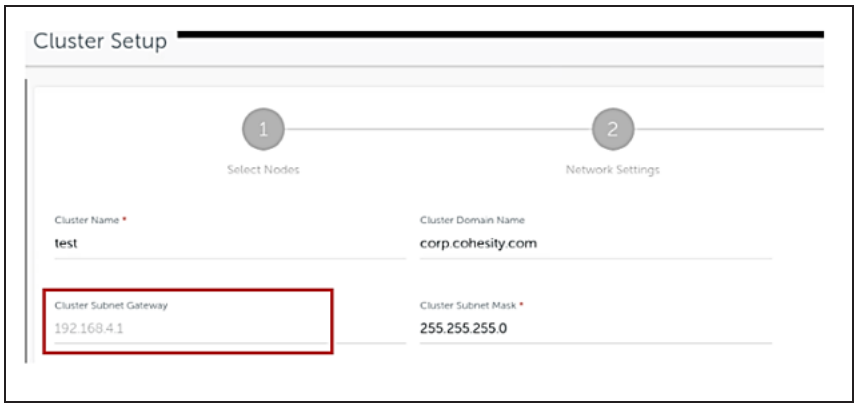
4. Use secondary interface IP or the Cohesity Dashboard and start cluster setup.



5. Assign node IP after the node selection (non-routable primary interface IP).



6. Continue with cluster setup and leave the **Cluster Subnet Gateway** field blank as the gateway is not available on the primary node IP network.



Expanding a Cohesity cluster

1. Install 6.6 on Cohesity free nodes.
2. Launch all free nodes' IPMI remote console. (ssh to nodes is not possible.)
3. You can use one of the following steps on each free node:

a. Use the following command to configure the IP address on a routable secondary interface.

```
iris_cli ip config interface-name=<primary_interface_name> iface-ips=xx subnet-gateway=yy subnet-mask-bits=zz mtu=qq(optional)
```

Example:

```
Iris_cli ip config interface-name=bond1 interface-ips=10.1.1.19 subnet-gateway=10.1.0.1 subnet-mask-bits=20
```

b. Use the following command to set the secondary interface used as the default route:

```
Iris_cli route add dest-network=0.0.0.0/0 interface-name=xx next-hop=yy
```

Example:

```
Iris_cli route add dest-network=0.0.0.0/0 interface-name=bond1 next-hop=10.1.0.1
```

Use the Cohesity Dashboard to add new nodes to the cluster. For more information, see Manage Hardware Nodes.

Set MTU

A maximum transmission unit, also called MTU, defines the largest size of the packet that can be transmitted as a single entity in a network connection. The size of the MTU determines the amount of data that can be transmitted in bytes over a network.

> **Note:** Ensure that the MTU is set with the same value end to end and there is no mismatch.

To enable jumbo frames, ensure the following:

- Switch ports have the MTU set to 9000
- Every network hop between client hosts, such as any cluster nodes, hypervisor hosts, Windows or Linux hosts, and the Cohesity cluster have the MTU set to 9000

After setting the MTU on the path between all hosts and the Cohesity cluster, follow these steps to manually set the MTU size to 9000 on each node of every required network interface:

1. Log in to the node via SSH.
2. Stop the cluster services by running the following command:

```
admin> cluster stop
```

3. Check the cluster status by running the following command:

```
admin> cluster status
```

> **Note:**
> Before proceeding, ensure the cluster status is as follows:
>
> - SERVICE STATE SYNC: DONE
> - CLUSTER HEAL STATUS: NORMAL

4. Update the MTU for a node in the Cohesity cluster, using the `interface-name` parameter in the CLI interface update command, where the `interface-name` is the name of the interface group:

```
iris_cli -username=<username> interface update interface-name=<name of
the interface-group> mtu=<new value of mtu>
```

   Example:

```
iris_cli -username=admin interface update interface-name=intf_group1
mtu=9000
```

5. Enter the password.
6. Start the cluster services by running the following command:

```
iris_cli -username=<user> cluster start
```

7. Enter the password.
8. Check the cluster status by running the following command:

```
admin> cluster status
```

> **Note:**
> Before proceeding, ensure the cluster status is as follows:
>
> - SERVICE STATE SYNC: DONE
> - CLUSTER HEAL STATUS: NORMAL

9. Run the following command to confirm that the MTU setting is on the physical interfaces and VIPs are set to 9000:

```
netstat -ian
```

   The netstat command output should show MTU of 9000 for all bond0* interfaces.

```
Iface      MTU    RX-OK RX-ERR RX-DRP RX-OVR    TX-OK TX-ERR TX-DRP TX-
OVR Flg
bond0     9000 41096477      0 3037 0      32947757      0      0
```

```

```

Note: To update the MTU for a free node that is not part of a Cohesity cluster, use the `interface-name` parameter in the CLI interface update command, where `interface-name` is the interface's name and then enter the password:

```
iris_cli -username=<user> interface update interface-name=<name of the interface> mtu=<new-mtu>
```

Example:

```
iris_cli -username=admin interface update interface-name=bond0 mtu=9000
```

Dual-Stack Network Configuration

Dual-stack network configuration enables Cohesity clusters to support both IPv4 and IPv6 addresses on the same network interfaces. This setup allows for a smooth transition between IP protocols and ensures compatibility with different network environments.

Process Overview

A quick overview of the process is as follows:

- Dual stack configuration for New clusters
  - Configure IPv6 and IPv4 on Free Nodes
  - Create Cluster
- Dual stack configuration for Existing clusters
  - Configure dual-stack networking with changing IP family preference
  - Configure dual-stack networking without changing IP family preference
- Create IPv6 and IPv4 subnet for Marketplace Apps
- Enable Apps Management on the Cohesity Cluster
- Install NoSQL and Hadoop Service

Dual stack configuration for New clusters

This topic provides detailed instructions for configuring dual-stack networking on new Cohesity clusters. It includes guidance on setting up IPv4 and IPv6 addresses and managing network settings.

Configure IPv6 and IPv4 on Free Nodes

You need to configure the IPv6 and IPv4 command on the primary interface of the free nodes using `iris_cli` command.

> **Note:** You must configure IPv6 address first and then followed by IPv4.

Run the following command to configure IPv6:

```
iris_cli ip config interface-name=<primary_interface_name> family=2 inter-
face-ips=<IPv6_address> subnet-mask-bits=<subnet_mask> subnet-gate-
way=<gateway>
```

Example

```
admin@127.0.0.1> ip config interface-name=bond0 family=2 interface-
ips=fc00:10:95:160::18 subnet-mask-bits=64 subnet-gateway=fc00:10:95:160::1
Success: Ip configured successfully
```

Run the following command to configure IPv4:

> **Note:** You must configure a private IPv4 address for internal communication within Cohesity cluster nodes.

```
iris_cli ip config interface-name=<primary_interface_name> family=1 inter-
face-ips=<IPv4_address> subnet-mask-bits=<subnet_mask>
```

Example

```
admin@127.0.0.1> ip config interface-name=bond0 family=1 interface-ips-
s=10.95.160.18 subnet-mask-bits=20
Success: Ip configured successfully.
```

Create Cluster

You can create a Cohesity cluster using either an IPv4 or IPv6 address. The IP preference setting determines which IP address is used for inter-node communication.

To complete the initial creation of the Cohesity cluster:

1. Enter the initial Cohesity cluster settings:

> **Note:**
> You can access the IPv6 cluster only from the IPv6 enabled host.
>
> **Syntax**: https://[IPv6]
>
> **Example**: https://[2400::5000:0:0:100:1001]/

Components	Description
Cluster Name	Specify a unique name for the Cohesity cluster. Only alphanumeric characters and hyphens are allowed. A hyphen cannot be the first or last character. Length cannot exceed 32 characters. No other characters are allowed.
Cluster Domain Name	The fully qualified domain name for the Cohesity cluster.
Cluster Subnet Gateway	Specify the IPv6 address of the Subnet Gateway for the Cohesity cluster.
Cluster Subnet Mask	Specify the Subnet Mask for the Subnet that the Cohesity cluster is a part of.
IPMI Subnet Gateway (optional)	Specify the IPv4 address of the subnet Gateway for the IPMI or iRMC network interfaces **Note:** You can either specify the IPMI configuration while creating the Cohesity cluster or after creating the cluster.
IPMI Subnet Mask (optional)	Specify the IPv4 Subnet Mask for the IPMI or iRMC Subnet.

Components	Description
IPMI Username (optional)	Specify the IPMI username to connect to the IPMI interface for each of the nodes in the Cohesity cluster. The cluster uses the IPMI username to get system health information about the nodes in the cluster. All nodes in the cluster must use the same IPMI username and IPMI password. Only alphanumeric characters and hyphens are allowed, but a hyphen cannot be the first character. The length cannot exceed 32 characters. The default IPMI username is **admin**. The Cohesity cluster does not depend on the IPMI configuration to get system health information about the nodes. For ease of managing the nodes remotely, you can configure IPMI.
IPMI Password (optional)	Specify the IPMI password to connect to the IPMI interface for each node in the Cohesity cluster. All nodes in the cluster must use the same IPMI username and IPMI password. The password can be 8 to 16 characters. It cannot include the following characters: dollar sign ($), asterisk (*), quote ("), single quote (`) or backslash (\). The default IPMI password is **admin**. Cohesity recommends changing the default password after creating the cluster. The IPMI password can be set for each node in the cluster, and the password can be different from the IPMI password configured for the cluster. The password can be 8 to 16 characters. It can include at least the following three characters: • Upper case • Lower case • Numbers • Special character, such as: _, -, @, #, ^, &, !, +, ~.
Search Domains	Specify a domain search list for hostname lookup.
DNS Servers	The IPv6 addresses of the Domain Name System (DNS) servers that the Cohesity cluster should use. Separate multiple IPs with commas. Ensure that the Active Directory DNS IP address (if applicable) is listed first. Verify that the NTP servers and other entities in the system can be resolved by the specified DNS server.

Components	Description
NTP Servers	Cohesity recommends using the external Google Public Network Time Protocol (NTP) server and specifying multiple servers (time1.google.com, time2.google.com, time3.google.com, time4.google.com). Avoid using the pool.ntp.org or time.nist.org NTP servers, as they are sometimes unavailable and their IP addresses tend to change. If using an internal NTP server, use only one server (and no external servers). Specify the IP address or the Fully Qualified Domain Name of the NTP server(s). The Cohesity cluster uses the specified NTP server to synchronize the time on all nodes in the cluster. **Note:** To use a Windows NTP server, follow the instructions in this Knowledge Base article. Add IPv6 NTP server if IPv6 DNS server is not added. Also, toggle on **Use Authentication Key** to secure the communication between the NTP server and the Cohesity cluster. In the **Key ID** field, enter the Key id associated with the SHA-1 key and in the **Key** field, enter the SHA-1 key **Note:** Only SHA-1 Keys are supported.
Configure Apps management network	Specify the private IPv4 or IPv6 address for the app subnets. The default IP 192.168.0.0/16 is used for app subnets. If the default IP 192.168.0.0/16 is allocated to a node network, cluster network, or any other network, provide any other private network IP range. Only a private IP range with a minimum subnet size /24 and a maximum subnet size /12 is supported.
Network Settings	Choose either IPv4 or IPv6 under "IP Assignment for Selected Nodes" to set the preferred IP address type for the cluster.

2. If desired, toggle **Encryption** on. Turning on encryption for a Cohesity cluster encrypts all data that will be stored on the cluster.

> **Note:** To encrypt an entire Cohesity cluster, you must specify the encryption option while creating the Cohesity cluster. After a cluster has been created, cluster encryption is not editable. If encryption is not enabled for a Cohesity cluster, you can enable encryption at the Storage Domain level.

The Cohesity cluster supports AES256 software encryption. The Cohesity cluster provides a built-in Key Management Service (KMS) that automatically generates keys.

After Encryption is turned on, the following option is available:

- The Rotation Period is how often the Cohesity cluster's encryption key is rotated. After the time period is reached, the old encryption key is replaced by a new key and the data on the Cohesity cluster remains as it was originally encrypted. The Rotation Period default value is 30 days. You can change this to the desired value.

  > **Note:** Use of Federal Information Processing Standard (FIPS) 140-2 certified modules is enabled by default for data at rest and cannot be disabled.

3. A partition and default Storage Domain are created automatically. Cohesity adds all currently selected nodes to the partition.
   - Specify a fully qualified domain name (**FQDN**). For a Cohesity cluster hosted directly on Cohesity hardware, specify an FQDN that DNS round robin resolves to the specified VIPs.

     > **Note:** You must use an IPv6 address if you are configuring a VIP.

     In situations where you have not yet added the FQDN with VIPs to DNS, enter the FQDN but do not add the VIPs.

     > **Note:** Best practice warrants a DNS entry for the cluster's FQDN and VIPs to achieve optimum cluster performance.

   - Complete **VIP Address** fields. Specify individual virtual IP addresses or ranges of virtual IP addresses for the Cluster. Specifying a VIP range means network traffic to the cluster can be routed to a range of IP addresses instead of a single IP address. For better load balancing, Cohesity recommends specifying the same number of VIPs as there are nodes in the Cohesity cluster. Click **Add VIP or VIP Range**.

     If you do not have VIP addresses yet, leave these fields empty. After the cluster is created, you can add VIP addresses in the Cohesity Platform. Select **Settings** > **Networking** and select the **VIPs** tab.

> **Note:** When the preferred network is IPv6, specify individual IPv6 virtual IP addresses or ranges in the VIP Address fields.

4. Click **Create Cluster**.

   The page displays the Cohesity cluster creation progress.

5. Wait several minutes to allow services to restart, and then click the displayed URL and log in to the Cohesity Platform using the default System Admin account called `admin`, and the default password, `admin`.
6. Read the EULA License Agreement and click **Agree**.
7. Select **SaaS** or **On Prem** configurations and click **Connect**.
8. In the **Change Password** dialog box, enter and confirm the new password for the System Admin account. The minimum length of the password must be 8 characters.

   An Overview Dashboard page displays.

   See Node Detection and Cluster Creation Issues if the cluster creation process is stuck or succeeds with warnings. If Cohesity detects an issue, make corrections before continuing.

You now need to configure the Cohesity cluster. For more information, see Configure Settings.

Dual stack configuration for Existing clusters

This topic provides instructions for configuring dual-stack networking on existing Cohesity clusters. It includes guidance on setting up IPv4 and IPv6 addresses and managing network settings.

Configure dual-stack networking with changing IP family preference

Follow these steps to configure dual-stack networking on existing Cohesity clusters when the IP family preference needs to be changed,

> **Note:** To configure dual-stack networking on CE clusters, please refer to Configure dual-stack networking without changing IP family preference, as changing IP family preference and Reset Networking are not supported on CE clusters.

1. Reset the network configuration settings from the Cohesity dashboard. For more information, see Reset Networking Configuration Settings.

> **Note:** Reset networking is applicable only for physical environments. For VE, a new cluster is needed to change the preferred network.

2. Complete the initial cluster creation process. For more information, see Create Cluster.
3. Configure the Cohesity cluster. For more information, see Configure Settings.

> **Important:** Resetting the network configuration settings, completing the initial cluster creation process, and configuring the Cohesity cluster will not result in data loss. These steps are designed to preserve existing data on the cluster.

Configure dual-stack networking without changing IP family preference

Follow these steps to configure dual-stack networking on existing Cohesity clusters without changing the IP family preference,

Run the following command to set the IP address (IPv4 or IPv6) for the respective Secondary Interface.

For IPv4

```
iris_cli ip config interface-name=<interface_name> interface-ips=<ip_
addresses> node-ids=<node_ids> subnet-gateway=<gateway> subnet-mask-bit-
s=<subnet_mask>
```

Example:

```
iris_cli ip config interface-name=intf_group2 interface-ips=10.1.1.1 node-
ids=1234 subnet-gateway=10.1.1.100 subnet-mask-bits=24
```

For IPv6

```
iris_cli ip config interface-name=<interface_name> interface-ips=<ip_
addresses> node-ids=<node_ids> subnet-gateway=<gateway> subnet-mask-bit-
s=<subnet_mask> family=<ip address_family>
```

Example:

```
iris_cli ip config interface-name=intf_group2 interface-ips=2001::100 node-
ids=1234 subnet-gateway=2001::1 subnet-mask-bits=64 family=
```

> **Note:** The preceding commands cannot be used to update the IPv4 or IPv6 addresses of a Primary Interface.

Create IPv6 and IPv4 subnet for Marketplace Apps

You need to create the IPv6 and IPv4 subnet for MarketPlace apps using `iris_cli` command.

Run the following command for IPv6:

> **Note:**
> - Make sure the subnet is unused to avoid routing conflicts.
> - Supported IPv6 subnet mask bits range is 8-118.

```
iris_cli cluster update-subnet subnet-ip="<ipv6_address>" subnet-mask-bit-
s=<subnet_mask> desc="<description>" service-name="<service_name>"
```

Example

```
admin@127.0.0.1> cluster update-subnet subnet-ip="fc00:192:168::0" subnet-
mask-bits=64 desc="testing ipv6" service-name="apps"
SUBNET ID                     : 0
SUBNET IP                     : fc00:192:168::0
SUBNET MASK BITS              : 64
SUBNET MASK                   : 64
SERVICE NAME                  : apps
DESCRIPTION                   : testing ipv6
```

Run the following command for IPv4:

> **Note:**
> - Make sure the subnet is unused to avoid routing conflicts.
> - Supported IPv4 subnet mask bits range is 12-24.

```
iris_cli cluster update-subnet subnet-ip=<ipv4_address> subnet-mask-ip4-
4=<subnet_mask> service-name=<service_name>
```

Example

```
admin@127.0.0.1> cluster update-subnet subnet-ip=192.168.0.0 subnet-mask-ip4-
4=255.255.0.0 service-name=apps
SUBNET ID                     : 0
SUBNET IP                     : 192.168.0.0
SUBNET MASK BITS              : 16
SUBNET MASK                   : 255.255.0.0
SERVICE NAME                  : apps
```

Enable Apps Management on the Cohesity Cluster

Before you can install and run apps, the cluster must be enabled to support app management.

Perform the following steps to enable app management:

1. Log in to the Cohesity cluster with valid credentials.
2. Navigate to **Marketplace** > **My Apps**.
3. Click the **My Apps** tab and then click **App Settings** located at the top right of the page.
4. Turn on the **Enable Apps Management** toggle.

You can also **Enable Apps Management** using the iris_cli command. Run the following command:

```
iris_cli apps update-apps-settings marketplace-apps-mode=kBareMetal
```

Example

```
admin@127.0.0.1> apps update-apps-settings marketplace-apps-mode=kBareMetal
APPS MODE                       : BareMetal
MARKETPLACE APPS MODE           : BareMetal
```

Install NoSQL and Hadoop Service

You need to download the NoSQL and Hadoop Service and install it on the cluster.

Perform the following steps:

1. Obtain the NoSQL and Hadoop Service package from your Cohesity Accounts contact. The app package format is `app1011-700xxxx.pkg` where `700xxxx` is the version number.
2. Download the package to a location from where you are planning to connect to the Cohesity Platform.
3. Log in to the Cohesity Platform with valid credentials.
4. Navigate to **Marketplace** > **Apps**.
5. Under the **My Apps** folder, click **Upload App** and navigate to the location where you have downloaded the app package, and select the app package.
6. Click **Upload and Install**.
7. Once the upload is complete, click **Run App** to launch the app.

Node Detection and Cluster Creation Issues

If you encounter issues during initial Cohesity cluster creation, read the following sections for possible resolutions:

Verify the following:

All of the following are reachable from the Cohesity cluster:

- Default gateway
- DNS server
- NTP server

Use a Proxy Server

The Cohesity cluster supports routing network traffic to a proxy server for:

- getting upgrade packages from Cohesity
- sending proactive monitoring (Helios) diagnostics from the Cluster to Cohesity
- connecting to the Cluster via the Cohesity Support Channel (if a proxy server is configured for the Cluster as described below, the Support Channel will use the proxy server)

This functionality has been qualified with the Squid3 proxy server.

Configure this functionality using the following CLI commands: `cluster update-proxy-server`, `cluster rm-proxy`, `cluster ls-proxies` and `cluster edit-proxies`. To learn more, log in to the Cohesity CLI and enter the name of the command followed by `help` such as: `cluster update-proxy-server help`.

To configure a proxy for outbound Web traffic using Squid, see the How to configure a proxy for outbound web traffic using Squid KB article.

Update the Proxy Server for the Cluster

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. Use the `cluster update-proxy-server` command, for example:

   ```
   admin>cluster update-proxy-server address=10.10.10.10 name=myproxy port-
   t=443
   ```

The command options are shown below:

CLI Option	Description
`address=`	Required. The hostname or IP address of the proxy server.
`name=`	Required. The name of the proxy server.

CLI Option	Description
`port=`	Required. The port to use for the proxy server.
`password=`	Optional. The password to use for the proxy server.
`schemes=`	Optional. A comma separated list of schemes supported by the proxy server. Choose either http or https.
`username=`	Optional. The username to use for the proxy server.

To configure Web Proxy from the Cohesity cluster, see Web Proxy settings.

Verify NTP Setup and Detect Issues

Starting with Cohesity cluster version 7.2.2, Cohesity will transition from Red Hat Enterprise Linux 7.9 OS to Red Hat Enterprise Linux 9.2 as the Host Operating System. Chronyd is now the default time daemon, replacing ntpd.

When a Cohesity cluster is first created, it must have connectivity to an NTP server. Common public NTP servers that can be used:

- time.nist.gov
- time.google.com

Verify the Cluster Can Query the NTP Server

Perform the following from the Cohesity node that is used to create the Cohesity cluster.

`ssh` to a Cohesity Node with the support user and run the `chronyd -Q` command:

```
#chronyd -Q 'server <hostname_of_ntp_server> iburst'
```

For example:

```
#chronyd -Q 'server time.nist.gov iburst'
```

If the NTP server is reachable, expect the following output:

```
[root@f7e746e6 ~]# chronyd -Q 'server time.nist.gov iburst'
2025-08-21T03:26:23Z chronyd version 4.5 starting (+CMDMON +NTP +REFCLOCK
+RTC +PRIVDROP +SCFILTER +SIGND +ASYNCDNS +NTS +SECHASH +IPV6 +DEBUG)
2025-08-21T03:26:23Z Disabled control of system clock
2025-08-21T03:26:27Z System clock wrong by 0.000159 seconds (ignored)
2025-08-21T03:26:27Z chronyd exiting
[root@f7e746e6 ~]#
```

Detect and Resolve NTP Synchronization Issues

NTP time synchronization is critical to Cohesity clusters. A cluster's opclock, which is a vector clock, relies on strict NTP synchronization. If time services become out of sync, they can shut down all I/O operations if a metadata opclock out-of-order condition occurs.

NTP out of sync condition symptoms include:

- Cluster creation does not complete. An error of "kClusterBringup" may be reported.
- After entering Node and IPMI IP addresses in the initial setup wizard, the screen begins to flicker and ultimately returns to the login prompt.
- Cluster creation fails with "WARNING | CE00411001 - FrequentProcessRestarts | Process bridge_exec is restarting frequently".
- "An internal component may be down" message is reported.
- The Cohesity Bridge service experiences FATAL errors with the following message:

```
F1013 01:21:08.107616 120432 client_base_op.cc:247] Server asked the
client to crash. Timestamp in the request is 10001 msecs in the future.
Please check the time difference between nodes.
logs/bridge_exec.FATAL (END)
```

Change operations may not be allowed within the Cohesity cluster. For example, the time cannot be set earlier because of the opclock dependency.

There are multiple ways to check the NTP server configuration and current state. This following information describes how to check an chronyd configuration and status.

- Verify the time difference on multiple Nodes:

```
[cohesity@9166193e ~]$ allssh.sh "date"
=========== 10.10.10.10 ===========
Mon Oct 12 16:27:48 PDT 2015     |-- NTP master is faster than other
nodes
=========== 10.10.10.11 ===========
Mon Oct 12 16:25:51 PDT 2015
=========== 10.10.10.12 ===========
Mon Oct 12 16:25:50 PDT 2015
=========== 10.10.10.13 ===========
Mon Oct 12 16:25:50 PDT 2015
```

- Verify the chrony.conf on all Nodes:

```
[cohesity@9166193e ~]$ allssh.sh "less /etc/chrony.conf"
=========== 10.10.10.10 ===========
# /etc/chrony.conf, configuration for chronyd

#-----------------------------------------------
#  DO NOT EDIT THIS FILE - it is machine generated
#  Don't change config without validation for security holes
```

```
#-------------------------------------------------

server 10.10.10.107 iburst maxpoll 16 |--- Configured to local NTP
server

# Record the rate at which the system clock gains/losses time.
driftfile /var/lib/chrony/drift

# Server(s)
=========== 10.10.10.11 ===========
# /etc/chrony.conf, configuration for chronyd

#-------------------------------------------------
#  DO NOT EDIT THIS FILE - it is machine generated
#  Don't change config without validation for security holes
#-------------------------------------------------

server 10.10.10.10 iburst maxpoll 16 |--- Configured to local cluster
NTP master

# Record the rate at which the system clock gains/losses time.
driftfile /var/lib/chrony/drift

=========== 10.10.10.12 ===========
# /etc/chrony.conf, configuration for chronyd

#-------------------------------------------------
#  DO NOT EDIT THIS FILE - it is machine generated
#  Don't change config without validation for security holes
#-------------------------------------------------

server 10.10.10.10 iburst maxpoll 16 |--- Configured to local cluster
NTP master

# Record the rate at which the system clock gains/losses time.
driftfile /var/lib/chrony/drift

=========== 10.10.10.13 ===========
#-------------------------------------------------
#  DO NOT EDIT THIS FILE - it is machine generated
#  Don't change config without validation for security holes
#-------------------------------------------------

server 10.10.10.10 iburst maxpoll 16 |--- Configured to local cluster
```

```
NTP master

# Record the rate at which the system clock gains/losses time.
driftfile /var/lib/chrony/drift
```

- Query the time from NTP server for internal and external:

```
[cohesity@9166193e ~]$ ifconfig | grep inet
inet 10.10.10.10  netmask 255.255.255.0  broadcast 10.10.10.255

[cohesity@9166193e ~]$ chronyd -Q 10.10.10.107
2025-08-21T03:26:23Z chronyd version 4.5 starting (+CMDMON +NTP
+REFCLOCK +RTC +PRIVDROP +SCFILTER +SIGND +ASYNCDNS +NTS +SECHASH +IPV6
+DEBUG)
2025-08-21T03:26:23Z Disabled control of system clock
2025-08-21T03:26:27Z System clock wrong by 0.000159 seconds (ignored)
2025-08-21T03:26:27Z chronyd exiting |-- NTP master node is 0.000159
seconds behind the local NTP server, 10.10.10.107
[cohesity@9166193e ~]$ chronyd -Q time.nist.gov
2025-08-21T03:26:23Z chronyd version 4.5 starting (+CMDMON +NTP
+REFCLOCK +RTC +PRIVDROP +SCFILTER +SIGND +ASYNCDNS +NTS +SECHASH +IPV6
+DEBUG)
2025-08-21T03:26:23Z Disabled control of system clock
2025-08-21T03:26:27Z System clock wrong by -0.000459 seconds (ignored)
2025-08-21T03:26:27Z chronyd exiting    |-- NTP master node is 0.000459
seconds faster than public time.nist.gov server
```

- Check detailed NTP status:

```
[cohesity@9166193e ~]$ sudo chronyc sources
MS Name/IP address         Stratum Poll Reach LastRx Last sample
===============================================================================
=========
^* 10.2.1.120                    2   6    77    31    +57us[ +242us]
+/-   21ms

[cohesity@9166193e ~]$ sudo ntpstat

synchronised to NTP server (10.2.1.120) at stratum 3
time correct to within 19 ms
polling server every 128 s
```

Once you identify a time inconsistency, correct it immediately. Cohesity recommends synchronizing the local time server time to a public time server. To do so, run the following command which stops chronyd daemon, resynchronizes to a public time server and starts chronyd daemon:

```
allssh.sh sudo systemctl stop chronyd && sudo chronyd -q time.google.com
```

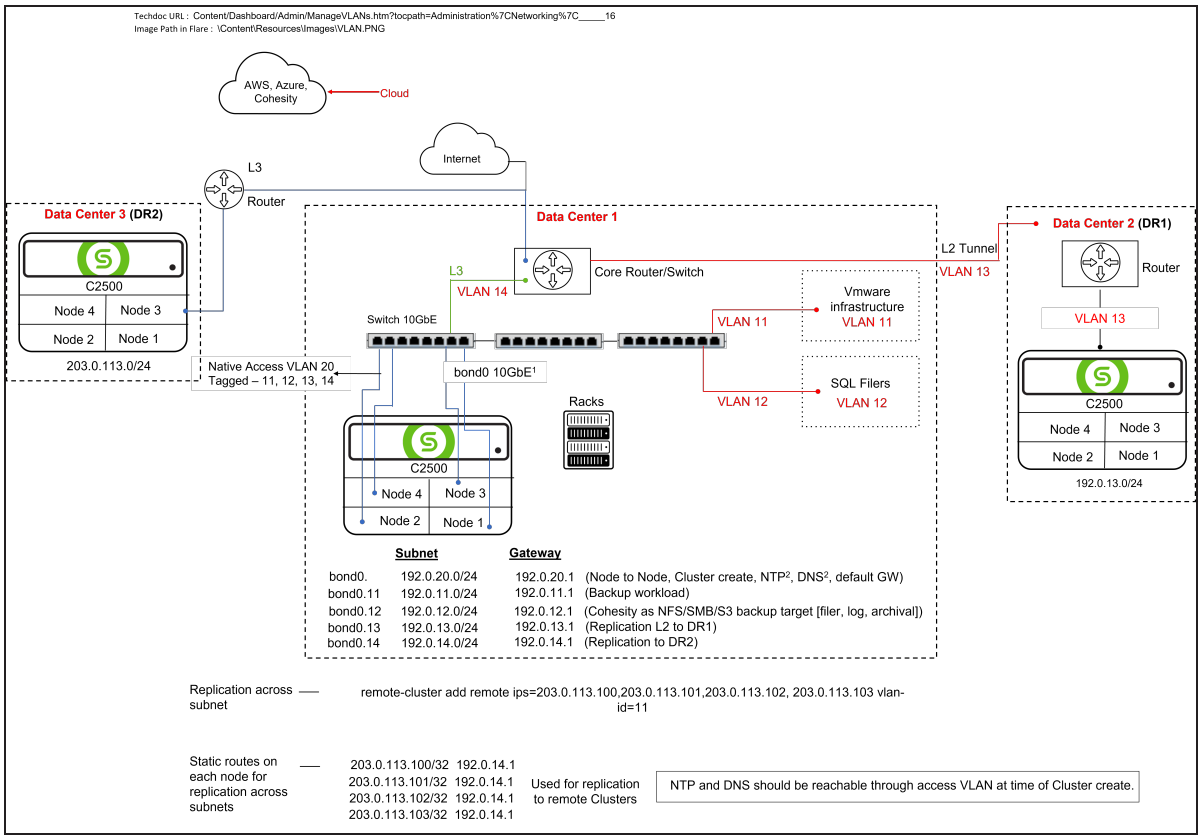
> **Note:** The Cohesity cluster time cannot be changed to an earlier time. If such a change is needed, the Cluster or a specific Node must be shutdown to allow for synchronization to occur.

Manage VLANs

After the initial setup of a Cohesity cluster, you can extend your existing on-premise VLANs into the Cohesity cluster to logically separate traffic and improve performance. After you add a VLAN to the Cohesity cluster, users can select the VLAN when recovering VMs, files, folders, Pure Storage volumes, NAS volumes, or when cloning a vCenter Source. Some recovery and clone tasks can auto-select the appropriate VLAN for the task, but users can override the selection.

The Cohesity cluster supports a maximum of 4094 VLAN IDs irrespective of the cluster size.

The following diagram shows an example Cohesity environment using VLANs.



Add a VLAN

Perform the steps in this section to add a VLAN.

> **Note:**
> Cohesity recommends the following:
>
> - Do not configure a VLAN gateway if you want to use global static route for outgoing traffic from the Cohesity cluster.
> - Enable a separate VLAN gateway (different from the default VLAN gateway) to route incoming traffic to the Cohesity cluster via a VLAN IP address such as NFS or UI. Static routes are required only for outgoing traffic, and the Default Gateway setting of the VLAN is only for incoming traffic regardless of Static Routing.

1. In the Cohesity Dashboard, select **Settings > Networking** and then select the **VLANs** tab.
2. Click **Add VLAN**.
3. Provide the following information:
   - **Interface Group:** Select the interface group to use for the VLAN.
   - **VLAN ID:** Specify the ID of the VLAN you want to add.
   - **Subnet:** Specify the IPv4 or IPv6 address of the subnet mask bits for the VLAN.
   - **Gateway:** Optional. Specify the IPv4 or IPv6 address of the subnet gateway for the VLAN.
   - **Enable For All Organizations**:Optional. Toggle this setting on if you want to enable VLAN for all organizations. For more information, see Enabling VLANs for all Organizations.
4. Click **Save**.

The VLAN is added to the Cohesity cluster and available for the supported recovery and clone tasks.

To add optional virtual IP addresses (VIPs) to the VLAN, select **Settings > Networking** and then select the **VIPs** tab. From the Interface Group drop-down, select **intf_group1**.

Edit a VLAN

1. In the Cohesity cluster, select **Settings > Networking** and select the **VLANs** tab.
2. In the list of VLANs, click the actions menu (⋮) for the VLAN and then click the edit icon ( ).
3. Change the settings as needed. Note the following:

- You cannot change the VLAN ID.
- If you are editing the subnet mask of a VLAN, you must also specify a new value for the subnet, as changing the subnet mask changes the subnet and, thereby, the number of hosts and subnets allowed.
- If the number of assigned VIPs is equal to the number of nodes, you must add the new IPs before you can remove the old IPs. This ensures that all the nodes always have a VIP assigned.

4. Click **Save**.

Delete a VLAN from the Cohesity cluster

1. In the Cohesity Dashboard, select **Settings > Networking** and select the **VLANs** tab.
2. In the list of VLANs, click the actions menu (⋮) for the VLAN and then click the delete icon ( ).
3. Click **Delete**.

Manage VIPs

When a cluster is created, every node in the cluster is assigned a Node IP (or static IP) address. However, if the cluster goes offline, the Node IP addresses become inaccessible and go down as well.

Virtual IP (VIP) is assigned to the cluster nodes after the cluster is created. Even if the cluster goes down, the assigned virtual IP remains available.

Add a VIP

You can add IPv4 or IPv6 virtual IP addresses (VIPs) to an interface group.

To add a VIP:

1. In the Cohesity Dashboard, select **Settings > Networking** and then select the **VIPs** tab.
2. Select the VIP type you want to add, **IPv4** or **IPv6**.
3. **Interface Group:** Select an interface group from the drop-down.
4. Provide the following information:
   - **Subnet:** Specify the IP address of the subnet mask bits for the interface group.
   - **FQDN:** Specify the fully qualified domain name associated with the interface group.
   - **Gateway:** Optional. Specify the IP address of the subnet gateway for the interface group.

- **VIP Address or Range:** Optional. Specify a single virtual IP (VIP) address or a range of addresses assigned to the interface group and then click **Add VIP or Range**. If providing a range, enter a complete address in the first field and just the upper limit of the range (such as 5) in the second field.

  For the non-primary interface group, the number of VIPs must be equal to or greater than the number of Nodes in the Cluster.

  If you provide a number of VIPs equal to or greater than the number of Nodes, the VLAN is automatically added to the Cluster.

  For the primary interface group, the number of VIPs can be lesser than the number of Nodes in the Cluster.

  > **Note:** VIPs cannot be assigned to two interfaces within the same subnet.

5. **Inbound DNS (Optional)**Type Zone name and Zone Server VIPs. Click the (+) icon to add multiple zones.

   > **Note:** Use this option to use the Cohesity cluster as an internal DNS server. For more information, see Internal DNS for Load Balancing.

   Configuring it helps in load balancing by selecting available VIPs for balancing network traffic.

   A Zone name consists of an internal DNS name and a client-side DNS name. For example, Testintdns.storage.eng. In the example, storage.eng is the DNS zone in the client environment and Testintdns is the child zone hosted on Cohesity cluster.

   > **Note:** You should know your DNS server name to add the zone name and can use one of the VIPs as Zone Server VIP. You cannot delete a VIP that is used as a Zone Server VIP.

6. Click **Update**.

   > **Note:** If you have updated any of the above mentioned fields, you must click **Update** before proceeding.

Delete a VIP

You can delete IPv4 or IPv6 virtual IP addresses (VIPs) from an interface group.

> **Important:** Ensure that no backup traffic using the subnet before deleting the VIPs.

To delete a VIP:

1. In the Cohesity Dashboard, select **Settings > Networking** and select the **VIPs** tab.
2. In the list of VIPs, click the delete icon ( ) to delete the VIP.

Internal DNS for Load Balancing

The Domain Name System (DNS) in the Cohesity cluster helps in load balancing by selecting available VIPs for balancing network traffic on VLANs. From release 6.6 onwards, your Cohesity cluster can act as a DNS server. You can configure your cluster as a DNS server by configuring **In Bound DNS** option and creating DNS load balancing zones in the Cohesity Cluster. The configured DNS load balancing zones are valid with a VLAN.

You can configure the **In Bound DNS** when creating a VIP.

Cohesity uses the round-robin technique for managing the client's requests.

You should register one cluster serving VIP on a DNS server (client-side DNS) in your environment. The Cohesity cluster acts as a subdomain for your DNS server. The configured DNS server inside the cluster addresses the issue of updating the client-side DNS when you add or remove a node in the Cohesity cluster or add a new VIP.

Advantages of DNS Load Balancing

The advantages of DNS load balancing are:

- You do not need to add all VIPs on the client-side DNS server for mapping.
- Map a single VIP with the client-side DNS.

Prerequisites

- Access to external DNS server

Considerations

- You can’t delete a VIP configured with an external DNS server.
- A single FQDN can resolve only with one zone.
    - The View mount paths for SMB, NFS, and S3 do not show paths for other DNS zones when you have a single FQDN and. the cluster is not registered with AD.
- In a multitenancy environment, DNS load balancing is supported only for VLAN-based organizations (tenants).

Create DNS Load Balancing Zone

DNS load balancing zone assigns available VIPs to clients using the round-robin method and manages network traffic.

When you configure the DNS load balancing zone on your Cohesity cluster, available VIPs are linked to a load balancing zone in a VLAN. You need to configure the client-side DNS server to delegate all DNS requests to the DNS load balancing zone on the Cohesity cluster.

You can create a DNS load balancing zone when creating a VIP. For more information, see Manage VIPs.

Configuration on Client-Side DNS Server

Create a new delegation zone in the DNS Server for the child domain that you have created on the Cohesity cluster. When you create a delegation, any request to your DNS server is forwarded to the DNS load balancing zone created on your Cohesity cluster.

Add A-record and Delegation Zone on Client-Side Windows DNS Server

You need to add an address mapping record (‘A’ Record for IPv4) or ‘AAAA’ (for IPv6) record in the client-side DNS server and add a delegation.

For example, we have this client-side DNS server zone.com and you added an internal DNS zone on your Cohesity cluster: cohesityV4dns.zone.com with VIP 10.1.1.1.

Now you need to make an 'A' record in the zone.com DNS for the VIP 10.1.1.1 and add a delegation using the 'A' record and the internal DNS zone name: cohesityV4dns.zone.com.

Prerequisites

- Cohesity DNS zone name.
- VIP address used for creating the DNS zone on the cluster.

To add a delegation zone on the client-side Windows DNS Server:

1. Log in to your Windows Server.
2. Navigate to **Windows Administrator Tools > DNS Manager > Forward Lookup Zones**.
3. Select the required domain and add an A or AAAA entry for one of the VIPs from your Cohesity cluster.
4. Enter a name for the Cohesity internal DNS server.
5. After adding the A or AAAA record entry, add a DNS delegation.
6. Right-click the domain and select **New Delegation**.
7. In the **New Delegation** wizard, enter the DNS zone name that you added in the cluster. Enter the A or AAAA record name that you added to the DNS server.
8. Complete the instructions in the wizard to add the delegation.

Once the A or AAAA record is added and delegation is created, any requests to the client-side DNS Server are forwarded to the DNS zone created on the Cohesity internal DNS server.

Add or Remove Inbound DNS Zone

You can add or remove a load balancing zone.

To add or remove DNS zone:

1. In the Cohesity cluster Dashboard, navigate to **Settings > Networking** and then click the **VIPs** tab.
2. In the **Inbound DNS (Optional)** section of the page, click the (+) icon to add multiple zones or click (-) to delete a zone.
3. Click **Update**.

Manage Host Mappings

Use the Cohesity cluster to provide Cluster-wide /etc/hosts entries that map IP addresses to domain names. Using the dashboard ensures that the entries are centrally stored in the Cluster and propagated to all existing Nodes and to any new Nodes added to the Cohesity cluster. The entries are also preserved during Cohesity cluster upgrades.

On a new or newly upgraded Cohesity cluster running release 6.5.1 or later, the Cluster-wide file is initialized automatically. The Cluster then monitors the Nodes at regular intervals for changes to /etc/hosts and propagates the changes to the other Nodes within a few seconds. For an upgraded Cohesity cluster, any existing /etc/hosts entries are retained and uploaded to the Cluster-wide file.

> **Note:** Do not directly edit the /etc/hosts files on the Nodes in the Cohesity cluster.

Manage /etc/hosts Entries

You can manually enter the host names and IP addresses or upload a host file with the mappings between them.

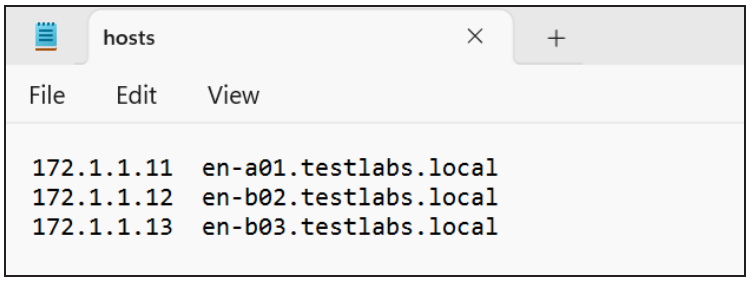
To manually enter the host names:

1. Select **Settings > Networking** and then select the **Host Mapping** tab.
2. Click the Edit icon (✎) next to **Host Mapping**.
3. Enter the IP addresses and host names.
4. Click **Save**.

To upload entries from a host file (in *.txt format):

> **Note:** Once you upload a host file, existing entries are overwritten. If the existing entries are critical, Cohesity recommends adding those entries to the host file.

1. Select **Settings > Networking** and then select the **Host Mapping** tab.
2. Click **Upload hosts file**.
3. Browse to open your text file that has the IP address vs. host name mapping. The IP address and hostnames must be separated by a space or tab, as shown below. Comma-separated values are not supported.



4. Click **Save**.

   Once you click **Save**, the contents of your text file are uploaded and displayed on the same page in the Cohesity cluster UI.

Configure a Non-native VLAN for Cohesity cluster Creation and Expansion

Create a Cohesity cluster

1. Install 7.3.1 on Cohesity cluster nodes.
2. Launch all Cohesity cluster nodes' IPMI remote console. (ssh to nodes is not possible.)
3. To create a Cohesity cluster, you can use one of the following methods:
   1. Through iris_cli. Perform these steps on all nodes:
      a. Use the `iris_cli add vlan` command to set up the non-native VLAN to be used for the Cohesity cluster create workflow.

      ```
      iris_cli vlan add interface-group=<name of the interface group> id=<VLAN-ID> subnet-mask-bits=<Subnet-Mask-Prefix>
      ```

      Example:

      ```
      iris_cli vlan add interface-group=intf_group1 id=5 subnet-mask-bits=20
      ```

b. Use the following command to set the non-native VLAN logical bond interface as primary. Replace vlan_id with the ID of the VLAN you added.

```
iris_cli ip config interface-name=<bond0.vlan_id> interface-role=primary
```

Example:

```
iris_cli ip config interface-name=bond0.5 interface-role=primary
```

Alternatively, to configure the IP on each node and access the node using the IP (not required if using Avahi to discover all nodes), use this command:

```
iris_cli ip config interface-name=<bond0.vlan_id> interface-ips=xx subnet-gateway=yy subnet-mask-bits=zz interface-role=primary
```

Example:

```
iris_cli ip config interface-name=bond0.5 interface-ips=10.5.1.5 subnet-gateway=10.5.0.1 subnet-mask-bits=20 interface-role=primary
```

2. Through configure_network.sh script: Perform these steps on all nodes.

   Use `configure_network.sh option 10` to add VLAN and follow the prompts to complete VLAN addition on the desired network bond.

   Location: /home/cohesity/bin/network/configure_network.sh

4. Restart the Cluster Manager Services:

```
sudo service nexus restart
```

5. Run `ifconfig` and ensure Avahi runs on the non-native VLAN bonded interface. Cohesity relies on Avahi for node discovery.

   Sample output from a node running on the primary non-native VLAN 5

```
bond0.5:avahi: flags=4163<UP,BROADCAST,RUNNING,MULTICAST> mtu 1500
inet 169.254.7.187 netmask 255.255.0.0 broadcast 169.254.255.255
ether a4:bf:01:2d:7e:b2 txqueuelen 1000 (Ethernet)
```

6. Perform these steps on any one node:

   If an IP was assigned on the VLAN interface, access the UI using the assigned IP on the VLAN interface. Otherwise, complete these steps:

   a. Connect the Mac laptop to the node for Avahi discovery for Cohesity cluster create.

b. Perform discovery through the browser, using this URL format:

   https://chassis-<chassis_serial_number>-<node_number>.local

7. On any node, start the Cohesity cluster create workflow and provide Cohesity cluster IPs from the configured non-native VLAN.

> **Note:** If necessary, the user can configure Cohesity cluster IPs and VIPs from the non-native VLAN and retain the IPMI in the native VLAN or some other subnet.

Expand a Cohesity cluster

To expand a Cohesity cluster, perform the following steps before adding new nodes to the Cohesity cluster.

1. You can use one of the following methods to achieve it:
   i. Through iris_cli
      a. Use the `iris_cli add vlan` command to set up the non-native VLAN to be used for the node add workflow.

```
iris_cli vlan add interface-group=<name of the interface group> id=<VLAN-ID> subnet-mask-bits=<Subnet-Mask-Prefix>
```

Example:

```
iris_cli vlan add interface-group=bond0 id=5 subnet-mask-bits=20
```

      b. Use the following command to set the non-native VLAN logical bond interface as primary. Replace vland_id with the ID of the VLAN you added.

```
iris_cli ip config interface-name=<bond0.vland_id> interface-role=primary
```

Example:

```
iris_cli ip config interface-name=bond0.5 interface-role=primary
```

Alternatively, to configure the IP on a new node and access the node using the IP (not required if using Avahi to discover all nodes), use this command:

```
iris_cli ip config interface-name=<bond0.vlan_id> interface-ips=xx subnet-gateway=yy subnet-mask-bits=zz interface-role=primary
```

Example:

```
iris_cli ip config interface-name=bond0.5 interface-
ips=10.5.1.5 subnet-gateway=10.5.0.1 subnet-mask-bits=20
interface-role=primary
```

ii. Through configure_network.sh script

Use `configure_network.sh option 10` to add VLAN and follow the prompts to complete VLAN addition on the desired network bond.

Location: /home/cohesity/bin/network/configure_network.sh

2. Restart the Cluster Manager Services:

```
sudo service nexus restart
```

3. Run `ifconfig` and ensure Avahi runs on the non-native VLAN bonded interface. Cohesity relies on Avahi for node discovery.

Sample output from a node running on the primary non-native VLAN 5

```
bond0.5:avahi: flags=4163<UP,BROADCAST,RUNNING,MULTICAST> mtu 1500
inet 169.254.7.187 netmask 255.255.0.0 broadcast 169.254.255.255
ether a4:bf:01:2d:7e:b2 txqueuelen 1000 (Ethernet)
```

4. On any node in the existing Cohesity cluster, start the node add workflow from the UI and provide Cohesity cluster IPs from the configured non-native VLAN.

> **Note:** If necessary, the user can configure Cohesity cluster IPs and VIPs from the non-native VLAN and keep the IPMI in the native VLAN or some other subnet.

Manage Firewall Rules and Ports

Using the Cohesity Dashboard or CLI, you can configure application-based firewall rules and manage incoming traffic on a Cohesity cluster. For more details, see Manage Application-Based Firewall Rules.

To allow the Cohesity cluster to transmit and receive data, you must open specific ports. For more details, see Manage Firewall Ports.

Manage Application-Based Firewall Rules

Firewall restricts network access and manages inbound traffic on Cohesity cluster. It allows you to secure your cluster from unauthorized access and malicious traffic. Cohesity lets you configure application-based firewall rules using firewall profiles. Firewall profiles are rules that define whether data from specific applications, ports, protocols, and ipsets (source IP address sets) are allowed or denied through one or more interface groups. You can

customize the supported firewall profiles based on your requirements and apply them to one or more interface groups.

> **Note:** Currently, you can apply firewall rules only on the incoming traffic on the Cohesity cluster.

The following table lists the firewall profiles supported on a Cohesity cluster.

Port (Protocol)	Source	Target	Profile	Description
80 (TCP)	Web UI	Cohesity cluster	Management	External management (HTTP/HTTPS) traffic. Configure the firewall settings to allow the VIPs.
443 (TCP)	Web UI	Cohesity cluster	Management	External management (HTTP/HTTPS) traffic. Configure the firewall settings to allow the VIPs.
	Cohesity cluster	Disaster Recovery Cluster	Replication	Required for replication Configure the firewall settings to allow the Cohesity IPs (VIPs or node IPs).

Port (Protocol)	Source	Target	Profile	Description
22 (TCP)	SSH Client	Cohesity cluster	SSH	SSH client. Support Channel used by Cohesity Support for troubleshooting. Configure the firewall settings to allow the Cohesity IPs (VIPs or node IPs).
68 (UDP)	Cohesity cluster	DHCP server	DHCP	DHCP traffic. Configure the firewall settings to allow the VIPs.
11111 (TCP)	Cohesity cluster	Disaster Recovery Cluster	Internal Traffic	I/O Operations Service. Configure the firewall settings to allow the Cohesity node IP addresses and not the VIPs.
111 (TCP/UDP)	Mount target	Cohesity cluster	Data Protection SmartFiles Recovery	NFS restores on Linux physical servers. Configure the firewall settings to allow the VIPs.

Port (Protocol)	Source	Target	Profile	Description
2049 (TCP/UDP)	ESXi host	VIPs and VLAN IPs on Cohesity cluster	Data Protection Recovery	VM restores. Configure the firewall settings to allow the VIPs.
	NFS Clients	Cohesity NFS target	Data Protection SmartFiles	Required for NFS Configure the firewall settings to allow the VIPs.
445 (TCP)	SMB Clients	Cohesity SMB target	Data Protection SmartFiles	Traffic for SMB mount. Configure the firewall settings to allow the VIPs.
3000 (TCP)	S3 Clients	Cohesity cluster	Data Access	Access to Cohesity views using S3 protocol. Configure the firewall settings to allow the VIPs.
11113 (TCP)	Oracle Source (Cohesity Agent)	Cohesity cluster	Backup and Recovery	Source side deduplication for Oracle when using the Remote Adapter RMAN script. Configure the firewall settings to allow the VIPs.

Port (Protocol)	Source	Target	Profile	Description
11117 (TCP)	Backup Target (any port)	Cohesity cluster	Backup	Secure gRPC connections on the cluster from the backup target. Configure the firewall settings to allow the VIPs.
20004 (TCP)	Cohesity cluster	Disaster Recovery Cluster	Replication	Required for replication. Configure the firewall settings to allow the Cohesity node IP addresses and not the VIPs.
20000 (TCP)	Cohesity cluster	Disaster Recovery Cluster	Replication	Interaction handling between Cohesity and target backup systems. Configure the firewall settings to allow the Cohesity node IP addresses and not the VIPs.
161 (UDP), 162 (UDP)	SNMP	Cohesity cluster	SNMP	For SNMP traffic, if the cluster is configured to use SNMP. Configure the firewall settings to allow the VIPs.

Port (Protocol)	Source	Target	Profile	Description
No specific ports	Archival target	Cohesity cluster	Archival	Cohesity cluster uses HTTP/HTTPS to archive data to the target. The connection is not initiated from the archive target to the Cohesity cluster.
27999	Cohesity cluster	Third-Party tools (for example Tableau, SSRS etc.)	Reporting Database	Used for connections to Custom Reporting Database.

Configure Firewall Rules

Using the Cohesity Dashboard or CLI, you can configure firewall rules and apply them to one or more interface groups on a cluster.

> **Note:** If you configure multiple bond interfaces on a cluster for various traffic types, ensure that you configure the same bond interfaces on the free nodes before adding them to the cluster.

To configure firewall rules using the supported profiles:

1. In the Cohesity Dashboard, select **Settings > Networking** and then click the **Firewall** tab.

   The Rules page appears and displays all the supported firewall profiles. By default, all the incoming application traffic listed in the firewall profiles are allowed on all the available interface groups.

2. Click the edit icon ( ).
3. Provide the details in the applicable fields for the application traffic you plan to manage:
   - **Application:** Predefined name of the firewall profile. Specifies an external service or a source of the incoming traffic.
   - **Interface Group:** Select one or more interface groups from the drop-down menu. By default, all the interface groups are selected.

- **Client's IPSet:** Select **Custom IP/Subnet** from the drop-down menu and specify the IP address and subnet mask bits of the source network. You can enter multiple IP addresses and subnet mask sets. For example, 10.1.1.2/24 and 10.2.3.2/16. By default, the **All IP Addresses** option is selected.
- **Action:** Select **Allow** or **Deny** from the drop-down menu to allow or restrict the traffic. By default, the **Allow** option is selected.

4. Optional. Repeat **Step 3** to customize the firewall profiles and manage other network traffic types based on your requirements.
5. Click **Apply** to save the configuration and apply the firewall rules.

Restore Firewall Rules to the Default Settings

If you misconfigured firewall rules or if you want to reset all your firewall settings, you can restore the configured firewall rules to their default settings.

> **Important:** If you restore firewall rules to default, all the configured firewall rules will be lost.

To restore firewall rules to the default settings:

1. In the Cohesity Dashboard, select **Settings > Networking** and then click the **Firewall** tab.

   The Rules page appears and displays all the supported firewall profiles.

2. Click the reset icon (↺).
3. Click **Restore** to confirm the reset operation.

You can also use the Cohesity CLI to configure the firewall rules or restore the rules to their default settings. For more details, see Cohesity CLI Commands Used to Manage Firewall Ports.

Manage Firewall Ports

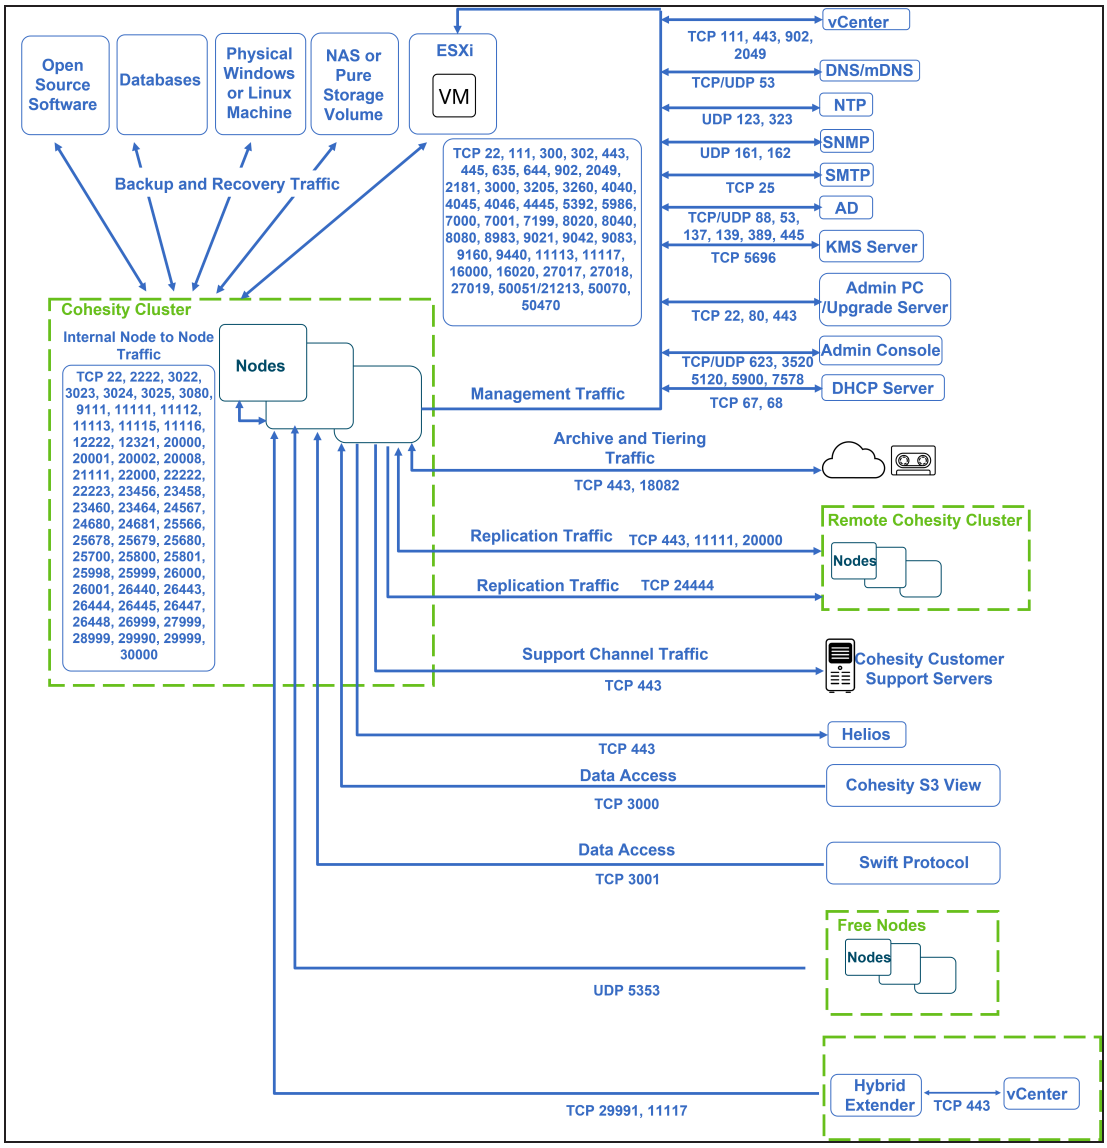
You must open certain ports in the firewall to allow the Cohesity cluster to transmit and receive data. The cluster sends the following types of traffic over the network. You can isolate traffic on physical or logical networks to improve performance and security.

- IPMI traffic for admins to access nodes, typically for pre-boot BIOS access and post-boot console access.
- Management traffic:
  - from Nodes to external services such as Active Directory, DNS, NTP, and SNMP
  - for admins to access the Cohesity cluster
- Backup and restore traffic for moving data between protected sources and the cluster.

- Replication traffic for replicating data from one cluster to another cluster.
- Data access (NAS) traffic for accessing data on the cluster by using protocols such as NFS, SMB, or S3.
- Archive and tiering traffic for moving data to external targets such as a cloud or tape system.
- Support Channel traffic between nodes and the Cohesity Support servers.
- Internal traffic between nodes on a cluster.

> **Note:**
> Note the following when applying firewall rules on a Cohesity cluster:
>
> - Cohesity uses Virtual IPs (VIPs) to manage incoming traffic to the cluster.
> - Cohesity uses Host IPs (node IP addresses) for outgoing traffic and node-to-node communication within the cluster.
> - When setting up replication on a Cohesity cluster, you can specify either the VIPs or node IP addresses of the remote cluster. Cohesity recommends specifying VIPs, as they can failover to other nodes if a node becomes unreachable or goes down.
> - Do not enable Deep Packet Inspection (DPI) for replication workflows and Teleport support traffic, as it can degrade replication performance and impact Teleport functionality.
> - Ensure to have network connectivity between the source and the cluster.

The following diagram shows the port requirements and directional flow for some of the traffic in a typical cluster. More information is provided following the diagram.



Using the Cohesity UI or CLI, you can configure application-based firewall rules and manage incoming traffic on a Cohesity cluster. For more details, see Manage Application-Based Firewall Rules.

Identify Source IP of Outgoing Traffic

The source IP of outgoing traffic depends on the matching static route's outgoing interface. If there is no static route, the source IP depends on the default route's outgoing interface. Use the route list command to view the list of routes configured on an interface in a Cohesity cluster and the IP address of the destination network.

In the following example, the route list command output shows the VLAN interface (intf_group1.100) of a cluster configured with the default route.

```
iris_cli route list
```

```
DEST NETWORK                    : 0.0.0.0/0
```

```
NEXT HOP                        : 10.1.100.1
```

```
INTERFACE GROUP NAME            : intf_group1.100
```

For more details, see Add a Static Route.

Cluster Management

Cluster Upgrade

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Outgoing Traffic

Source	Destination	Destination Port	Protocol	Usage Notes
Cohesity cluster	• https://downloads.cohesity.com/oauth2/login • https://s3-us-west-2.amazonaws.com • Amazon CloudFront CDN (Content Delivery Network) Facility: https://dipowd173xxgy.cloudfront.net/	443	TCP	For cluster upgrade packages. You can select and download the version packages from downloads.cohesity.com, AWS location, or CloudFront site. The cluster upgrade packages are hosted on the Amazon S3 CloudFront server to increase the download speed of release packages.

Agent Upgrade

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes
Client	Cohesity cluster	80,443	TCP	For Agent upgrade from UI.

> **Note:** The ports listed here are designated solely for the initial upgrade of agents from versions older than 7.2.2. For all subsequent upgrades on newer agent versions, only the agent port will be utilized.

Troubleshooting

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes
SSH client	Cohesity cluster	22	TCP	Support Channel used by Cohesity Support for troubleshooting

Networking

Agent Communication

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Outgoing Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity cluster	Cohesity Agent	50051*	TCP	Used for Cohesity Agent and agentless data transfer to the cluster. Needs to be open on all nodes on the cluster and any backup target using the Cohesity Agent, such as SQL servers, physical servers, and VMs running the Cohesity-installed Agent. Cohesity clusters pick any available ephemeral port to initiate communication with the agent service via port 50051. The firewall needs to allow the connection request from the Cohesity nodes if the destination port is 50051.	Backup and Recovery

Network Services

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity cluster	DNS	53	TCP/UDP	DNS, if an external DNS server is configured.	Management
Cohesity cluster	DNS server	5353	UDP	mDNS multicasting.	

Outgoing Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity cluster	External NTP Server (time.google.com)	123	UDP	Requests to external NTP servers are sent via port 123.	Management
		323		• Required for cluster setup. • Chrony is the default implementation of NTP used by recent versions of CentOS, RHEL, and AlmaLinux. Open port 323 if you want to use the chronyc tool to monitor the synchronization status of Chrony and make changes if necessary.	

Bidirectional Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity cluster	Cohesity cluster	123	UDP	Time synchronization among Cohesity nodes during node-to-node communication is implemented via port 123.	Management
Cohesity cluster	DNS	53	TCP/UDP	Required if an internal DNS server is configured.	
Cohesity cluster	Cohesity cluster	5353	UDP	mDNS multicasting.	

Cohesity IPMI Network

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Admin (Browser)	Cohesity IPMI address on each node	80, 443	TCP	Required for HTTP and HTTPS	Management and IPMI
		3520, 5900		Required for IKVM web browser access	

Bidirectional Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity cluster (bond0 on each node)	Cohesity IPMI address on each node	623	UDP	IPMI, Intel standard manageability port.	IPMI
		7578	TCP		
Admin		5120	UDP/TCP	Required for virtual media mount.	

SMB and NFS Media Servers

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
NFS Clients	Cohesity NFS target	2049	TCP	Required for NFS	Data Protection
SMB Clients	Cohesity SMB target	445		SMB filer functionality. SMB and SMB2 restore.	Data Access

NFS For Cohesity Views

Bidirectional Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
NFS Client	Cohesity cluster (with NFS server)	2049 (NFS server), 111 (port mapper)	NFS	Port 111 needs to be open on the NFS client and server. NFS Linux clients do not need any additional configuration on the Cohesity cluster	Required for mounting the Backup and Recovery views.

DHCP Server

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Bidirectional Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity cluster	DHCP Server	67, 68	TCP	Required for DHCP. Required for SMB and ICMP.	Management

SNMP

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
SNMP	Cohesity cluster	161	UDP	SNMP, if the cluster is configured to use SNMP.	Management

Outgoing Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity cluster	Network Management System (NMS)	162	UDP	SNMP, if the cluster is configured to use SNMP traps.	Management

SMTP

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Outgoing Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity cluster	SMTP server	Frequently opened ports on the SMTP server are either 25 or 465 or 587	TCP	Depends on the port setting on the SMTP server. If SMTP opens a random port, the same port must be opened on the Cohesity cluster.	Management

Virtualization

VMware

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
ESXi host	VIPs and VLAN IPs on the Cohesity cluster	111 2049	TCP	Required for VMDK restore with Instant Recovery Required for VMDK Restore Required for Test & Dev clone Required for File Recovery and Instant Volume Mount for Windows VMs when using agent-based recovery.	Recovery

Outgoing Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity cluster	ESXi Host	902	TCP	Ensure that SSL communication for TCP port 902 to the ESXi host is enabled. Otherwise, backups will fail.	Backup and Recovery

Bidirectional Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity cluster	VMware vCenter ESXi Host VMware vCloud Director	443	TCP	The Cohesity cluster uses HTTPS by default. Required for VMware API. Required for VMware Tools-based file and folder recoveries. Required for HTTPS/HTTPS (TLS). Required for VMware vRealize Automation (vRA) and Orchestration (vRO) integration.	Backup and Recovery

Microsoft SCVMM and Hyper-V

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Outgoing Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Windows machine with Cohesity Agent installed	SCVMM	5986	TCP	SCVMM machines can be LOCALHOST or remote targets.	Management
	Hyper-V			The Hyper-V host machine is LOCALHOST.	Backup and Recovery
Cohesity cluster	Host	50051*	TCP	Required for both SCVMM machines and Hyper-V host machines.	Backup and Recovery

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity cluster	Destination or target Windows machine	445 (SMB), 135 (WMI)	TCP	Required for agentless file recovery	Backup and Recovery

Bidirectional Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Host	Cohesity cluster	445	TCP	Required by the Hyper-V host to access SMB data.	Recovery

Nutanix Acropolis

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Data Services IP and IP of all CVMs on the Nutanix cluster and Prism Central.	VIPs and VLAN IPs on the Cohesity cluster	111 2049	TCP	Required for Instant Recovery	Backup and Recovery

Outgoing Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity cluster	Data Services IP and IP of all CVMs on the Nutanix cluster and Prism Central.	9440	TCP	Used for REST API calls	Backup and Recovery
		3205, 3260		iSCSI port for AHV backups.	

RHV

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Bidirectional Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Host	Cohesity cluster	50051*	TCP	Required for RHV host machines.	Backup and Recovery

Instant Volume Mount

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
ESXi host	VIPs and VLAN IPs on Cohesity cluster	111, 2049	TCP	Instant Volume Mount	Recovery

File Restore to Windows VM

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
ESXi host	VIPs and VLAN IPs on Cohesity cluster	111, 2049	TCP	File restore to Windows VM	Recovery

Bidirectional Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Host	Cohesity cluster	50051*	TCP	Required for persistent agent workflow for file-level recovery and IVM.	Recovery

File Restore to Linux VM

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Linux VM	VIPs and VLAN IPs on the Cohesity cluster	111, 2049	TCP	Required for file restore to Linux VM.	Recovery

Bidirectional Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Host	Cohesity cluster	50051*	TCP	Required for Linux VM file restores.	Backup and Recovery

NAS

Isilon

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Bidirectional Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Isilon	Cohesity cluster	111	TCP/UDP	Required for RPC connection.	Backup and Recovery
		300, 302, 304, 2049		Required for NFS.	
		8080		Required for HTTP connection.	
		443	TCP	Required for HTTPS connection with Isilon.	
		445		Required for SMB.	

NetApp

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Bidirectional Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
NetApp	Cohesity cluster	111	TCP/UDP	Required for RPC connection.	Backup and Recovery
		443		Required for HTTPS connection with NetApp.	
		635, 2049, 4045, 4046		Required for NFS.	
		445	TCP	Required for SMB.	
		1052, 10569	TCP	Required for SnapDiff-based backup.	
		3000	TCP	Required by NetApp clusters to write to Cohesity S3 storage during SnapDiff backups.	

Generic NAS

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Bidirectional Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Generic NAS	Cohesity cluster	111	TCP/UDP	Required for RPC connection.	Backup and Recovery
		635 2049		Required for NFS.	
		445	TCP	Required for SMB.	

Pure FlashBlade and IBM Storage FlashSystem

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Bidirectional Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity	Pure Storage	3260, 3205	TCP	iSCSI and FC port for Pure Storage.	Backup and Recovery
Cohesity	IBM Storage FlashSystem	3260, 7443	TCP	3260 port for iSCSI 7443 port for API	Backup and Recovery

Elastifile

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Bidirectional Traffic

Source	Target	Destination Port	Protocol	Usage Notes	Type of Traffic
Elastifile	Cohesity cluster	443	TCP	Required for EMS/API operations.	Backup and Recovery
		111, 2049, 644, 4040, 4045	TCP/UDP	Required for NFS Operations.	

Databases

MS SQL Servers

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Server	Cohesity cluster	445	TCP	Required for SQL servers.	Backup and Recovery
MS SQL server (any port)	Cohesity cluster	11113, 11117		Required for VDI-based backup and restore of the MS SQL database (using RemoteWANSnapFS).	
MS SQL server (any port)	Cohesity cluster	11117		Required for log backup and restore of MS SQL database.	

Oracle

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Oracle Source (Cohesity Agent)	Cohesity cluster	11113	TCP	Source-side deduplication for Oracle when using the Remote Adapter RMAN scriptX. Secure gRPC used by Oracle SBT.	Backup and Recovery
Oracle Source	Cohesity cluster	11117	TCP	Required from 6.8.1_u3 onwards with the introduction of secure gRPC for Oracle SBT.	Backup and Recovery

PostgreSQL

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
PostgreSQL	Cohesity cluster	11113	TCP/IP	Required for physical backups and recovery at the cluster level.	Backup and Recovery

Outgoing Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity cluster	PostgreSQL	50051*	TCP/IP	Required for physical backups and recovery at the cluster level.	Backup and Recovery

SAP HANA

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Incoming Traffic

Source	Destination	DestinatiAon Port	Protocol	Usage Notes	Type of Traffic
SAP HANA	Cohesity cluster	11113	TCP	Access to Cohesity views.	Backup and Recovery

Cassandra

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Outgoing Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity cluster	Cassandra nodes	22	TCP	Required for Cassandra backup. Required for Cassandra optimized restore/DSE 6.x restore.	Backup and restore
		7000		Required for Cassandra bulk restore.	Restore
		7001		Required for Cassandra bulk restore in case of an SSL-enabled cluster.	
		7199		Required for Cassandra repository registration. Required for Cassandra backup (snapshot operation). Required for Fetching Cassandra configurations (list of nodes, token map, etc).	Management
		8983		Required for Cassandra solr index management.	
		9042		Required for Cassandra backup. Required for Cassandra restore. Required for Cassandra source registration.	
		9160		Required for Cassandra bulk restore (DSE 4.x / Cassandra 2.x).	

MongoDB

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Outgoing Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity cluster	MongoDB Nodes	27017, 27018, 27019	TCP	Required for MongoDB backups and recovery.	Backup and Recovery

Open-Source Software Platform

Hadoop - HDFS

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Outgoing Traffic

The following ports must be open to enable communication between Cohesity and **Cloudera Data Platform 7.1.x**. These are the default ports used. Refer the configuration in Cloudera Manager if you have overridden these ports.

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity cluster	Hadoop Primary node	8020	TCP	Required to connect to Namenode through native protocol	Backup and Recovery
Cohesity cluster	Hadoop Primary node	9870	TCP	Required to connect to Namenode through REST APIs (Non-SSL)	Backup and Recovery
Cohesity cluster	Hadoop Primary node	9871	TCP	Required to connect to Namenode through REST APIs (SSL)	Backup and Recovery
Cohesity cluster	Hadoop Primary node	9864	TCP	Required to connect to datanode through REST APIs (Non-SSL)	Backup and Recovery
Cohesity cluster	Hadoop Primary node	9865	TCP	Required to connect to datanode through REST APIs (SSL)	Backup and Recovery
Cohesity cluster	Hadoop Primary node	9866	TCP	Required to connect to datanode through native protocol	Backup and Recovery
Cohesity cluster	Hadoop Primary node	9292	TCP	HTTP port required to connect to KMS	Backup and Recovery
Cohesity cluster	Hadoop Primary node	9494	TCP	HTTPS port required to connect to KMS (SSL)	Backup and Recovery

Hadoop - Hive

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Outgoing Traffic

The following ports must be open to enable communication between Cohesity and **Cloudera Data Platform 7.1.x**.

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity cluster	Hadoop Primary node	9083	TCP	Required to connect to Hive Metastore through the native protocol (Thrift)	Backup and Recovery

Hadoop - HBase

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Outgoing Traffic

The following ports are required for **Cloudera Data Platform 7.1.x**.

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity cluster	Hadoop Primary node	22001	TCP	Required to connect to HMaster through native protocol	Backup and Recovery
Cohesity cluster	Hadoop Primary node	22002	TCP	Required to connect to HMaster through HTTP protocol	Backup and Recovery
Cohesity cluster	Hadoop Primary node	22101	TCP	Required to connect to Region server through native protocol	Backup and Recovery
Cohesity cluster	Hadoop Primary node	22102	TCP	Required to connect to Region server through HTTP protocol	Backup and Recovery
Cohesity cluster	Hadoop Primary node	2181	TCP	Required to connect to Zookeeper service through native protocol	Backup and Recovery

gRPC

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Backup Target (any port)	Cohesity cluster	11117	TCP	Required for secure gRPC connections on the cluster from the backup target.	Backup

Kubernetes

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Kubernetes cluster	VIPs on Cohesity cluster	3000	TCP	Velero S3 communication for metadata backup and restore.	Backup and Recovery

Outgoing Traffic

Source	Destination	Destination Port	Protocol	Usage Notes
Cohesity cluster	Kubernetes cluster api-address	6443	TCP	Kubernetes cluster and Velero API Access. For more details on Velero support, see the Considerations section.
Cohesity cluster	Kubernetes cluster worker nodes	32000	TCP	Cohesity cluster to Cohesity Datamover communication

S3-Compatible Storage

Bidirectional Traffic

Source	Destination	Destination Port	Protocol	Usage Note	Type of Traffic
Cohesity cluster	Dell EMC ECS	9021	TCP	Required for backup	Backup and Recovery
Cohesity cluster	Pure Storage Flashblade	443	TCP	Required for backup	Backup and Recovery
Cohesity cluster	NetApp StorageGrid	443	TCP	Required for backup	Backup and Recovery
Cohesity cluster	IBM Cloud Object Storage	443	TCP	Required for backup	Backup and Recovery

Cloud VMs

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Outgoing Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic

Cohesity cluster	• **AWS**
	  • *amazonaws.com
	• **Azure**
	  • Login.windows.net
	  • management.azure.com
	  • *.blob.core.windows.net
	• **GCP**
	  • *.googleapis.com
		443	TCP	Required for CloudSpin, CloudRetrieve, and Native Snapshot
				XL DataProtect for cloud and DataProtect for cloud deployment.
				Required for HTTPS connections.
					Backup and Recovery

	Fleet instances	50051		Required for CloudSpin to AWS EC2. Required for Native Snapshot backup for AWS/GCP.	
	Cloud Source VMs			Required for file-level recovery from Native Snapshot backup. Required for Agent Protection and Restore for AWS EC2. Required for Agent Protection and Restore for Azure VM.	

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cloud Source VMs	Cohesity Cluster	50051	TCP	Required for file-level recovery from Native Snapshot backup. Required for Agent Protection and Restore for AWS EC2. Required for Agent Protection and Restore for Azure VM.	Backup and Recovery

External Targets

Cloud Workflow

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity cluster	Cohesity cluster	29999	TCP	Required for Archive Services.	Backup and Recover

Outgoing Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic

Cohesity cluster	• **AWS**
	  • *amazonaws.com
	• **Azure**
	  • *.blob.core.windows.net
	  • *vault.azure.net
	• **GCP**
	  • *.googleapis.com
		443	TCP	Required for CloudArchive, CloudTier.	Backup and Recovery

Cohesity S3 View

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity S3 View	Cohesity cluster	3000	TCP	Access to Cohesity views using the S3 protocol.	Data Access

QStar

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Bidirectional Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity cluster	QStar ASM host	18082	TCP	QStar External Target - Port number 18082 is set on the QStar host by default. If your QStar host is not using the default Web Services Port, update the port number. SOAP over HTTPS.	Backup and Recovery

Storage Arrays

Nimble Storage

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Outgoing Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity cluster	Nimble Storage	5392	TCP	REST API	Backup and Recovery
		3260, 3205		iSCSI port for Nimble Storage.	

Pure Storage

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Outgoing Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity	Pure Storage	3260, 3205	TCP	iSCSI port for Pure Storage.	Backup and Recovery
Cohesity	IBM Storage FlashSystem	3260, 7443	TCP	3260 port for iSCSI 7443 port for API	Backup and Recovery

Active Directory

Microsoft Active Directory (RBAC)

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Client	Cohesity	53	TCP/UDP	Serve DNS requests from an external source.	Management
Cohesity cluster	Active Directory	445	TCP	Required only when initially joining the Cluster to Active Directory.	

Outgoing Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity cluster	Kerberos Key Distribution Center (AD)	88	TCP/UDP	Required for Kerberos if the cluster is configured to use Active Directory.	Management
	LDAP	389		Required if the cluster is configured to use Active Directory or LDAP.	Management
	Active Directory	137	UDP	User and Computer Authentication and NetLogon, NetBIOS Name Resolution. Required only when initially joining the Cluster to Active Directory.	Management
		139	TCP	Required only when initially joining the Cluster to Active Directory (for the NetBIOS session service).	Management

Microsoft Exchange Servers

No specific ports need to be opened to protect Microsoft Exchange Servers, provided the following requirements have been met as part of your cluster configuration:

- The ports listed in the Physical Servers section are open to allow communication between your Physical Servers and the Cohesity cluster for backup operations.
- The ports listed in the SMB and NFS Media Servers section are open to allow communication between the Cohesity cluster and SMB clients for recovery operations.
- The ports listed in the Active Directorysection are open to allow communication between the Cohesity cluster and the Active Directory for recovery operations.

Physical Servers

Physical Server Backup

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Bidirectional Traffic

Source	Destination	Destination Port	Protocol	Usage Notes
Mount Target	Cohesity cluster	111	TCP/UDP	NFS restores on Linux physical servers.
Local Host (Physical Windows or Linux Server)	Local Host (Physical Windows or Linux Server)	59999	TCP	Required only if local-to-local communication (used for self-monitoring and debugging purposes) is blocked by your firewall.

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes
Physical Linux Server	Cohesity cluster	111, 2049	TCP	Required for NFS block-based file recovery.
Physical Windows Server	Cohesity cluster	445	TCP	Required for SMB block-based file recovery.

Outgoing Traffic

Source	Destination	Destination Port	Protocol	Usage Notes
Cohesity cluster	Physical Server with Cohesity Agent installed	50051*	TCP	Linux and Windows physical server backups.

Bare Machine Recovery

CBMR

Port	Protocol	Source	Target	Usage Notes
50051*	TCP	Cohesity cluster	Physical server	Backup operations.
111, 2049	TCP	Cohesity cluster	Physical server	NFS restore operations on a Linux server.
445	TCP	Cohesity cluster	Physical server	SMB restore operations on a Windows server.
443	TCP	Recovery environment	Cohesity cluster	To connect the CBMR recovery environment with the Cohesity cluster.
50051*	TCP	Cohesity cluster	Recovery environment	To connect the CBMR recovery environment with the Cohesity cluster.

CoBMR

Port	Protocol	Source	Target	Usage Notes
50051*	TCP	Cohesity cluster	Physical server	Backup operations.
111, 2049	TCP	Cohesity cluster	Physical server	NFS restore operations on a Linux server.
445	TCP	Cohesity cluster	Physical server	SMB restore operations on a Windows server.
443	TCP	Recovery environment	Cohesity cluster	Port 443 is only required to perform a CoBMR recovery. It is not required for backup. You need this port open on the target system to which you are performing the recovery.

Port	Protocol	Source	Target	Usage Notes
50051*	TCP	Cohesity cluster	Recovery environment	To connect the CBMR recovery environment with the Cohesity cluster.

Key Management Service

KMS (Key Management Service)

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Outgoing Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity cluster	SafeNet KeySecure server	5696	TCP	Required if the cluster is configured to use an external Key Management Service (KMS) such as SafeNet KeySecure. 5696 is the default KMIP port, and can be changed when configuring the external KMS. For more information, see External Key Management Service.	Management

OpenStack Integration

Swift Protocol

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Swift Clients	Cohesity cluster	3001	TCP	Access to Cohesity views using the Swift protocol.	Data Access

Helios Ports

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Outgoing Traffic

Source	Destination	Destination Port	Protocol	Usage Notes
Cohesity cluster	https://helios.cohesity.com https://helios-data.cohesity.com	443	TCP	SSL connection for Cohesity Support telemetry upload. Standard Helios traffic is sent to helios.cohesity.com. Query and API call traffic is sent to helios-data.cohesity.com.

Bidirectional Traffic

Source	Destination	Destination Port	Protocol	Usage Notes
Cohesity cluster	https://helios.cohesity.com https://helios-data.cohesity.com	30005	TCP	Cluster connects to Helios through this port and uses it to send and receive data

DataHawk App

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Outgoing Traffic

Source	Destination	Destination Port	Protocol	Usage Notes
Cohesity cluster	helios-data2.cohesity.com	443	TCP	Heartbeats and telemetry from the DataHawk app to Cohesity Helios.
Cohesity cluster	helios-dc3p.cohesity.com			Classification of heartbeats, telemetry, and results from the DataHawk app to Cohesity Helios.

MarketPlace Apps

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
HTTP client	Cohesity cluster	61001 through 63786	TCP	Used for Cohesity MarketPlace Apps, which are available from the MarketPlace and Helios. One port is dynamically assigned from this range for the user interface of each app instance.	Management

Multitenancy

Hybrid Extender

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Hybrid Extender	DNS	53	TCP/UDP	DNS, if an external DNS server is configured.	Management
Client	Hybrid Extender	53		Serve DNS requests from an external source.	Management

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
SSH client	Hybrid Extender	22	TCP	Required for SSH server on Bifrost VM for Bifrost-RT	Management
Server	Hybrid Extender	445		Required for SQL servers.	Backup and Recovery
MS SQL server (any port)	Hybrid Extender	11113, 11117		VDI-based backup and restore of MS SQL database (using RemoteWAN SnapFS)	Backup and Recovery
MS SQL server (any port)	Hybrid Extender	11117		Required for log backup and restore of the MS SQL database.	Backup and Recovery
Hybrid Extender	Organization (Tenant)	29994		The internal port used on the organization's network for debugging and uploading the configuration file on the Hybrid Extender VM.	Management
NFS Clients	Hybrid Extender NFS target	2049		Required for NFS	Data Protection
SMB Clients	Hybrid Extender SMB target	445		SMB filer functionality. SMB and SMB2 restore.	Data Access
Linux VM	Hybrid Extender	111, 2049		File restore to Linux VM	Recovery
Hybrid Extender	Cohesity Cluster	11117		Required for Hybrid Extender with Oracle SBT	Backup and Recovery
ESXi host	Hybrid Extender	111, 2049		File restore to Windows VM	Recovery

Outgoing Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Hybrid Extender	NTP Server	123	UDP	NTP, if an external NTP server is configured.	Management
HTTP client	Hybrid Extender	80	TCP	HTTP	Management
Hybrid Extender	ESXi Host	902		Ensure that SSL communication for TCP port 902 to the ESXi host is enabled, otherwise, backups will fail.	Backup and Recovery
Hybrid Extender	Active Directory	137	UDP	User and Computer Authentication and NetLogon, NetBIOS Name Resolution. Required only when initially joining the Cluster to Active Directory.	Management
Hybrid Extender	Active Directory	139	TCP	Required only when initially joining the Cluster to Active Directory (for the NetBIOS session service).	Management
Hybrid Extender	Active Directory	445		Required only when initially joining the Cluster to Active Directory.	Management
Hybrid Extender	Kerberos Key Distribution Center (AD)	88	TCP/UDP	Required for Kerberos if the cluster is configured to use Active Directory.	Management
Hybrid Extender	LDAP	389		Required if the cluster is configured to use Active Directory or LDAP.	Management
	LDAPS	636			

Bidirectional Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Hybrid Extender	DHCP Server	67, 68	TCP	DHCP. SMB/ICMP	Management
Hybrid Extender	VMware vCenter VMware Standalone ESXi Host VMware vCloud Director	443	TCP	The Cohesity cluster uses HTTPS by default. Required for Pure FlashBlade Required for HTTPS/HTTPS(TLS).	Backup and Recovery
Hybrid Extender	Cohesity cluster	29991	TCP	Used in a multi-tenant environment for interaction between the Hybrid Extender and Cohesity cluster.	Management
Hybrid Extender	Isilon	111	TCP/UDP	Required for RPC connection.	Backup and Recovery
		300, 302, 304, 2049		Required for NFS.	
		443	TCP	Required for HTTPS connection with Isilon.	
		445	TCP	Required for SMB.	
		8080	TCP/UDP	Required for HTTP connection.	
Generic NAS	Hybrid Extender	111	TCP/UDP	Required for RPC connection.	Backup and Recovery
		445	TCP	Required for SMB.	
		635, 2049	TCP/UDP	Required for NFS.	

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Mount Target	Hybrid Extender	111	TCP/UDP	NFS restores on Linux physical servers.	Backup and Recovery
Host	Hybrid Extender	50051*	TCP	Linux and Windows physical server backups. Use Node IP. If VLANs are configured, use VLAN VIPs.	Backup and Recovery
Hybrid Extender	Cohesity cluster	29991	TCP	For the Oracle Adapter, need this port for communication, and NFS ports for mounting the Backup/Recovery Views.	Backup and Recovery.
Host	Hybrid Extender	50051	TCP	Required for persistent agent workflow for file-level recovery and IVM.	Recovery

Cohesity Node Detection

Cohesity Node Detection

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes	Type of Traffic
Cohesity cluster node or free node	Cohesity cluster	5353	UDP	Used for node discovery during cluster creation and code addition.	Management

Cohesity Support

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Outgoing Traffic

> **Note:** Make sure your network team has unblocked and is not monitoring the Cohesity support channel sites or ports for seamless connectivity and effective communication.

Source	Destination	Destination Port	Protocol	Usage Notes
Cohesity cluster	support-connect-v1.cohesity.com	443	TCP	For establishing an SSH reverse tunnel to the Support Channel server. Ensure to disable the SSL/TLS certificate inspection on the firewall.
	support-connect-trust-v1.cohesity.com	443	TCP	For establishing a secure tunnel for connecting to the Support Channel server. Ensure to disable the SSL/TLS certificate inspection on the firewall.
	Cohesity cluster	3022, 3023, 3024, 3025, 3080	TCP	The primary node of the Cohesity cluster connects to the Support Channel server, and the other nodes use these ports to communicate with the primary node. For more information, see Manage the Support Channel.

Internal Traffic

Internal Traffic Between Nodes

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Incoming Traffic

Source	Destination	Destination Port	Protocol	Usage Notes
Cohesity cluster	Cohesity cluster	2222	TCP	As the support user, access the Host Shell via port 2222. Enabling Host Shell access requires generating and sharing the Support Token with Cohesity Support. For details, see Using the Secure Shell.
Cohesity cluster	Cohesity cluster	9111	TCP	Serviceability Service
Cohesity cluster	Cohesity cluster	11112	TCP	I/O Operations Service (Low Latency)
Cohesity cluster	Cohesity cluster	11115	TCP	Archive Helper Service
Cohesity cluster	Cohesity cluster	11116	TCP	I/O Operations Helper Service
Cohesity cluster	Cohesity cluster	11121	TCP	For Fusion FS server
Cohesity cluster	Cohesity cluster	12222	TCP	Distributed Key-Value Store Service

Source	Destination	Destination Port	Protocol	Usage Notes
Cohesity cluster	Cohesity cluster	12321	TCP	Distributed Key-Value Store Helper Service
Cohesity cluster	Cohesity cluster	20001	TCP	NAS Backup Helper Service
Cohesity cluster	Cohesity cluster	20002	TCP	SMB Backup Helper Service v1
Cohesity cluster	Cohesity cluster	20008	TCP	Bandwidth Throttling for Archive Services
Cohesity cluster	Cohesity cluster	21111	TCP	Alert Service
Cohesity cluster	Cohesity cluster	22222	TCP	Cluster Configuration Manager Service
Cohesity cluster	Cohesity cluster	22223	TCP	Cluster Configuration Manager Service
Cohesity cluster	Cohesity cluster	23458	TCP	Cluster Health Monitor Service
Cohesity cluster	Cohesity cluster	23460	TCP	Support Automation & Proactive Wellness Service
Cohesity cluster	Cohesity cluster	24567	TCP	UI and REST API Helper Service
Cohesity cluster	Cohesity cluster	24680	TCP	Healer and Space Reclamation Service
Cohesity cluster	Cohesity cluster	25566	TCP	Cluster Metrics Service
Cohesity cluster	Cohesity cluster	25678	TCP	Hardware and Health Monitor Service

Source	Destination	Destination Port	Protocol	Usage Notes
Cohesity cluster	Cohesity cluster	25679	TCP	Hardware and Health Monitor Helper Service
Cohesity cluster	Cohesity cluster	25680	TCP	Cluster Metrics Store Service
Client	Cohesity cluster	25700	TCP	Indexing Service
Cohesity cluster	Cohesity cluster	25800	TCP	Indexing Service
Cohesity cluster	Cohesity cluster	25801	TCP/UDP	Analytics & Indexing Service
Cohesity cluster	Cohesity cluster	25998	TCP	Marketplace Apps Service
Cohesity cluster	Cohesity cluster	25999	TCP	Indexing Helper Service
Cohesity cluster	Cohesity cluster	26000	TCP	Index Catalog Service v2
Cohesity cluster	Cohesity cluster	26001	TCP	Index Catalog Service v1
Cohesity cluster	Cohesity cluster	26440	TCP	Kubernetes Infra Management API Server
Cohesity cluster	Cohesity cluster	26443	TCP	Kubernetes API Server Load Balancer
Cohesity cluster	Cohesity cluster	26444	TCP	Kube Lifecycle Manager Service Peer Communication
Cohesity cluster	Cohesity cluster	26445	TCP	Kube Lifecycle Manager Service Client Communication

Source	Destination	Destination Port	Protocol	Usage Notes
Cohesity cluster	Cohesity cluster	26447	TCP	Kubernetes API Server
Cohesity cluster	Cohesity cluster	26448	TCP	Kubelet API
Cohesity cluster	Cohesity cluster	26999	TCP	Reporting Service
Cohesity cluster	Cohesity cluster	27999	TCP	Reporting Service PostgreSQL
Cohesity cluster	Third-Party tools (for example: Tableau, SSRS etc.)		TCP	Used for connections to the Custom Reporting Database.
Cohesity cluster	Cohesity cluster	29999	TCP	Required for Archive Services
Cohesity cluster	Cohesity cluster	30000	TCP	Required for applying a patch.

Outgoing Traffic

Source	Destination	Destination Port	Protocol	Usage Notes
Cohesity cluster	Cohesity cluster	3022, 3023, 3024, 3025, 3080	TCP	For the Cohesity cluster to communicate with the Teleport support server. Make sure the Support Channel is enabled for the cluster (**Settings** > **Summary**).
Cohesity cluster	Cohesity cluster	22222	TCP	For Cohesity cluster Cloud Edition operations.

Bidirectional Traffic

Source	Destination	Destination Port	Protocol	Usage Notes
Cohesity cluster	Cohesity cluster	22	TCP	Support Channel used by Cohesity Support for troubleshooting.
Cohesity cluster	Cohesity cluster	11113	TCP	Source-side Deduplication Service
Cohesity cluster	Cohesity cluster	22000	TCP	Key Management Service
Cohesity cluster	Cohesity cluster	23456	TCP	Cluster configuration and cluster management traffic
Cohesity cluster	Cohesity cluster	23464	TCP	
Cohesity cluster	Cohesity cluster	28999	TCP	Reporting Service
Cohesity cluster	Cohesity cluster	29990	TCP	Hybrid Extender Service

Cluster-to-Cluster Traffic

> **Note:** If the Cohesity cluster uses an interface with the node IP address to reach the external server or client, configure the firewall settings to allow the node IP addresses. If the Cohesity cluster uses an interface with only virtual IP addresses, configure the firewall settings to allow the virtual IP addresses. To identify whether the source IP is a Static IP or Virtual IP for outgoing traffic, see Identify Source IP of Outgoing Traffic.

Bidirectional Traffic

Source	Destination	Destination Port	Protocol	Usage Notes
Cohesity cluster	Remote Cohesity cluster (target or receiving)	443	TCP	Required for replication pairing and ongoing secure communications between replication pairs.
Cohesity cluster	Remote Cohesity cluster (target or receiving)	11111	TCP	Required for I/O Service between all nodes and replication pairs when replication is enabled.
Cohesity cluster	Remote Cohesity cluster (target or receiving)	23335	TCP	If both the local and remote Cohesity clusters support TLS, port number 23335 is utilized for TLS communication during replication.
Cohesity cluster	Remote Cohesity cluster (target or receiving)	20000	TCP	• Required for replication. • Required for interaction handling between Cohesity and target backup systems.

Outgoing Traffic

Source	Destination	Destination Port	Protocol	Usage Notes
Cohesity cluster	Remote Cohesity cluster (target or receiving)	24444	TCP	Required for Health Check when replication is enabled on the Cohesity cluster

*Although Cohesity uses port 50051 by default, it is not exclusively reserved for Cohesity. If a conflicting application is already using 50051, then as an alternative, you can use port 21213, which is reserved for Cohesity by IANA's service registry.

Note that using port 21213 is an early access feature. To enable this feature, contact Cohesity account team. Only add 21213/tcp to your firewalls if you have enabled this feature, to avoid requesting unnecessary firewall rules from your network, firewall, or security teams.

Cohesity CLI Commands Used to Manage Firewall Ports

For on-premises clusters, you can use the following Cohesity CLI commands to manage the cluster firewall configuration. For more information, see Using the Cohesity CLI and List of Cohesity CLI Commands.

The firewall commands use the following terminology: Active Cohesity rules are called *attachments*. An attachment includes a *profile* and multiple *ipsets*. A profile is a group of TCP or UDP ports. An ipset is a subnet with the format of <IP/prefix>. An attachment can be on one or more specific network interfaces, or it can apply to all interfaces when no interface is specified.

CLI Command	Description
firewall-profile activate	Activates a profile on a list of interfaces with a list of ipsets.
firewall-profile add	Adds a collection of service ports with the protocol of each port for the firewall.
firewall-profile deactivate	Deactivates a list of active firewall profiles.
firewall-profile delete	Removes a list of firewall profiles.
firewall-profile list	Lists the groups of firewall profiles.

CLI Command	Description
firewall-profile list-active	Lists all the active firewall profiles. Each attachment activates a profile on specific network interfaces and ipsets.
firewall-ipset list	Lists the IP sets for a firewall.
firewall-profile activate revert-to-default	Reverts all the firewall rules to the default settings.

To list the parameters for each command, type `help` after the `firewall-profile <option>` or `firewall-ipset <option>`. For example:

```
admin@node-1> firewall-profile activate help
```

Access Management

Cohesity Access Management ensures secure and efficient access control by allowing only authorized users to interact with specific resources. It is designed to enforce User Authentication, Authorization, Access Control, and Security Settings, ensuring users have the necessary permissions to perform their roles.

The Users & Groups tab in the Access Management page lists all local users, Active Directory users, and SSO users and groups that can access the Cohesity cluster. Administrators can assign roles to users and groups to grant specific privilege levels. For detailed instructions, see Users and Groups. You can also edit or delete existing users.

Key Components of Access Management

User Authentication and Authorization

User and Group Management: Administrators can create and manage user accounts and groups, specifying roles and permissions that determine access levels to various Cohesity resources.

Role-Based Access Control (RBAC): Organization admins can add and manage users through role-based access controls (RBAC). Applying principles of least privilege and separation of duties is simple with fine-grained control over standard and custom defined roles.

Multi-Factor Authentication (MFA): Multi-factor Authentication (MFA) is an additional layer of security used to verify the identity of a user. Cohesity strongly recommends enabling Multi-factor Authentication for Local and Active Directory Users for all users and groups for enhanced security. After the administrator enables MFA, users are prompted for an additional authentication factor along with the Cohesity cluster user credentials during the sign-in process.

Single Sign-On (SSO): Streamlines the login process by allowing access to all the Cohesity resources with a single set of credentials, reducing the risk of password fatigue and enhancing user convenience. For more information, see Single Sign-On (SSO).

Users and Groups

Cohesity allows adding users with different privileges by assigning them various roles within the cluster. These users and groups can manage data and view statistics based on their assigned roles.

Cohesity supports the following types of users and groups. Except for the **support** user, all user types can log in to the Cohesity Dashboard to manage data on the Cohesity cluster and view statistics, depending on their role.

- **Local users:** Local users exist on the Cohesity cluster only.
- **Local groups:** You can define groups by adding local users and Active Directory principals.
- **SSO users:** If the Cohesity cluster is configured to use an identity provider for single sign-on access, you can add SSO users and assign them roles. For more information, see SSO Users.
- **Active Directory principals:** If the Cohesity cluster is joined to an AD domain, you can assign roles to principals in the AD or the AD's trusted domains, which determine the Cohesity cluster access. For more information, see Active Directory (AD).
- **Support user:** Used to access the bash shell of the Cohesity cluster using SSH. The support user account is disabled by default. For more information, see Manage Support User.

Types of Users and Groups

Local Users

Local users are exclusive to the Cohesity cluster. They can be created and managed directly within the system.

Add or Edit a Local User

1. Navigate to **Settings > Access Management**.

   In the **Users & Groups** tab, from the **Add AD Users & Groups** drop-down list, select **Add Local User**, or click the action menu and select **Edit** to edit a local user.

2. Enter the following information:

Add Local User	Enter the user name. Do not enter whitespace characters such as spaces. Do not specify any of these characters: `/ < > : #`
Email Address	Enter the email address associated with this user.
Password	Enter a password that is at least eight characters.
Confirm Password	Enter the same password again to confirm.
Groups	Add the user to one or more user groups by selecting the groups from the drop-down list
Roles	(Optional) Select the appropriate roles. For a detailed description of each role, see Manage Roles.
Effective Date	Specify the date that the user can begin using the account.
Expiration Date	Specify the date when the user's access will be revoked.

Restrict access to specific Objects	Optionally restrict access to specific Objects and Views only by toggling this option on. By default, the allowed actions apply to all Source Objects registered with the Cohesity cluster and all Views. After restricting access, you must specifically add Objects and Views through **Add Registered Object(s)** and **Add Cohesity View(s)**. The user or group does not have access to any Objects or Views until you add them. When a user has access to an Object, that user also has access to all previous Snapshots of that Object and any Objects added to the selected Source folder in the future. For example, if a user has access to an ESX host, they will also have access to VMs added to the host later. Users that have access restricted to specific Objects cannot modify users or Sources even if their role grants them these privileges. Object permissions are replicated for Virtual Machine Objects but not currently for physical Server and View Objects. The Object permissions for a local user or group are not replicated to the remote Cohesity cluster. Local users inherit the permissions of the Restricted Objects provided to the Restricted Groups to which the users belong. Users that have access restricted to specific objects cannot update the Protection Group created by an admin user even if the restricted user has access to all the objects in the Protection Group.
Set Primary User Group for File Access	Enable this option for the user to access file services. From the **Primary Group** drop-down list, select a group as a Primary group. The user can be a part of one or more groups and the SMB/NFS protocol requires a primary group to access the files.

3. Click **Add** or **Save Changes** if editing a user.

Local Groups

Local groups consist of local users and Active Directory (AD) principals. These groups can be defined and managed within the Cohesity cluster.

Add or Edit a Local Group

1. Navigate to **Settings > Access Management**.
2. In the **Users & Groups** tab, from the **Add Users & Groups** drop-down list, select **Add Local Group**, or click the action menu and select **Edit** for a local group.

3. Enter the following information:

Group Name	Enter the group name. Do not enter whitespace characters such as spaces. Only letters, numbers and the special characters given below are allowed: _ - .
Local User	Add one or more users to the group by selecting the users from the drop-down list.
Roles	Select the appropriate roles from the drop-down list. For more information on roles, see Manage Roles.
Effective date	Specify the date when the user group can begin using the account
Restrict access to specific Object	Optionally restrict access to specific Objects and Views only by toggling this option on. By default, the allowed actions apply to all Source Objects registered with the Cohesity cluster and all Views. After restricting access, you must specifically add Objects and Views through **Add Registered Object(s)** and **Add Cohesity View(s)**. The user or group does not have access to any Objects or Views until you add them. When a user has access to an Object, that user also has access to all previous Snapshots of that Object and any Objects added to the selected Source folder in the future. For example, if a user has access to an ESX host, they will also have access to VMs added to the host later. Users that have access restricted to specific Objects cannot modify users or Sources even if their role grants them these privileges. Object permissions are replicated for Virtual Machine Objects but not currently for physical Server and View Objects.
Set Primary User Group for File Access	Enable this option for the user to access file services. From the **Primary Group** drop-down list, select a group as a Primary group. The user can be a part of one or more groups and the SMB/NFS protocol requires a primary group to access the files.

4. Click **Add**, or **Save Changes** if editing a group.

Add a Local Administrator Group Using the CLI

You can use local administrator groups to grant SMB access to views and/or administrative access to the Cohesity cluster.

The Cohesity cluster has a built-in local administrators group called Administrators. By default, the group has only SMB Security privileges and the standard Windows administrator Security ID (SID) S-1-5-32-544. You can use and modify the Administrators group, or create your own local administrator groups and assign roles and SIDs by using the Cohesity CLI.

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. Use the following command syntax to add a local administrator group.

   ```
   group add name=<group-name> smb-only=true roles=<cohesity_roles>
   ```

   (You can use the `role list` command to list the roles defined in the Cohesity cluster.)

   For example:

   ```
   admin@node1> group add name=admin2 smb-only=true roles=cohesity_admin
   GROUP NAME                    : admin2
   DOMAIN                        : LOCAL
   ROLES                         : COHESITY_ADMIN
   SMB PRINCIPAL ENABLED         : true
   ```

Use the following command syntax to add a user or group.

```
group add-smb-principal name=<group_name> type=<user or group> domain=<AD_
domain> principal-name=<user or group> sid=<SID>
```

For example:

```
admin@node1> group add-smb-principal name=admin2 type=group
domain=myorg.ad.domain.com principal-name=PIMS sid=S-1-5-21-4152169185-
4221176486-4244366766-1001
GROUP NAME                    : admin2
DOMAIN                        : LOCAL
ROLES                         : COHESITY_ADMIN
SMB PRINCIPAL ENABLED         : true
SMB PRINCIPAL                 :
NAME                          : PIMS
DOMAIN NAME                   : myorg.ad.domain.com
SID                           : S-1-5-21-4152169185-4221176486-4244366766-
1001
TYPE                          : group
```

> **Tip:** Use the CLI Help by running the following command: `group add-smb-principal help`.

CLI Option	Example	Description
`domain=`	`org.ad.domain.com`	Optional. The AD domain name that includes the principal you are adding.
`name=`	`admin2`	Required. Your choice of a name for the local administrator group.
`principal-name=`	`group1` `jsmith`	Optional. The name of the SMB principal user or group. The name must exist in the AD domain.
`sid=`	`S-1-100-21-8372`	Optional. A unique Security ID for the principal.
`type=`	`group` or `user`	Optional. Specify `user` or `group` to indicate the type of principal you are adding.

Enable User Account Lockout

The admin user can enable account lockout on the user account. User accounts can get locked after a threshold number of failed login attempts. The user cannot log in to the Cohesity Dashboard after three consecutive invalid login attempts for 15 minutes.

> **Note:** You can enable account lockout only for non-admin local users.

Perform the following steps to enable user account lockout:

1. Navigate to **Settings > Access Management**.
2. Select the **Users & Groups** tab.
3. Select the user, click the actions menu (⋮) and select **Lock**.

Disable User Account Lockout

The admin user can disable the account lockout on a user account.

Perform the following steps to disable user account lockout:

1. Navigate to **Settings > Access Management**.
2. Select the **Users & Groups** tab.
3. Select the user, click the actions menu (⋮) and select **Unlock**.

Delete Users and Groups

You can delete users and groups.

> **Note:** You cannot delete default users and groups.

Perform the following steps to delete user and group:

1. Navigate to **Settings > Access Management**.
2. Select the **Users & Groups** tab.
3. Select the user, click the actions menu (⋮) and select **Delete**.
4. Click **Delete**.

Change Local User Password

Using the Cohesity Dashboard, you can change your local user password. By default, the new password must replace at least eight characters with the current password.

Using the following Cohesity CLI command, you can define the number of characters you have to replace in your existing local user password:

```
iris_cli security-config update num-diff-chars=<number_of_characters>
```

For example:

If you want to restrict those six characters in your existing local user password must be replaced while changing the password, then use the following command:

```
iris_cli security-config update num-diff-chars=6
```

> **Note:** The restriction is not applicable if the admin user wants to change the password of other local users in the Cohesity cluster.

To change the local user password:

1. Navigate to **Settings** > **Access Management**.
2. Click the actions menu (⋮) next to the user and click **Edit**.
3. In the **Edit Local User: <user>** page:
    1. Enable **Change Password**.
    2. Enter the **Current Password** and then enter and confirm the new **Password**.
    3. Click **Save Changes**.

SSO Users

Single sign-on (SSO) users are added if the Cohesity cluster is configured to use an identity provider for SSO access. These users can be assigned roles within the cluster.

Add SSO Users

You can add single sign-on (SSO) users only if the Cohesity cluster is configured to use an identity provider. For more information, see Single Sign-On (SSO).

> **Note:**
> - SSO users can authenticate to the cluster either through the authorization of groups, default roles, or roles assigned to them. But they cannot access the apps on the cluster since their identity cannot be verified by the IDP.
> - When a user tries to access the app, a token is obtained for that user.
> - The identity can be verified only for LOCAL and AD domain users. It cannot be done for SSO users since IDP supports only SAML. For more information on how to make the apps accessible to SSO users, see the Giving App access to SSO users KB article.

1. Navigate to **Settings > Access Management**.
2. In the **Users & Groups** tab, from the **Add AD Users & Groups** drop-down list, select **Add SSO Users & Groups**, or click the action menu and select **Edit** for an SSO user.

3. Enter the following information:

SSO Domain	Select the SSO domain from the drop-down list.
SSO Users	Type the SSO user names.
SSO Groups	Type the SSO group names.
Roles	Select the appropriate roles. For a detailed description of each role, see Manage Roles.
Description	Optionally add a description.
Restrict access to specific Objects	Optionally restrict access to specific Objects and Views only by toggling this option on. By default, the allowed actions apply to all Source Objects registered with the Cohesity cluster and all Views. After restricting access, you must specifically add Objects and Views through **Add Registered Object(s)** and **Add Cohesity View(s)**. The user or group does not have access to any Objects or Views until you add them. When a user has access to an Object, that user also has access to all previous Snapshots of that Object and any Objects added to the selected Source folder in the future. For example, if a user has access to an ESX host, they will also have access to VMs added to the host later. Users that have access restricted to specific Objects cannot modify users or Sources even if their role grants them these privileges. Object permissions are replicated for Virtual Machine Objects but not currently for physical Server and View Objects. The Object permissions for a local user or group are not replicated to the remote Cohesity cluster.

4. Click **Add**, or **Save Changes** if editing a group.

Active Directory Users and Groups

An Active Directory User is an account that is stored and managed within an Active Directory domain. This user can be authenticated and authorized to access various resources within the domain, including the Cohesity cluster.

Add Active Directory Users and Groups

1. Navigate to **Settings > Access Management**.
2. Click **Add AD Users & Groups** and select **Active Directory Users & Groups**.
3. Enter the following information:

Active Directory Domain	Select the Active Directory domain or a trusted domain that contains the users and groups to assign roles to.
User(s) or Group(s)	Select the AD users or groups to assign roles to. .
Roles	Select the appropriate roles. For a detailed description of each role, see Manage Roles.
Restrict access to specific Objects	Optionally restrict access to specific Objects and Views only by toggling this option on. By default, the allowed actions apply to all Source Objects registered with the Cohesity cluster and all Views. After restricting access, you must specifically add Objects and Views through **Add Registered Object(s)** and **Add Cohesity View(s)**. The user or group does not have access to any Objects or Views until you add them. When a user has access to an Object, that user also has access to all previous Snapshots of that Object and any Objects added to the selected Source folder in the future. For example, if a user has access to an ESX host, they will also have access to VMs added to the host later. Users that have access restricted to specific Objects cannot modify users or Sources even if their role grants them these privileges. Object permissions are replicated for Virtual Machine Objects but not currently for physical Server and View Objects. When Snapshots are replicated from a local to a remote Cohesity cluster, the Object permissions for AD users or groups are also replicated. However, the privileges for an AD user or group are not replicated. For example, if an AD user called Fred has permission to access the Virtual Machines called VM1, VM2 and VM3 on the local Cohesity cluster, when Snapshots of those Virtual Machines are replicated to a remote Cohesity cluster, those Object permissions are also replicated. However, an administrator on the remote Cohesity cluster must add the AD User called Fred or an AD group that includes Fred and grant him privileges so Fred can access and recover from Snapshots of these VMs on the remote Cohesity cluster. AD users inherit the permissions of the Restricted Objects provided to the Restricted AD Groups to which the users belong.
Description	Optionally add a description.

Role and privilege updates for currently logged-in users take effect after logging out and logging in again. Updates for users that are not currently logged in take effect when they log in.

Support User

The support user account is designed for accessing the bash shell of the Cohesity cluster through SSH for troubleshooting and support purposes. This account is disabled by default for security reasons.

Manage Support User

Cohesity provides a support user account for improved security and you need to use the support user account to log in to the Cohesity cluster bash shell using SSH.

By default, the support user account is disabled on the Cohesity node that is part of a Cohesity cluster. You need to enable the support user account by setting a password for the user account in the Cohesity Dashboard. Also, you can Enable Linux Sudo Access for the support user account.

Set the Support User Password for the First Time

Using the Cohesity Dashboard or Cohesity CLI, you can set the password for the support user. You cannot retrieve the password once it is set. Therefore, ensure that you set a strong password that is longer and easy to remember. In case, if you want to reset the support user password and have forgotten the existing password then contact Cohesity Support.

Perform the following steps to set the support user password:

1. In the Cohesity Dashboard, select **Settings > Access Management** and click the **Support** tab.
2. Under **Linux Shell Password**, click **Set Password** and perform the following steps:
    a. In the **New Password** field, enter the new password. The password requirements are:
        - Must be at least 15 characters long.
        - Must contain at least one digit, one special character, one uppercase & one lowercase character.

          > **Note:** Do not use `!`, `` ` ``, `"` and `\`.

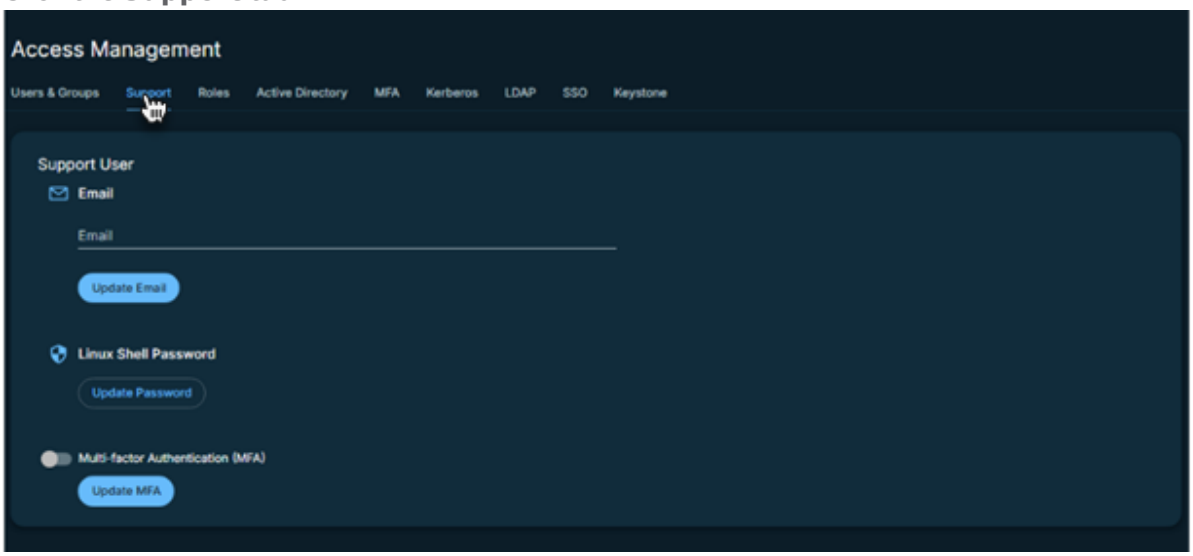
        - Do not use more than two of the same characters in a row. For example, 123aa is allowed. 123aaa is not allowed.
        - Do not use more than four identical consecutive character types (digit, special character, uppercase and lowercase character). For example, 123aa is allowed. 12345aa is not allowed.
    b. In the **Confirm Password** field, enter the new password.
    c. Click **Set**.

> **Note:** By default, the support user logs in to the secure shell and access to the host shell is restricted through SSH. For more information on how to enable host shell access using the support user account, see Enable Host Shell Access.

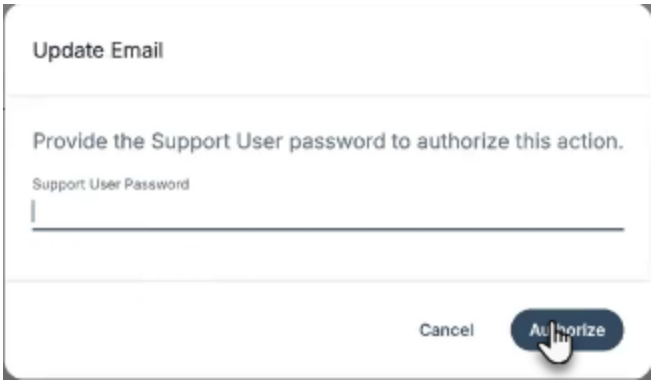
Add Support User Email Address

Perform the following steps to add the support user email address:

1. In the Cohesity Dashboard, select **Settings > Access Management**.
2. Click the **Support** tab.



3. In the **Email** field, enter the email address and click **Update Email**.
4. In the **Update Email** pop-up window that appears, enter the support user password and click **Authorize**.



Change the Support User Password

Perform the following steps to change the support user password:

1. In the Cohesity Dashboard, select **Settings > Access Management**.
2. Click the **Support** tab.
3. Under **Linux Shell Password**, click **Update Password**.
4. Specify the current and the new password for the support user account and click **Update**.

In case, if you have forgotten the current password, contact Cohesity Support to reset the password.

Also, from the Cohesity CLI, you can use the following iris_cli command to change the support user password:

```
iris_cli user linux-user current-password=<current-password> linux-user-name=support linux-password=<new-password>
```

Enable or Disable Multi-factor Authentication

Multi-factor Authentication (MFA) is an additional layer of security used to verify the identity of a user. Cohesity supports MFA for the support user account. MFA enforces users to provide an additional authentication factor to access the Cohesity Dashboard or Cohesity CLI. For more information, see Multi-factor Authentication for the Support User Account.

Modify User Settings

Cohesity allows you to modify user settings such as email, password, and language preferences.

You can perform the following steps to edit the user settings:

1. In the Cohesity Dashboard, click the user icon ( ) > **User Settings**.
2. Enter the following information:

Field	Description
Email	Enter the email address associated with this user.
Change Password	Toggle on the setting to change the password.
Current Password	Enter the current password.
Password	Enter a new password that is at least eight characters.
Confirm Password	Enter the new password again to confirm.
Roles	Select the appropriate roles. For a detailed description of each role, see Manage Roles.
Description	Optionally enter a description

Field	Description
Language	Select the preferred language. The available options are: • English (US) • Japanese (JP)
Restrict access to specific Objects	Optionally restrict access to specific Objects and Views only by toggling this option on. By default, the allowed actions apply to all Source Objects registered with the Cohesity cluster and all Views. Object permissions are replicated for Virtual Machine Objects but not currently for physical Server and View Objects. The Object permissions for a local user or group are not replicated to the remote Cohesity cluster. Users that have access restricted to specific Objects cannot modify users or Sources even if their role grants them these privileges. Local users inherit the permissions of the Restricted Objects provided to the Restricted Groups to which the users belong.
Add Registered Object(s)	Click this option to add Objects. The user or group does not have access to any Objects until you add them. When a user has access to an Object, that user also has access to all previous Snapshots of that Object and any Objects added to the selected Source folder in the future. For example, if a user has access to an ESX host, they will also have access to VMs added to the host later
Add Cohesity View(s)	Click this option to add Views. The user or group does not have access to any Views until you add them.
Set Primary User Group for File Access	Enable this option for the user to access file services. Then from the **Primary Group** drop-down list (lists all the groups the user belongs to), select a primary group to access files using SMB/NFS protocol.

3. Click **Save Changes**.

Manage Roles

The Manage Roles page lists all defined roles that you can assign to users and groups. From the Manage Roles page you can add and edit custom roles. For detailed instructions, see Create or Edit a Role. You can also delete existing custom roles. For users with restricted access, their allowed actions can be performed on the explicitly selected object set only; they do not have access to other objects. This restricted access protects your data from any

ransomware attack because the data is managed only by the users who have the necessary privileges on your cluster.

> **Note:** Admins can create and modify custom roles. Pre-defined system roles cannot be modified.

Pre-defined System Roles

Admin

Users with the Admin role have full access to all actions and workflow within the Cohesity UI and Cohesity CLI except for changing DataLock Views and setting their expiration dates. For example, a user assigned the Admin role can create backups, recover Snapshots and files from backups, add sources, delete sources, set up and manage the Cohesity cluster, manage Nodes, manage Views, resolve Alerts, etc. A user with the Admin role can also add and delete users.

By default, the Cohesity cluster is preconfigured with a default System Admin user called `admin` that has the same privileges as a user with the Admin role. This default System Admin account (`admin`) cannot be deleted.

Viewer

Users with the Viewer role have read-only access for all workflows within the Cohesity Dashboard.

Operator

Users with the Operator role have Viewer role privileges and the following additional privileges:

- Run existing Protection Groups.
- Create and Manage Clone tasks.
- Create and Manage Recover tasks.

A user with this privilege cannot download files from a snapshot and cannot recover from External targets.

SMB Security

Users with the SMB Security role have all SMB privileges when accessing data over SMB.

SMB Backup Operator

Users with SMB Backup Operator role have the privilege to perform SMB backup and SMB restore.

Self Service Data Protection

Users with the Self Service Data Protection role have Viewer role privileges and the following additional privileges:

- Create and Manage Protection Policies.
- Create and Manage Protection Groups.
- Create and Manage Clone tasks.
- Create and Manage Recover tasks
- Create and Manage Cohesity Views.

Data Security

Users with the Data Security role have all privileges granted by the Self Service Data Protection and Viewer roles and the following additional privileges:

- Create DataLock Views and set DataLock expiration dates.
- Create a Protection Group.
- Start an on-demand protection run and edit a protection run.
- Delete protection runs and snapshots.
- Add and remove Legal Hold to existing snapshots.

Replication

Users with the Replication role have basic privileges for replication. This role allows the user to perform replication of data to other clusters.

A user with this privilege cannot log in to the Cohesity Dashboard.

FortKnox Self Managed Vault Admin

FortKnox Self-Managed vault admin users have full access to create, update, and delete FortKnox Self-Managed cluster pairing.

Create or Edit a Role

Use this page to create or edit a custom role. For example, you can create a user with the Operator role and certain admin privileges such as Upgrade Cluster and Manage Cluster. All custom roles have Viewer role privileges.

> **Note:** Admins can create and modify custom roles. Pre-defined system roles cannot be modified.

Create or Edit a Custom Role

1. Name the role. Role names cannot be edited after you create them.

   > **Note:** Only letters, numbers, spaces and the special characters . - _ are allowed.

2. You can optionally provide a description for the role.
3. Set the role's privileges by using the toggles and check boxes. For a description of the privileges, see Privileges.

   > **Tip:** In the Cohesity Dashboard, hover your mouse over the privilege name to display its description in a pop-up tooltip.

4. Click **Create Role** or **Save Changes**.

   Role and privilege updates for currently logged-in users take effect after logging out and logging in again. Updates for users that are not currently logged in take effect when they log in.

Privileges

The privileges for all workflows are described below.

> **Tip:** To select privileges in the Source Management workflow, you must select the Manage Sources privilege in the Data Protection workflow.

Access Management

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
View API Key	Allow user to view other users' API Keys.	YES	NO	YES	NO
View Users	Allows viewing users, groups and other access control information.	YES	NO	YES	NO

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
Manage API Key	Allow user to modify other users' API Keys.	YES	NO	YES	NO
Manage Users	Allows modifying users, groups and other access control information. If the user's access is restricted to specific Objects, then this privilege is not granted, even if the role grants it.	YES	NO	YES	NO
Manage S3 Keys	Allow user to manage and view other users' S3 keys.	YES	NO	YES	NO

Analytics Management

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
View Analytics Workbench	Allows the user to view Analytics Workbench related entities.	NO	NO	YES	NO
Reporting	Allows the user to generate and view reports.	YES	NO	YES	NO
Manage Analytics Workbench	Allows the user to modify Analytics Workbench related entities.	NO	NO	YES	NO

Apps

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
Launch Apps Instances	Allows viewing apps, instances and app management information. For an app instance, access is restricted to the user who launched the app instance.	NO	NO	YES	NO
Manage Apps and Instances	Allows install, uninstall and launch of the app, and pause, resume and stop of the app instance. User specific restrictions of app instance do not apply.	NO	NO	YES	NO

Clone Management

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
View Clone Tasks	Allows the user to view clone tasks.	YES	NO	YES	NO
Manage Clone Tasks	Allows the user to create, modify and delete clone tasks.	YES	NO	YES	NO

Cluster Management

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
Download Hybrid Extender	Allows the user to download Hybrid Extender VM or configuration file.	YES	YES	YES	YES
View report Schedules	Allows the user to view report schedules on cluster. The user cannot make changes.	YES	NO	YES	NO
View Cluster Details	Allows the user to view Cluster settings. The user cannot make changes.	NO	NO	YES	NO
Manage report schedules	Allows the user to create or modify schedules for a report.	YES	NO	YES	NO
Manage External Targets	Allows the user to register and modify External Targets for archival.	NO	NO	YES	NO
View Alert Details	Allows the user to view alerts. The user cannot make changes.	YES	NO	YES	NO

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
Allow access to Cohesity UI	Allows the user to access Cohesity cluster through UI.	YES	NO	YES	NO
Manage MFA	Allow users to modify cluster level MFA settings.	NO	NO	YES	NO
Manage AD and LDAP	Allows the user to manage active directory and LDAP providers on the cluster.	YES	NO	YES	NO
Manage Keystone	Allows the user to manage Keystone configuration on the cluster.	YES	NO	YES	NO
Upgrade Cluster	Allows the user to upgrade and patch the Cluster.	NO	NO	YES	NO
View Hybrid Extender Details	Allows the user to view the Hybrid Extender details.	YES	YES	YES	YES
Manage Alerts	Allows the user to resolve alerts and manage email addresses where alert notifications should be received.	YES	NO	YES	NO

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
Manage VLANs	Allows the user to modify VLANs.	NO	NO	YES	NO
View AD and LDAP Details	Allows the user to view active directory and LDAP providers. The user cannot make changes.	YES	NO	YES	NO
Manage Linux user sudo access	Allows the user to grant sudo access to Linux support user.	YES	NO	YES	NO
View NIS	Allows the user to view NIS providers on the cluster.	NO	NO	YES	NO
Cluster Support	Allows the user to perform support related operations such as collecting data and browsing logs.	NO	NO	YES	NO
View External Targets	Allows the user to view External Targets for archival.	YES	NO	YES	NO
Manage Helios	Manage connection to Helios.	NO	NO	YES	NO

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
View Remote Clusters	Allows the user to view the Remote Clusters for remote access or replication.	YES	NO	YES	NO
View VLANs	Allows the user to view available VLANs.	YES	NO	YES	NO
Manage Remote Clusters	Allows the user to register and modify Remote Clusters for replication.	YES	NO	YES	NO
View Audit Logs	Allows the user to view the Audit Logs.	YES	NO	YES	NO
Manage Patches	This privilege allows a User to apply or revert patches to the Cluster.	NO	NO	YES	NO
Manage Cluster	Allows the user to modify Cluster setup and to add and remove Nodes.	NO	NO	YES	NO
Manage NIS	Allows the user to manage NIS providers on the cluster.	NO	NO	YES	NO

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
View Keystone Details	Allows the user to view Keystone configuration. The user cannot make changes.	YES	NO	YES	NO
Modify Bifrost VLANs	Allows a user to modify available Hybrid Extender VLANs.	YES	NO	YES	NO
View Bifrost VLANs	Allows the user to view available Bifrost VLANs.	YES	NO	YES	NO
View KERBEROS	Allows the user to view registered Kerberos providers on the cluster.	NO	NO	YES	NO
Manage KERBEROS	Allows the user to manage registered Kerberos providers on the cluster.	NO	NO	YES	NO
Manage Tags	Allows the user to apply/ remove tags on the cluster.	YES	NO	YES	NO
View Tags	Allows the user to view tags on the cluster.	YES	NO	YES	NO

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
Modify Tags	Allows the user to create/ modify tags on the cluster.	YES	NO	YES	NO
Manage Support Channel	Allows the user to modify Support Channel settings on the cluster.	NO	NO	YES	NO
View Account Security	Allows the users to view the Account Security settings on the cluster.	NO	NO	YES	NO
View data-source connections	Allows a user to view data-source connections.	NO	NO	NO	NO
Modify data-source connections	Allows a user to create or modify data-source connections.	NO	NO	NO	NO
View data-source connectors	Allows a user to view data-source connectors.	NO	NO	NO	NO
Modify data-source connectors	Allows a user to create or modify data-source connectors.	NO	NO	NO	NO
View Bifrost Connections	Allows a user to have view the available Bifrost Connections.	YES	YES	YES	YES

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
Modify Bifrost Connections	Allows a user to create or modify Bifrost Connections.	YES	YES	YES	YES

Data Protection

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
Protection Group Operator	Allows the user to run, cancel or pause a protection group.	YES	NO	YES	NO
View Protection Groups	Allows the user to view protection groups, protection sources and protection group runs. The user cannot make any changes.	YES	NO	YES	NO
Manage Protection Groups	Allows the user to create, modify and delete Protection Groups as well as the ability to delete runs.	YES	NO	YES	NO
View Protection Policies	Allows the user to view protection policies. The user cannot make any changes.	YES	NO	YES	NO

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
Manage Protection Policies	Allows the user to create, modify and delete Protection Policies.	NO	NO	YES	NO
Search Objects	Allows the user to perform search of objects from sources registered on the cluster.	NO	NO	YES	NO
View Runbooks	Allows the user to list and view the created Runbooks.	NO	NO	YES	NO
Manage Runbooks	Allows the user to create, modify, remove and execute Runbooks	NO	NO	YES	NO
Manage Sources	Allows the user to register or delete a Protection Source and modify its information. If the user's access is restricted to specific Objects, then this privilege is not granted, even if the role grants it.	YES	NO	YES	NO
Manage Agents	Allows the user to Deploy and Register the Cohesity Agent on servers.	NO	NO	YES	NO

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
Execute Runbooks	Allows the user to execute Runbooks.	NO	NO	YES	NO
Delete snapshots	Allows user to delete snapshots.	YES	NO	YES	NO
View agent upgrade tasks	Allows the user to access agent upgrade tasks	YES	NO	YES	NO
Create or Modify agent upgrade tasks	Allows the user to create or modify agent upgrade tasks	YES	NO	YES	NO

Free Node Management

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
View Free Nodes	Allows the user see information about free nodes.	NO	NO	YES	NO

Organization Management

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
Switch Organization	Allows to switch to an organization's perspective and perform actions on their behalf.	NO	YES	YES	NO

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
View Organizations	Allows viewing organizations registered on the cluster.	NO	YES	YES	NO
Manage Organizations	Allows managing organizations registered on the cluster.	NO	YES	YES	NO

Recovery Management

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
Download File	Allows the user to download files. The user also needs the 'Manage Recover Tasks' privilege to download files.	YES	NO	NO	NO
View Recover Tasks	Allows the user to view Recover and Clone Tasks. The user cannot make any changes.	YES	NO	YES	NO
Manage Recover Tasks	Allows the user to create Recover Tasks.	YES	NO	YES	NO
Recover from External Targets	Allows the user to search External Targets and recover using data archived from a Remote Cluster.	NO	NO	YES	NO

SMB Security

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
SMB Backup	This privilege causes the system to grant all read access control to any file, regardless of the access control list (ACL) specified for the file. Any access request other than read is still evaluated with the ACL.	YES	NO	YES	NO
Take ownership of SMB files	This privilege allows the owner value to be set only to those values that the holder may legitimately assign as the owner of an object.	YES	NO	YES	NO
Manage system access control list on SMB files	Required to perform a number of security-related functions, such as controlling and viewing audit messages. This privilege identifies its holder as a security operator.	YES	NO	YES	NO

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
SMB Restore	This privilege causes the system to grant all write access control to any file, regardless of the ACL specified for the file. Any access request other than write is still evaluated with the ACL. Additionally, this privilege enables you to set any valid user or group SID as the owner of a file.	YES	NO	YES	NO

Source Access Control

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
Manage Enterprise File DataLock	Allows the user to decrease the Enterprise File DataLock expiration period and to delete a view with Enterprise File DataLock configured.	YES	NO	YES	NO
Data Security	Allows the user to lock a View and set its lock expiration date.	YES	NO	YES	NO

Source Management

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
Manage VMware Standalone Hosts	Allows a user to manage VMware Standalone Hosts.	YES	NO	YES	NO
Manage VMware VCenters	Allows a User to manage all VMware vCenter Servers.	YES	NO	YES	NO
Manage VMware VCloud Director	Allows a User to manage all VMware vCloudDirector.	YES	NO	YES	NO
Manage HyperV SCVMM Servers	Allows a User to manage HyperV SCVMM Servers.	YES	NO	YES	NO
Manage HyperV Standalone Hosts	Allows a User to manage HyperV Standalone Hosts.	YES	NO	YES	NO
Manage HyperV Failover Clusters	Allows a User to manage HyperV Failover Clusters.	YES	NO	YES	NO
Manage Acropolis Standalone Clusters	Allows a User to manage Acropolis Standalone Clusters.	YES	NO	YES	NO
Manage GCP IAM users	Allows a User to manage GCP IAM users.	YES	NO	YES	NO

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
Manage AWS IAM users	Allows a User to manage AWS IAM users.	YES	NO	YES	NO
Manage Azure Subscriptions	Allows a User to manage Azure Subscriptions.	YES	NO	YES	NO
Manage KVM OVirtualManager Sources	Allows a User to manage KVM OVirtualManager Sources.	YES	NO	YES	NO
Manage Physical Servers	Allows a User to manage Physical Servers.	YES	NO	YES	NO
Manage Office365 Domains	Allows a User to manage Office365 Domains.	YES	NO	YES	NO
Manage SQL Servers	Allows a User to manage SQL Servers.	YES	NO	YES	NO
Manage Oracle Servers	Allows a User to manage Oracle Servers.	YES	NO	YES	NO
Manage Pure Storage Arrays	Allows a User to manage Pure Storage Arrays.	YES	NO	YES	NO
Manage Nimble Storage Arrays	Allows a User to manage Nimble Storage Arrays.	YES	NO	YES	NO

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
Manage Hyperflex Servers	Allows a User to manage Hyperflex Servers.	YES	NO	YES	NO
Manage Active Directory Servers	Allows a User to manage Active Directory Servers.	YES	NO	YES	NO
Manage Isilon Clusters	Allows a User to manage Isilon Clusters.	YES	NO	YES	NO
Manage NetApp Clusters	Allows a User to manage NetApp Clusters.	YES	NO	YES	NO
Manage NetApp VServers	Allows a User to manage NetApp VServers.	YES	NO	YES	NO
Manage Generic NAS hosts	Allows a User to manage Generic NAS hosts.	YES	NO	YES	NO
Manage Pure Flashblade Storage Arrays	Allows a User to manage Pure Flashblade Storage Arrays.	YES	NO	YES	NO
Manage GPFS Cluster	Allows a User to manage GPFS Cluster.	YES	NO	YES	NO
Manage Elastifile Clusters	Allows a User to manage Elastifile Clusters.	YES	NO	YES	NO

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
Manage Exchange Servers	Allows a User to manage Exchange Servers.	YES	NO	YES	NO
Manage Cassandra Clusters	Allows a User to manage Cassandra Clusters.	YES	NO	YES	NO
Manage All Protection Sources	This privilege allows a User to manage all Source types.	YES	NO	YES	NO
Manage Couchbase Clusters	This privilege allows a User to manage Couchbase Clusters.	YES	NO	YES	NO
Manage HBASE Sources	This privilege allows a User to manage HBASE sources of Hadoop Clusters.	YES	NO	YES	NO
Manage Acropolis Generic Standalone Clusters	This privilege allows a User to manage Acropolis Generic Standalone Clusters.	YES	NO	YES	NO
Manage SFDC Adapter Sources	Allows a user to manage SFDC Adapter Sources	YES	NO	YES	NO

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
Manage HDFS Sources	This privilege allows a User to manage HDFS sources of Hadoop Clusters.	YES	NO	YES	NO
Manage Universal Data Adapter Sources	This privilege allows a User to manage Universal Data Adapter sources.	YES	NO	YES	NO
Manage Kubernetes Sources	This privilege allows a User to manage Kubernetes sources.	YES	NO	YES	NO
Manage MongoDB Clusters	This privilege allows a User to manage MongoDB Clusters.	YES	NO	YES	NO
Manage HIVE Sources	This privilege allows a User to manage HIVE sources of Hadoop Clusters.	YES	NO	YES	NO

Storage Management

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
Manage Cohesity Storage Domains	Allows the user to create and modify Cohesity Storage Domains.	NO	NO	YES	NO
Manage Cohesity Views	Allows the user to create, modify and delete Cohesity Views.	YES	NO	YES	NO
Read Cohesity Views	Allows the user to view Cohesity Views.	YES	NO	YES	NO
Read Cohesity Storage Domains	Allows the user to view Cohesity Storage Domains.	YES	NO	YES	NO

High Classified

Privilege	Description	Available to Organizations	Available when Multitenancy is Enabled	Available during Impersonation	Available with Hybrid Extender
High Classified	Allows the user to fetch cluster details needed for specific API calls.	NO	NO	YES	NO

Single Sign-On (SSO)

You can configure the Cohesity cluster to use an Identity Provider (IdP) for single sign-on (SSO) access to the cluster. For a multitenancy-enabled cluster, you can configure SSO for an organization defined in the cluster.

> **Important:** If you are using SSO for authentication, Cohesity recommends that you enable multi-factor authentication (MFA) for your SSO system.

First, add the cluster as an application to your IdP and get an SSO URL and certificate file. Then configure the SSO in the cluster and provide the SSO URL and certificate file. After the integration is configured, users can sign in to the cluster using the following methods:

- Use the IdP sign-in page.
- Use the Cohesity cluster sign-in page. Click the **Sign in with SSO** link at the bottom of the cluster sign-in page.

> **Note:** Cohesity supports any Identity Provider (Idp) as long as it uses SAML 2.0 based SSO. The Assertion Consumer Service (ACS) url and Entity ID for any IdP is https://cluster_fqdn/idps/authenticate.

Integrate an Identity Provider

You have to integrate an identity provider to configure SSO. The following identity providers are supported and you can follow the documentation link to learn more about how to integrate it with the Cohesity.

> **Note:** You can configure multiple Identity Providers (IDPs) when using Organizations. Each organization can have one IDP configured at the cluster level.

Identity Provider	Documentation Link
Active Directory Federation Services (ADFS)	Integration with Active Directory Federation Services for SSO
Azure Active Directory	Integration with Azure Active Directory for SSO
Duo Single Sign-on	Integration with Duo for SSO
Ping Identity	Integration with Ping Identity for SSO
Okta Single Sign-on	Integration with Okta for SSO

Add an SSO Provider to the Cohesity cluster

1. In the Cohesity Dashboard, select **Settings > Access Management** and select the **SSO** tab.
2. Click **Add SSO**.

3. Select one of the following options:
   - **SAML**: Security Assertion Markup Language (SAML) is an XML-based protocol used for SSO login.
   - **OpenID Connect**: OpenID Connect is an open authentication protocol that uses OAuth2.0 framework.
4. If you select **SAML**, then refer to the following table:

Name	Description
SSO Domain	Your choice of domain name, such as abc.com. This name must be unique within the cluster.
SSO Provider	Your choice of provider name, such as Okta.
Assign to Organization	Optional. In a multitenant-enabled cluster, you can configure SSO for an organization that has been added to the Cohesity cluster. Select an organization from the drop-down.
Single Sign-on URL	Paste the URL that you copied from your IdP. For example: https://mycompany.okta.com/app/cohesitymycompany_clusterapp/******/sso/sam
Provider Issuer ID	Paste the issuer ID that you copied from your IdP. For example: http://okta.com/*****
X.509 Certificate	Click Select File and browse to the location to select the file you downloaded and renamed previously. For example, okta.pem. Select Edit to edit the certificate.

5. Click **Add**. If you select **OpenID Connect** (OIDC), perform the following steps and then refer to the table:

   Prerequisites:

   1. Create the OIDC app within your Identity Provider (IdP). For more information, see Create OIDC app integrations.

      > **Note:** OIDC is an open standard and Single-Sign-On with Cohesity Platform is intended to work with any OpenID Connect supported Identity Provider. For setup details, refer to your Identity Provider's documentation.

   2. Map the OIDC configuration details from Okta IDP to Cohesity Platform side configurations:

1. To get the Issuer ID:
    1. Navigate to **Security** > **API**.
    2. On the **API** page, click **Authorization Servers**.

       You can find the issuer ID in the Issuer URI section.

2. To get the Client ID:
    1. Navigate to Applications.
    2. On the Helios Test OIDC App page, click **General**.
3. To generate the **JSON Web Key Set (JWKS)** URL:
    1. Construct the URL as follows:

       Format: <issuer ID>/.well-known/openid-configuration

       For example: `https://***-00000000.okta.com/oauth2/default/.well-known/openid-configuration`.
    2. Enter the constructed URL in the address bar of the browser and JSON output will be displayed.

Name	Description
OpenID Server Domain	Enter a unique domain name.
OpenID Server URL for the public (JWKS)	Enter the JSON Web Key Set (JWKS) URL. You can get this URL from your identity provider.
Polling Interval (Hours)	Specifies the caching duration for responses from the JWKS endpoint.
Audience IDs	Enter the IDs verified against the 'aud' field in the JWT. The 'aud' in the JWT must align with one of the strings listed in the Audience IDs field.

> **Important:**
> When enabling signed requests in Okta (or any SAML identity provider), you must explicitly set the following values:
>
> - Signature Algorithm: RSA-SHA256
> - Digest Algorithm: SHA256

6. Click **Add**.

> **Important:** Make sure to add an SSO user before you add the SSO provider. For more information, see Add SSO Users.

The cluster validates the connection to the IdP. If the connection succeeds, the SSO provider is added to the provider list and you can edit, delete or deactivate it as described in the following sections.

Users can start accessing the cluster via their IdP home page or the cluster sign-in page by clicking the **Sign in with SSO** link.

Edit an SSO Provider

You can change any of the SSO provider options.

1. In the Cohesity Dashboard, select **Settings > Access Management** and select the **SSO** tab.
2. Click the Actions Menu (⋮) and then click **Edit**.
3. Change the options as needed.
4. Click **Update**.

The cluster validates the connection to the IdP using the new information.

Deactivate or Activate an SSO Provider

You might want to deactivate an SSO provider for testing or investigation purposes. Deactivation does not delete the provider configuration, so you can activate it later. Once deactivated, users associated with the IdP will no longer bypass the Cohesity sign-in page.

1. In the Cohesity Dashboard, select **Settings > Access Management** and select the **SSO** tab.
2. Click the Actions Menu (⋮) and then click **Deactivate** or **Activate**.

Delete an SSO Provider

You can permanently delete an SSO provider if you no longer need it. Once deleted, users associated with the IdP provider will no longer bypass the Cohesity sign-in page.

1. In the Cohesity Dashboard, select **Settings > Access Management** and select the **SSO** tab.
2. Click the Actions Menu (⋮) and then click **Delete**.
3. Respond to the confirmation prompt.

Active Directory (AD)

Active Directory (AD) in Cohesity Access Management is a directory service implemented by Microsoft that provides several services such as LDAP (Lightweight Directory Access Protocol), Kerberos, and DNS. It is used for user and group identity management and authentication within a Cohesity cluster.

You can join the Cohesity cluster to one or more Active Directory (AD) domains. Joining to AD allows the following:

- Existing AD users and groups can be assigned Cohesity roles
- SMB shares created by the Cohesity cluster can be authenticated based on AD credentials

Cohesity Roles

Once the Cohesity cluster is joined to an AD domain, existing AD principals can be added assigned different roles so they can access the Cohesity Dashboard. For example, you can assign the View role to the AD group "ITGroup." This gives all group members read-only access to the Cohesity Dashboard. You can also assign the Admin role to the AD user "ITManager."

Cohesity SMB Share Access

The action steps in the following procedure are represented in the figure below with blue numbered time squares:

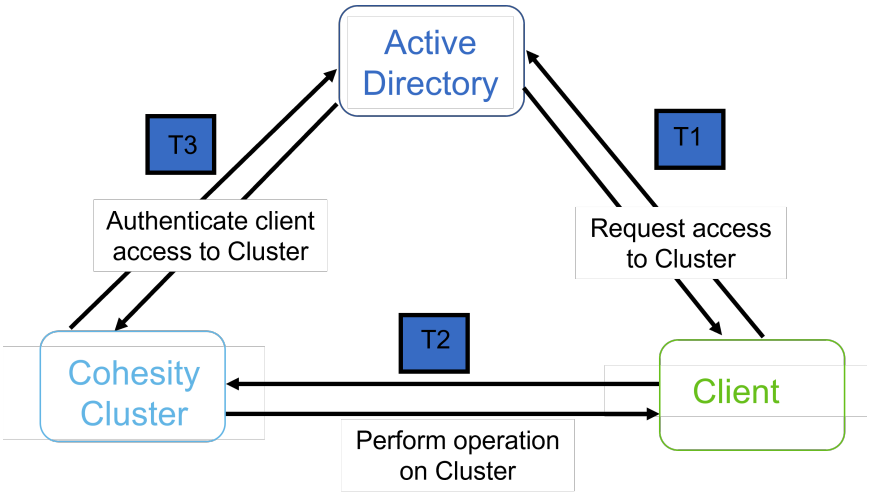
. The procedure assumes the Cohesity cluster is already joined to an Active Directory domain.

Client access to an Active Directory-joined Cohesity cluster SMB share consists of the following actions:

T1) A client requests access to a Cohesity cluster SMB share.

T2) The client attempts to perform an operation on the Cohesity cluster SMB share.

T3) Active Directory authenticates the client's membership within a group that can perform the requested operations on the Cohesity cluster SMB share.



Join to Active Directory Domain

For detailed instructions, see Join to Active Directory.

Join Active Directory

This topic explains how to configure a Cohesity cluster to use Active Directory (AD) credentials for SMB access to views and to access the Cohesity Dashboard. (For information about protecting Active Directory domain controllers, see About Active Directory Data Protection.)

Joining the Cohesity cluster to an AD domain is optional. You can join the Cohesity cluster to one or more AD domains to enable:

- existing AD users can access Cohesity cluster SMB shares based on their AD credentials
- existing AD users and groups can be assigned Cohesity roles and access the Cohesity Dashboard

On Cohesity clusters that are **not** joined to AD, all views are accessible as SMB shares and there is no authentication. If the AD administrator blocks NTLM, the shares on the Cohesity cluster are not accessible.

All accounts and Cohesity cluster SMB share privileges for users in AD are managed through Active Directory or where the SMB shares are mounted. Non-admin AD users must be granted backup and restore privileges on Windows clients explicitly. This is in addition to backup and restore privileges for the Cohesity cluster.

Migrated AD Users and Groups with Historical SIDs

Cohesity supports migrated AD users and groups with historical SIDs and grants access accordingly in Active Directory domains. The SID history retains user and group membership and access rights during Active Directory domain migration.

Considerations

Review the following considerations of migrated AD users and groups with historical SIDs:

- Historical SIDs with multiprotocol access is not supported.
- Historical SIDs user quota accounting is not supported.
- Privilege assignment for Historical SIDs is not supported.

Prerequisites and Considerations

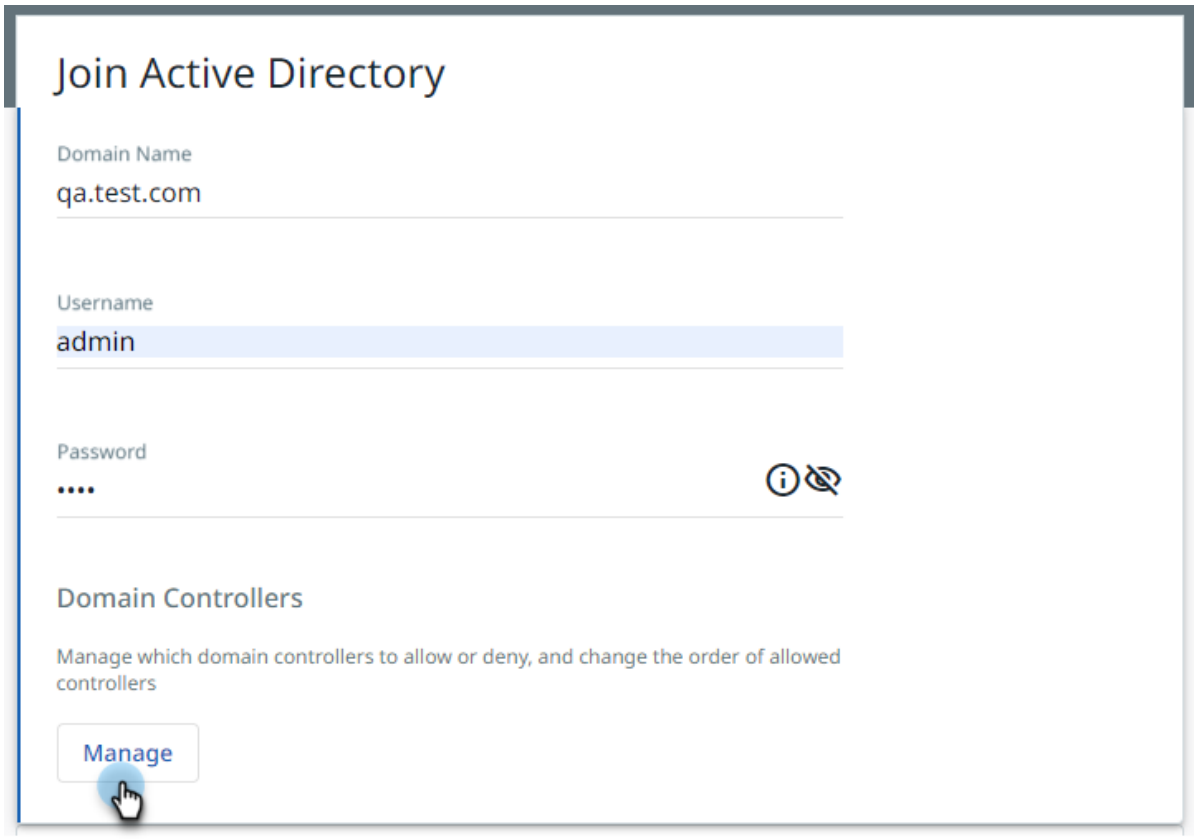
For information about the required firewall ports for AD, see Manage Firewall Ports.

Join the Cohesity cluster to an AD Domain

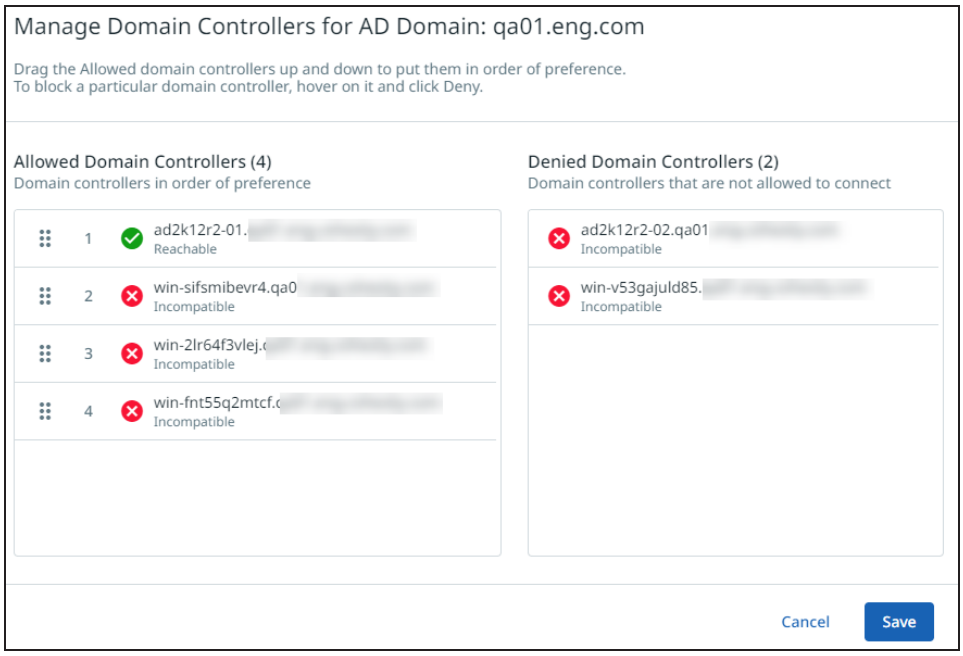
1. Go to **Settings > Access Management** and click the **Active Directory** tab.
2. Click **Add Active Directory**.
3. **Domain Name:** Provide the fully qualified domain name (FQDN) of the Active Directory domain to join.
4. **Username**: Provide the samAccountName.
5. **Password**: Provide the password for the username.
6. **Domain Controllers:** Add preferred domain controllers to the AD domain to ensure that the Cohesity cluster uses a local domain controller (when possible) to speed up AD queries. You can set preferred domain controllers for the following:
   - Domain controllers
   - Trusted domains of the domain controller

   > **Note:**
   > - The SRV records must exist for the domain (the list of domain controllers displayed in the Cohesity Dashboard is generated by querying the SRV records).
   > - You can add any number of preferred domain controllers.

   1. Click **Manage** to allow or deny domain controllers and change the order of allowed controllers:



2. In the **Manage Domain Controllers for AD Domain** dialog, the domain controllers are listed in order of preference. You can move the allowed domain controller(s) up and down to put them in order of preference. To block a particular domain controller, hover on it and click **Deny:**



3. Click **Save**.

   The allowed domain controllers are listed in the **Domain Controllers** section:

   The Cohesity cluster uses these domain controllers to join the AD domain and for all future communication with the AD domain.

7. **Machine Accounts:** Click **Add** and specify the following details:
   - **Machine Account**—Provide at least one machine account to identify the Cohesity cluster on the domain. For example, you can use the Cohesity cluster name.
   - **DNS Hostname**—Optionally, specify the DNS hostname of the machine account. For AD to work with the internal DNS server, apart from machine account names, you should add DNS hostnames that should be configured for each machine account. The DNS hostnames should have one of the In Bound DNS zone suffixes configured for the internal DNS server. For more information, see Internal DNS for Load Balancing.

> **Note:**
> - When you specify the DNS hostname, it is treated as a customized Service Principal Name (SPN), resulting in successful Kerberos authentication with this customized SPN.
> - If the DNS Hostname is modified when editing the machine accounts, all existing configuration of the machine account is overwritten on the Active Directory.

- **Encryption Types**—Optionally, select the encryption type(s) that must be used by the machine account. You can select multiple encryption types. The following encryption types are supported:
  - AES128-CTS-HMAC-SHA1-96
  - AES256-CTS-HMAC-SHA1-96
- **SPNs**—Service Principal Names (SPNs) are identifiers used to associate a service with a specific AD account. SPNs enable authentication and authorization for services. Specify the SPN in the following format:

  <service class>/<host>:<port>/<service name>

  The SPN syntax has four elements.
  - The following two elements are required:
    - **Service Class**: Specify the type of service.
    - **Host**: Specify the hostname or Fully Qualified Domain Name (FQDN) of the server on which the service is hosted.
  - If necessary, you can specify the following optional elements:
    - **Port**: Specify the port number on which the service is running.
    - **Service Name**: Specify the specific service instance on the host.

Note:

- All (or a subset) of the VIPs will resolve to the machine account. You can optionally add multiple machine accounts, which creates aliases for the same cluster. You can map these aliases to a subset (or all) of the VIPs to direct I/O to a subset (or all) of the nodes. Separate names with commas. For example: cluster1, cluster1-vip1, cluster1-vip2, cluster1-vip3, cluster1-vip4.
- If using VLANs—One of the machine accounts must be a DNS hostname for a virtual IP (VIP) of a VLAN configured on the cluster in order to recover to servers within that VLAN.
- After adding a Cohesity cluster to an AD, ensure the machine account used to register the Cohesity cluster in AD has the **Read membership** permissions across all users and groups.
- The same configuration must be done on every additional domain to which the Cohesity cluster is joined.
- The machine account must follow NetBIOS naming conventions of 15 maximum character length, those described in Naming conventions in Active Directory for computers, domains, sites, and OUs and the additional restriction that the ! @ ( ) characters are not supported.

8. **Use the above Machine Accounts even if they already exist in AD Domain:** Optionally toggle on to use the machine accounts that you specified above even if they already exist in the Active Directory domain.
9. **Mapped Provider:** Select the type of mapped provider to join the domain. By default, no mapped provider is selected. Optionally, select **LDAP** or **NIS**. If you select the **LDAP** option, you can select the provider from the **LDAP Provider** drop-down list. If you select the **NIS** option, you can select the NIS provider from the **NIS Provider** drop-down list.
10. **Organizational Unit:** Provide the organizational unit if applicable. Use the format: *OUName* or *OUName*/*SubOUName*. For example: Engineering or Sales/West or West Coast Sales/ North California.
11. **AD Workgroup / NetBIOS Name:** Provide the workgroup / NetBIOS name if applicable.
12. **Discover Trusted Domains:** Optionally, turn on this toggle to discover the trusted domains associated with an AD. You can exclude certain trusted domains after the

Cohesity cluster is joined to the AD domain. For more information, see Trusted Domains.

13. Click **Join**.
14. This step is required only for SMB access to views. On the DNS server that is integrated with the AD domain, add the A record for each machine account used to identify the Cohesity cluster to the AD domain. This is necessary to allow clients to access the Cohesity cluster as a resource. (Adding the A record is not generally necessary for Windows resources because Active Directory automatically adds it to the DNS server. However, the Cohesity cluster does not include the components that enable automatic addition to the DNS server.)
15. Optionally, repeat these steps to join the Cohesity cluster to another AD domain. For more information, see Guidelines for Joining Multiple AD Domains.
16. Optionally, you can add user ID mapping. For more information, see User ID Mapping for Multi Protocol Network Access.

Guidelines for Joining Multiple AD Domains

A cluster can join multiple Active Directory domains even if there are trust relationships between the AD domains.

After the Cohesity cluster joins the AD domain, you can add trusted domains to the allowlist or denylist. By default, all trusted domains are used for authentication unless added to the denylist. For more information, see Trusted Domains.

Only Kerberos authentication is supported for SMB shares when multiple AD domains are joined to the Cohesity cluster. NTLM authentication is disabled.

Leave Active Directory Domain

1. Go to **Settings > Access Management** and click the **Active Directory** tab.
2. Click the domain name and then click the leave domain icon ( ).
3. Provide the **AD Admin** and **Password** for the domain.
4. Click **Leave Domain**.

   When this succeeds, the machine accounts associated with the Cohesity cluster are removed from the Active Directory domain.

   > **Note:** If the Cohesity cluster is removed from a domain, ensure the corresponding DNS entries have been removed from the DNS server.

Enable Load Balancing

You can enable load balancing over multiple Cohesity cluster IPs by following these steps:

> **Note:** These example steps refer to the Windows DNS Manager. If you're using a different DNS Manager, ensure you perform step 3.

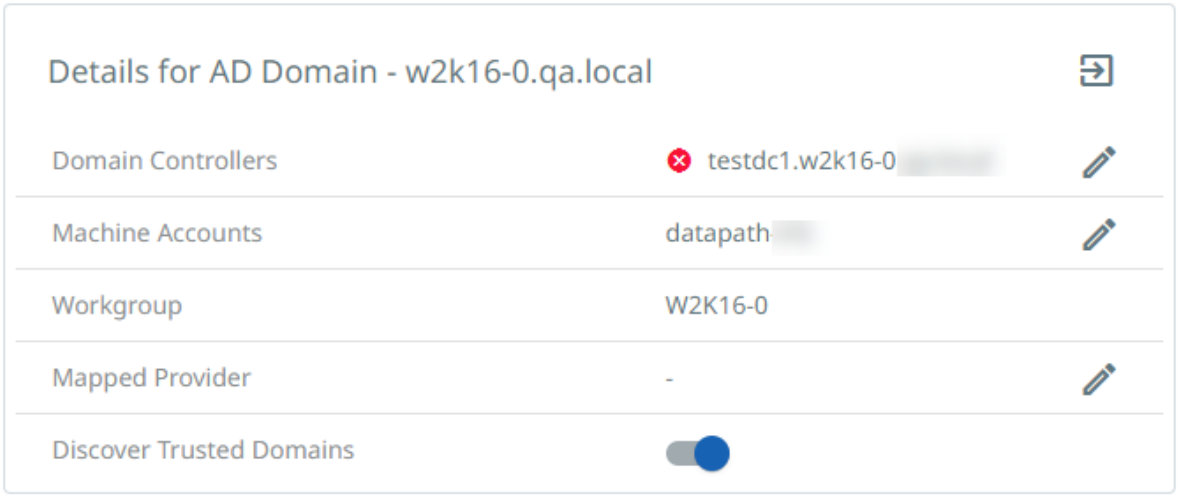
1. Open DNS Manager in Windows using the DNS Admin client: **Control Panel > Administrative Tools > DNS**.
2. Enable the Advanced view: **View > Advanced**.
3. Add multiple entries with the same Cohesity cluster name and do the following:
    - Give each entry a different **IP address** that corresponds to a VIP allocated to the Cohesity cluster in the DNS Zone where it will be added.
    - Generally, you can leave **Time to live (TTL)** at its default setting. You should only change this setting for specific use cases. Set TTL to a low value (such as 5 seconds or less) for backup use cases where a low number of clients are accessing the Cohesity cluster. Set TTL to a high value (such as 12 hours) for file services use cases with a high number of clients. This ensures that clients access the same Cohesity cluster nodes and benefit from caching.

Manage Domain Controllers From the Active Directory Details Page

You can also manage domain controllers from the Active Directory details page.

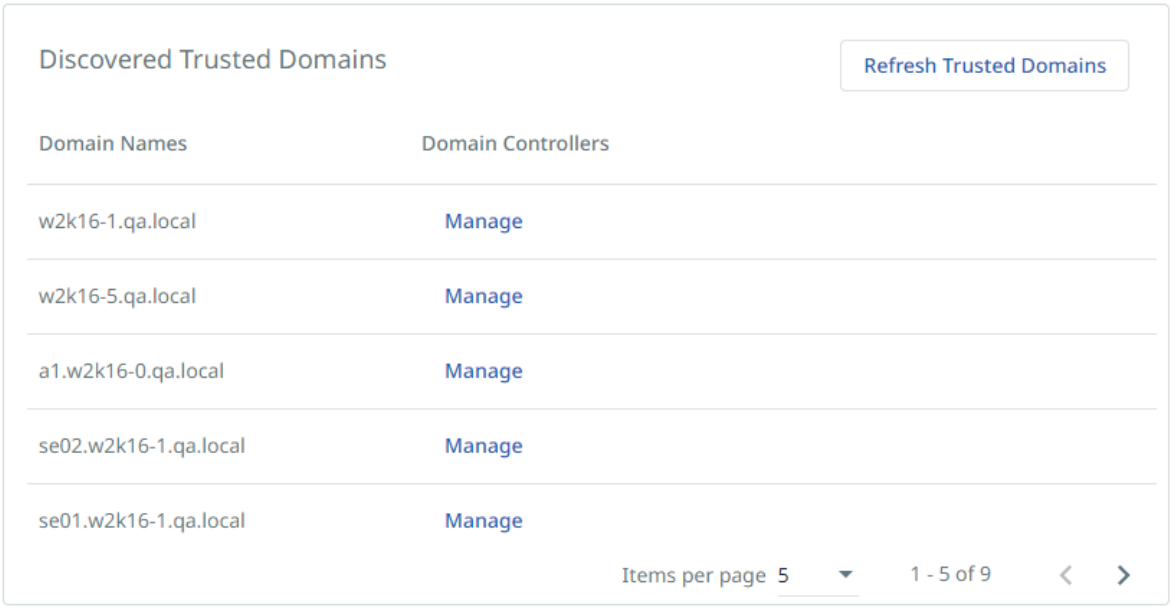
To manage domain controllers from the Active Directory details page:

1. Navigate to **Settings > Access Management** and click the **Active Directory** tab.
2. Click the active directory for which you want to manage domain controllers.
    - In the **Details for AD Domain** section, click the edit icon corresponding to **Domain Controllers**:



The **Manage Domain Controllers for AD Domain** dialog is displayed. You can manage the domain controllers for this AD domain.

- In the **Discovered Trusted Domains** section, the trusted domain controllers associated with the AD are discovered and listed. Click **Manage** corresponding to the domain name:



The **Manage Domain Controllers for AD Domain** dialog is displayed. You can manage the trusted domain controllers for the AD domain:

- **Allowed Domain Controllers**—All the domain controllers for the AD domain are listed in the **Allowed Domain Controllers** section. Drag a domain controller up or down to reorder the preference. To block a domain controller, hover over it and click **Deny**.
- **Denied Domain Controllers**—Domain controllers that are disallowed to connect the AD domain are listed in the **Denied Domain Controllers** section. To unblock a domain controller, hover over it and click **Allow**.

User ID Mapping for Multi Protocol Network Access

After the Cohesity cluster is joined to an Active Directory domain, you can add user ID mapping. The ID map database is stored in AD using industry-standard protocols. For more information, see ID Mapping for Multi-Protocol Views.

1. Go to **Settings > Access Management** and click the **Active Directory** tab.
2. Click **Add ID Mapping** or the edit icon ( ).
3. Select an **ID Mapping Type** and enter the required information:

- **Centrify**
  - **AD Domain:** Name of the Active Directory domain where the corresponding Centrify zone is located.
  - **Centrify Zone:** Selected zone that has the ID mappings.

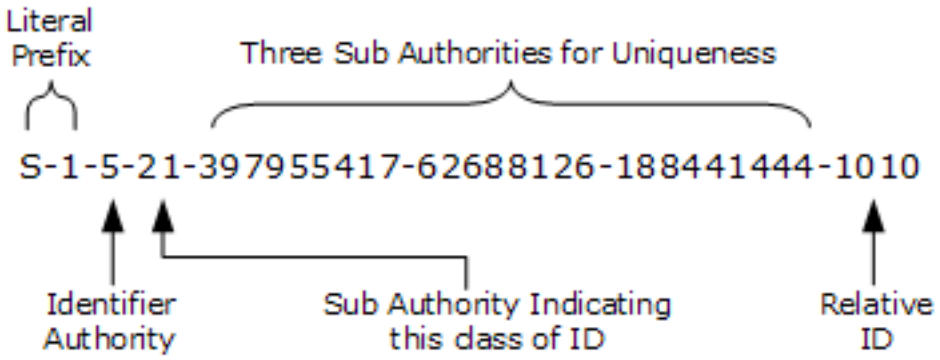
  For Native security style Views, SMB will get Unix IDs from the Active Directory provider and NFS will get Unix IDs from the LDAP provider.

  For Unified or NTFS security style Views, SMB and NFS will get Unix IDs from the corresponding Centrify zone for the Active Directory provider.
- **Fixed**
  - **Unix UID to be applied to all files created:** Enter a user ID to apply to all created files.
  - **Unix GID to be applied to all files created:** Enter a group ID to apply to all created files.
- **LDAP Provider**

  The UID and GID corresponding to the Active Directory users are fetched from the configured LDAP provider. In LDAP, the most commonly used attributes to store the UID and GID are 'uidNumber' and 'gidNumber', respectively.

  All Views, regardless of their security style setting (Native, Unified or NTFS), will get Unix IDs from the LDAP provider and SIDs from the Active Directory provider.
- **RID (Relative ID of SID)**

  RID is a variable length number that is assigned to objects at creation and becomes part of the object's Security Identifier (SID) that uniquely identifies an account or group within a domain. For every Windows user or group, the RID of the corresponding SID is used as the UID or GID.



- **RFC2307**

  In RFC2307, the UID and GID are stored along with Active Directory objects in the following attributes: the UID for a user is stored in the attribute ‘uidNumber’ and GID for a group is stored in the attribute 'gidNumber'.

  For Native security style Views, SMB will get Unix IDs from the Active Directory provider and NFS will get Unix IDs from the LDAP provider.

  For Unified or NTFS security style Views, SMB and NFS will get Unix IDs from the Active Directory provider.

- **SFU (Services for Unix 3.0)**

  In SFU, the UID and GID are stored along with Active Directory objects in the following attributes: the UID for a user is stored in the attribute ‘uidNumber’ and GID for a group is stored in the attribute 'gidNumber'.

  For Native security style Views, SMB will get Unix IDs from the Active Directory provider and NFS will get Unix IDs from the LDAP provider.

  For Unified or NTFS security style Views, SMB and NFS will get Unix IDs from the Active Directory provider.

4. Select a **Fallback Option** to use if the selected ID Mapping Type is, for instance, not populated. This is available if the ID Mapping Type is not Fixed or RID.

   If you select Fixed for the Fallback Option, provide the following information:

   - **Unix UID to be applied to all files created:** Enter a user ID to apply to all created files.
   - **Unix GID to be applied to all files created:** Enter a group ID to apply to all created files.
5. Select the **AD User mapped to the Linux Root User** by selecting the AD domain and user.
6. Click **Save**.

Trusted Domains

After the Cohesity cluster joins the Active Directory domain, you can add trusted domains to the allowlist or denylist. By default, all trusted domains are used for authentication unless added to the denylist. You can add trusted domains to the allowlist so that only trusted domains added to the allowlist are used for authentication.

> **Note:** If the domain controller is not functioning correctly, the discovery of trusted domains may take a relatively long period of time or may provide inconsistent results. Therefore, a trusted domain might not be discovered at all. You must manually enter such domains in the allowlist or denylist.

A trusted domain forest can have multiple trusted domains. To provide optimized access, you can use a subset of trusted domains so that the Cohesity cluster does not send group membership queries to all trusted domains. You can choose a subset of trusted domains by using one of the following modes:

- **Denylist**—Ignores specified trusted domains. For example, if there are three trusted domains T1, T2, and T3 and if T2 is added to the denylist, T1 and T3 are the trusted domains used for authentication.
- **Allowlist**—Allows only specified trusted domains. For example, if there are three trusted domains T1, T2, and T3 and if T1 and T2 are added to the allowlist, T1 and T2 are the trusted domains used for authentication.

Add Trusted Domains to the Allowlist

To add a trusted domain to the allowlist:

1. Navigate to **Settings > Access Management** and click the **Active Directory** tab.
2. Click the domain name to navigate to the AD domain details page.
3. Click the edit icon in the **Denied Trusted Domains** section.
4. Click **Allowlist** and add the domain name in the **Allowed Trusted Domains** field. Click + to add another domain.

   Cohesity recommends adding at least one domain or switching to a denylist.
5. Click **Save**.

   The trusted domain is added to the allowlist.

Add Trusted Domains to the Denylist

If you want Cohesity to ignore specific trusted domains so that their principals are not assigned roles and denied access to Cohesity SMB shares, you can add the desired domains to the denylist.

To add a trusted domain to the denylist:

1. Navigate to **Settings > Access Management** and click the **Active Directory** tab.
2. Click the domain name to navigate to the AD domain details page.
3. Click the edit icon in the **Denied Trusted Domains** section.
4. Click **Denylist** and add the domain name in the **Denied Trusted Domains** field. Click + to add another domain.
5. Click **Save**.

   The trusted domain is added to the denylist.

Refresh Trusted Domains

If the **Discover Trusted Domains** option is enabled, the trusted domains associated with the AD are discovered and listed in the **Discovered Trusted Domains** section. After any

configuration change, trusted domains are not automatically refreshed in the **Discovered Trusted Domains** section. You must manually refresh the trusted domains.

To refresh the trusted domains list:

1. Navigate to **Settings > Access Management** and click the **Active Directory** tab.
2. Click the domain name to navigate to the AD domain details page:
3. In the **Discovered Trusted Domains** section, click **Refresh Trusted Domains**.

Add or Edit Preferred Domain Controllers

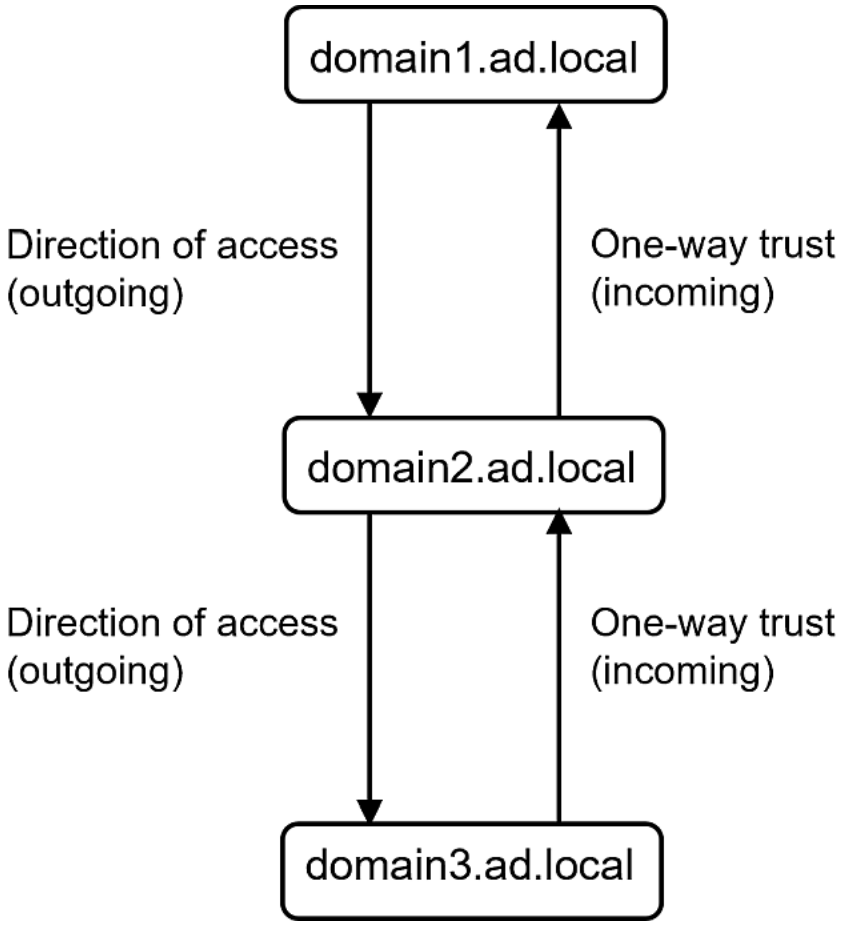
To add or edit preferred domain controllers of the discovered trusted domains:

1. Navigate to **Settings > Access Management** and click the **Active Directory** tab.
2. Click the domain name to navigate to the AD domain details page:
3. In the **Discovered Trusted Domains** section, click **Select** corresponding to the domain name.
4. On the **Edit Preferred Domain Controllers** dialog, modify the domain controllers and click **Save**.

One-Way Trust

A one-way trust is a unidirectional authentication path created between two AD domains. In a one-way trust, the trust relationship is only one way.

The following is an illustration of one-way trust and the direction of access:



As shown in the above figure:

- domain2.ad.local has a one-way trust with domain1.ad.local. domain1.ad.local does not have a trust relationship with domain2.ad.local. Users in domain2.ad.local can access resources in domain1.ad.local. However, users in domain1.ad.local cannot access resources in domain2.ad.local.
- domain3.ad.local has a one-way trust with domain2.ad.local. domain2.ad.local does not have a trust relationship with domain3.ad.local. Users in domain3.ad.local can access resources in domain2.ad.local. However, users in domain2.ad.local cannot access resources in domain3.ad.local.

In a one-way trust, the direction of trust is the opposite of the direction of access. An outgoing trust allows incoming access and an incoming trust allows outgoing access.

If one-way trust is enabled on the AD domain, trusted domains are listed in the following way in the Cohesity cluster:

- If the Cohesity cluster joins domain2.ad.local and if trusted domains are enabled:
    - domain1.ad.local is displayed as a trusted domain because domain1.ad.local trusts domain2.ad.local

    - domain3.ad.local is not displayed as a trusted domain because domain3.ad.local does not trust domain2.ad.local
- If the Cohesity cluster joins domain3.ad.local, both domain2.ad.local and domain1.ad.local are displayed as trusted domains because domain2.ad.local trusts domain3.ad.local and domain1.ad.local trusts domain2.ad.local.
- If the Cohesity cluster joins domain1.ad.local, no domain is displayed as a trusted domain because domain1.ad.local does not have a trust relationship with domain2.ad.local or domain3.ad.local.

Two-Way Trust

Two-way trust refers to the trust relationship between two domains where each domain trusts the other. Users and resources in both domains can access resources in the other domain. In a two-way trust relationship, authentication requests can flow in both directions, allowing users from one domain to access resources in another and vice versa without encountering authentication issues. For example, if domain A establishes a two-way trust with domain B, it implies that domain B reciprocally trusts domain A. As a result, both domains can seamlessly share resources.

Cohesity supports the following types of two-way trust:

- Parent-Child Trust
- Tree-Root Trust

Parent-Child Trust

A parent-child trust is a two-way, transitive trust relationship between a parent domain and its child domain within the same forest. The parent domain sits atop the forest and governs its child domains. A child domain is a subdomain established beneath its parent, inheriting policies and settings while also capable of possessing its distinct policies and objects.

This trust relationship facilitates seamless access for users, groups, and computers within the child domain to resources located in the parent domain, and vice versa. Tree-root trust is bi-directional as it allows authentication and authorization traffic to flow in both directions between the parent and child domains.

Tree-Root Trust

A tree-root trust is a two-way, transitive trust relationship automatically established between a new domain tree and the forest root domain when the tree is added to a forest. Users from any domain in the tree can access resources in the forest root domain and vice versa, without needing additional trust relationships. Tree-root trust is bi-directional as it allows authentication and authorization traffic to flow in both directions between the two forests.

View Active Directory Join and Leave Status

You can add one or more Active Directory (AD) domains to a Cohesity cluster. Joining the AD domain to a Cohesity cluster is a multi-step process and involves the following steps:

- Connecting to the DNS server
- Getting the list of domain controllers from the DNS server
- Connecting to the DC server
- Adding machine account(s)
- Setting the encryption type

You can view the progress of each subtask. For example, while joining an AD domain, you can check whether the machine account was added successfully. This log helps in troubleshooting and identifying the exact step at which the task failed.

View Active Directory Join Status

To view the AD join status:

1. Follow the steps described on the Join Active Directory page to join the Cohesity cluster to the AD domain.
2. After you click **Join**, the following error message is displayed if the process fails:

   ```
   Joining Active Directory <ad-domain-name> failed. Show Subtasks
   ```

3. Click **Show Subtasks**.

   A dialog is displayed and the subtasks are listed.

   You can view the subtask at which the process failed.

You can also view the status when you edit an AD domain. For example, if you add or modify a machine account after the Cohesity cluster joins the AD domain and if the process fails, you can view the status by following the steps outlined below:

1. Navigate to **Settings > Access Management** and click the **Active Directory** tab.
2. Click the AD domain that you want to edit.

   The AD Domain details page is displayed.
3. Click the edit icon corresponding to **Machine Accounts**.
4. Modify the machine account details as necessary.
5. Click **Save**.

   The following error message is displayed if the process fails:

   ```
   Failed to join Active Directory. Show Subtasks
   ```

6. Click **Show Subtasks** to view the subtask at which the process failed.

View Active Directory Leave Status

Leaving an AD domain is a multi-step process. You can view the progress of each subtask. For example, while leaving an AD domain, you can check whether the machine account was removed successfully. This log helps in troubleshooting and identifying the exact step at which the task failed.

To view the AD leave status:

1. Follow the steps described in the Leave Active Directory Domain section to remove the Cohesity cluster from an AD domain.
2. Click **Leave Domain**.

   The following error message is displayed if the process fails:

   ```
   Failed to leave Active Directory. Show Subtasks
   ```
3. Click **Show Subtasks** to view the subtask at which the process failed.

Certificate-Based Authentication

If the Cohesity cluster is joined to an Active Directory domain, certificate-based authentication can be enabled for the Cluster, requiring users to sign in using a digital certificate instead of a user name and password.

For added security, if you want to determine if the incoming certificate is from a trusted source, you must set up a trust store in the Cohesity cluster and add trusted root certificates to the trust store. For more information, see Trust Store in Cohesity Cluster.

Prerequisites and Considerations

- The Cohesity cluster must be joined to an Active Directory domain. For more information, see Join Active Directory.
- Active Directory should have Certificate Services installed if you plan to use self-signed certificates. For more information, see Install the Certification Authority.
- Each user must have a valid self-signed certificate or Authority-issued certificate in `.pem` format. The key resides on the user's computer.
- An AD user or group must be mapped to one or more Cohesity roles. For example, you might map the Administrators group to the Cohesity Admin role to grant users in the group Admin privileges in the Cohesity cluster. See the following procedure for details.
- If an AD user is defined in different AD groups and those groups are mapped to different Cohesity roles, the user will have the privileges for the combined roles on the Cluster.

To enable certificate-based authentication:

> **Note:** Enabling or disabling certificate-based authentication automatically restarts the Cluster and signs out all users. The Cluster restart can take a several minutes to complete.

1. In Active Directory Certificate Services, map the certificates to users.
2. Make sure Cohesity users have access to their certificates so they can install them when prompted to do so.

3. Map each AD user or group to one or more Cohesity cluster roles:
    a. In the Cohesity Dashboard, select **Settings > Access Management**.
    b. Click **Add AD Users & Groups**.
    c. Select **Active Directory Users & Groups**.
    d. Select a domain from the **Active Directory Domain** dropdown.
    e. Select a user or group from the **User(s) or Group(s)** dropdown.
    f. Select one or more roles for the group or user in the **Roles** dropdown.
    g. Click **Add**.
4. Enable certificate-based authentication for the Cohesity cluster:
    a. In the Cohesity Dashboard, select **Settings > Summary** and click **Configure**.
    b. Toggle on **Enable Certificate-based Authentication**.
    c. Respond to the confirmation prompt.

You and other users will be automatically signed out of the Cluster when it restarts. After the Cluster restarts:

- Users defined in AD are prompted to install the certificate the first time they access the Cohesity Dashboard. Once the certificate is installed and the user is authenticated against AD, the Cohesity Dashboard is displayed (the user bypasses the sign-in prompt).
- Users who attempt to sign in with an invalid certificate will see a `403 forbidden` error and message indicating that certificate authentication is enabled.
- Users who attempt to sign in with no certificate are presented with the sign-in prompt, but no AD domains are shown in the prompt.
- Local users (defined locally in the Cluster) can continue to sign in as usual with their user name and password.

To authenticate using the Cohesity CLI:

If certificate-based authentication is enabled on the Cohesity cluster, users who want to use the Cohesity CLI must first authenticate to the Cluster by using the following command:

```
iris_cli --server=<ip address> -cert <absolute path to public key file> -key
<absolute path to private key>
```

A sample command is shown below:

```
./iris_cli --server=192.0.2.3 -cert /a/b/c -key /a/b/c
```

The command options are:

- `-server` The IP address or hostname of the Cohesity cluster.
- `-cert` The absolute file path for the public key file (`.pem`).
- `-key` The absolute file path to the private key file (`.key`) that corresponds to the certificate file.

To change the authentication type via the Cohesity CLI:

In addition to enabling and disabling certificate-based authentication in the Cohesity Dashboard, you can use the following Cohesity CLI command. Note that the Cluster must be restarted after changing authentication with the CLI command.

```
iris_cli cluster update authentication-type=<string>
```

Specify one of the following options for `<string>`:

- `password-only` Disables certificate-based authentication. All users must provide passwords to sign in.
- `certificate-only` Enables certificate-based authentication. Users defined in the joined AD domain must have certificates to sign in to the Cluster. Local users must provide passwords.

Certificate Mapping-Based Authentication

If the Cohesity cluster is joined to an Active Directory (AD) domain, Active Directory (AD) users can authenticate to the Cohesity cluster using certificate mapping-based authentication.

In certificate mapping-based authentication, the AD user is authenticated based on the attribute mappings you have configured for the certificate and AD. In the Cohesity cluster, you can define the following attributes of the certificate and AD that must map for the user authentication:

- Certificate Attributes:
  - CommonName
  - EmailAddress
  - UserPrincipalName
- Active Directory Attributes:
  - SamAccountName
  - UserPrincipalName

Configure the Authentication Attributes

In the Cohesity cluster, you can define the certificate and AD attributes that must map for user authentication.

To configure the authentication attributes:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

```
./iris_cli -server 172.16.3.101 -username=admin
```

2. To define the certificate and AD attributes that must map for user authentication, run the following command:

   ```
   iris_cli security-config update ad-mapping=<AD_attributes> certificate-mapping=<cert_attributes>
   ```

   Where:

   - `<AD_attributes>` - Any one of the following AD attributes:
     - SamAccountName
     - UserPrincipalName
   - `<cert_attributes>` - Any one of the following certificate attributes:
     - CommonName
     - EmailAddress
     - UserPrincipalName

   Sample:

   ```
   iris_cli security-config update ad-mapping=UserPrincipalName certificate-mapping=EmailAddress
   ```

Enable Certificate Mapping-Based Authentication

In the Cohesity cluster, you can enable certificate mapping-based authentication using the Cohesity CLI.

To enable certificate mapping-based authentication:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. To enable certificate mapping-based authentication, run the following command:

   ```
   iris_cli security-config update enable-mapping-based-auth=true
   ```

The AD users are now authenticated to the Cohesity cluster using certificate mapping-based authentication. For added security, if you want to determine if the incoming certificate is from a trusted source, you must set up a trust store in the Cohesity cluster and add trusted root certificates to the trust store. For more information, see Trust Store in Cohesity Cluster.

Trust Store in Cohesity Cluster

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

For security purposes, you can set up a trust store in the Cohesity cluster and add trusted root certificates or certificate authority (CA) to the trust store. If the incoming certificate forms a valid certificate chain with at least one of the trust store certificates, then the incoming certificate is determined to be from a trusted source.

Once the AD users are authenticated using certificate mapping-based authentication and the digital certificate is determined to be from a trusted source, the AD user can log into the Cohesity cluster.

Set Up Trust Store

You can set up a trust store in the Cohesity cluster using the Cohesity CLI.

Prerequisites

Ensure that:

- The certificate is in PEM format.
- You copy the certificate to the Cohesity cluster.

To set up a trust store:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. Validate the certificate. Run the following command:

   ```
   iris_cli trusted-cas register name=rootCert desc=testing file-
   path=rootCert.pem only-validate=true
   ```

3. If the certificate is valid, add the certificate to the trust store. Run the following command:

   ```
   iris_cli trusted-cas register name=rootCert desc=testing file-
   path=rootCert.pem
   ```

4. You can view the added certificates to the trust store using the following command:

   ```
   iris_cli trusted-cas ls
   ```

5. Enable the feature that validates if the incoming certificate forms a valid certificate chain. Cohesity Support to enable the feature.
6. If you have not enabled certificate-based authentication or certificate mapping-based authentication on the Cohesity cluster, enable it. For more information, see Certificate-Based Authentication or Certificate Mapping-Based Authentication.

The AD users are now authenticated to the Cohesity cluster based on the type of authentication you have configured, such as certificate-based authentication or certificate mapping-based authentication. And, the user can log in to the Cohesity cluster using only the trusted certificates.

Kerberos

Cohesity supports Kerberos authentication using both NFSv3.0 and NFSv4.1. Kerberos prevents unauthorized users from accessing Cohesity NFS exports.

Kerberos is a network authentication protocol that allows users to securely access services over a physically insecure network.

Kerberos has three parts:

- Client
- Server
- Kerberos Key Distribution Center (KDC) - KDC mediates between client and server.

Clients obtain tickets from the Kerberos Key Distribution Center(KDC), and they present these tickets to servers when connections are established. For more information, see Kerberos.

Supported Kerberos Flavors

Cohesity supports the following two flavors of Kerberos:

- Microsoft AD Kerberos
- MIT Kerberos

Kerberos Terminology

Realm

A network that uses Kerberos, composed of one or more servers called KDCs and a potentially large number of clients.

Key Distribution Center (KDC)

A service that issues Kerberos tickets, usually run on the same host as the Ticket Granting Server.

Ticket Granting Service (TGS)

A server that issues tickets for the desired service which are in turn given to users for access to the service. The TGS usually runs on the same host as the KDC.

Ticket Granting Ticket (TGT)

A special ticket that allows the client to obtain additional tickets without applying for them from the KDC.

Principal

A user or service that can authenticate using Kerberos. A principal's name is in the form root [/instance]@REALM. For a typical user, the root is the same as their login ID. The instance is optional. If the principal has an instance, it is separated from the root with a forward slash ("/"). An empty string ("") is considered a valid instance (which differs from the default NULL instance), but using it can be confusing. All principals in a realm have their own key, which is derived from their password or randomly set for services.

For more information on Service Principal Name and Host Principal Name, see Service Principal Names.

Client

An entity on the network (a user, a host, or an application) that can get a ticket from Kerberos.

Microsoft AD Kerberos

Kerberos is the authentication service in Microsoft Active Directory.

Configure AD Kerberos on Cohesity Cluster

Components in AD Kerberos configuration on the cluster:

- AD Server
- LDAP Server
- Unix Clients
- Cohesity cluster

NFS User and Group Configuration Parameters in AD

When you use AD as an LDAP provider for NFS with Kerberos, you must set the following parameters for a user or group.

You must set the following parameters for a user:

- uid—username (same as sAMAccountName)
- uidNumber—User identifier
- gidNumber—Group identifier of the primary group

- objectClass—posixAccount

  Instead of setting the objectClass in AD, you can contact Cohesity Support to help use one of the objectClasses for a user in AD.

You must set the following parameters for a group:

- gidNumber—Group identifier of the group
- objectClass—posixGroup

  Instead of setting the objectClass in AD, you can contact Cohesity Support to help use one of the objectClasses for a group in AD.
- If a group is a secondary group for some users, then set:

  memberUid—List of uidNumbers

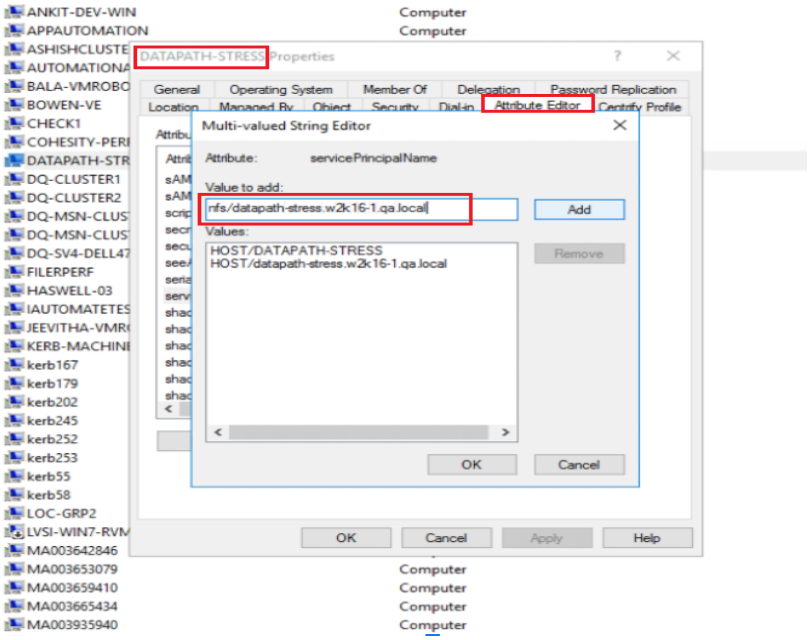
> **Note:** Make sure the AD group memberships reflect the same as these UNIX memberships.

Configure AD Kerberos on a Cohesity Cluster

To configure AD Kerberos on a Cohesity cluster, complete the following high-level steps:

1. Create a DNS entry (in the DNS Manager option) on the AD server with the machine account name to provide IP mapping.
2. Add the AD domain to the Cohesity cluster. For more information, see Join the Cohesity cluster to an AD Domain.
3. Add an LDAP server to the Cohesity cluster and map it to the AD server.
4. Log in to the AD server and complete the following steps:
    1. Right-click the corresponding machine account and select **Properties**.
    2. Go to the **Attribute Editor** tab and double-click the **servicePrincipalName** parameter.
    3. In the **Value to add** text box, add **nfs** followed by the machine account name and domain name and click **Add**. For example, considering **datapath-stress** is the machine account name and **w2k16-1.test.local** is the domain name, the

value is: **nfs/datapath-stress.w2k16-1.test.local**:



5. If your environment has multiple domain controllers for the same AD domain, you must sync all of them.
    1. To sync, run the following command on all domain controller:

    ```
    repadmin /syncall /adep
    ```

    > **Note:** If an IP address for the existing entry is changed, make sure that DNS cache is flushed at AD DCs.

6. Add the Mapped LDAP+ AD as Authorization Provider for a Storage Domain. For more information, see Map LDAP+AD as an Authorization Provider to a Storage Domain.
7. If your environment has multiple domain controllers for the same AD domain, you must sync all of them.
    1. To sync, run the following command on all domain controller:

    ```
    repadmin /syncall /adep
    ```

    > **Note:** If an IP address for the existing entry is changed, make sure that DNS cache is flushed at AD DCs.

8. Configure Unix client for mounting Kerberos based View: For more information, see Configure Unix client for Mounting Kerberos Based View
9. Mount Kerberos-based NFS View. For more information, see Mount a View Using NFS.

Map LDAP+AD as an Authorization Provider to a Storage Domain

To map LDAP+AD as an authorization provider to a storage domain, complete the following steps:

1. In the Cohesity UI, select **Settings > Summary** and select the **Storage Domains** tab.
2. On the **Storage Domains** page, complete one of the following actions:
    1. Edit an existing Storage Domain by clicking the Actions Menu (⋮) and selecting **Edit**.
3. In the **Authentication Provider** drop-down, select required LDAP +AD.
4. Click **Save**.

Configure Unix client for Mounting Kerberos Based View

> **Note:** The commands in the steps are CentOS commands.

To configure a Unix client for mounting Kerberos-based View, complete the following steps:

1. Stop SELinux and disable the service.
2. Open the `/etc/selinux/config` file and set the SELINUX mode to be disabled.
3. Run the following commands and stop the firewall and disable the service.
    - `systemctl stop firewall`
4. Reboot the Unix client node.
5. Open `/etc/hosts` and change the hostname of the node.

    For example, consider **Kerb245** is the hostname of the client and **w2k16-1.test.local** is the domain name

    "198.51.100.12 kerb245.w2k16-1.test.local kerb245"
6. Change the hostname using the following command.
    - `hostnamectl set-hostname`
7. Install all the required packages for `realm/krb5`.
    1. Run the following command
        - `yum update;`
        - `yum install realmd sssd oddjob oddjob-mkhomedir adcli samba-common samba-common-tools ntpdate ntp`
        - systemctl enable ntpd.service
    2. realm discover w2k16-1.qa.local

3. realm join w2k16-1.qa.local --user=Administrator@W2K16-1.QA.LOCAL --verbose
4. realm list

8. Starting from Cohesity Data Cloud (Self-managed) 6.6.0a onwards, you need not create a user for each client machine that you intend to mount from. Instead, you can map all clients to the default (nobody) hostname of the client. You must create a **nobody** user in the AD server and configure the attributes as described in NFS User and Group Configuration Parameters in AD.

   > **Note:** If the Cohesity Data Cloud (Self-managed) version is 6.6, you must create a user and ensure that the username is the same as the hostname of the client.

   If you create a user, ensure that the username is the same as the hostname of the client. For example, if the hostname of the client is **krb245**, you should configure the attributes as follows:

   - Username—*krb245*
   - objectClass—posixAccount
   - Uid—*krb245$*
   - UidNumber—User identifier. The value can be any integer.
   - GidNumber—Group identifier of the group this user is a part of. This group must have the value **posixGroup** in the objectClass attribute.

   > **Note:** For the AD server user, UID number and UID value are different fields.

9. Create a group on the AD server and add the user to the group.

   Once you are done with configuring the Unix client, you can mount a NFS View using Kerberos.

> **Note:** If you are using an AD user from a Linux client, ensure to set the following parameters on the client:

For AD users to work, `/etc/sssd/sssd.conf` file should have the following values:

```
ldap_id_mapping = False
use_fully_qualified_names = False
fallback_homedir = /home/%u
```

To mount a Kerberos-based NFS View, see Mount a View Using NFS.

MIT Kerberos

MIT Kerberos is another flavor of Kerberos similar to AD Kerberos. You need to add the MIT Kerberos provider to the Cohesity cluster from the Access Management page and configure. For more information, see MIT Kerberos.

> **Note:** MIT Kerberos does not support NTFS View type.

Prerequisites for Configuring MIT Kerberos on NFS Client

The following are the prerequisites for NFS client to configure Kerberos:

- Have DNS entries for all servers involved in the Kerberos environment.
- Ensure that the NFS users of client machines should have corresponding accounts in both LDAP and KDC.
- Host principal name for clients and servers.
- Configure KDC.
- Configure OpenLDAP server.
- Prepare a Client-Machine as:
  - OpenLDAP client: Validate client-ops for OpenLdap.
  - KDC-client: Validate client-ops for KDC.
  - NFS-client.

Configuring MIT Kerberos on a Cohesity Cluster

> **Note:** Use iris_cli cluster add-etc-hosts if servers are not DNS routable from Cohesity cluster.

Configuring MIT Kerberos on a Cohesity Cluster involves the following high-level steps:

1. Add OpenLDAP server to Cohesity cluster. For more information, see Add an LDAP Provider to the Cohesity cluster.
2. Add MIT Kerberos Provider to Cohesity Cluster. Adding MIT Kerberos Provider procedure allows you to map it to the LDAP.
3. Map MIT Kerberos + LDAP as an Authorization Provider to a Storage Domain.
4. Optional: Create a View (if not already exists), with kerberos security modes enabled (default on).
5. Log in as one of the LDAP-user, or change the user;

1. Get user Ticket Granting Ticket (TGT). If not acquired on login: Run '`kinit`
6. Access the mounted directory.

Add MIT Kerberos Provider to Cohesity Cluster

You need to add the MIT Kerberos provider to the Cohesity cluster to authenticate Unix users to access the Cohesity view in a Kerberos environment.

Prerequisites

- Realm name
- KDC server name and credentials

To add MIT Kerberos Provider to the Cohesity cluster, complete the following steps:

1. Click **Settings > Access Management > Kerberos**
2. In the Kerberos tab, click **Add Kerberos Provider**.
3. In the Add Kerberos Provider screen, complete the following steps:
    1. Type **Realm Name**.
    2. Type **Host Alias**.

        > **Note:** Host alias is Cohesity cluster names. Default host alias is your Cohesity cluster name. You can add more than one host alias names.

    3. (Optional) Toggle the **Use existing Host Aliases**.
    4. Type **KDC Servers** names.

        > **Note:** You can add multiple KDC Server host names. Use a comma to separate the names.

    5. Add **Admin Server** (KDC).

        > **Note:** You can select one of the added KDC servers as an admin server.

    6. Type **Admin password**.
    7. Select Mapped LDAP Provider.

        You can add the LDAP provider if it is not added already.
    8. Click **Add**.

Map MIT Kerberos + LDAP as an Authorization Provider to a Storage Domain

After adding the MIT Kerberos to the Cohesity cluster that is mapped to an LDAP server, you must map MIT Kerberos + LDAP server to a storage domain. The Views created under the storage domain mapped with MIT Kerberos + LDAP uses the MIT Kerberos for authentication.

To map MIT Kerberos Provider with a Storage Domain, complete the following:

1. In the Cohesity UI, select **Settings > Summary** and select the **Storage Domains** tab.
2. On the Storage Domains page, complete one of the following actions:
    1. Edit an existing Storage Domain by clicking ⋮ and select **Edit**.
3. In the **Authentication Provider** drop-down, select the required **MIT Kerberos +LDAP** in the **Kerberos + LDAP** section.
4. Click **Update Storage Domain**.

Edit MIT Kerberos Provider

You can edit the MIT Kerberos provider to update any modifications made in the Kerberos server.

To edit the MIT Kerberos provider, complete the following steps:

1. Click **Settings > Access Management > Kerberos**.
2. In the **Kerberos** tab, select the required **MIT Kerberos Provider** and select the edit icon for the required **MIT Kerberos**.
3. In the **Edit Kerberos Provider** screen, you can update the following:
    - Host Alias. Host alias is Cohesity cluster names.
    - (Optional) Toggle the Use existing Host Aliases
    - KDC servers names
    - Admin Server (KDC). You can select one of the KDC servers as an admin server.
    - Mapped LDAP provider.
4. Click **Save**.

Unmap MIT Kerberos Provider from Storage Domain

You first need to unmap the MIT Kerberos provider from the storage domain when you want to stop using it for authentication and delete it from the Cohesity cluster. If you do not unmap Views from the storage domain, the existing clients observe errors.

To unmap MIT Kerberos provider from the Storage Domain, complete the following:

1. In the Cohesity UI, select **Settings > Summary** and select the **Storage Domains** tab.
2. On the Storage Domains page, complete one of the following actions:
    1. Edit an existing Storage Domain by clicking ⋮ and select **Edit**.
3. In the **Authentication Provider** dropdown, select **None** in the Kerberos + LDAP section.
4. Click **Save**.

Delete MIT Kerberos Provider

When you no longer want to use the MIT Kerberos for authentication, you may delete. You can delete the MIT Kerberos Provider once you unmap from all storage domains.

To delete the MIT Kerberos from the Cohesity cluster, you must have MIT Kerberos password.

Prerequisite

You must unmap MIT Kerberos from the storage domain before deleting it.

To delete the MIT Kerberos Provider, complete the following:

1. Click **Settings > Access Management > Kerberos**.
2. In the **Kerberos** tab, select the required **MIT Kerberos Provider** and click the delete icon for the required **MIT Kerberos**.
3. In the **Delete MIT Kerberos** screen, type the **MIT Kerberos** admin password.
4. Click **Delete**.

Secure Login

Secure Login provides additional layers of security that enable the verification of the identity of a user, restricting unauthorized access and malicious activity in the cluster environment. Secure Login includes,

- Multi-factor Authentication (MFA)
- Split Key

For enhanced security, Cohesity strongly recommends that you enable MFA for all users and groups. After MFA is enabled by the administrator, users are prompted for an additional authentication factor along with the Cohesity cluster user credentials during the sign-in process.

> **Note:** A user must have a user account in the Cohesity Data Cloud (Self-managed) to use MFA provided by Cohesity.

Cohesity supports multi-factor authentication for the following types of users and groups:

- Local user
- Active Directory users with user accounts created in Cohesity
- SSO users and groups
- Support user

Cohesity supports split key for the following types of users:

- Cohesity Console user
- Support user

> **Important:**
> If you are using SSO for authentication, then Cohesity recommends that you enable MFA in your SSO system.

By default, MFA is enabled for Active Directory users with user accounts created in the Cohesity. You can enable MFA for local users and the **support** user account in the Cohesity. For more information, see:

- Multi-factor Authentication for Local and Active Directory Users
- Multi-factor Authentication for the Support User Account
- Enable Split Key

Multi-factor Authentication for Local and Active Directory Users

Multi-factor Authentication (MFA) is an additional layer of security used to verify the identity of a user. Cohesity supports MFA for local users. MFA enforces users to provide an additional authentication factor to access the Cohesity GUI or Cohesity CLI.

By default, MFA is enabled for Active Directory users with user accounts created in Cohesity. Administrators can enable MFA so that all or specific local users are prompted during the sign-in process for an additional authentication factor along with the local user credentials that they use to log in to the Cohesity cluster.

Cohesity supports the following authentication methods:

- **Authenticator App**—Users must enter the verification code generated by a TOTP authenticator app such as Okta Verify.

> **Note:** For Active Directory users, the Authenticator App is the only supported MFA method.

- **Email**—Users must enter the verification code sent to their email address.

After MFA is enabled by the administrator, an additional authentication factor is enforced for all users on their next login.

Points to Note

- Only administrators or users with the following privileges can enable or disable MFA for local users:
  - Users with the **Manage MFA** privilege can enable or disable MFA at the cluster level:

  - Users with the **Manage Users** privilege can enable or disable MFA at the user level:

    For more information about users and roles, see Access Management.
- Users must download, install, and enroll in a TOTP authenticator app on their devices. See Supported TOTP Apps.
- Administrators must configure the email server on the Cohesity cluster. For more information about configuring an email server, see Email Configuration.
- Administrators must configure an email address for each user. Verification code is sent to this email address.
- Administrators can select one or both of the following authentication methods:
  - Authenticator app
  - Email
- Although administrators can select any authentication method as an additional factor, Cohesity strongly recommends that you:

    - Use the authenticator app as the primary MFA method
    - Do not use email as the primary MFA method because email messages can be intercepted and their contents potentially compromised by intermediary parties, especially when messages are routed over the internet.
- The lifetime of an email OTP code is two minutes.
- Disabling MFA for AD (Active Directory) users is not supported due to security reasons.

Supported TOTP Apps

Cohesity supports the following TOTP authenticator apps:

- Okta Verify
- Google Authenticator
- Duo Mobile
- Microsoft Authenticator

Enable MFA for Local Users

To enable MFA:

1. Navigate to the **MFA** tab using one of the following methods:
    - If MFA is not enabled on the Cohesity cluster, a banner appears at the top of the page; click **Manage Settings** to navigate to the **Secure Login** tab:

    - Go to **Settings > Access Management** and click the **Secure Login** tab.
    - Turn on the **MFA** toggle, select one or both authentication methods:

      > **Note:** Cohesity recommends that you select both authentication methods. If you select only one authentication method, users may get locked out if they do not have an alternative method to access the system.

        - **Authenticator App**—All users must configure an authenticator app and use a verification code generated by the app for verification.

          > **Note:** If you are using a TOTP authenticator app, the Cohesity cluster need not be connected to the internet.

- **Email**—The administrator must configure an email address for each user. The verification code is sent to this email address.

  > **Note:** If you are using email for authentication, the SMTP should be configured in the Cohesity cluster and should be active.

2. Click **Save**.

   MFA is enabled for all users. Navigate to **Settings > Access Management > Users & Groups** to view the **MFA** column.

   > **Note:** Administrators or users with the **Manage Users** privilege can turn on or turn off the toggle to enable or disable MFA for the corresponding user.

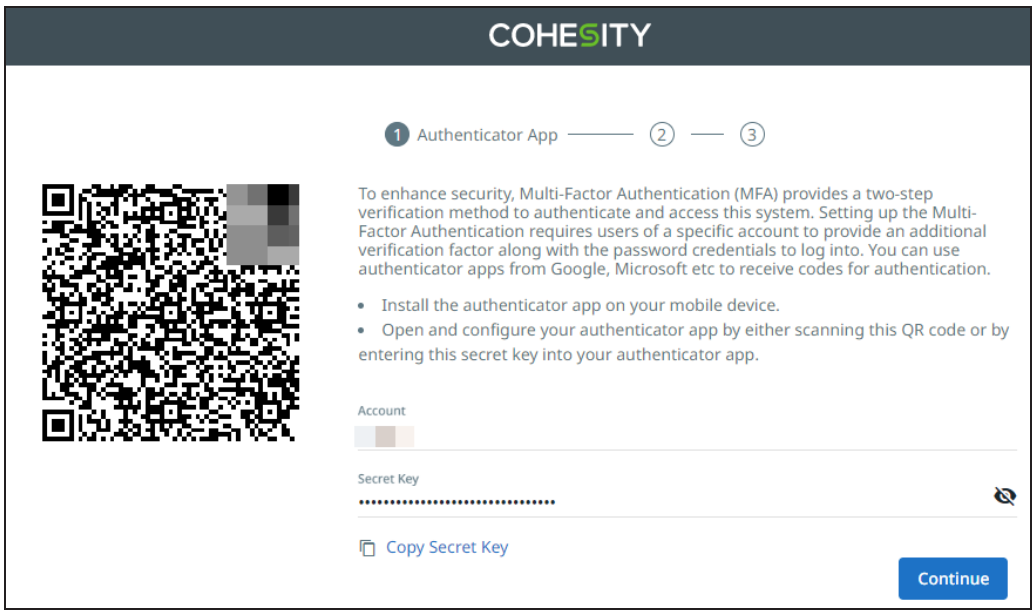
Set Up MFA for Local and Active Directory Users

After MFA is enabled, users are prompted to set up MFA when they log in for the first time.

> **Note:** For Active Directory users, the Authenticator App is the only supported MFA method.

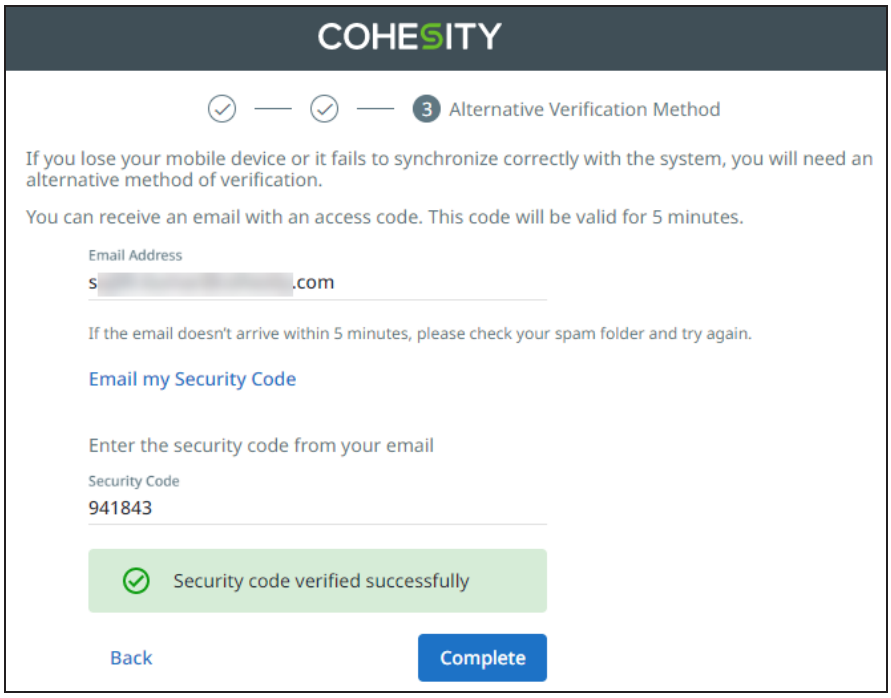
To set up MFA through the Cohesity GUI, users must do the following:

1. Open a web browser and enter the hostname or IP address of the Cohesity cluster.
2. Enter the credentials and click **Sign In**.
3. Scan the QR code and click **Continue**:



4. Enter the verification code generated by the authenticator app and click **Verify**.
5. A message is displayed after the code is successfully verified:
    - If the administrator has enabled only one authentication method, click **Complete** to finish the setup process and log in to the Cohesity cluster:

    - If the administrator has enabled both authentication methods:
        i. Click **Next** to verify the email authentication method.
        ii. Enter the verification code received on your email address and click **Verify**.
        iii. Click **Complete** to finish the setup process and log in to the Cohesity cluster:



> **Note:** Users cannot update their email addresses. Users must contact the administrator to update the email address.

Log In to the Cohesity GUI After MFA is Enabled

After MFA is enabled, users are prompted to enter the verification code after entering their credentials.

> **Note:** If the administrator has enabled both authentication methods, the default authentication method used is the authenticator app.

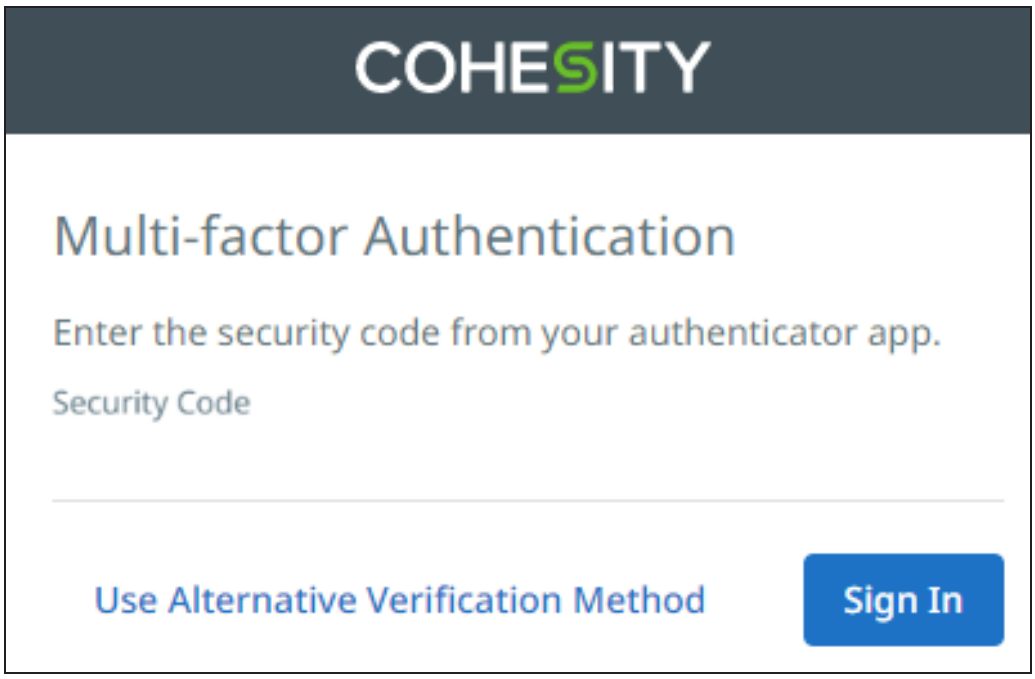
To log in to the Cohesity GUI:

1. Open a web browser and enter the hostname or IP address of the Cohesity cluster.
2. Enter the username and password and click **Sign In**.
3. Enter the verification code from the authenticator app and click **Sign In** to log in to the Cohesity cluster.

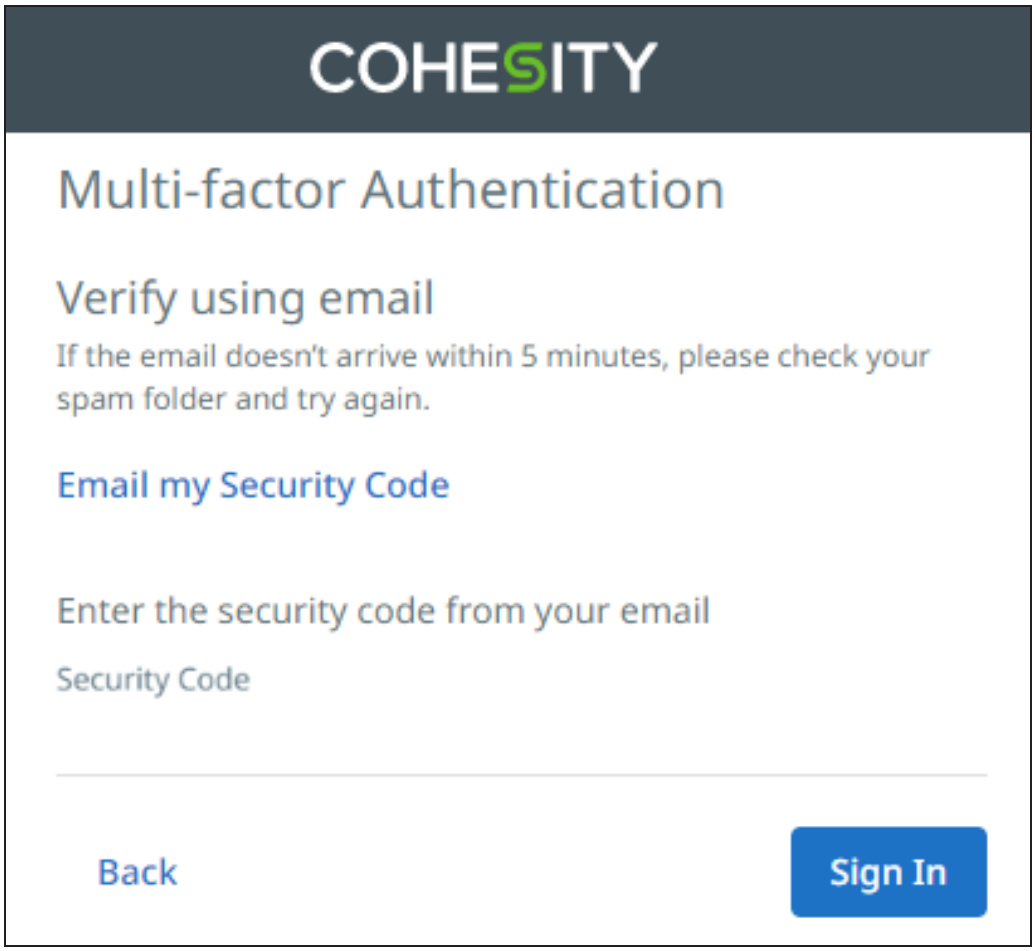
If you have lost access to the device on which the authenticator app is installed, complete the following steps to log in to the Cohesity cluster:

1. Open a web browser and enter the hostname or IP address of the Cohesity cluster.
2. Enter the username and password and click **Sign In**.

3. Click **Use Alternative Verification Method**:



4. Click **Email my Security Code**:



5. Enter the verification code received on your email address and click **Sign In**.

Log In to the Cohesity CLI After MFA is Enabled

After MFA is enabled through the Cohesity GUI, MFA is enabled for users logging in to the Cohesity CLI as well. Note the following important points:

- Enable the **support** user account on the Cohesity cluster. For more information, see Multi-factor Authentication for the Support User Account.
- Currently, Cohesity does not support setting up MFA through the CLI.
- If the administrator has enabled only the authenticator app, users must set up MFA through the Cohesity GUI. For more information, see Set Up MFA for Local and Active Directory Users.
- If the administrator has enabled only email-based TOTP, users need not set up MFA as the verification code is sent to their email address.

To log in to the Cohesity CLI:

1. Open the SSH terminal and execute the following command to log in to the Cohesity cluster Linux shell as a **support** user:

   ```
   ssh support@<ip address or hostname of the Cohesity cluster>
   ```

   Examples

   - IP address example: `ssh support@192.0.2.1`
   - Hostname example: `ssh support@cohesityhost`

2. Enter the following command:

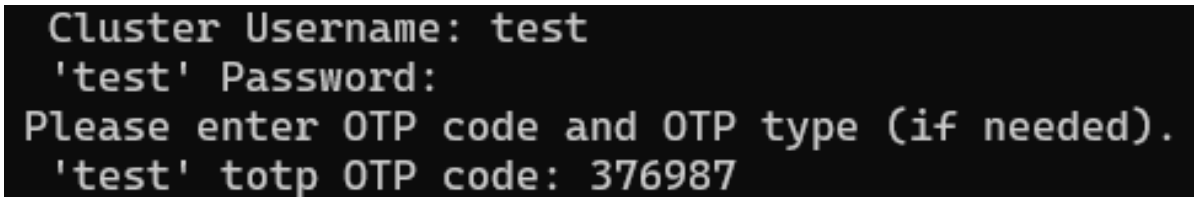
   ```
   iris_cli
   ```

3. Enter the cluster username and password.
4. If the administrator has enabled both authentication methods, enter `Email` or `Totp` to select the authentication method that you want to use:

   
   - If you selected Email authentication, enter `Y` to trigger the email and enter the verification code received in your email:

     
     > **Note:** You can generate the email verification code only once every two minutes.

   - If you selected TOTP authentication, enter the verification code generated by the authenticator app.

> **Note:** If you have not set up MFA, the following message is displayed:
>
> ```
>  'test' OTP type (Email or Totp): Totp
> The user has not setup Time-base One-time Password (TOTP). Please finish the TOTP setup via UI.
> ```
>
> You must set up MFA through the Cohesity GUI to continue. For more information, see Set Up MFA for Local and Active Directory Users.

5. After you enter the verification code, press **Enter** to log in to the Cohesity CLI.

Disable MFA for Local Users

Administrators or users with the requisite privileges can disable MFA for a user or all users. Cohesity recommends that you keep MFA enabled for enhanced security.

> **Note:**
> - If the administrator re-enables MFA, users must set up MFA again on their device. For more information on setting up MFA, see Set Up MFA for Local and Active Directory Users.
> - Disabling MFA for AD (Active Directory) users is not supported due to security reasons.

To disable MFA for a local user:

1. Navigate to **Settings > Access Management > Users & Groups**.
2. In the **MFA** column, turn off the toggle corresponding to the user.
3. Click **Disable**.

To disable MFA for all users:

1. Navigate to **Settings > Access Management** and click the **Secure Login** tab.
2. Turn off the **MFA** toggle and click **Disable**.
3. Click **Save**.

Frequently Asked Questions

1. How can I log in to the Cohesity cluster if I lose my device?

   If the authenticator app is the primary MFA method and if you lose your device, you can use the alternative verification method. For more information, see Click Use Alternative Verification Method:

   Cohesity recommends that administrators enable both authentication methods for local users:

- Authenticator app
- Email

If email is not enabled as an authentication method, users can contact the administrator to reset MFA for their account.

2. How do I connect the authenticator app to my new device?

   If you are changing your device, check whether the authenticator app allows transferring accounts to your new device. For example, Google Authenticator supports transferring accounts to your new device. For more information, see the **Transfer Google Authenticator codes to a new phone** section on this page.

   As a best practice, Cohesity recommends that you check the authenticator app that you are using and confirm whether you can transfer accounts to your new device as different authenticator apps handle this in different ways. Users can also contact the administrator to reset MFA for their account.

3. How can the administrator reset the MFA for a user?

   If the authenticator app does not support transferring accounts or if a user does not have access to their old device, the administrator or users with the **Manage Users** privilege can reset MFA for users.

   > **Note:** MFA can be disabled only for local users and not Active Directory user with user accounts created in the Cohesity.

   To reset MFA:

   a. Navigate to **Settings > Access Management > Users & Groups** tab.
   b. Turn off the toggle and disable MFA for the user.
   c. Turn on the toggle and reenable MFA for the user.
   d. The user must install and set up the authenticator app on their new device.

4. How can the administrator reset MFA for all local users?

   Administrators or users with the **Manage MFA** privilege can reset MFA for all local users. To reset MFA:

   1. Navigate to **Settings > Access Management > Secure Login** tab.
   2. Turn off the **MFA** toggle and disable MFA at the cluster level.
   3. Turn on the **MFA** toggle and re-enable MFA at the cluster level.

      MFA is reset for all local users. Users must set up MFA again. For more information, see Set Up MFA for Local and Active Directory Users.

5. What should I do if my email-based verification code expires?

If email is the primary MFA method and if there is a delay in receiving the email, the verification code expires. Users can request a new verification code. Cohesity recommends that you use the authenticator app method instead. An authenticator app can generate verification codes even if the device has no connectivity.

6. What should I do if I am locked out of my account?

   A login attempt may fail if users enter an incorrect password or verification code. User accounts are locked out after three consecutive failed attempts.

   If the user account is locked out because of an incorrect verification code, retry after one minute. If the user account is locked out because of an incorrect password, retry after 15 minutes or contact the administrator and request to unlock the user account.

   If an administrator is locked out, contact the peer administrator to reset MFA.

7. Can the default MFA be disabled for AD accounts?

   Yes, the default MFA can be disabled for the AD accounts through Cohesity CLI. Contact the Cohesity Support to disable the default MFA.

Multi-factor Authentication for the Support User Account

Multi-factor Authentication (MFA) is an additional layer of security used to verify the identity of a user. Cohesity supports MFA for the **support** user account. MFA enforces users to provide an additional authentication factor to access the Cohesity or Cohesity CLI.

Administrators can enable MFA for the **support** user account through Cohesity. For more information about the **support** user, see Manage Support User.

> **Warning:** MFA is not supported for the Cohesity console user accounts.

The administrator can select only one of the following authentication methods:

- Authenticator app
- Email

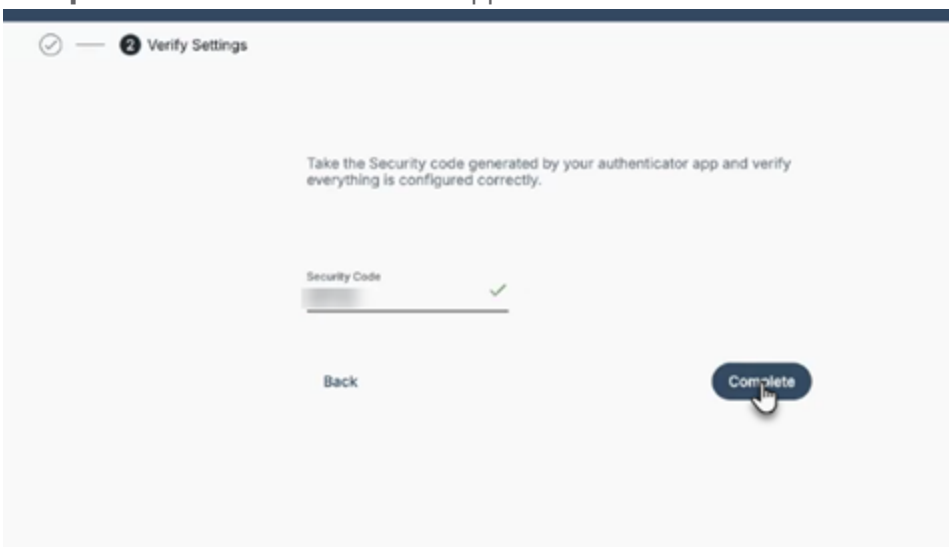
> **Note:** If you select **Email**, then you should establish a connection between Cohesity and SMTP server. For more information, see Configuring MFA for the support user to work with the SMTP server.

To enable MFA for the support user account:

1. Navigate to **Settings > Access Management > Support**.
2. In the **Support User** section:
    - Enter the email address of the **support** user and click **Update Email**.
    - To update the Linux Shell password, click **Update Password** and update the password.
3. Turn on the **Multi-factor Authentication** toggle, select one authentication method, and click **Update MFA**:
    - **Authenticator App**—The **support** user has to set up MFA and enter the verification code from the authenticator app to access the Cohesity cluster Linux shell through SSH.
    - **Email**—The **support** user has to enter the verification code received on the email address to access the Cohesity cluster Linux shell through SSH.
4. In the **Enable MFA** pop-up window that appears, enter the support user password and click **Authorize**.
    - Authenticator App – To enable MFA using an authenticator app, perform the following steps:
        a. Scan the QR code displayed on the screen using your authenticator app, or manually enter the account name and secret key.
        b. Click **Continue**.
        c. Enter the security code generated by the authenticator app and click **Verify**.

        d. Upon successful verification, a check mark appears next to the code. Click

Complete to enable MFA for the support user.



- Email – To enable MFA through email, perform the following steps:
  a. Enter the registered email address of the support user.
  b. Click **Send Email**. Cohesity sends a verification code to the email address provided.

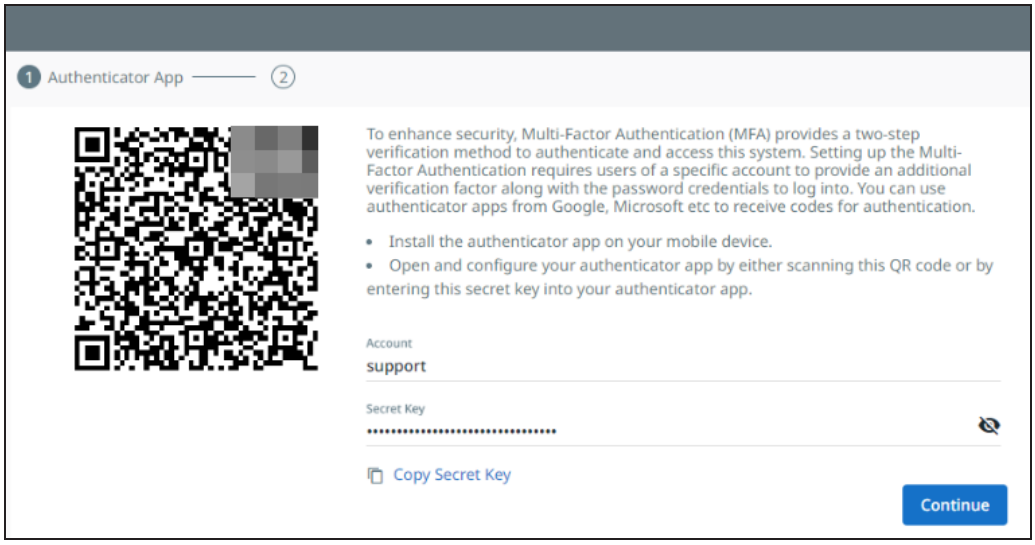
  c. Enter the security code you received and click **Verify**.
  d. Upon successful verification, a check mark appears next to the code. Click **Complete** to enable MFA for the support user.

Set Up MFA for the Support User Account

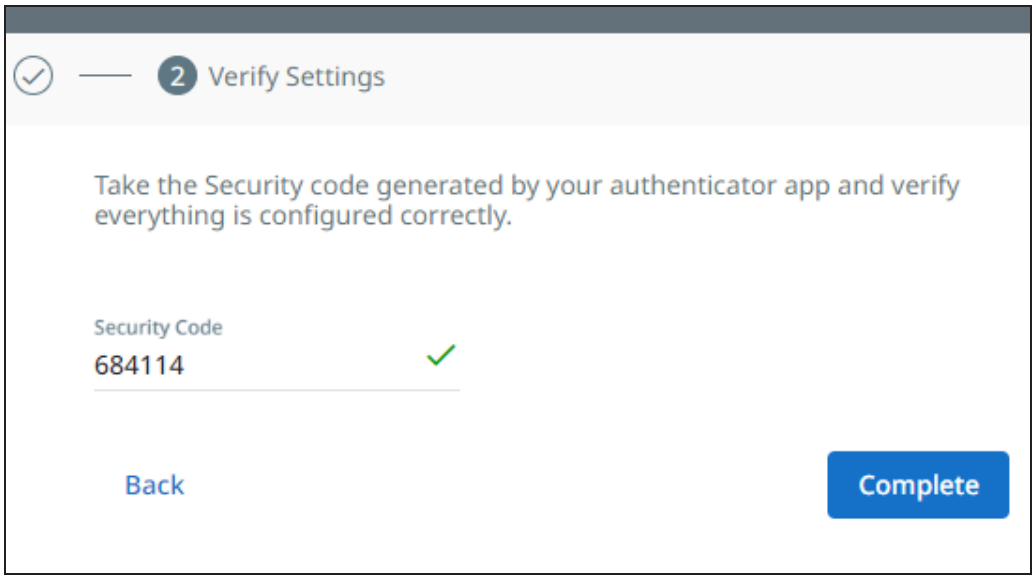
If MFA is enabled for the **support** user account, the **support** user is prompted to set up MFA during the subsequent login attempt.

To set up MFA through the Cohesity, the **support** user must complete the following steps:

1. Open a web browser and enter the hostname or IP address of the Cohesity cluster.
2. Enter the credentials and click **Sign In**.
3. Scan the QR code and click **Continue**:



4. Enter the verification code generated by the authenticator app and click **Verify**.
5. After the code is successfully verified, click **Complete** to finish the setup process and log in to the Cohesity cluster:



> **Note:** If the administrator has configured **Email** as the authentication method, the **support** user need not set up MFA as the verification code is sent to the email address.

Log In to the Cohesity Cluster Linux Shell

After MFA is enabled, the **support** user is prompted to enter the verification code after entering the password.

To log in to the Cohesity cluster Linux shell as a **support** user:

1. Open the SSH terminal and execute the following command:

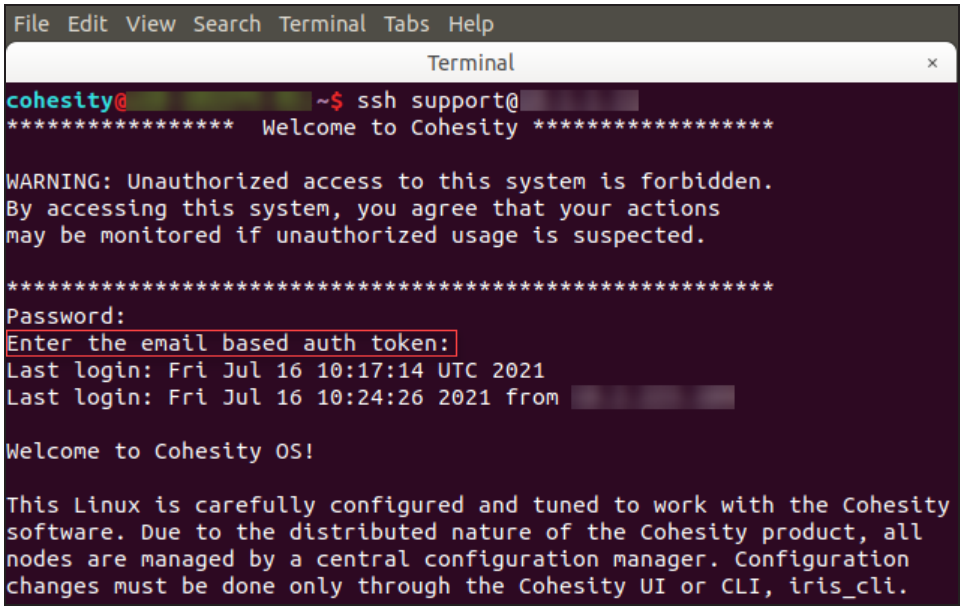
   ```
   ssh support@<ip address or hostname of the Cohesity cluster>
   ```

   Examples

   - IP address example: `ssh support@192.0.2.1`
   - Hostname example: `ssh support@cohesityhost`
2. Enter the **support** user password.
3. Enter the verification code:
   - If the administrator has configured **Authenticator App** as the authentication method, enter the verification code generated by the authenticator app at the **Verification code** prompt:

     
   - If the administrator has configured **Email** as the authentication method, enter the verification code received in the email at the **Enter the email based auth**

token prompt:



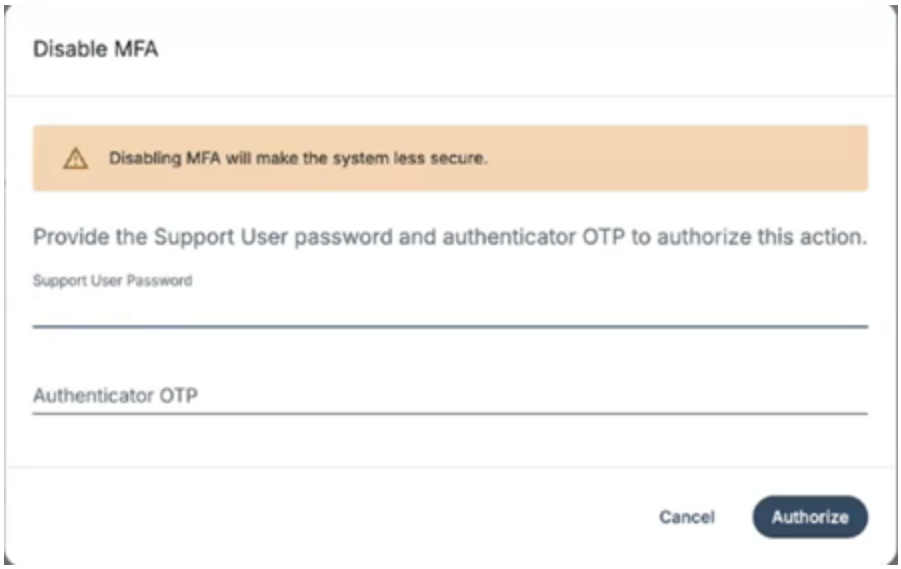
Disable MFA for the Support User Account

Administrators can disable MFA for the **support** user account. Cohesity recommends that you keep MFA enabled for enhanced security.

> **Note:** If the administrator reenables MFA, the **support** user must set up MFA again on the device. For more information on setting up MFA, see Set Up MFA for the Support User Account.

To disable MFA for the support user account:

1. Navigate to **Settings > Access Management > Support**.
2. In the **Support** tab,turn off the **Multi-factor Authentication** toggle.
3. In the **Disable MFA** pop-up window that appears, enter the support user password and the security code received via the authenticator app or email, depending on your MFA settings.



4. Click Authorize to disable MFA for the support user.

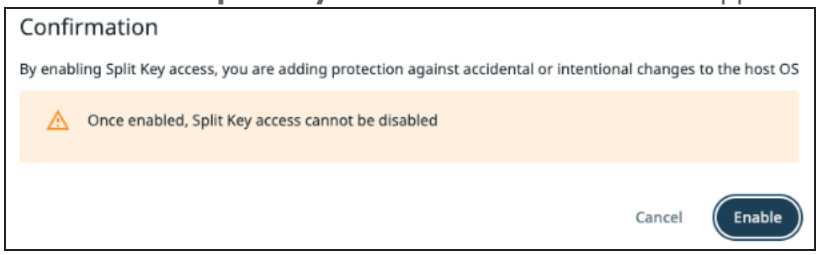
Enable Split Key

Split Key is an additional layer of security that protects the Cohesity host OS against any malicious activity. It restricts access to the host OS through multi-layer security that requires login credentials, and a challenge and response workflow.

Follow these steps to enable Split Key on your cluster,

1. Navigate to **Settings > Access Management > Secure Login**.
2. In the **Secure Login** tab, turn on the **Split Key** toggle.
3. Make sure the **Split Key** enable confirmation screen appears.



4. Click Enable to enable the Split Key.

> **Important:** Once you enable the Split Key, it cannot be disabled.

For clusters upgraded from 6.8.1 to 7.1, the UI offers the option to enable the Split Key.

By default, the Split Key is enabled for 7.1 fresh installations or upgrades from 7.0.1.

Certificates

The **Certificates** page lists all the certificates available in the certificate store. You can generate a new certificate or import a certificate in the Personal Information Exchange (PFX) format. You can also add, edit, and delete the certificates.

> **Note:** This is a Controlled Availability feature. Contact your Cohesity account team to enable the feature.

Generate Cohesity Managed Certificate

To generate a Cohesity Managed Certificate:

1. Navigate to **Settings** > **Access Management** > **Certificates**.
2. Click on the **Certificates** drop-down and select **Generate**.
3. In the **Generate Cohesity Managed Certificate** window, enter the following details:
    - **Given Name** – A name for the certificate that is easy to recall.

      This can be edited later.
    - **Common Name (CN)** - Domain name or the entity for which the certificate is issued.
    - **Cluster** – Cluster for which the certificate is generated. Only required when accessing from global mode or Data Protect mode.
    - **Valid Till** – Validity of the certificate. The default validity is one year.
    - **Organization Issued To** - *[Optional]* Organization to which the certificate is issued. The default value is **Cohesity Inc**.
    - **Department Issued To** - *[Optional]* Department to which the certificate is issued. The default value is **Cohesity Inc**.

4. Click **Generate**.
5. The new certificate will be generated and displayed on the **Certificates** page.

Import Custom Certificate

> **Note:** Certificates only in the Personal Information Exchange (PFX) format are supported.

To import custom certificates:

1. Navigate to **Settings > Access Management > Certificates**.
2. Click on the **Certificates** drop-down and select Import.
3. In the **Import a Certificate** window, enter the following details:
   - **Given Name** – A name for the certificate. This can be edited later.
   - Drag and drop the PFX certificate or click and upload the certificate file.
   - **Password** – Password of the protected file.
4. Click **Import**.

The certificate will be imported and displayed on the Certificates page.

Download a Certificate

You can download a certificate from the certificate store.

1. In the Cohesity Dashboard, select **Settings > Access Management** and select the **Certificates** tab.
2. Click the actions icon (⋮) for the required certificate and click **Download**.

The certificate will be downloaded in the **.cer** format.

Edit a Certificate

You can edit the name of the certificate.

1. In the Cohesity Dashboard, select **Settings > Access Management** and select the **Certificates** tab.
2. Click the actions icon (⋮) for the required certificate and click **Edit**.
3. Update the name of the certificate as needed.
4. Click **Update**.

Delete a Certificate

You can delete a certificate if you no longer need it.

1. In the Cohesity Dashboard, select **Settings > Access Management** and select the **Certificates** tab.
2. Click the actions icon (⋮) for the required certificate and click **Delete**.
3. Respond to the confirmation prompt.
4. Click **Delete**.

Configure Account Security Settings

The Account Security page on a Cohesity cluster allows you to secure your Cohesity cluster through policy-driven user settings for managing passwords, user sessions, user inactivity, and locking the user account after multiple wrong password attempts. You can refer to the sections below to learn more about using and configuring these policies.

- View the Default Password Policy
- Define the Account Lockout Policy
- Define the Account Session Policy

View the Default Password Policy

On the Cohesity cluster, by default, a password policy is assigned to the local users. For added security, you can edit and customize the password policy based on your organization's requirements. It's important to change the passwords immediately as a response to ransomware attacks. This helps in minimizing the impact of the attack while keeping the data secured.

In the default password policy, you can update:

- Password strength
- Restrict the reuse of recently used passwords
- Set the password lifetime

From the Cohesity Dashboard, you can view the password policy that is applied by default to the local user account in the Cohesity cluster.

To view the default password policy:

1. In the Cohesity Dashboard, select **Settings** > **Account Security**.
2. From the **Password Policy** tab, you can view the configuration of the default password policy.

Update the Password Strength

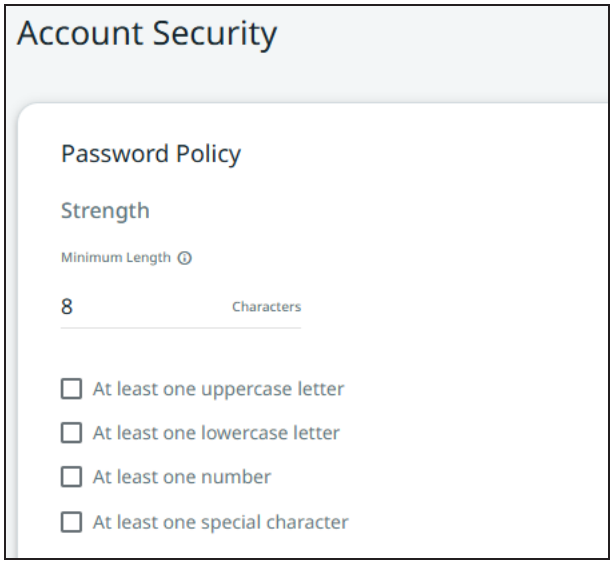
The strength of a password depends on its length, complexity, and unpredictability. You can make the local user access to your Cohesity cluster more secure by changing the default password strength defined in the password policy.

To update the password strength:

1. In the Cohesity Dashboard, select **Settings** > **Account Security**.
2. On the **Password Policy** tab, click the **Edit** icon.
3. In the **Strength** section, based on your requirement, set the following values:
    1. In the **Minimum Length** field, enter the length of the password. By default, the length of the password is set to eight characters.

        > **Note:** Ensure that you select any one of the following options.

    2. Select **At least one uppercase letter** to mandate, including one uppercase letter in the password.
    3. Select **At least one lowercase letter** to mandate, including one lowercase letter in the password.
    4. Select **At least one number** to mandate, including one numerical digit in the password
    5. Select **At least one special character** to mandate, including one special character in the password. For more details on what special characters are allowed in the local user password, see the Users and Groups section.



4. Click **Save**.

Restrict Reuse of Passwords

You can prevent local users from reusing a specified number of previous passwords. By default, the password policy is set to restrict five previously used passwords.

To update the password reuse limit:

1. In the Cohesity Dashboard, select **Settings** > **Account Security**.
2. On the **Password Policy** tab, click the **Edit** icon.
3. Under the **Reuse** section, do the following:
    - In the **Minimum Characters Different** field, set the minimum character that must be different than the characters used in the previous password.
    - In the **Minimum Reuse Difference** field, set the password reuse limit.
4. Click **Save**.

Set Password Lifetime

In the password policy, you can restrict the local user from resetting the password for a certain number of days. Also, you can set the local user password to expire after a specific number of days. By default, passwords are set to expire in 60 days. You can set the minimum and maximum number of days for the password lifetime.

The minimum number of days defines the number of days the local user is restricted to reset the password. For example, if the minimum number of days is set to five, the local user cannot reset his password for five days after the password is set for the local user.

The maximum number of days defines the number of days the local user password is valid. After the defined number of days, the password expires, and the local user is automatically prompted to change the password.

To set the password lifetime:

1. In the Cohesity Dashboard, select **Settings** > **Account Security**.
2. On the **Password Policy** tab, click the **Edit** icon.
3. In the **Lifetime** section, based on your requirement, set the following values:
    1. In the **Minimum Password Reset Duration** field, enter the minimum number of days to restrict the local user from resetting the password.
    2. In the **Password Expiry** field, enter the maximum number of days after which the local user password must expire.
4. Click **Save**.

> **Note:** The password lifetime can be set to a maximum value of 365.

Define the Account Lockout Policy

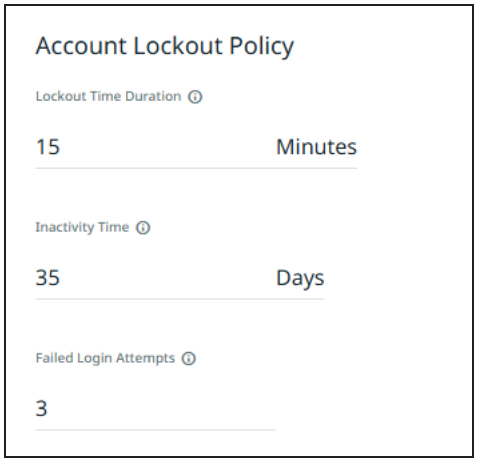
The Account Lockout policy in your password policy enables you to automatically lock the local user account if an attempt has been made to brute-force a local user password.

> **Note:** Users with the admin role are exempt from lockouts even after the failed login attempts.

In the Account Lockout policy, you can define:

- The number of consecutive failed login attempts causes a local user account to be locked.
- The time duration within which the consecutive failed login attempts cause a local user account to be locked.
- The inactivity timeout period for the user account. If the local user account is inactive for the configured inactivity timeout period, the local user account is automatically locked.

Once a user account is locked, the System Admin can unlock the account from the **Settings** > **Account Security** page in the Cohesity Dashboard.



To define the account lockout policy:

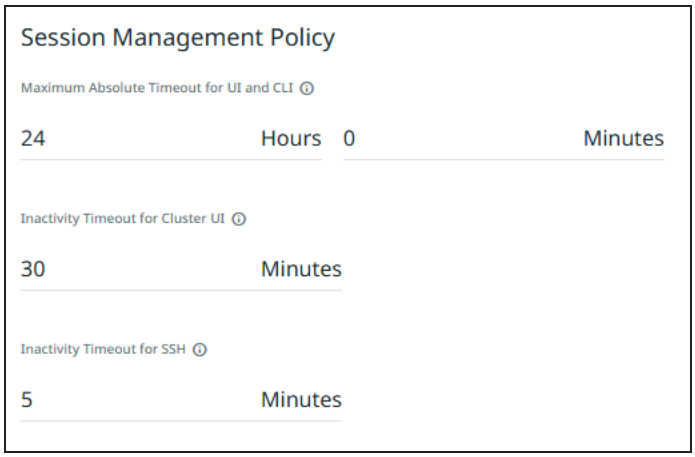
1. In the Cohesity Dashboard, select **Settings** > **Account Security**.
2. On the **Password Policy** tab, click the **Edit** icon.
3. In the **Account Lockout Policy** section, based on your requirement, set the following values:
    1. In the **Lockout Time Duration** field, enter the time duration within which the consecutive failed login attempts must cause a local user account to be locked. By default, the time duration is set to 15 minutes.
    2. In the **Inactivity Time** field, enter the inactivity timeout period for the user account after which the account is automatically locked. By default, the inactivity timeout period is set to 35 days.
    3. In the **Failed Login Attempts** field, enter the number of consecutive failed login attempts that must cause a local user account to be locked. By default, the number of failed attempts is set to 3.
4. Click **Save**.

Define the Account Session Policy

The Session policy enables you to define the session timeout for various interfaces such as UI, CLI, and SSH.

In the Account Session policy, you can define:

- The maximum time limit after which the user is logged out from Cohesity UI and Cohesity CLI.
- The time limit after which any user on the Cohesity cluster is logged out from Cohesity Dashboard.
- The time limit after which any user on the Cohesity cluster is logged out when the user accesses the Cohesity through an SSH tunnel.



To define the account session policy:

1. In the Cohesity Dashboard, select **Settings** > **Account Security**.
2. On the **Password Policy** tab, click the **Edit** icon.
3. In the **Session Management Policy** section, based on your requirement, set the following values:
    1. In the **Maximum Absolute Timeout for UI and CLI**, enter the maximum time duration for UI and CLI after which the user account will be logged out irrespective of the status of the session. The default value is set to 1440 minutes, i.e. 24 hours. The minimum value can be 1 hour and the maximum value can be 24 hours.
    2. In the **Inactivity Timeout for Cluster UI** field, enter the inactivity time limit on Cluster UI for the user account to get logged out. The default value is set to 30 minutes. The minimum value can be 1 minute and the maximum value can be 12 hours.
    3. In the **Inactivity Timeout for SSH**, enter the inactivity timeout limit on SSH sessions for the user account to get logged out. The default value is set to 5

minutes. The minimum value can be 1 minute and the maximum value can be 24 hours.

4. Click **Save**.

Best Practices for Managing Users

This page provides best practices for managing and administering various user accounts, roles, and access to Cohesity products. You can access the system through:

- Cohesity Data Cloud (SaaS)
- Local Cohesity cluster

This page does not provide security-level recommendations. You must refer to the Cohesity Security Hardening Guide and configure your Cohesity products to meet your security requirements.

About MyCohesity

MyCohesity is a secure, easy-to-access portal, giving users fast, centralized access to the following Cohesity resources:

- **Helios**—Access all your data management services, whether self-managed or SaaS, through our one simple UI.
  - The Helios Super Admin can grant access to other MyCohesity users from the same organization. For more information, see this knowledge base article.
  - If you are unable to access Cohesity Data Cloud, see Why can't I access Helios from MyCohesity?
- **Support**—Manage support tickets and download software updates. Connect with our support resources for expert insights.
- **Product Documentation**—Access the latest product documentation to make the most of Cohesity for your business.
- **Academy**—Build your next-generation data management skill set to keep learning with our training, accreditation, and certification programs for sales and technical professionals.
- **User Group**—Learn from and connect with other local IT professionals, and enjoy exclusive access to Cohesity resources.
- **Galaxy Community**—Be a part of our vibrant global customer community to network with your peers.

For more information about MyCohesity, review this page.

Manage Helios (SaaS) Users

Cohesity Data Cloud is a next-gen data management platform that provides a comprehensive range of data services. You can log in to the SaaS-based management

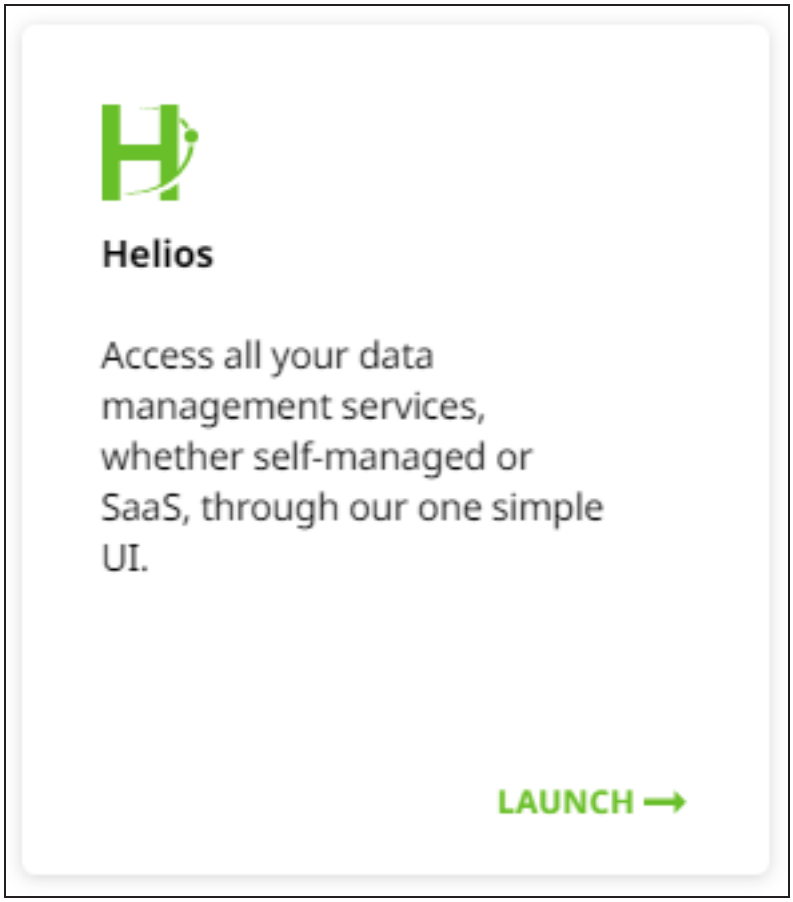
portal and manage multiple Cohesity clusters. This is a service managed by Cohesity and Cohesity Support grants the initial access. Go through the following subsections:

- Understanding Helios Users
- Best Practices for Managing Helios Users
- Shared User Accounts
- Enable Multi-factor Authentication for Cohesity Data Cloud Users
- SSO Usage Notes
- Summary

Understanding Helios Users

When you request access to the Cohesity Data Cloud platform, an initial user account is created. To get Super Admin access, the user has to:

1. Self-register and sign up for a MyCohesity account.
2. Log in to MyCohesity.
3. On the **Helios** tile, click **Launch**:



The user is granted Super Admin access.

> **Important:** If there are multiple users in the same domain, the first user who clicks the **Helios** tile gets Cohesity Data Cloud Super Admin access.

To keep your digital and cloud experience safer and compliant to your business needs, Cohesity supports Multi-Factor Authentication (MFA) for your MyCohesity account. For more information, see this knowledge base article.

> **Note:** By default, MFA is not enabled for this initial Super User account.

Best Practices for Managing Helios Users

Firstly, Cohesity recommends that you decide the primary authentication mechanism you wish to use. You have two options:

- Helios (SaaS) authentication
- Your own SSO provider

  For more information about configuring Cohesity Data Cloud to use an Identity Provider (IdP), see Add a Single Sign-on Provider.

Cohesity does not recommend one over the other. However, regardless of which authentication mechanism you choose, there are a few things you should do right away to avoid any access issues in the future:

- Create custom roles to provide access to individuals/groups in your organization. Cohesity recommends following the principle of least privilege.
- Cohesity recommends that you create a custom role with privileges equivalent to the built-in Super Admin role as you cannot modify the privileges of the built-in account. For more information about roles and privileges, see Custom Roles and Privileges.
- You must have multiple system administrator level users. Cohesity recommends that you have at least three users assigned with the built-in Super Admin role or custom role that you created with equivalent permissions.

  > **Note:** Cohesity recommends assigning the custom role.

  > **Warning:** If you have only one user with the Super Admin role or the equivalent custom role and if this user leaves your organization, you may experience issues, so ensure that you create additional users with the Super Admin role or the equivalent custom role.

- Enable MFA for all users:

- To enable MFA for Cohesity Data Cloud local accounts, you should follow the steps mentioned in Multi-factor Authentication.
- To enable MFA for SSO users, you must set up MFA in your SSO provider's system. For example, if you use Okta as the Identity Provider, you must set up and enable MFA in Okta.

Shared User Accounts

Cohesity does not recommend using a shared user account for any administration of our platform. If you use a shared user account, you will not be able to determine who made changes within your Cohesity Data Cloud account as audit logs are recorded for actions performed at the user account level.

> **Warning:** A shared user account is considered insecure and Cohesity strongly recommends you to not use a shared user account.

If you decide to use the shared user account method, Cohesity strongly recommends that you enable MFA by following the steps outlined below.

Enable Multi-factor Authentication for Cohesity Data Cloud Users

Multi-factor Authentication (MFA) provides a two-step verification method to authenticate and access Cohesity Data Cloud (SaaS). Setting up the MFA requires users to provide an additional verification factor along with the password credentials to log in to Cohesity Data Cloud. You can use codes from any authenticator app to log into Cohesity Data Cloud. After you enable MFA, access to your Cohesity Data Cloud is secured. MFA prevents unauthorized access and protects your data from ransomware attacks. For more information, see Multi-factor Authentication.

SSO Usage Notes

If you enable SSO to maintain your organization's users within Cohesity Data Cloud, then Cohesity recommends that you maintain two native accounts in case of an outage or impact to your SSO provider.

If you choose to use your own SSO provider, after all SSO users are created, you can remove the initial Helios/MyCohesity account from the Cohesity Data Cloud portal. Subsequently, only users from your SSO organization can access the Cohesity Data Cloud portal. However, note that SSO users cannot access MyCohesity, so you need MyCohesity user accounts to manage support tickets and download software updates.

If you need additional users strictly for MyCohesity, you can create them in the Cohesity Data Cloud portal and once the user logs in for the first time, you can remove the application access. These users would still maintain MyCohesity access. Cohesity strongly recommends that you enable MFA for MyCohesity user accounts as well. For more information, see this knowledge base article.

Summary

- If you have followed the guidelines outlined in the Manage Helios (SaaS) Users section, you should have multiple Cohesity Data Cloud and MyCohesity users with elevated permissions to perform additional functions.
- Create custom roles based on your operational requirements. You can then create additional users and assign custom role(s) based on your requirement. For more information about roles and privileges, see Custom Roles and Privileges.
- Periodically evaluate your three elevated users to ensure that as people change roles, you are maintaining a minimum of three active users with elevated permissions.

Manage Users Locally on the Cohesity Cluster

You can directly access the Cohesity cluster UI through the Virtual IP address (VIP) or the FQDN associated with the VIP. This management plane is out-of-band from the Cohesity Data Cloud application, so you can access the cluster even if the cluster is not connected to it. Go through the following subsections:

- About Cohesity Cluster Local Users
- Best Practices for Managing Local Cohesity Cluster Users
- Important Points to Note Regarding Initial Local Admin User
- Summary

About Cohesity Cluster Local Users

You can add local users to a Cohesity cluster. By default, when a new cluster is created, default built-in local users and groups are also created. The first user created is assigned the built-in Local Admin role. You have multiple options to add users in the Cohesity cluster:

- Local users and groups (GUI and iris_cli)
- SSO users (GUI only)
- Active Directory (GUI and iris_cli)
- Generic LDAP (GUI and iris_cli)

Local users have direct access to the cluster if the Cohesity Data Cloud application is unavailable for cloud-based multi-cluster management. The **support** user can be used to access the bash shell of the Cohesity cluster using SSH.

Cohesity does not recommend one over the other. However, regardless of which authentication mechanism you choose, there are a few things you should do right away to avoid any access issues in the future.

SSO users cannot execute `iris_cli` commands. If you decide to use SSO on the local cluster and if you want to avoid using the initial admin user and local user accounts, you can import users from Active Directory or any other domain for executing `iris_cli` commands.

Best Practices for Managing Local Cohesity Cluster Users

- Create custom roles to provide access to individuals/groups in your organization. Cohesity recommends following the principle of least privilege.
- Cohesity recommends that you create a custom role with privileges equivalent to the built-in Admin role as you cannot modify the privileges of the built-in account.
- You must have multiple system administrator level users. Cohesity recommends that you have at least three users assigned with the built-in Admin role or custom role that you created with equivalent permissions.

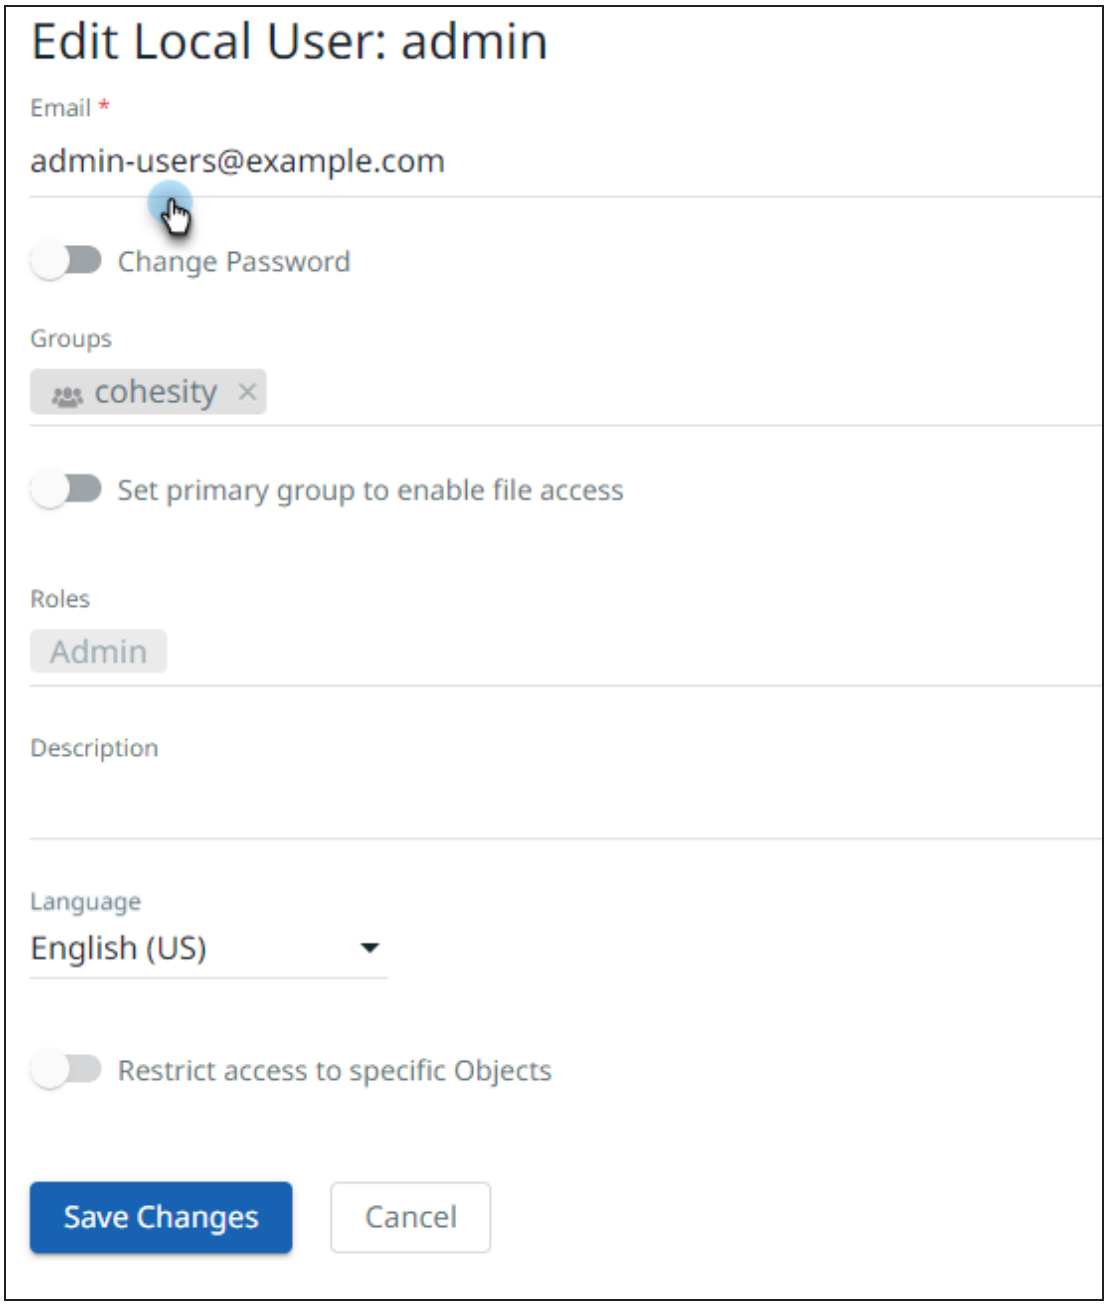
  > **Note:** Cohesity recommends assigning the custom role.

  > **Warning:** If you have only one user with the Admin role or the equivalent custom role and if this user leaves your organization, you may experience issues, so ensure that you create additional users with the Admin role or the equivalent custom role.

- Leverage named local users such as Active Directory users so that you can track `iris_cli` usage through audit logs.
- Enable MFA for all users:
  - To enable MFA for SSO users, you must set up MFA in your SSO provider's system. For example, if you use Okta as the Identity Provider, you must set up and enable MFA in Okta.

Important Points to Note Regarding Initial Local Admin User

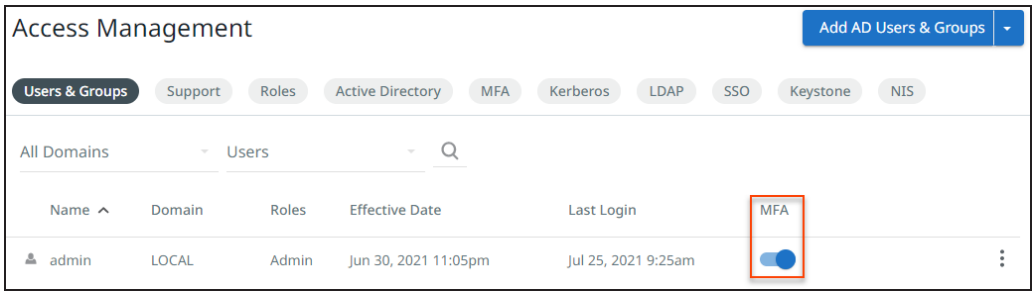
Currently, you cannot remove or disable the initial local user. Therefore, Cohesity recommends that you edit the local user and add a shared email address that is a distribution list:



> **Note:** Even if you add a distribution list as an email address, you can still enable MFA for this local user.

To enable MFA for the local admin user, complete the following steps:

1. Log in to the Cohesity cluster GUI as the admin user.
2. Enable SMTP Server as you will be enabling email for authentication.
3. Turn on the **MFA** toggle:



4. When you log in for the first time after MFA is enabled, save the QR code and/or verification code and securely share the code with all users in the distribution list to set up MFA on their own devices.

> **Note:** The Cohesity cluster supports the authenticator app and email-based authentication. You can use one or both authentication methods.

> **Important:** Cohesity 6.8 and above supports MFA for Active Directory users. For more information, see this knowledge base article.

Summary

- If you have followed the guidelines outlined in the Manage Users Locally on the Cohesity Cluster section, you should have multiple local users with elevated permissions to perform additional functions.
- Create custom roles based on your operational requirements. You can then create additional users and assign custom role(s) based on your requirements.
- Periodically evaluate your three elevated users to ensure that as people change roles, you are maintaining a minimum of three active users with elevated permissions.

Open ID Connect Support for Cluster APIs

You can integrate your identity provider solution with Cohesity Data Cloud (Self-managed) to access Cohesity REST APIs through single sign-on.

> **Note:** OpenID Connect is supported only for cluster APIs, and is not available for Single Sign-On (SSO) login via the UI.

Prerequisites

1. You should get the JSON Web Token from your identity server. To create JWT, enter the following parameters:
   - **alg** - The type of algorithm used to generate JWT. For example, **RS256**.
   - **typ** - The type should be JSON Web Token and the value for it is **JWT**.
   - **x5t** - This is X509 Thumbprint. It's a Base64 encoded string.
   - **exp** - This is a Timestamp.
   - **aud** - The audience ID of the client application on the identity server.
   - **upn** - The username or email address of the user.

   > **Note:** The validity of JWT is defined on the Open ID Connect server.

2. You should create an Open ID user on Cohesity Data Cloud (Self-managed) to access Cohesity REST APIs through SSO. For more information, see Create an Open ID User.
3. You should register Cohesity as an application on your identity server.
4. You should create a public key and get the URL to it. Refer to the sample key below,

```
{
"n": "<Modulus_of_Public_Key_in_Base64>",
"e": ["<Exponent_of_Public_Key_in_Base64>"]
"x5t": "<Certificate_Thumbprint_of_Public_Key_in_Base64>"
}
```

How it works

You can use Cohesity REST APIs to run cluster operations. To use Cohesity REST APIs, you can use your credentials or configure single sign-on (SSO) to authenticate without credentials. Cohesity uses OAuth 2.0 authorization framework to allow access to its REST APIs.

Configure SSO

When you configure SSO, Cohesity fetches the public key from the identity server based on the time defined for the parameter **pollingFrequencyMins**.

Access Cohesity REST APIs

The API request is sent from a client application to Cohesity. As a prerequisite, the client application should have the access token in JSON Web Token (JWT) format. This token consists of information about the user's claims, the algorithm used for encoding, and the public and private keys. The client application fetches this token from the identity server such as the Open ID Connect server.

Once the client application receives the token, it sends an API request to the Cohesity REST API endpoint with the JWT in its headers. Cohesity decodes the JWT from the API request

and matches the information against the public key. If the public key matches, then Cohesity allows the user mentioned in the JWT to access its REST APIs.

Configure Identity Provider

This API endpoint allows you to configure your identity provider on Cohesity. As a result, Cohesity requests the public key from the identity server regularly and uses it to authenticate users.

API URL

```
https://<IP_Address>/v2/identity-provider
```

> **Important:** Make sure to use the POST method.

Sample Body

```
{
"id": 1,
"domain": "<Domain_Name>",
"isEnabled": true,
"identityProviderType": "OpenIdConnect"
"openIdConnectParams": {
"audienceIds": [
"<Audience_ID1>"
"<Audience_ID2>"
]
"publicKeyURL": "<URL>",
"pollingFrequencyMins": 1
}
```

Parameters

Parameter	Description
id	Enter the value.
domain	Enter the domain name of the identity server. The domain should be the same as available in the JWT.
isEnabled	If this is set to False, then the OAuth access is disabled. If no value is entered by default, it is set to True.
identityProviderType	Enter the value “OpenIdConnect”.

Parameter	Description
audienceIds	The audience ID of the client application on the identity server.
publicKeyUrl	The URL to the public key on the identity server.
pollingFrequencyMins	The rate at which Cohesity sends the request for the public key to the identity server. The minimum value is one minute and the maximum value is one week. By default, it is set to one day.

Response

The status code 200 is returned.

Create an Open ID User

API URL

```
https://<IP_Address>/irisservices/api/v1/public/idps/principals
```

> **Important:** Make sure to use the POST method.

Sample Body

```
[
{
"principalName": "<Email_Address>",
"objectClass": "kUser",
"Roles":
[
"COHESITY_ADMIN"
],
"domain": "<Domain_Name>"
"restricted": false
}
]
```

Parameters

Parameter	Description
principalName	Enter the username or email address of the user. This should match the value of 'upn' in JWT.
objectClass	You should enter the value "kUser" to create a user.

Parameter	Description
roles	Enter the roles you want to define for the user.
domain	Enter the domain name of the identity server. The domain should be the same as available in the JWT.
restricted	Enter the value “false”.

Response

The status code 200 is returned.

Refresh Public Key

This API endpoint allows you to fetch the public key from the identity server.

API URL

```
https://<IP_Address>/v2/identity-providers/actions
```

> **Important:** Make sure to use the GET method.

Sample Body

```
[
{
“identityProviderType”: “OpenIdConnect”,
“openIdConnectParams”:
{
“action”: ”RefreshPublicKeys”
}
}
]
```

Parameters

Parameter	Description
identityProviderType	Enter the value “OpenIdConnect”.
action	Enter the value “RefreshPublicKeys”.

Response

The status code 200 is returned.

Support Toolbox Overview

The Support Toolbox is a utility provided by Cohesity that assists you with various support and maintenance tasks on Cohesity clusters.

The key features of the Support Toolbox are as follows:

- **Health Checks**: The toolbox can run various health checks to diagnose issues within the cluster. For instance, it can check network node reachability and other critical parameters before an upgrade.
- **Diagnostics**: It provides tools for diagnosing and troubleshooting issues within the cluster, helping you to identify and resolve problems quickly.
- **Reporting**: The toolbox can generate reports on the health and status of the cluster, which can be useful for both support and maintenance purposes.

You can use Support Toolbox using one of the following options:

- CLI
- Siren Web UI

Access Support Toolbox from CLI

To use Support Toolbox through CLI, you must download the Support Toolbox from the Cohesity downloads portal and then install it on one of the nodes of the cluster.

This version of the Support Toolbox is supported on the Cohesity 6.8.1 and above versions.

Prerequisites

Before you can install the Support Toolbox to your Cohesity cluster, you must enable Host shell access.

To enable host shell access:

1. Log on to the node's secured shell using the support user:

   ```
   $ ssh support@<node_IP>
   ```

   Where node_IP is the IP address of the node in your Cohesity cluster.

2. Log on to the iris_cli and generate a support token using the following command:

   ```
   $ iris_cli support host-access-token
   ```

   By default, the support token is only valid for an hour. You can extend the support token validity for up to 12 hours using the following command:

   ```
   $ iris_cli support host-access-token validity-in-hours=12
   ```

3. Obtain the Cohesity cluster information using the following command:

   ```
   $ iris_cli cluster info
   ```

4. Share the following details with Cohesity Support to generate an access code:
   - Support Token
   - Cluster ID
   - Cohesity Software Version
   - The number of hours you require the host shell access
5. After you receive the access code with Cohesity Support, enable host shell access using the following command in iris_cli:

   ```
   $ iris_cli support host-access ssh-enable=true
   ```

   ```
   access-code=<access_code>
   ```

   Where access_code is the access code you received from Cohesity Support.

   Ensure you enable host shell access before the support access token you generated in Step 2 expires.
6. Access the host shell of the node on port 2222 using the support user. Use the following command:

   ```
   $ ssh support@<node_IP> -p 2222
   ```

   > **Note:** Sudo access is disabled by default. For support channel access, you need to enable sudo access for the support user to the host shell using the following command:

   ```
   $ iris_cli user linux-sudo-access enable=true duration-in-hours=12
   ```

Install Support Toolbox

Perform the following steps to download and install the Support Toolbox:

1. Go to the Cohesity download page, and select **Cohesity Tools** tab.
2. Select the fast link for support-toolbox-installer and download to your local computer.
3. Use `WinSCP` or `SCP` command to upload the support-toolbox-installer file from your local computer to the Cohesity node.
4. SSH to the Cohesity node where you uploaded the package and navigate to the folder where the package was uploaded to.
5. Unpack the tar file:

   ```
   tar -xzvf toolboxFullInstaller.tgz
   ```

   The following files will be present in the package.

- **st-utilities-20241024-aff631b3.x86_64.rpm**
  - Toolbox utilities
- **st-signatures-20241024-aff631b3.x86_64.rpm**
  - Toolbox health checks
- **st-brigidServer-20241024-aff631b3.x86_64.rpm**
  - Backend API Server
- **st-dart-20241024-aff631b3.x86_64.rpm**
  - Detect and resolve tool
- **st-upgradeSignatures-20241024-aff631b3.x86_64.rpm**
  - Pre and post upgrade checks
- **st-framework-3.1.0-20240731-cfdadf52.x86_64.rpm**
  - Framework package
- **st-sirenui-2.0.0-cfdadf52.x86_64.rpm**
  - Siren UI upgrade package

6. Install the package by running the following command:

```
./install
```

Upon successful installation, an output similar to the following will be displayed:

```
[support@cohesity-00056bdf4f1-node-1 ~]$ ./install

Installing Support Toolbox Full Install : 3.1.0
Local Node IP : 10.14.59.91
SSH Port : 2222

Installing :
st-brigidServer-20250731-cfdadf52.x86_64

Install Complete, with Errors
```

Support Toolbox CLI Execution Options

The Support Toolbox uses its command-line interface, `hc_cli` to perform health checks and diagnostics on Cohesity clusters. You can run the health checks by logging into one of the Cohesity cluster nodes.

The Support Toolbox supports the following CLI execution options with `hc_cli`:

- hc_cli run
- hc_cli show
- hc_cli debug
- hc_cli version

> **Important:** Cohesity continuously develops and refines this tool. While these tests are set for release on X date, they may be updated and improved over time with subsequent upgrade packages.

hc_cli run

The `hc_cli run` command executes all available health checks for all the modules on the Cohesity cluster, across all nodes. The modules on the Cohesity cluster are as follows:

- Services
- Thirdparty
- Backup
- Vendor
- Software
- Networking
- Hardware
- Archival
- Performance

- Fingerprint
- Upgrade
- Patch

Services

This module verifies the health of all Cohesity services and checks that best practices were adhered to during the cluster configuration process.

If required, you can run the following command to perform only the health check of the services on the Cohesity cluster:

```
hc_cli run -m services
```

Available Service Health Checks

Following are the health checks that will be performed for the Service module:

- Alerts uptime check
- Apollo uptime check
- Athena uptime check
- Bifrost Broker uptime check
- Bridge Proxy uptime check
- Bridge uptime check
- Gandalf uptime check
- Groot uptime check
- Keychain uptime check
- Librarian uptime check
- Magneto uptime check
- Newscribe uptime check
- SMB2 Proxy uptime check
- Stats uptime check
- Storage Proxy uptime check
- Vault Proxy uptime check
- Vault Proxy uptime check
- Yoda uptime check
- Cluster Check if Kerberos is Enabled
- Helios Connectivity Check

- My Cohesity Connectivity Check
- Alert Mail Configuration Check
- Apollo MR Pipelies Gflag Check
- IPMI Permissions Check

Alerts uptime check

Description

This health check verifies whether the alert process has been running for the past 5 minutes.

Data Source

```
hc_cli service_uptime.py alerts
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the alert process has been running for the past 5 minutes.
Fail	Indicates that the alert process has not been running consistently or stable for the past 5 minutes.
Error	Indicates an error while retrieving the alert process uptime; the service may be unstable.

Apollo uptime check

Description

This health check verifies whether the Healer and Space Reclamation Services process has been running and stable for the past 5 minutes.

Data Source

```
service_uptime.py apollo
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the Healer and Space Reclamation Services process has been running and stable for the past 5 minutes.
Fail	Indicates that the Healer and Space Reclamation Services process has not been running consistently or stable for the past 5 minutes.
Error	Indicates an error while retrieving the Healer and Space Reclamation Services process uptime; the service may be unstable.

Athena uptime check

Description

This health check verifies whether the Marketplace Apps Services process has been running and stable for the past 5 minutes.

Data Source

```
service_uptime.py athena
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the Marketplace Apps Services process has been running and stable for the past 5 minutes.
Fail	Indicates that the Marketplace Apps Services process has not been running consistently or stable for the past 5 minutes.
Error	Indicates an error while retrieving the Marketplace Apps Services process uptime; the service may be unstable.

Bifrost Broker uptime check

Description

This health check verifies whether the Hybrid Extender Services process has been running and stable for the past 5 minutes.

Data Source

```
service_uptime.py bifrost_broker
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the Hybrid Extender Services process has been running and stable for the past 5 minutes.
Fail	Indicates that the Hybrid Extender Services process has not been running consistently or stable for the past 5 minutes.
Error	Indicates an error while retrieving the Hybrid Extender Services process uptime; the service may be unstable.

Bridge Proxy uptime check

Description

This health check verifies whether the I/O Operations Helper process has been running and stable for the past 5 minutes.

Data Source

```
service_uptime.py bridge_proxy
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the **I/O Operations Helper** process has been running and stable for the past 5 minutes.
Fail	Indicates that the **I/O Operations Helper** process has not been running consistently or stable for the past 5 minutes.
Error	Indicates an error while retrieving the **I/O Operations Helper** process uptime; the service may be unstable.

Bridge uptime check

Description

This health check verifies whether the I/O Operations Services process has been running and stable for the past 5 minutes.

Data Source

```
service_uptime.py bridge
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the I/O Operations Services process has been running and stable for the past 5 minutes.
Fail	Indicates that the I/O Operations Servicess processhas not been running consistently or stable for the past 5 minutes.
Error	Indicates an error while retrieving the I/O Operations Services process uptime; the service may be unstable.

Gandalf uptime check

Description

This health check verifies whether the Cluster Configuration Manager Services process has been running and stable for the past 5 minutes.

Data Source

```
service_uptime.py gandalf
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the Cluster Configuration Manager Services process has been running and stable for the past 5 minutes.
Fail	Indicates that the Cluster Configuration Manager Services process has not been running consistently or stable for the past 5 minutes.
Error	Indicates an error while retrieving the Cluster Configuration Manager Services process uptime; the service may be unstable.

Groot uptime check

Description

This health check verifies whether the Reporting Services process has been running and stable for the past 5 minutes.

Data Source

```
service_uptime.py groot
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the Reporting Services process has been running and stable for the past 5 minutes.
Fail	Indicates that the Reporting Services process has not been running consistently or stable for the past 5 minutes.
Error	Indicates an error while retrieving the Reporting Services process uptime; the service may be unstable.

Keychain uptime check

Description

This health check verifies whether the Key Management Services process has been running and stable for the past 5 minutes.

Data Source

```
service_uptime.py keychain
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the Key Management Services process has been running and stable for the past 5 minutes.

Status	Description
Fail	Indicates that the Key Management Services process has not been running consistently or stable for the past 5 minutes.
Error	Indicates an error while retrieving the Key Management Services process uptime; the service may be unstable.

Librarian uptime check

Description

This health check verifies whether the Index Catalog Services process has been running and stable for the past 5 minutes.

Data Source

```
service_uptime.py librarian
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the Index Catalog Services process has been running and stable for the past 5 minutes.
Fail	Indicates that the Index Catalog Services process has not been running consistently or stable for the past 5 minutes.
Error	Indicates an error while retrieving the Index Catalog Services Services process uptime; the service may be unstable.

Magneto uptime check

Description

This health check verifies whether the Backup Manager Service process has been running and stable for the past 5 minutes.

Data Source

```
service_uptime.py magneto
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the Backup Manager Service process has been running and stable for the past 5 minutes.
Fail	Indicates that the Backup Manager Service process has not been running consistently or stable for the past 5 minutes.
Error	Indicates an error while retrieving the Backup Manager Service process uptime; the service may be unstable.

Newscribe uptime check

Description

This health check verifies whether the Distributed Key Value Store Services process has been running and stable for the past 5 minutes.

Data Source

```
service_uptime.py newscribe
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the Distributed Key Value Store Services process has been running and stable for the past 5 minutes.
Fail	Indicates that the Distributed Key Value Store Services process has not been running consistently or stable for the past 5 minutes.
Error	Indicates an error while retrieving the Distributed Key Value Store Services process uptime; the service may be unstable.

SMB2 Proxy uptime check

Description

This health check verifies whether the SMB Backup Helper v2 Services process has been running and stable for the past 5 minutes.

Data Source

```
service_uptime.py smb2_proxy
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the SMB Backup Helper v2 Services process has been running and stable for the past 5 minutes.
Fail	Indicates that the SMB Backup Helper v2 Services process has not been running consistently or stable for the past 5 minutes.
Error	Indicates an error while retrieving the SMB Backup Helper v2 Services process uptime; the service may be unstable.

Stats uptime check

Description

This health check verifies whether the Cluster Metrics Services process has been running and stable for the past 5 minutes.

Data Source

```
service_uptime.py stats
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the NAS Backup Helper Services process has been running and stable for the past 5 minutes.
Fail	Indicates that the NAS Backup Helper Services process has not been running consistently or stable for the past 5 minutes.
Error	Indicates an error while retrieving the NAS Backup Helper Services process uptime; the service may be unstable.

Storage Proxy uptime check

Description

This health check verifies whether the NAS Backup Helper Services process has been running and stable for the past 5 minutes.

Data Source

```
service_uptime.py storage_proxy
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the NAS Backup Helper Services process has been running and stable for the past 5 minutes.
Fail	Indicates that the NAS Backup Helper Services process has not been running consistently or stable for the past 5 minutes.
Error	Indicates an error while retrieving the NAS Backup Helper Services process uptime; the service may be unstable.

Vault Proxy uptime check

Description

This health check verifies whether the Archive Helper Services process has been running and stable for the past 5 minutes.

Data Source

```
service_uptime.py vault_proxy
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the Archive Helper Services process has been running and stable for the past 5 minutes.
Fail	Indicates that the Archive Helper Services process has not been running consistently or stable for the past 5 minutes.

Status	Description
Error	Indicates an error while retrieving the Archive Helper Services process process uptime; the service may be unstable.

Yoda uptime check

Description

This health check verifies whether the Indexing Services process has been running and stable for the past 5 minutes.

Data Source

```
service_uptime.py yoda
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the Indexing Services process has been running and stable for the past 5 minutes.
Fail	Indicates that the Indexing Services process has not been running consistently or stable for the past 5 minutes.
Error	Indicates an error while retrieving the Indexing Services process uptime; the service may be unstable.

Cluster Check if Kerberos is Enabled

Description

This health check verifies whether Kerberos authentication is enabled on the cluster.

Data Source

```
nohup cluster_config.sh fetch /tmp/cc_tmp_ng > /dev/null 2>&1; echo $?
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates Kerberos authentication is enabled on the cluster.

Status	Description
Fail	Indicates Kerberos authentication is not enabled on the cluster.

Helios Connectivity Check

Description

This health check verifies whether Helios is accessible from the cluster.

Data Source

```
curl -Is https://helios.cohesity.com >/dev/null 2>&1 ; echo $?
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that Helios is accessible from the cluster.
Fail	Indicates that Helios is not accessible from the cluster.

My Cohesity Connectivity Check

Description

This health check verifies whether the mycohesity website is accessible from the cluster.

Data Source

```
curl -Is https://my.cohesity.com/ >/dev/null 2>&1 ; echo $?
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that mycohesity is accessible from the cluster.
Fail	Indicates that mycohesity is not accessible from the cluster.

Alert Mail Configuration Check

Description

This health check verifies whether any email is configured on the cluster for alert notifications.

Data Source

```
gt.sh fetch alerts_data cohesity.alerts.AlertsDataProto 2>/dev/null | grep -q email_address ;echo $?
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that email is configured on the cluster for alert notifications.
Fail	Indicates that email is not configured on the cluster for alert notifications.

Apollo MR Pipelies Gflag Check

Description

This health check verifies whether the Apollo MR Pipelines Gflag is set correctly

Data Source

```
allssh.sh links http://localhost:24680/flagz | grep apollo_mr_pipelines_to_run=[0-9].[0-9].[0-9][a-z] | wc -l
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that Gflag is configured correctly (not present).
Fail	Indicates that the Gflag is enabled, disable once agressive garbage collection has been completed.

IPMI Permissions Check

Description

This health check verifies whether the IPMI tool has its permissions set properly.

Data Source

```
ls -l /usr/bin/ipmitool | sed 's/=//g' | awk '{print $3, $4}'
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the permissions for the IPMI tool are set to `root:root`.
Fail	Indicates that the permissions for the IPMI tool are defined incorrectly.

Third-party

This module verifies the health of all the third-party softwares used by the Cohesity cluster, such as active directory.

If required, you can run the following command to perform only the health check of the Thrid-Party software on the Cohesity cluster:

```
hc_cli run -m thirdparty
```

Available Third-party Health Checks

Following are the health checks that will be performed for the Thrid-party module:

- LDAP Server Connectivity Check

LDAP Server Connectivity Check

Description

This health check verifies whether all LDAP servers are accessible from the nodes of the cluster.

Data Source

```
domain_connectivity.py
```

State

The following table lists the output state of this check:

Status	Description
Pass	Indicates that all LDAP servers are available via port 389.
Fail	Indicates that one or more LDAP servers discovered are not accessible via port 389.

Backup

This module verifies the health and status of the Backup Manager Service process and any other related functions regarding data backup and restore.

If required, you can run the following command to perform only the health check of the Backup Manager Service process on the Cohesity cluster:

```
hc_cli run -m backup
```

Available Backup Health Check

Following are the health checks that will be performed for the Magneto module:

- Backup

Backup Manager ServiceMagneto uptime check

Description

This health check verifies whether the Backup Manager Service process has been running and stable for the past 5 minutes.

Data Source

```
service_uptime.py magneto
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the Backup Manager Service process has been running and stable for the past 5 minutes.
Fail	Indicates that the Backup Manager Service process has not been running consistently or stable for the past 5 minutes.

Vendor

This module verifies the health and status of the OEM Hardware Platforms from Cisco, Dell, HPE, and other qualified vendors.

If required, you can run the following command to perform only the health check of the OEM Hardware Platforms:

```
hc_cli run -m vendor
```

Available Vendor Health Checks

Following are the health checks that will be performed for the vendor module:

- Cisco C240 M5 BIOS 4.0.4p.0.1112191020 Version Check

Cisco C240 M5 BIOS 4.0.4p.0.1112191020 Version Check

Description

This health check verifies if any UCS C240 nodes running BIOS 4.0.4p.0.1112191020.

Data Source

```
sudo dmidecode -t bios | grep Version | cut -d ':' -f2 | grep
'C240M5.4.0.4p.0.1112191020' ; echo $?
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that none of the UCS C240 nodes are running BIOS 4.0.4p.0.1112191020.
Fail	Indicates that one or or more UCS C240 nodes are running BIOS 4.0.4p.0.1112191020.

Software

This module verifies the software-specific health checks of the Cohesity cluster.

If required, you can run the following command to perform only the software-specific health checks of the Cohesity cluster:

```
hc_cli run -m software
```

Available Software Health Checks

Following are the health checks that will be performed for the Software module:

- One-Minute Average Load Check
- Five-Minute Average Load Check
- Fifteen-Minute Average Load Check
- Root Partition Size Check
- Log Partition Size Check
- Data Partition Size Check
- tmp Partition Size Check
- Outstanding Disk command Backlog Check
- D State Process Check
- Disks stuck in marked for removal check
- Node stuck in marked for removal check

One-Minute Average Load Check

Description

This health check verifies whether the node has been overloaded for the past 1 minute.

Data Source

```
average_load_one.py
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the Average CPU Load is less than 3 times the number of cores.
Fail	Indicates that the Average CPU load is greater than or equal to 3 times the number of cores.
Error	Indicates an error running the command.

Five-Minute Average Load Check

Description

This health check verifies whether the node has been overloaded over the past 5 minutes.

Data Source

```
average_load_five.py
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the average CPU load is less than 5 times the number of cores.
Fail	Indicates that the average CPU load is greater than or equal to 5 times the number of cores.
Error	Indicates an error running the command.

Fifteen-Minute Average Load Check

Description

This health check verifies if the node has been overloaded over the past 15 minutes.

Data Source

```
average_load_five.py
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the average CPU load is less than 5 times the number of cores.
Fail	Indicates that the average CPU load is greater than or equal to 5 times the number of cores.
Error	Indicates an error running the command.

Root Partition Size Check

Description:

This health check verifies the usage of the root partition. The root partition is used for the Cohesity node system and OS-related files.

Data Source

```
df -h /| awk '{ print $5 }' | tail -1 | tr -d '%'
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the root partition usage is less than 75%.
Fail	Indicates that the root partition usage is equal to or greater than 85%.
Warning	Indicates that the root partition usage is between 75 and 85%.

Log Partition Size Check

Description:

This health check verifies the usage of the log partition. A log partition is used for storing logs that belong to each of the Cohesity cluster components. It helps monitor and troubleshoot by keeping detailed logs of system activities and errors.

Data Source

```
df -h /cohesity_logs | awk '{ print $5 }' | tail -1 | tr -d '%'
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the log partition usage is less than 75%.
Fail	Indicates that the log partition usage is equal to or greater than 85%.
Warning	Indicates that the log partition usage is between 75 and 85%.

Data Partition Size Check

Description:

This health check verifies usage of the `home_cohesity_data` partition.

The data partition is used by various services to store configuration files and maintain consistency across all nodes in the cluster. This partition has a symlink to `/home/cohesity/data` and holds all the configuration files and data related to each of the Cohesity services.

Data Source

```
df -h /home_cohesity_data | awk '{ print $5 }' | tail -1 | tr -d '%'
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the `home_cohesity_data` partition usage is less than 75%.
Fail	Indicates that the `home_cohesity_data` partition usage is equal to or greater than 85%.
Warning	Indicates that the `home_cohesity_data` partition usage is between 75 and 85%.

tmp Partition Size Check

Description:

This health check verifies the usage of the tmp partition. The tmp partition is used for temporary file storage.

Data Source

```
ps aux | grep 'sg_' |wc -l
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the tmp partition usage is less than 75%.
Fail	Indicates that the tmp partition usage is equal to or greater than 85%.
Warning	Indicates that the tmp partition usage is between 75 and 85%.

Outstanding Disk command Backlog Check

Description:

This health check verifies if there are any excessive disk commands queued up in the backlog.

Data Source

```
ps aux | grep 'sg_' |wc -l
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that there is no backlog of disk operations detected.
Fail	Indicates that there are more than 20 outstanding disk commands in the backlog.
Warning	Indicates that there are 10 to 20 disk commands in the backlog.

D State Process Check

Description:

This health check verifies if there are any processes in the D (defunct) state.

Data Source

```
ps aux | awk ' { print $8 } ' | grep D | wc -l
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that there are no or less than 15 processes in the D (defunct) state.
Fail	Indicates that there are more than 25 processes in the D (defunct) state.
Warning	Indicates that there are between 15 to 25 processes in the D (defunct) state.

Disks stuck in marked for removal check

Description:

This health check verifies if there are any disks marked for removal.

This health check helps Cohesity Support to identify disks awaiting removal and locate any services that have not acknowledged the disk chunks, enabling Cohesity to take necessary remedial actions.

Data Source

```
disk_removal_check.py
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that there are disks marked for removal.
Fail	Indicates that no disks are marked for removal.
Warning	Indicates that an exception error occurred during this health check.

Node stuck in marked for removal check

Description:

This health check verifies whether there are any nodes in the cluster stuck in marked for removal state.

This checks helps the Cohesity support to identify nodes which are marked for removal in cluster and find the services which have not ACKed the disks chunks and take necessary remedy steps.

Data Source

```
node_removal_check.py
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that there are nodes marked for removal.
Fail	Indicates that no nodes are marked for removal.
Warning	Indicates that an exception error occurred during this health check.

Networking

This module verifies the health state and configuration of the networking and interfaces of the individual nodes within a Cohesity cluster.

If required, you can run the following command to perform only the networking and interfaces health checks of the Cohesity cluster:

```
hc_cli run -m network
```

Available Networking Health Checks

Following are the health checks that will be performed for the Networking module:

- Firewall Check running state
- Bond mode configuration check
- Network interface MTU check
- Default gateway check
- Firewalld Status Check
- Primary interface health check
- VIP on Bond check
- Helios external server connectivity test
- Microsoft o365 external server connectivity test
- Support Channel external server connectivity test
- GCP (Google cloud) External Server Connectivity Test
- AWS (Amazon Web Services) External Server Connectivity Test

Firewall Check running state

Description

This health check verifies whether the Firewalld Daemon is running.

Supported Cluster Types

You can run this health check on the following cluster types:

- Virtual Edition
- Cloud Edition
- Physical Edition

Data Source

```
sudo firewall-cmd --state | grep -qx running; echo $?
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the firewall is currently running.
Fail	Indicates that the firewall is currently not running.

Bond mode configuration check

Description

This health check verifies whether the bonding mode configured for the Cohesity cluster is 1 or 4.

Supported Cluster Types

You can run this health check on the following cluster types:

- Virtual Edition
- Cloud Edition
- Physical Edition

Data Source

The following data source finds the names of all the bonds on the node:

- `grep bond /proc/net/dev | awk '{print $1}' | tr -d ':'`

The following data source evaluates the bond mode

- `cat /etc/sysconfig/network-scripts/ifcfg-<bond_name> | grep BONDING_OPTS| cut -d '\"' -f2 | cut -d ' ' -f1 | cut -d '=' -f2`

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the bonding mode configured for the cluster is either 1 (active-backup) or 4 (LACP).
Fail	Indicates that the bonding mode configured for the cluster is 0,2,3,5 or 6.

Network interface MTU check

Description

This health check verifies whether the maximum transmission unit (MTU) is set to 1500.

MTU defines the largest packet size that can be transmitted as a single entity in a network connection. The size of the MTU determines the amount of data that can be transmitted in bytes over a network.

Supported Cluster Types

You can run this health check on the following cluster types:

- Virtual Edition
- Cloud Edition
- Physical Edition

Data Source

- To gather all interface names:
  - `list_all_nic_ports.sh | grep UP | awk '{print $(NF-2)}'`
- To pull MTU configuration:
  - `ip link show dev <innterface_name> | cut -d ' ' -f5 | head -1`

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the MTU is set to 1500.
Warning	Indicates that the MTU is set to a value greater than 1500.
Fail	Indicates that the MTU is set to a value less than 1500.

Default gateway check

Description

This health check verifies the status of the Address Resolution Protocol (ARP) for the default gateway.

Supported Cluster Types

You can run this health check on the following cluster types:

- Virtual Edition
- Cloud Edition
- Physical Edition

Data Source

- Collect default gateway IP:
  - `for g in `route -n | grep -w 0.0.0.0 | grep UG| awk ' { print $2 } '`; do ping -c 1 -W 3 $g > /dev/null 2>&1; echo $g;done`

- Evaluate if the default gateways had a successful ARP
  - `arp -an | grep '<gateway_ip>)' | grep incomplete; echo $?`

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the ARP for the default gateway is successful.
Fail	Indicates that the ARP for the default gateway is incomplete.

Firewalld Status Check

Description

This health check verifies if the daemon for firewalld is active.

Supported Cluster Types

You can run this health check on the following cluster types:

- Virtual Edition
- Cloud Edition
- Physical Edition

Data Source

```
sudo systemctl is-active firewalld | grep -qx active; echo $?
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the firewalld is active.
Fail	Indicates that the firewalld is inactive.

Primary interface health check

Description

This health check verifies whether all the interfaces connected to the primary bond of the cluster are healthy.

Supported Cluster Types

You can run this health check on the following cluster types:

- Physical Edition

Data Source

- Collect all interface names on the primary bond:
  - `cat /proc/net/bonding/`primary_interface_name.sh`|grep 'Slave Interface:'| awk '{print $3}'`
- Verify if all the interfaces are in an UP state
  - `ip link | grep <interface_name> | grep -q 'state UP';echo $?`

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the interfaces connected to the primary bond of the cluster are healthy.
Fail	Indicates that the interfaces connected to the primary bond of the cluster are not healthy.

VIP on Bond check

Description

This health check verifies whether any VIP is present on the bond and displays VIP assigned on each of the cluster nodes.

Supported Cluster Types

You can run this health check on the following cluster types:

- Virtual Edition
- Cloud Edition
- Physical Edition

Data Source

- To grep the bond interfaces having VIP present on them:
  - `ip addr show|  /usr/bin/awk '{print $NF}' | /usr/bin/grep '^bond'`
- To get the current VIP assignment:
  - ```
    gt.sh fetch vip_assignments
    cohesity.nexus.services.vip.VipAssignmentProto 2> /dev/null
    ```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the bond interface isn't holding any VIP.
Fail	Indicates that the bond interface is holding a VIP.

Helios external server connectivity test

Description

This health check verifies whether the external Helios server connectivity for SSL/TLS certificate is working from all the nodes in a cluster.

This checks helps the Cohesity Support to identify if the external Helios server are reachable and accessible via SSL/TLS.

Supported Cluster Types

You can run this health check on the following cluster types:

- Virtual Edition
- Cloud Edition
- Physical Edition

Data Source

```
external_server_connection_test.py
```

State

The following table lists the status of this check:
```

Status	Description
Pass	Indicates that the external Helios server connectivity for SSL/TLS certificate is working from all the nodes in a cluster.
Fail	Indicates that the external Helios server connectivity for SSL/TLS certificate is not working from all the nodes in a cluster.

Microsoft o365 external server connectivity test

Description

This health check verifies whether the external Microsoft o365 server connectivity for SSL/TLS certificate is working from all the nodes in a cluster.

This checks helps the Cohesity Support to identify if the external Microsoft o365 server are reachable and accessible via SSL/TLS.

Supported Cluster Types

You can run this health check on the following cluster types:

- Virtual Edition
- Cloud Edition
- Physical Edition

Data Source

```
external_server_connection_test.py
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the external Microsoft o365 server connectivity for SSL/TLS certificate is working from all the nodes in a cluster.
Fail	Indicates that the external Microsoft o365 server connectivity for SSL/TLS certificate is not working from all the nodes in a cluster.

Support Channel external server connectivity test

This health check verifies whether the external Support Channel server connectivity for SSL/TLS certificate is working from all the nodes in a cluster.

This checks helps the Cohesity Support to identify if the external Support Channel server is reachable and accessible via SSL/TLS.

Supported Cluster Types

You can run this health check on the following cluster types:

- Virtual Edition
- Cloud Edition
- Physical Edition

Data Source

```
external_server_connection_test.py
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the external Support Channel server connectivity for SSL/TLS certificate is working from all the nodes in a cluster.
Fail	Indicates that the external Support Channel server connectivity for SSL/TLS certificate is not working from all the nodes in a cluster.

GCP (Google cloud) External Server Connectivity Test

This health check verifies whether the external GCP server connectivity for SSL/TLS certificate is working from all the nodes in a cluster.

This checks helps the Cohesity Support to identify if the external GCP server is reachable and accessible via SSL/TLS.

Supported Cluster Types

You can run this health check on the following cluster types:

- Virtual Edition
- Cloud Edition
- Physical Edition

Data Source

```
external_server_connection_test.py
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the external GCP server connectivity for SSL/TLS certificate is working from all the nodes in a cluster.
Fail	Indicates that the external GCP server connectivity for SSL/TLS certificate is not working from all the nodes in a cluster.

AWS (Amazon Web Services) External Server Connectivity Test

This health check verifies whether the external AWS server connectivity for SSL/TLS certificate is working from all the nodes in a cluster.

This checks helps the Cohesity Support to identify if the external AWS server is reachable and accessible via SSL/TLS.

Supported Cluster Types

You can run this health check on the following cluster types:

- Virtual Edition
- Cloud Edition
- Physical Edition

Data Source

```
external_server_connection_test.py
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the external AWS server connectivity for SSL/TLS certificate is working from all the nodes in a cluster.
Fail	Indicates that the external AWS server connectivity for SSL/TLS certificate is not working from all the nodes in a cluster.

Hardware

This module verifies the health state of the hardware of the individual nodes in a Cohesity cluster.

If required, you can run the following command to perform only the hardware-related health checks of the Cohesity cluster:

```
hc_cli run -m hardware
```

Available Archival Health Checks

Following are the health checks that will be performed for the archival module:

- SMARTCTL Status Check
- IO Stat SD Disk Usage Status Check
- HBA Health Check
- NVME Error Check
- HDD Read Error Check
- HDD Write Error Check
- HDD Verify Error Check
- CPU Throttle State Check
- PCIE Bus Error Check
- Node Uptime Check
- HDD Disk availability Check
- SSD Read only check
- Missing NVME Disk Check
- Missing System Disk Check
- Missing HDD Disk Check
- Missing DIMM Disk Check
- Correctable DIMM error check
- Cohesity Firmware Check
- Product Model Name Check
- Disk Serial Number Check
- NVME slot check

SMARTCTL Status Check

Description

This health check verifies the smartctl status of all disks in the cluster.

Data Source

This health check uses the following commands to check the status:

- To gather disk names :
  - `ls /dev | awk '/^sd[a-z]$/ { print $1 }'`
- To evaluate status ($data is replaced with disk name):
  - `sudo smartctl -H --json /dev/<disk_name> | grep passed | cut -d ':' -f2 | tr -d ' '`

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the smartctl is reporting all the disks in the cluster as healthy.
Fail	Indicates that the smartctl is reporting disk failure in the cluster.

IO Stat SD Disk Usage Status Check

Description

This health check verifies whether the disks in the cluster are utilized at 80% or greater of their IO capacity.

Data Source

This health check uses the following commands to check the status:

- To gather disk names:
  - `ls /dev | awk '/^sd[a-z]$/ { print $1 }'`
- To pull IOStat data ($data is replaced with the disk name from above:
  - `iostat -dx <disk_name> | awk '{ print $14 } ' | tr -d ' '| tail -2| head -1`

Supported Cluster Types

You can run this health check on the following cluster types:

- Physical Edition

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the disk usage is below 80% of their IO capacity.
Fail	Indicates that the disk usage is equal to or more than 80% of their IO capacity.

HBA Health Check

Description

This health check verifies whether there are any DWORD errors on the disk HBA.

Data Source

This health check uses the following commands to check the status:

- To gather disk names:
  - `ls /dev | awk '/^sd[a-z]$/ { print $1 }'`
- To pull sg_logs data:
  - `sudo sg_logs -a /dev/<disk_name> |grep -qi 'invalid dword' ; echo $?`

Supported Cluster Types

You can run this health check on the following cluster types:

- Physical Edition

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that there are no DWORD errors on the disk HBA.
Fail	Indicates that there are one or more DWORD errors on the disk HBA.

NVME Error Check

Description

This health check verifies whether there are any NVME drive data and media integrity errors.

Data Source

This health check uses the following commands to check the status:

- Precheck to evaluate if the node has NVME drives:
  - `ls /dev | grep -q nvme ; echo $?`
- To gather disk names:
  - `ls /dev | awk '/^nvme[0-99]$/ {print $1}'`
- To pull sg_logs data:
  - `sudo smartctl -a /dev/<disk_name> | grep Media | cut -d ':' -f 2| tr -d ' ,'`

Supported Cluster Types

You can run this health check on the following cluster types:

- Physical Edition

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that there are no errors on the drive.
Fail	Indicates that there are errors on the drive.

HDD Read Error Check

Description

This health check verifies whether the spinning disks in the cluster are encountering any read errors.

Data Source

This health check uses the following commands to check the status:

- To gather disk names:
  - `ls /dev | awk '/^sd[a-z]$/ { print $1 }'`
- To pull sg_logs data:

- `sudo smartctl -l error /dev/<disk_name> | grep -q 'read:' ; echo $?`

Supported Cluster Types

You can run this health check on the following cluster types:

- Physical Edition

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the spinning disks in the cluster are not encountering any read errors.
Fail	Indicates that the spinning disks in the cluster are encountering one or more read errors.

HDD Write Error Check

Description

This health check verifies whether the spinning disks in the cluster are encountering any write errors.

Data Source

This health check uses the following commands to check the status:

- To gather disk names:
  - `ls /dev | awk '/^sd[a-z]$/ { print $1 }'`
- To pull sg_logs data:
  - `sudo smartctl -l error /dev/<disk_name> | grep -q 'read:' ; echo $?`

Supported Cluster Types

You can run this health check on the following cluster types:

- Physical Edition

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the spinning disks in the cluster are not encountering any write errors.
Fail	Indicates that the spinning disks in the cluster are encountering one or more write errors.

HDD Verify Error Check

Description

This health check verifies whether the spinning disks in the cluster are encountering any verify errors.

Data Source

This health check uses the following commands to check the status:

- To gather disk names:
  - `ls /dev | awk '/^sd[a-z]$/ { print $1 }'`
- To pull sg_logs data:
  - `sudo smartctl -l error /dev/<disk_name> | grep -q 'read:' ; echo $?`

Supported Cluster Types

You can run this health check on the following cluster types:

- Physical Edition

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the spinning disks in the cluster are not encountering any verify errors.
Fail	Indicates that the spinning disks in the cluster are encountering one or more verify errors.

CPU Throttle State Check

Description

This health check verifies whether the CPU in the node is running at the right frequency and is not throttled down.

Data Source

This health check uses the following command to check the status:

```
lscpu | grep 'CPU MHz' | cut -d ':' -f 2| tr -d ' '
```

Supported Cluster Types

You can run this health check on the following cluster types:

- Physical Edition

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the CPU in the node is running at a frequency greater than 1GHZ.
Fail	Indicates that the CPU in the node is running at a frequency less than 1GHZ.

PCIE Bus Error Check

Description

This health check verifies whether the PCI Bus is reporting any errors.

Data Source

This health check uses the following command to check the status:

```
dmesg |grep -q 'PCIe Bus Error';echo $?
```

Supported Cluster Types

You can run this health check on the following cluster types:

- Physical Edition

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the PCI Bus is not reporting any errors.
Fail	Indicates that the PCI Bus is reporting one or more errors.

Node Uptime Check

Description

This health check verifies how long the node has been up.

Data Source

This health check uses the following command to check the status:

```
cat /proc/uptime | cut -d ' ' -f1
```

Supported Cluster Types

You can run this health check on the following cluster types:

- Physical Edition
- Virtual Editon

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the node has been up for a day or more.
Warning	Indicates that the node is up for more than 5 minutes but not longer than a day.
Fail	Indicates that the node is up for less than 5 minutes.

HDD Disk availability Check

Description

This health check verifies whether at least two or more disks are mounted on the node.

Data Source

This health check uses the following command to check the status:

```
smartctl --scan | wc -l
```

Supported Cluster Types

You can run this health check on the following cluster types:

- Cloud Edition
- Physical Edition
- Virtual Editon

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that more than two disks are mounted on the node.
Fail	Indicates that less than two disks are mounted on the node.

SSD Read only check

Description

This health check verifies whether there are any SSD(s) that are currently set to read-only.

Data Source

This health check uses the following command to check the status:

```
grep ' ro,' /proc/mounts |awk '{print $1}' | grep nvme
```

Supported Cluster Types

You can run this health check on the following cluster types:

- Physical Edition

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that there are no SSD(s) that are currently set to read-only.
Fail	Indicates that there are SSD(s) that are currently set to read-only.

Missing NVME Disk Check

Description

This health check verifies whether all expected NVME disks are present and mounted.

Data Source

This health check uses the following command to check the status:

```
platform.py missing_disks:NVME_Disk
```

Supported Cluster Types

You can run this health check on the following cluster types:

- Physical Edition

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that all expected NVME disks are present and mounted.
Fail	Indicates that not all expected NVME disks are present or mounted.

Missing System Disk Check

Description

This health check verifies whether all expected system disks are present and mounted.

Data Source

This health check uses the following command to check the status:

```
platform.py missing_disks:SystemDisk
```

Supported Cluster Types

You can run this health check on the following cluster types:

- Physical Edition

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that all expected system disks are present and mounted.
Fail	Indicates that not all expected system disks are present or mounted.

Missing SATA SSD Disk Check

Description

This health check verifies whether all expected SATA SSD disks are present and mounted.

Data Source

This health check uses the following command to check the status:

```
platform.py missing_disks:SataSsdDisk
```

Supported Cluster Types

You can run this health check on the following cluster types:

- Physical Edition

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that all expected SATA SSD disks are present and mounted.
Fail	Indicates that not all expected SATA SSD disks are present or mounted.

Missing HDD Disk Check

Description

This health check verifies whether all expected HDD disks are present and mounted.

Data Source

This health check uses the following command to check the status:

```
platform.py missing_disks:HddDisk
```

Supported Cluster Types

You can run this health check on the following cluster types:

- Physical Edition

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that all expected HDD disks are present and mounted.
Fail	Indicates that not all expected HDD disks are present or mounted.

Missing DIMM Disk Check

Description

This health check verifies whether the node has all the expected DIMM slots populated with working memory.

Data Source

This health check uses the following command to check the status:

```
platform.py missing_dimm:none
```

Supported Cluster Types

You can run this health check on the following cluster types:

- Physical Edition

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the node has all the expected DIMM slots populated with working memory.
Fail	Indicates that the has one or more DIMMs missing.

Correctable DIMM error check

Description

This health check verifies whether there are any correctable DIMM errors present on the node.

Data Source

This health check uses the following command to check the status:

```
platform.py correctable_dimm_error:none
```

Supported Cluster Types

You can run this health check on the following cluster types:

- Physical Edition

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that there are no correctable DIMM errors present on the node.
Fail	Indicates that are are one or more correctable DIMM errors present on the node.

Cohesity Firmware Check

Description

This health check verifies whether the firmwares of the cluster nodes are up to date with the latest Cohesity release version .

Data Source

This health check uses the following command to check the status:

```
platform.py check_firmware:none
```

Supported Cluster Types

You can run this health check on the following cluster types:

- Physical Edition

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that there all firmware is up to date with the latest Cohesity releases version.
Fail	Indicates that are are one or more devices in the node that needs a firmware update.

Product Model Name Check

Description

This health check verifies whether the product model of the nodes of the cluster is unknown.

Data Source

This health check uses the following command to check the status:

```
grep -i productModel\\\" /home_cohesity_data/nexus/hardware.json | grep -q
unknown ; echo $?
```

Supported Cluster Types

You can run this health check on the following cluster types:

- Physical Edition

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the product model of the nodes of the cluster is not unknown.
Fail	Indicates that the product model of the nodes of the cluster is unknown.

Disk Serial Number Check

Description

This health check verifies whether all disks mounted on the node match a serial number available in the cluster config.

Data Source

This health check uses the following command to check the status:

- To gather disk serial:
  - `list_all_disks.sh | grep -v '=\\|Disk\\|SLOT\\|^[[:space:]]*$'|awk '{print$2}'`
- To validate serial numbers:
  - `grep -q $<disk_serial> /tmp/cc_tmp_ng; echo $?`

Supported Cluster Types

You can run this health check on the following cluster types:

- Physical Edition

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that all disks mounted on the node match a serial number available in the cluster config.

Status	Description
Fail	Indicates that one or moew disks mounted on the node does not match a serial number available in the cluster config.

NVME slot check

Description

This health check verifies whether current mapping of the NVMe disk slot to the physical slot matches the expected configuration.

Data Source

This health check uses the following command to check the status:

- To get the expected mapping:
  - `/home/cohesity/software/crux/bin/product_helper --op=GET_DISK_SLOT_TO_PHY_MAP --diskType=NvmeSsdDisk`
- To get the current mapping of the NVME slot to the phy slot:
  - `/usr/sbin/lspci -D  | grep 'Non-Volatile' | awk '{print $1}'`

Supported Cluster Types

You can run this health check on the following cluster types:

- Physical Edition

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the current mapping of the NVMe disk slot to the physical slot matches the expected configuration – No slot mismatch detected.
Fail	Indicates that the current mapping of the NVMe disk slot to the physical slot does not matches the expected configuration – Slot mismatch detected.

Archival

This module verifies the health state of the I/O Operations Services and Archive Services.

If required, you can run the following command to perform only the archival health checks of the Cohesity cluster:

```
hc_cli run -m archival
```

Available Archival Health Checks

Following are the health checks that will be performed for the archival module:

- Bridge uptime check
- Vault Connectivity Check

Bridge uptime check

Description

This health check verifies whether the I/O Operations Services is up on all cluster nodes and has been running and stable for the past 5 minutes.

Data Source

```
service_uptime.py bridge
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the I/O Operations Services has been running and stable for the past 5 minutes.
Fail	Indicates that the I/O Operations Services is not stable for the past 5 minutes.

Vault Connectivity Check

Description

This health check verifies whether all configured vaults are reachable via port 3000.

Data Source

```
vault_connectivity.py
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that all configured vaults are reachable via port 3000.
Fail	Indicates that all configured vaults are not reachable via port 3000.

Performance

This module checks performance indicators on the cluster, to verify if it is operating within expected parameters.

If required, you can run the following command to perform only the performance-related health checks of the Cohesity cluster:

```
hc_cli run -m perform
```

Available Performance Health Checks

Following are the health checks that will be performed for the Performance module.

External IO Percentage Usage Check

Description

This health check verifies the I/O consumption on the I/O Services.

Data Source

```
elinks -dump http://0:11111 | grep -i 'external io' | awk '{ print $6 }' |
head -1
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the I/O consumption on the I/O services is less than 75%.
Fail	Indicates that the I/O consumption on the I/O services is 100%.
Warning	Indicates that the I/O consumption on the I/O services is less than 75%.

Upgrade

This module verifies the upgrade-specific health checks of the Cohesity cluster.

If required, you can run the following command to perform only the upgrade-specific health checks of the Cohesity cluster:

```
hc_cli run -m preUpgrade
```

Available Upgrade Health Checks

Following are the health checks that will be performed for the archival module:

- Boot Partition Size Check
- CPU Throttle State Check
- Gandalf Stability Check
- Bond Configuration Check
- Downloads Site Connectivity Check
- /home_cohesity_data Read Only Check
- Nexus Stability Check
- SMARTCTL Status Check
- NVME Error Check
- Missing NVME Disk
- Missing System Disk
- Missing SATA SSD Disk
- Missing HDD Disk
- /home_cohesity_data Space Check
- Virtualization Enabled Check
- Disk(s) marked for removal Check
- Stale Mount Check
- Athena app subnet overlap check

Boot Partition Size Check

Description

This health check verifies the usage of the boot partition.

Data Source

```
df -h /boot | awk '{ print $5}' | tail -1 | cut -d '%' -f1
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the boot partition usage is less than 80%.
Fail	Indicates that the boot partition usage is equal to or greater than 80%.

CPU Throttle State Check

Description

This health check verifies whether the CPU's of the cluster are running at their default frequency and not throttled slower

Data Source

```
lscpu | grep 'CPU MHz' | cut -d ':' -f 2| tr -d ' '
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the CPU is running at frequency greater than 1GHz.
Fail	Indicates that the CPU is throttled below 1GHz.

Gandalf Stability Check

Description

This health check verifies whether the gandalf service has been stable for the past 5 minutes.

Data Source

```
service_uptime.py gandalf
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the gandalf service has been stable for the past 5 minutes.
Fail	Indicates that the gandalf service has not been stable or down for the past 5 minutes.

Node Connectivity Check

Description

This health check verifies whether a node can ping all other nodes in a cluster.

Data Source

```
nping -c 1 -p 22 $data | grep attempts | cut -d '|' -f3 | cut -d ':' -f2 |
cut -d '(' -f1 | tr -d ' '
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the node is able to be reach over the network.
Fail	Indicates that the node is unable to be reach over the network.

Bond Configuration Check

Description

This health check verifies whether the bonding mode configured for the cluster is either 1 (active-backup) or 4 (LACP).

Data Source

- The following data source finds the names of all the bonds on the node:
  - `grep bond /proc/net/dev | awk '{print $1}' | tr -d ':'`
- The following data source evaluates the bond mode
  - `cat /etc/sysconfig/network-scripts/ifcfg-<bond_name> | grep BONDING_OPTS| cut -d '\"' -f2 | cut -d ' ' -f1 | cut -d '=' -f2`

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the bonding mode configured for the cluster is either 1 (active-backup) or 4 (LACP).
Fail	Indicates that the bonding mode configured for the cluster is 0,2,3,5 or 6.

Downloads Site Connectivity Check

Description

This health check verifies whether the downloads.cohesity.com site is reachable from the cluster node.

Data Source

```
curl -Is https://downloads.cohesity.com | head -1 | awk '{print $2}'
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the downloads.cohesity.com site is reachable from the cluster node.
Fail	Indicates that the downloads.cohesity.com site is not reachable from the cluster node.

SSD Lifetime Write Limit Check

Description

This health check verifies whether the SSD of the cluster has reached its End of Life.

Data Source

```
service_uptime.py gandalf
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the SSD of the cluster has not reached its End of Life.
Fail	Indicates that the SSD of the cluster is approaching its End of Life.

/home_cohesity_data Read Only Check

Description

This health check verifies whether the /home_cohesity_data partition is mounted as read-write or read-only.

Data Source

```
mount | grep home_cohesity_data | cut -d '(' -f2 | cut -d ',' -f1
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the /home_cohesity_data partition is mounted as read-write.
Fail	Indicates that the /home_cohesity_data partition is mounted asread-write or read-only.

Nexus Stability Check

Description

This health check verifies whether the Cluster Manager Service has been stable for the past 5 minutes.

Data Source

```
service_uptime.py nexus
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the Cluster Manager Service has been stable for the past 5e has been stable for the past 5 minutes.
Fail	Indicates that the Cluster Manager Service has not been stable or down for the past 5 minutes.
Error	Indicates an error while retrieving the Cluster Manager Service uptime; the service may be unstable.

SMARTCTL Status Check

Description

This health check verifies the smartctl status of all disks in the cluster.

Data Source

```
sudo smartctl -H --json /dev/$data | grep -io \"\\\"passed\\\": [a-zA-Z\\!]*\\|USB\" | cut -d ':' -f2 | tr -d ' '
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the smartctl is reporting all the disks in the cluster as healthy.
Fail	Indicates that the smartctl is reporting disk failure in the cluster.

NVME Error Check

Description

This health check verifies health of NVME disks on the cluster.

Data Source

- To collect NVME Names
  - `ls /dev | awk '/^nvme[0-99]$/ {print $1}'`
- To evaluate NVME Error counts:
  - `sudo smartctl -a /dev/<nvme_name> | grep Media | cut -d ':' -f 2| tr -d ' ,'`

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that no errors on the NVME disks.
Fail	Indicates that there are errors on the NVME disks.

Missing NVME Disk

Description

This health check verifies whether all the expceted NVME disks are available and mounted.

Data Source

```
platform.py missing_disks:NVME_Disk
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that all the expceted NVME disks are available and mounted.
Fail	Indicates that one ore more NVME disks are missing.

Missing System Disk

Description

This health check verifies whether all the expceted systemE disks are available and mounted.

Data Source

```
platform.py missing_disks:SystemDisk
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that all the expceted system disks are available and mounted.
Fail	Indicates that one ore more system disks are missing.

Missing SATA SSD Disk

Description

This health check verifies whether all the expceted SATA SSD disks are available and mounted.

Data Source

```
platform.py missing_disks:SATA_SSD_Disk
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that all the expceted SATA SSD disks are available and mounted.
Fail	Indicates that one ore more SATA SSD disks are missing.

Missing HDD Disk

Description

This health check verifies whether all the expceted HDD disks are available and mounted.

Data Source

```
platform.py missing_disks:HDDDisk
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that all the expceted HDD disks are available and mounted.
Fail	Indicates that one ore more HDD disks are missing.

/home_cohesity_data Space Check

Description

This health check verifies whether the /home_cohesity_data partition has 14 GiB or more free space.

Data Source

```
df -h /home_cohesity_data/ | awk '{print $4}'|tail -1|tr -d 'G'
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the node has sufficient space for upgrade.
Fail	Indicates that the node has insufficient space for upgrade.

Virtualization Enabled Check

Description

This health check verifies whether virtualization technology is enabled on the CPU.

Data Source

This health check uses the following command to check the status:

```
sudo virt-host-validate qemu | grep -q FAIL;echo $?
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the node has hardware virtualization enabled.
Fail	Indicates that the node does not have hardware virtualization enabled.

Disk(s) marked for removal Check

Description

This health check verifies whether there are any disks marked for removal.

Data Source

This health check uses the following command to check the status:

```
grep -q MarkedForRemoval /tmp/cc_tmp_ng ; echo $?
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that there are no disks marked for removal.
Fail	Indicates that one ore more disks marked for removal.

Stale Mount Check

Description

This health check verifies whether there are any stale Indexing Service mounts on the cluster.

Data Source

This health check uses the following commands to check the status:

- To collect list of any Indexing Service mounts
  - `mount | grep yoda_clone_backup | awk '{print $3}'`
- To evaluate mount time
  - `find $<index_service_mount>/clone_backup/ -maxdepth 1 -mtime +365`

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that the node has no old or stale backup views present.
Fail	Indicates that there are one or more stale backup views present.

Athena app subnet overlap check

Description

This health check verifies whether the Marketplace Apps Service subnets overlaps with any internal subnet.

Data Source

This health check uses the following command to check the status:

```
grep 'is_athena_subnet_clash' /tmp/cc_tmp_ng | awk '{print $2}'
```

State

The following table lists the status of this check:

Status	Description
Pass	Marketplace Apps Service subnets do not overlap with any internal subnet.
Fail	Marketplace Apps Service subnets overlap with an internal subnet.

Vendor

This module verifies the health and status of the OEM Hardware Platforms from Cisco, Dell, HPE, and other qualified vendors.

If required, you can run the following command to perform only the health check of the OEM Hardware Platforms:

```
hc_cli run -m vendor
```

Available Vendor Health Checks

Following are the health checks that will be performed for the vendor module:

- Cisco C240 M5 BIOS 4.0.4p.0.1112191020 Version Check

Cisco C240 M5 BIOS 4.0.4p.0.1112191020 Version Check

Description

This health check verifies if any UCS C240 nodes running BIOS 4.0.4p.0.1112191020.

Data Source

```
sudo dmidecode -t bios | grep Version | cut -d ':' -f2 | grep
'C240M5.4.0.4p.0.1112191020' ; echo $?
```

State

The following table lists the status of this check:

Status	Description
Pass	Indicates that none of the UCS C240 nodes are running BIOS 4.0.4p.0.1112191020.
Fail	Indicates that one or or more UCS C240 nodes are running BIOS 4.0.4p.0.1112191020.

hc_cli show

The Show method enables you to review previous runs, and regenerate the reporting.

You can run the hc_cli show command to view the results of recent health checks and other diagnostic tests that are run on the cluster.

To view the result of a specific health check, run the following command:

```
hc_cli show <health_check_test_ID>
```

Options

You can use the following options with the hc_cli show command using the format,

```
hc_cli show <option>:
```

Option	Description
`-h or --help`	Displays help output for the hc_cli show command.
`-C or --current-node`	Displays the health check output from only the current node.
`-F or --failed`	Displays only failed health checks.
`-V or --verbose`	Displays detailed output of all checks across all nodes.
`--warning`	Displays detailed output of health checks that show warnings.
`--skipped`	Displays detailed output of health checks that were skipped.
`hc_cli show --all`	Displays detailed output of all health checks.

hc_cli debug

The hc_cli debug command provides a detailed logging or verbose output to help diagnose issues within the health check process.

You can use the debug method within the CLI shell or outside of it.

You can run the following command to enter the debug shell:

```
$ hc_cli debug
```

Running the above command will drop you into the debug shell where you can execute various maintenance commands.

Following are the modules available with in the debug shell:

- Apps
- Archival

- Backup
- Cert
- Data Management
- Data Sources
- Gflag
- Indexing
- Log Utilities
- Metadata
- Networking
- OS U
- Platform

hc_cli version

The Version method prints the current version of the support toolbox installed on the Cohesity cluster.

You can run the following command to know the version of the support toolbox installed:

```
$ hc_cli version
```

Access Support Toolbox from Siren Web UI

Siren is a web-based tool that provides access to logs and other serviceability information on a Cohesity cluster. You can access Support Toolbox through the Siren Web UI and perform health checks and resolve cluster issues.

Perform the following steps to access Support Toolbox:

1. Login to the cluster's Siren UI. The user logging into the cluster must have either admin credentials, or cluster support roles defined for their user.

   ```
   <cluster_ip_address>/ siren/v2
   ```

   Where, <`cluster_ip_address`> is the IP address of your cluster.
2. From the Siren Landing page, select **Support Toolbox**.

Support Toolbox Operations

The Support Toolbox in the siren UI provides diagnostic and maintenance utilities such as:

- Health Check
- Results
- Maintenance

Health Check

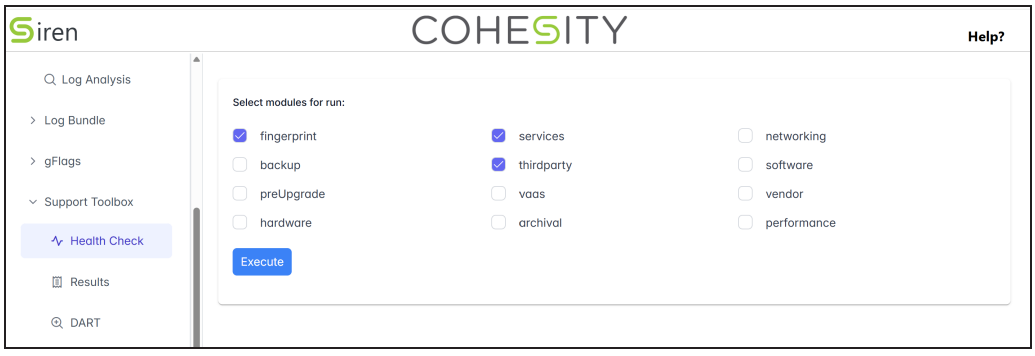
From the **Health Check** Tab, you can perform the health checks for all the modules across all nodes in the Cohesity cluster. The modules on the Cohesity cluster are as follows:

- fingerprint
- services
- vaas
- hardware
- performance
- preUpgrade
- thirdparty
- networking
- archival
- vendor
- software
- Backup

To perform the health check:

1. From the Siren UI of your cluster, navigate to Support Toolbox.
2. Click **Health Check**.

   The page displaying the list of modules for which you can perform the heath check appears.
3. Select the modules for run.



4. Click **Execute**.

   The health check has been initiated. The execution may take a few minutes to complete. Once finished, a View Results link will appear, directing you to the Results page.

Results

The **Results** page allows you to review the most recent health check results, as well as a limited history of past runs. You can:

- Sort results (ascending or descending) by **Severity**, **Node Name**, or **Test Name**.
- Download the results in JSON format to attach to a support case.

Result Categories

Health check results are organized into the following categories:

- **Passed** – No failures detected.
- **Warning** – An issue was found, but it has not reached a full failure state. Consider it an early indication of a potential failure.
- **Fail** – The test has failed and remediation is required.
- **Skip** – The test is irrelevant to the current platform, hardware, or codebase.
- **Error** – The test itself encountered an error.

Severity Levels

Each test is assigned a severity level from 1 (Imminently Critical) to 4 (Informational).

A **Severity 1 Failure** is the most urgent and must be addressed immediately.

A **Severity 4 Failure** is the least critical and primarily informational.

Result Details

Expanding an individual test result displays the following details:

Result – Human-readable description of the issue.

Test Name – The command or script executed.

State – The outcome of the test (Pass, Fail, or Warning).

Severity – The criticality of the issue, from 1 (Most Critical) to 4 (Least Critical).

Node IP – IP address of the reporting node.

Node ID – Cohesity Cluster Config ID of the reporting node.

Node Name – Hostname of the reporting node.

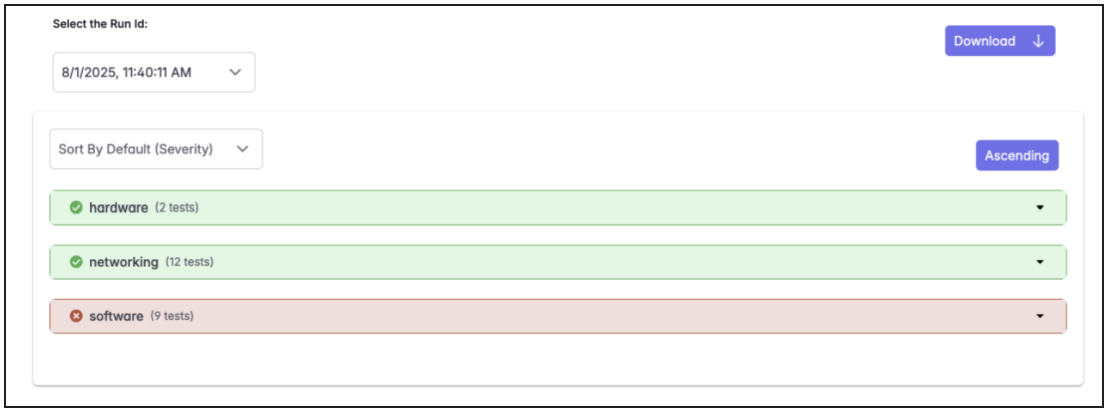
Test KB Link – Link to a Cohesity Support KB article explaining the test and possible resolutions.

View Health Check Results

1. To view results of the health checks performed:
2. From the siren UI of your cluster, navigate to **Support Toolbox**.
3. Click **Results**.

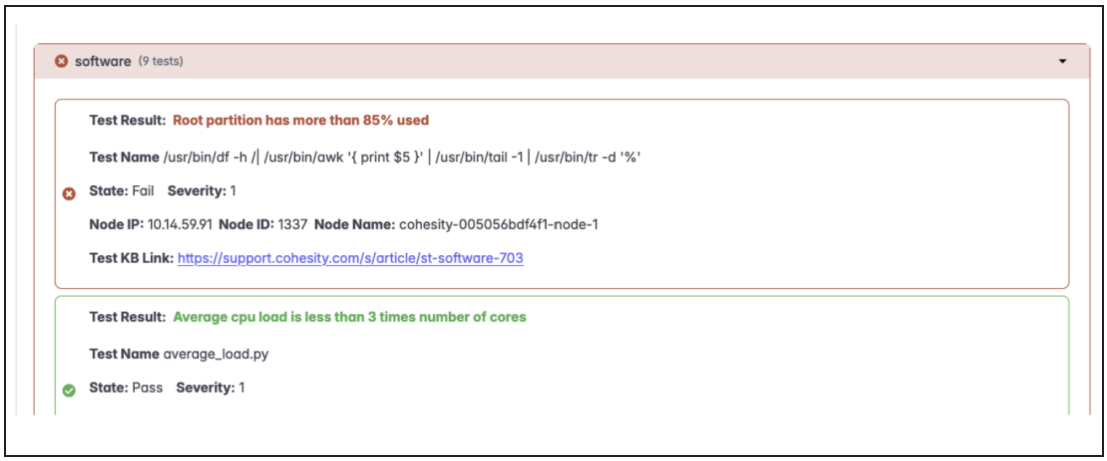
4. From the **Select the Run Id** drop-down list, choose the health check executed on the desired date and time.
5. The results of the checks performed for the selected run are displayed.

You can also download the results in JSON format by clicking the **Download** button located at the top-right of the page.



You can expand health check results by click on them.

Any module presented in red has a failure, yellow a warning, green is all passed.



Maintenance

From the **Maintenance** tab, you can perform the following actions:

- Restart Brigid API Server
- Update Support Toolbox
- Rolling Reboot

Restart Brigid API Server

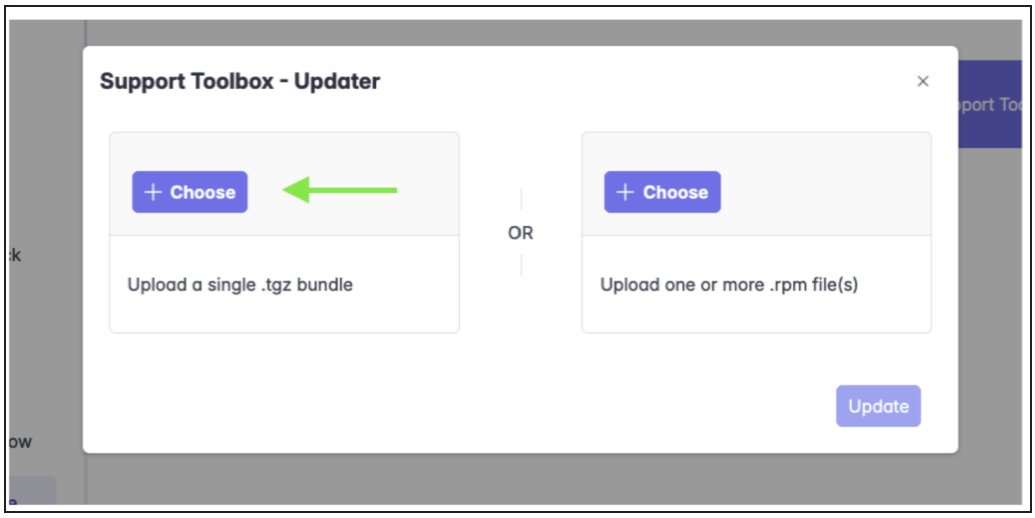
By selecting the Restart Brigid API Servicer button, reports the status of the underlying API server.

Update Support Toolbox

Using the **Update Support Toolbox** option, you can upgrade the Support Toolbox to the latest version.

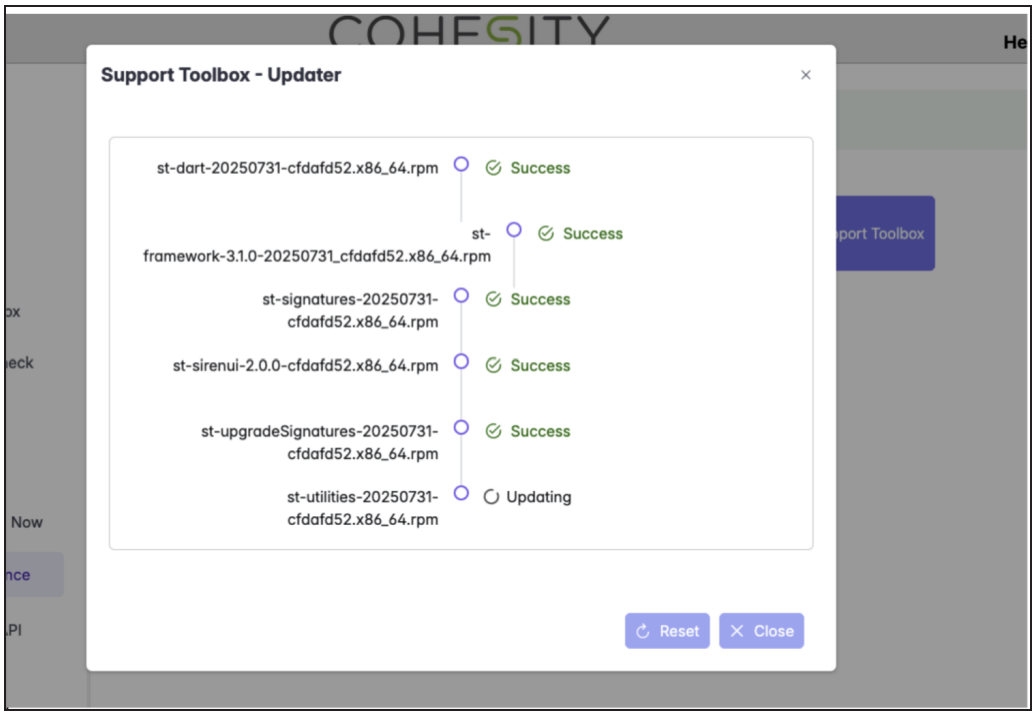
To upgrade the Support Toolbox to the latest version, perform the following steps:

1. Go to the Cohesity download page, and select **Cohesity Tools** tab.
2. Select the fast link for support-toolbox-installer and download to your local computer.
3. From the Siren UI of you cluster, navigate to **Support Toolbox** > **Maintenance** > **Update Support Toolbox.**.
4. A window will pop up, prompting you to provide either a single **.TGZ** bundle, or a single RPM. We recommend using the **.TGZ** bundle from the downloads portal for simplicity. Click the choose button and select your **.TGZ** file.

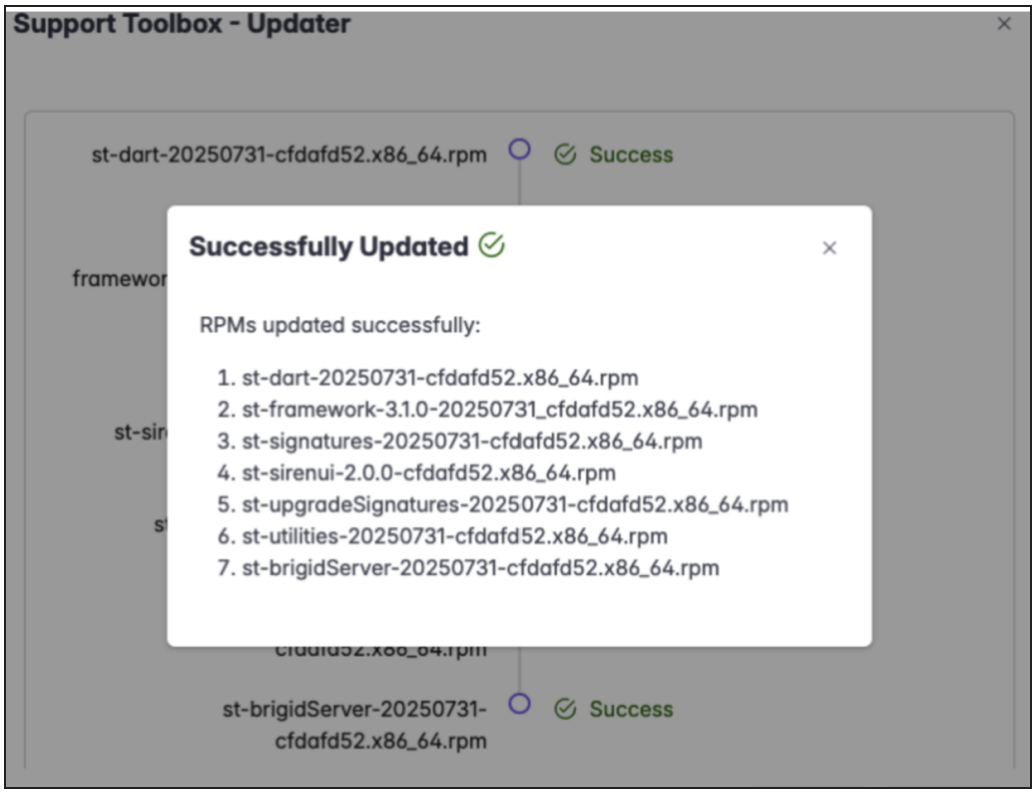


5. Click **Update**.

   A progress screen will be displayed, showing the update status for each package.



6. When the update is complete, a confirmation message appears indicating that the package update was successful.



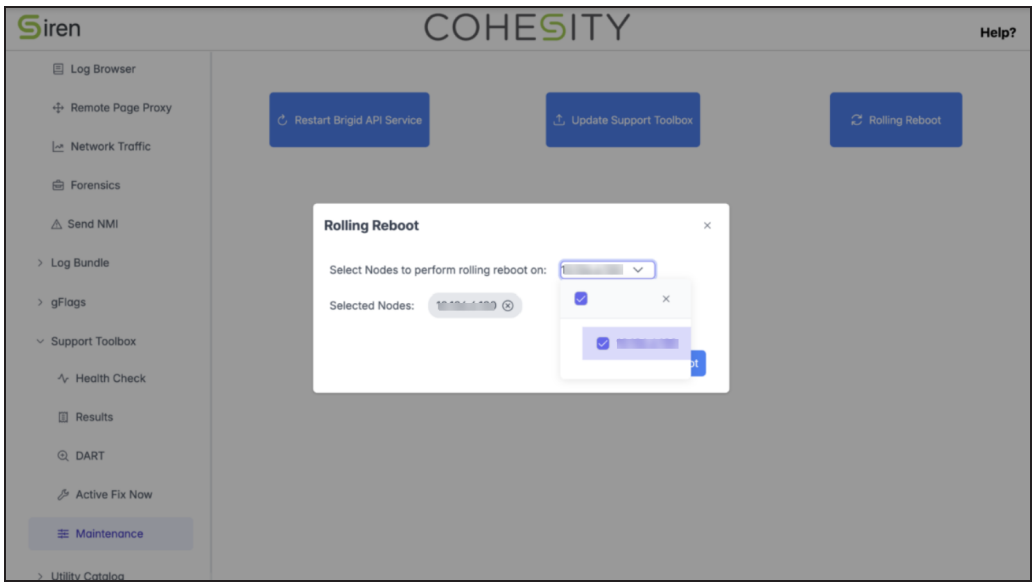
Rolling Reboot

The **Rolling Reboot** option allows you to reboot cluster nodes sequentially. This process helps identify disks that spin down during the reboot but fail to spin up again, potentially causing upgrade operations to hang.

> **Note:** Cluster nodes are rebooted sequentially, not in parallel.

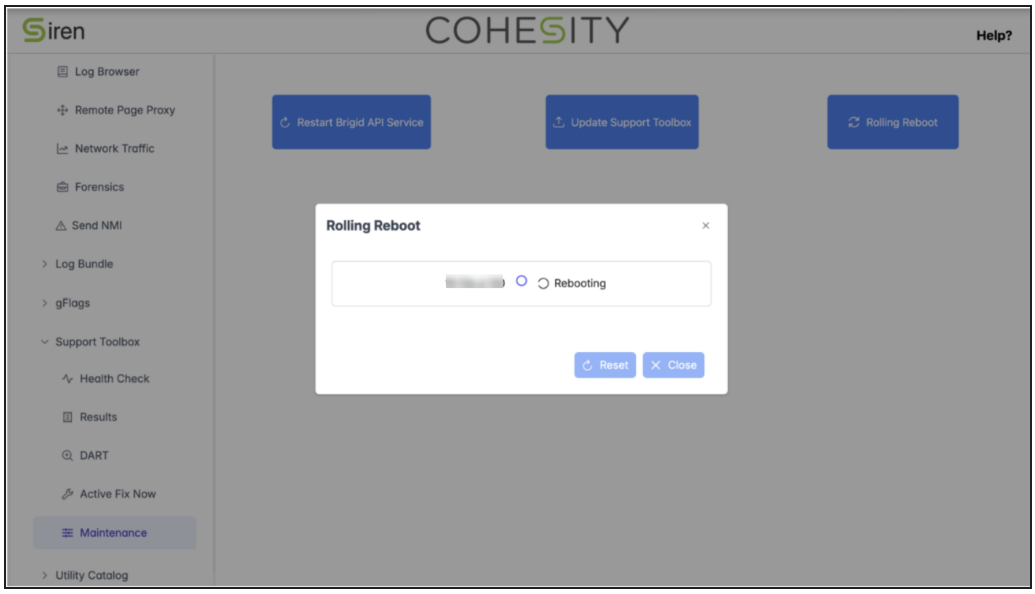
To reboot the cluster nodes, perform the following steps:

1. Select one or more nodes on which you want to perform the rolling reboot.

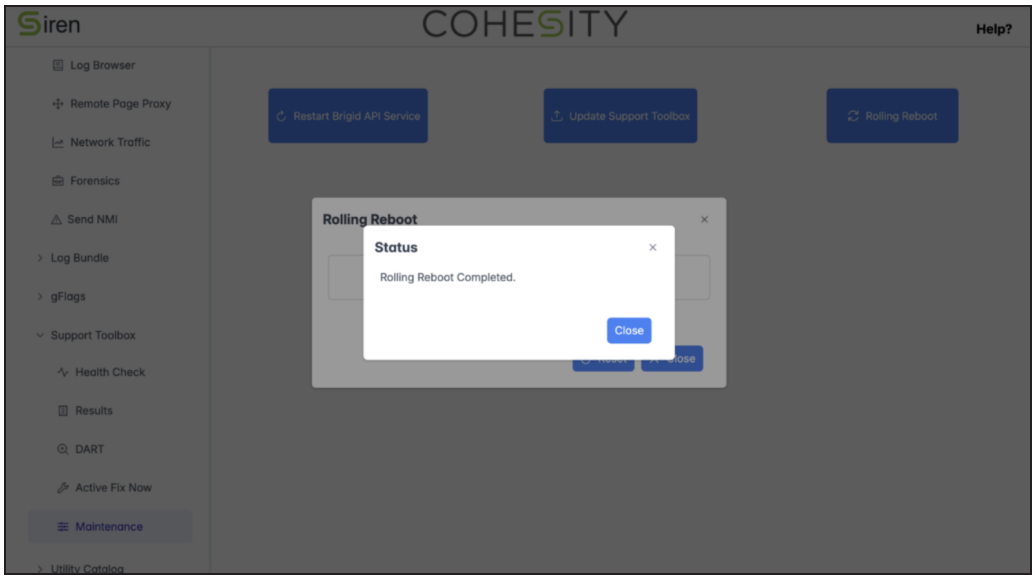


2. Click **Reboot** to initiate the process.
3. A confirmation dialog appears. Click **Yes** to proceed.

4. The rolling reboot begins. A timeline displays the status of each node during the process.



5. After completion, a status dialog appears showing the outcome.



Each node's timeline indicates whether the reboot:

- Completed successfully
- Timed out
- Ended with an error

Environment Setup

This section provides information about setting up environments that interface with the Cohesity cluster.

Backup Manager Service Replica

A Cohesity multi-node cluster consists of a primary instance of the Backup Manager Service. The Backup Manager Service is responsible for handling all the requests from the Cohesity and APIs.

A multi-node cluster environment with a large amount of data increases the load on the primary instance of the Backup Manager Service. Heavy workloads on the primary instance of the Backup Manager Service increase the response time of Cohesity and API calls.

Enabling the Backup Manager Service Replica allows the primary instance of the Backup Manager Service to serve a high volume of traffic. Each Cohesity cluster can have only one Backup Manager Service Replica.

Benefits of enabling Backup Manager Service Replica on a multi-node Cohesity cluster are:

- Offloads the read requests on the primary instance of the Backup Manager Service.
- Improves performance of Cohesity.
- Lower API latency.

Cohesity recommends enabling Backup Manager Service Replica on a multi-node cluster only.

> **Note:** Backup Manager Service Replica reads the primary instance of the Backup Manager Service once in 15 seconds.

Ensure Adequate Privileges for Cohesity on the Source

The Cohesity cluster must perform various actions on the source. For the Cohesity cluster to perform these actions, the user specified to connect to the source (the one used to register the source) must have adequate privileges. For information about each source type, refer to the appropriate section:

- VMware vCenter
- Standalone ESXi
- Microsoft Hyper-V
- vCloud Director
- Nutanix Acropolis
- NetApp
- Dell EMC Isilon
- Storage Snapshot Integration
- Active Directory

- Linux Servers
- Windows Servers

Create a Role with Necessary vCenter Server Privileges

The Cohesity cluster performs various VMware actions such as creating VMware snapshots, restoring VMware snapshots to ESXi hosts using vSphere Storage vMotion and creating new VMs by mounting the new VMDKs. For the Cohesity cluster to have adequate vCenter server privileges, the VirtualCenter user specified to connect to the source (vCenter Server) must have the role privileges listed in Role Privileges for vCenter Server and that VirtualCenter user must be associated with vCenter objects that the Cohesity cluster interfaces with.

> **Note:** By default, the **VMware Consolidated Backup user (sample)** role does not have adequate privileges for the VMware activities performed by the Cohesity cluster.

Create a Role with adequate vCenter Server Privileges

1. Using the vSphere Web Client, log in to the vCenter server that contains the VM to protect.
2. Create a new role.
3. Select the appropriate privileges for the new role as listed below.
4. Assign this role to the vCenter users that will access the Cohesity cluster. Assign this role to users at the top vCenter object level and enable **Propagate to children** check box.
5. When registering a source on the Cohesity cluster, specify a VirtualCenter user assigned to a role with the required Cohesity privileges (defined below).

For more information on VMware vCenter permissions, refer the knowledge base article, Required Cohesity Permissions for VMware vCenter Environments.

Role Privileges for vCenter Server

The following table lists all the privileges that you need to use a Cohesity cluster with VMware vCenter.

Note:

- The Session view and stop sessions privilege is applied to all the tasks to close any sessions after a process finishes. The Cryptographic privileges for Add Disk and Direct Access are only needed for encrypted VMs. The Configure Datastore privilege is only needed for throttling or storage snapshot integration.
- Starting with VMware vSphere 8.0 version, the **Profile-driven Storage** privilege level is replaced with **VM Storage Policies**.

Privilege Level	Permissions Required When Using	
	VMware Snapshot Only	Storage Snapshot Integration (Pure, Nimble, NetApp)
Cryptographic operations	• Add Disk • Direct Access • Encrypt new • Migrate • Manage key servers **Note:** Cryptographic privileges are only needed for encrypted VMs.	• Add Disk • Direct Access • Encrypt new • Migrate • Manage key servers **Note:** Cryptographic privileges are only needed for encrypted VMs.

Privilege Level	Permissions Required When Using	
	VMware Snapshot Only	Storage Snapshot Integration (Pure, Nimble, NetApp)
Datastore	• Allocate space • Browse datastore • Configure datastore • Low level file operations • Move datastore • Remove file • Configure datastore IO management **Note:** Configure Datastore privilege is only needed for throttling.	• Allocate space • Browse datastore • Configure datastore • Low level file operations • Move datastore • Rename datastore • Remove file • Configure datastore IO management **Note:** Configure Datastore privilege is only needed for throttling.
Folder	• Create folder • Delete folder	• Create folder • Delete folder

Privilege Level		Permissions Required When Using

	Inventory	Create Delete Register Unregister
	Provisioning	DiskRandomRead GetVmFiles
	State	Create snapshot Remove snapshot Revert to snapshot

Privilege Level	Required Permissions
Cryptographic Operations	Add Disk Direct Access Encrypt Migrate

Microsoft Hyper-V

For Hyper-V SCVMM, specify the domain user with administrative privileges when registering the SCVMM application. Cohesity recommends you to specify a user with the LOCAL SYSTEM account privileges when installing the Cohesity Agent. For more information, see Download and Install the Agent on the SCVMM Server.

For Hyper-V Standalone and Hyper-V Failover clusters, perform the following actions:

- Add all hosts' machine accounts:
  1. Start the **Failover Cluster Manager**.
  2. Right-click the standalone cluster from the clusters list and select **Properties > Cluster Permissions > Add > Object Types > Check Computers > OK**.
  3. Type <the hostname>$ in **"Enter the object names to select"** and select **Check Names > OK > Allow "Read" > OK**.
- Add all machine accounts to the administrators group of each host in the standalone cluster.

vCloud Director

The following table lists all the privileges that you need to use a Cohesity cluster with vCD.

Permission	Application	Privilege	
		View	Manage
Access Control	Organization	Allow Access to All Organization VDCs	Change the Owner of the Content Hub External Source
		View the Content Hub External Source	Edit the External Source in Content Hub
		View Content Hub External Source ACL	Share the Content Hub External Source

Permission	Application	Privilege	
		View	**Manage**
		View Catalog ACL	Manage Quotas of Organization
		View the LDAP settings	Implicitly Import User/Group from IdP while Editing VDC ACL
		View Organization Networks	Administer and traverse into other organizations
		View Organization Administrative Details	Use Provider LDAP as Tenant
		*View Access Control List of Organization VDCs	Edit Organization Properties
		*View Organization Associations	
		*View OAuth Settings	
		View vApp ACL	
	User	View Users and Groups	Manage user's own API token
Administration	General	Administrator View	Administrator Control
		View Error Details	Resume / Cancel / Fail a Task
		Perform administrator queries

			Edit Properties
			Import Network
			Create Shared Organization VDC Network
	Provider Gateway Services	View Limited Provider Gateway	
	Provider Network	View Provider Network	Create / Delete Provider Network
			Edit Provider Network
			Open Provider Network in vSphere

*These permissions apply only to users who access the plugin through a tenant login. Users performing backup and recovery operations directly on the Cohesity platform do not require them. Additionally, these permissions are needed in addition to the existing permissions when enabling tenant users to access and interact with the plugin.

Nutanix Acropolis

Specify either the local Prism admin user or a service account that has admin privileges to ensure that the user has adequate privileges to perform actions on the source.

Set up a service account

1. In Prism create a link to the Active Directory (AD) domain that you want to use for authentication.
    a. Click the settings icon and select **Authentication**.
    b. Click **New Directory**.

   c. Complete the Authentication Configuration fields and click **Save**.
2. Map the AD account to the Cluster Admin role.
   a. Click the settings icon and select **Role Mapping**.
   b. Click **New Mapping**.
   c. Complete the Create Role Mapping fields.
      - For **LDAP Type**, select User.
      - For **Role** select Cluster Admin.
   d. Click **Save**.
3. Through the Prism self-service portal, assign SSP administrator privileges to the user.

AHV Prism Element

The minimum privileges required for a custom user role are **Cluster Admin**.

> **Note:** Cluster Administrators are automatically granted Backup Administrator privileges.

AHV Prism Central

Starting with version 7.2.2_u2, the minimum privileges required for AHV Prism Central are listed in the table below.

Entity type	Operations
AHV VM	Allow Virtual Machine Power On Allow Virtual Machine Power Off Update Virtual Machine Update Virtual Machine Boot Config Update Virtual Machine Categories Update Virtual Machine CPU Update Virtual Machine Description Update Virtual Machine Disk List Update Virtual Machine Power State View Virtual Machine
Category	View Name Category View Value Category
Cluster	View Cluster
Domain Manager (Prism Central)	View Prism Central

NetApp

To protect NetApp SMB, specify a user that has adequate privileges to perform actions on the source.

Set up a user to protect SMB

1. Log in to the NetApp cluster as an administrator.
2. If registering a cluster, add a cluster role that has the following attributes:

Command	Access Level	Details
export-policy (optional)	all	Adds the Cohesity cluster subnet to the export-policy so that Cohesity can mount volumes
volume snapshot	all	Allows fetching, creating and deleting snapshots for volumes
cifs	readonly	Fetches information about CIFS/SMB shares for volumes
cluster identity	readonly	Fetches information about the cluster
network interface	readonly	Fetches information about network interfaces that Cohesity connects to for mounting volumes
volume	readonly	Fetches information about volumes
vserver	readonly	Fetches information about SVM

3. If registering a SVM, add a SVM role that has the following attributes:

Command	Access Level	Details
vserver export-policy	all	Adds the Cohesity cluster subnet to the export-policy so that Cohesity can mount volumes
volume snapshot	all	Allows fetching, creating and deleting snapshots for volumes
vserver cifs	readonly	Fetches information about CIFS/SMB shares for volumes
network interface	readonly	Fetches information about network interfaces that Cohesity connects to for mounting volumes

Command	Access Level	Details
volume	readonly	Fetches information about volumes
vserver	readonly	Fetches information about SVM

4. Create a cluster/SVM user and assign the role you created previously. The user must have ONTAPI allowed as one of the User Login methods.

> **Note:** The username used to register the NetApp cluster and SVM is case sensitive.

5. To enable the Cohesity cluster to back up volumes on a share, do one of the following:
   - Set permissions on a share so that any necessary Active Directory principals have at least Read access.
   - Add an Active Directory principal that has at least read access for the c$ share (if this share on the SVM is available)

To protect NetApp NFS, specify a user that has privileges to perform actions on the source.

Set up a user to protect NFS

1. Log in to the NetApp cluster as an administrator.
2. If registering a cluster, add a cluster role that has the following attributes:

Command	Access Level	Details
export-policy	all	Adds the Cohesity cluster subnet to the export-policy so that Cohesity can mount volumes
volume snapshot	all	Allows fetching, creating and deleting snapshots for volumes
cluster identity	readonly	Fetches information about the cluster
network interface	readonly	Fetches information about network interfaces that Cohesity connects to for mounting volumes
volume	readonly	Fetches information about volumes
vserver	readonly	Fetches information about SVM

3. If registering a SVM, add a SVM role that has the following attributes:

Command	Access Level	Details
vserver export-policy	all	Adds the Cohesity cluster subnet to the export-policy so that Cohesity can mount volumes
volume snapshot	all	Allows fetching, creating and deleting snapshots for volumes
network interface	readonly	Fetches information about network interfaces that Cohesity connects to for mounting volumes
volume	readonly	Fetches information about volumes
vserver	readonly	Fetches information about SVM

4. Create a cluster/SVM user and assign the role you created previously. The user must have ONTAPI allowed as one of the User Login methods.

> **Note:** The username used to register the NetApp cluster and SVM is case sensitive.

> **Note:** For the applicable NetApp volumes, Cohesity adds the node IPs in the export rule that has the **Allow Superuser Access** option enabled for NFS.

Dell EMC Isilon

User Permissions to Register Isilon

To register an Isilon NAS with Cohesity Isilon Adapter, ensure that the following permissions are configured in the Isilon cluster:

Name	Description	Access
Platform API	To have access to Isilon's APIs	Read-Only
Auth	To verify users and passwords	Read-Only
Cluster	To obtain cluster identity and settings	Read-Only

Name	Description	Access
Job Engine	To read and write ChangeList jobs	Read/Write
Network	To obtain the network interfaces	Read-Only
SMB	To read the settings in SMB server	Read-Only
Snapshot	To fetch, create, and delete snapshots for shares and exports	Read/Write
NFS	To read and write settings to and from the NFS server. **Note:** This setting modifies the NFS export used to mount, such as /ifs.	Read/Write **Note:** If NFS backup is not required, the user must have **Read-Only** permission.

Snapshot IQ License

You must have the SnapshotIQ license to take a snapshot on Isilon.

Storage Snapshot Integration

The Cohesity cluster integrates natively with Pure Storage or Nimble Storage to improve snapshot-based data protection. To leverage storage snapshot integration, Cohesity cluster needs to perform the following tasks:

1. Discover, configure, and register iSCSI LUN.
2. Perform VMFS datastore updates and configure storage I/O control on datastore.
3. Rename, mount/unmount, and delete the datastore.
4. Remove iSCSI LUN.
5. Delete VM and folder.

User Permission

For storage snapshot integration, the following additional privileges are required along with the permissions described in Role Privileges for vCenter Server .

Privilege Level		Required Permissions
Virtual Machine	Change Configuration	Acquire disk lease Add or remove device Change Settings
	Provisioning	Allow disk access

Active Directory

For more information, see Active Directory Protection Requirements.

Linux Servers

For more information on source privileges for Linux servers, see Install and Manage the Agent on Linux Servers.

Windows Servers

Specify the local or AD user with administrative privileges on the server. For more information, see Install and Manage the Agent on Windows Servers.

For information on minimum permissions, prerequisites and considerations to protect physical servers with Cohesity cluster, see Plan and Prepare for Physical Server Protection.

Antivirus Software Exclusions

To prevent antivirus software from interfering with backup and recovery operations involving Cohesity Agent on your Windows or Linux servers, Cohesity recommends adding the following files to the antivirus software exclusion list.

The following utilities can be added to the exception list.

For Windows:

For **Backups**: Provide the agent deployment path.

Examples:

- `C:\Program Files\Cohesity\cohesity_windows_agent_service.exe` (This is the installed Agent.)
- `C:\_Cohesity_\windows_agent\cohesity_windows_agent.exe` (This is the auto-deployed Agent.)

For **Recovery**:

- `*restoreFilesUtil.exe` (the * represents the variable task ID used as a file name prefix)

- `volumes_util.exe C:\Cohesity\windows_agent\cohesity_windows_agent.exe` (This is the auto-deployed Agent.)

The above utilities may be deployed during the recovery process and copied to a temporary directory such as `C:\Users\<Username>\AppData\Local\Temp\Cohesityvmware`*`nnnnnn`*, where *`nnnnnn`* is a variable task ID.

For Linux:

The following table provides the list of files that need to be added to the antivirus software exclusion list:

Installation Type	Base directory	Files
RPM	/opt/cohesity/agent/software/crux/bin/	/opt/cohesity/agent/software/crux/bin/linux_agent_exec
Script	/home/cohesityagent/cohesityagent/software/crux/bin/	/home/cohesityagent/cohesityagent/software/crux/bin/linux_agent_exec

> **Note:** Add the paths above to the antivirus exclusion list to prevent the antivirus software from interfering with backup and recovery operations.

Access Cohesity Host OS

You can access the host OS on a node through the Intelligent Platform Management Interface (IPMI) remote console and Secure Shell by using **cohesity_console** and **support user** accounts respectively.

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

Cohesity restricts the access to host OS through multi-layer of security that requires login credentials, and a challenge and response workflow.

> **Note:** If you've upgraded your Cohesity cluster from an earlier version to 7.0, then you have to run the following command to enable this feature.
> *iris_cli cluster split-key-host-access enable=true*

About Challenge and Response Text

A challenge is an alphanumeric text that is displayed after you attempt to log in to the Cohesity host OS with your credentials through an IPMI remote console or a VE node's console. The challenge appears in the following format.

-----Challenge String-------

<Alphanumeric_Value>

-----Challenge String End-------

This challenge is an 81-character text. It is valid for 60 minutes if you have accessed the Cohesity Platform through an IPMI console.

To proceed further, you have to copy this challenge and share it with Cohesity Support. The Support team verifies the request and shares a 16-character alphanumeric response.

On the IPMI remote console or the Secure Shell, a prefix is also displayed along with the challenge. The prefix should be combined with the response you have received from the Cohesity Support team to generate the login password and give you access to the host OS.

> **Note:** The prefix should not be shared with Cohesity.

Access Host OS through IPMI remote console

Follow the steps below to access the host OS on a node via IPMI.

1. Create a support ticket to access the host OS. For more information, see Cohesity Support.
2. Launch your preferred IPMI utility tool IPMI remote console.
3. Enter the IP address of the node with the required command. For more information on using Secure Shell and IPMI remote console, see Using the Secure Shell and Using the Cohesity CLI.

   The message **Welcome to Cohesity OS!** is displayed with details about accessing the host OS. Towards the end of the message, a challenge text is displayed in the format mentioned in the About Challenge and Response Text topic.
4. Copy the challenge text and share it with Cohesity Support through the support ticket.
5. After receiving the challenge, Cohesity Support verifies the request and shares the response text.
6. Enter the **Prefix** followed by the response text from Cohesity Support together as the password.

The console should now display a live session to the host OS on the node.

Hardware Replacement

Hardware replacement procedures (PDFs) are available at: Hardware Universe.

Chapter 5: FortKnox Self-Managed

FortKnox Self-Managed enables you to vault a copy of your backup data in a securely isolated Cohesity cluster using pull based method. It allows you to maintain an isolated, immutable copy of your data within your own self-managed infrastructure. This also ensures protection against cyber threats or primary cluster failures while enabling full control, security, and compliance over the vaulted data.

Key Concepts

Vault Cluster

A vault cluster stores another copy of data from the Cohesity cluster and recovers data to the original or a new location. You can convert a Cohesity cluster into a vault cluster to vault the data. The vault cluster provides isolated copy, immutable, WORM (Write Once, Read Many) storage, ensuring protection against unauthorized modifications, deletions or a cyber event.

Air Gapping

The Cohesity vault cluster operates on a pull-based model, leveraging outbound-only connections from an isolated network and ensuring no unauthorized external access. Connections are strictly established during designated vaulting windows, reinforcing air-gapped data protection.

Storage Immutability & WORM Support

The vaulted data is stored with Write Once, Read Many (WORM), ensuring immutability and protection against unauthorized modifications or deletions.

Quorum-Based Access Control

Helios Self-Managed, running within the secure Vault network, enforces quorum control, requiring multiple approvals for any critical vault operations, enhancing security and governance.

Multi-Tenancy Support

FortKnox Self-Managed supports multi-tenancy, allowing the service provider to manage the mapping of storage domains and vaulting windows for the tenants in a secure infrastructure.

Low Recovery Time Objective (RTO)

FortKnox Self-Managed is optimized for fast data recovery by maintaining a local copy within your premises, minimizing downtime in the event of a cyber-attack.

Vaulting Window

The Vaulting Window in FortKnox Self-Managed is an air-gapping mechanism that defines when the vault cluster can connect to the primary cluster. During the configured time window, connections are opened to pull data. Once the window closes, connections are dropped and active jobs are paused. These jobs automatically resume when the window opens again.

Supported Workloads

FortKnox Self-Managed supports the vaulting workflow for all workloads that are currently qualified for the Replication workflow. The workloads listed in the table below have been qualified for vaulting, while qualification for the remaining workloads is in progress. This list will be updated periodically as additional workloads are qualified.

Supported Workload Name
VMware VM
AHV VM
Physical VM (Block and File based)

Supported Workload Name
Network Attached Storage (NAS) • NetApp • Isilon • Generic NAS
MS SQL

Get Started

The following topics provide guidance that helps you to get started with FortKnox Self-Managed.

Prerequisites

Ensure the following prerequisites are met before enabling FortKnox Self-Managed:

- Encrypt Storage Domains
- Enable Cluster Level Encryption
- Enable Node to Node Encryption
- Configure Firewall
- Enable MFA
- Disable Archival and Replication
- Disable Support Channel

Encrypt Storage Domains

Storage Domains must be encryption enabled. Delete the unencrypted storage domains before converting the cluster to the vault cluster.

Encryption can be enabled only when you are creating the Storage Domain. Once the Storage Domain is created, the options to enable encryption or modify its encryption settings are disabled in the Cohesity cluster.

To create a storage domain and enable encryption, see Create or Edit Storage Domains.

Enable Cluster Level Encryption

Enable the software encryption at the cluster level to convert the cluster to vault cluster.

> **Note:** Cluster-level encryption can be enabled only during the cluster creation, and it cannot be disabled or modified later.

To enable the encryption,

1. Navigate to **Settings** > **Summary** and click **Configure**.
2. Turn on the **Encryption** toggle.
3. Scroll down to the end of the page and click **Save**.

> **Note:** Once encryption is enabled for a cluster, it cannot be disabled. Additionally, any storage domains created without encryption before cluster-level encryption was enabled must be deleted for this pre-requisite to succeed.

Enable Node to Node Encryption

Enable Node-to-node encryption for all services.

Node-to-node encryption is enabled by default starting from, 7.1.X and later for Physical Clusters

For Clusters upgraded from earlier versions, run the following command to enable node-to-node encryption manually,

```
$ iris_cli cluster tpenc enable-encryption=true
```

After enabling, run the following command to restart all services to stabilize the cluster,

```
$ iris_cli cluster restart-services all-services=true
```

Configure Firewall

You need to configure firewall, before converting a Cohesity cluster to a vault cluster.

To configure the firewall:

1. Navigate to **Settings** > **Networking** and select the **Firewall** tab.
2. Click edit icon ( ) to edit the incoming firewall rules.
3. Select **Allow** action for **Management**.
4. Select **Deny** action for all other applications.
    1. To deny **SSH**, users must manually select each interface group individually from the drop-down when configuring the deny rule.
    2. To deny other applications, no selection is required from the drop-down, the rule automatically applies to all interface groups by default.

5. After configuring the firewall to deny all firewall rules except management, follow these steps to add a single trusted IP address to the **Management** firewall rule to enforce least security measure.
    1. Select **Custom IP/Subnet** from the **Source** drop-down menu.
    2. Enter any one IP address to access the vault cluster.

> **Important:** Deny action should be set for all applications other than the Management inbound traffic.

Manage Firewall Ports

You need to open the following replication ports on the primary and vault cluster.

Primary Cluster to Vault cluster Traffic

For replication between the Primary cluster and the Vault cluster, the vault cluster's outbound replication ports must be open, and the primary cluster's inbound and outbound ports must be open.

Outgoing Traffic

Source	Destination	Port	Protocol	Usage Notes
Vault cluster	Cohesity cluster	23335	TCP	Required for vaulting scenario.
Vault cluster	Cohesity cluster	23336	TCP	Required for vaulting scenario.

Cohesity recommends keeping IPMI ports turned off.

For more information, see Manage Firewall Ports.

Enable MFA

Before you convert a Cohesity cluster into a vault cluster, you need to enable MFA to provide an additional authentication factor to access the vault cluster.

To enable MFA for local and active directory users:

1. Navigate to **Settings** > **Access Management** and click the **Secure Login** tab.
2. Turn on the **MFA** toggle, select one or both authentication methods, and click **Save**. For more information, see Enable MFA for Local and Active Directory Users.

To enable MFA for the support user account:

1. Navigate to **Settings > Access Management> Support**.
2. In the **Support** tab, click **Unlock to make changes**.

3. In the **Unlock Support User Settings** pop-up window, enter the **support** user password and click **Unlock**.
4. In the **Support User** section:
    - Enter the email address of the **support** user and click **Update Email**.

      > **Note:** A verification code will be sent to the current email to update the email address if you enable MFA with Email. The update completes only after successful verification.

    - To update the Linux Shell password, click **Update Password** and update the password.
5. Turn on the **Multi-factor Authentication (MFA)** toggle, select one or both authentication methods, and click **Save**. For more information, see Enable MFA for Support User Account.

Disable Archival and Replication

Ensure that the Vault cluster does not have any active policies with outgoing Archive or Replication workflows enabled, and do not configure it as an Archive or Replication target for any other Cohesity cluster.

To verify:

Navigate to **Data Protection** > **Policies** and check the existing policies.

Delete all existing replication and archival policies before proceeding if any active policies are present.

> **Note:** Snapshot data does not need to be removed and can be retained for recovery purposes.

Disable Support Channel

You must disable the support channel to convert the cluster to vault cluster.

To disable the support channel:

1. Navigate to **Settings** > **Summary** and locate the **Support Channel** option in the Cluster Summary list.
2. Click edit icon ( ) and select **Off** option from the dropdown.
3. Click **Save** to disable the Support Channel.

Create a Local User with Vault Admin Role on Primary and Vault Clusters

Vault admin role is required to configure and manage vault operations. Create a local user with the **FortKnox Self Managed Vault Admin** role on both the primary and vault

clusters.

To create a local user with vault admin role, see Add or Edit a Local User.

Convert a Cluster to Vault Cluster

To vault the data from the primary Cohesity cluster to an isolated Cohesity cluster, first you need to convert the cluster to vault cluster.

To convert a cluster to vault cluster:

1. Log in as the user with FortKnox Self-Managed Vault Admin role.
2. Navigate to **Settings** > **Summary** and select the **Vault** tab.
3. In the **Vault** page, click **Get Started**.
4. Ensure that the eligibility list is ticked on the **Convert to Vault Cluster** dialog box.

   > **Note:** Refer to Prerequisites section if any eligibility criteria is not met.

5. Click **Continue**.
6. Type YES on the confirmation field and click **Complete**.

> **Important:** Once a cluster is converted into a vault cluster, it cannot be converted back into the normal cluster. To convert it back, you need to perform cluster reset operation in which all the data will be deleted from the cluster, and the cluster will be a new cluster.

Now, you will see a confirmation message that the cluster is converted into a vault cluster.

Pair Primary Cluster to Vault cluster

Pair the primary cluster with vault cluster to enable the connection between the clusters.

Primary cluster can be a brand new cluster or an existing cluster you use for backup and restore operations. For more information on initial cluster setup, see Initial Cluster Setup.

Connect Vault Cluster to the Primary Cluster

To connect the vault cluster to primary cluster:

1. On the vault cluster, navigate to **Vault** > **Paired Clusters** and click **Pair Cluster**.

   > **Note:** Only users with the FortKnox Self Managed Vault Admin role can perform cluster pairing and update the existing pairing configurations including those previously created by Admin role users. For more details on vault admin role, See Manage Roles.

2. Enter all the Virtual IPs or Node IP Addresses of the cluster that you need to pair with the vault cluster in the **VIP or Node IP Addresses** column.
3. Enter the Username and Password of the user with the FortKnox Self Managed Vault Admin role on the primary cluster.
4. Select the required Interface Group **Automatic** or **Manual**.

   > **Note:** If you select Manual, you can choose from the list of Interface Groups.

5. Click **Continue: Storage Domain Pairing**.

Pair Storage Domain

To pair the primary and vault cluster storage domains:

1. Select the source storage domain on the **Source** column. Source is the storage domain on the primary cluster that is paired with the destination storage domain on the vault cluster.
2. Select the destination storage domain on the **Destination** column. Destination is the storage domain on the vault cluster.

   > **Note:** Vault cluster is the destination cluster.

3. Select the **Vaulting window**. The vaulting window is the time you choose to vault the data from the primary cluster to the vault cluster.

   > **Note:** Cohesity recommends configuring the vaulting window only after the initial full and a few incremental vaultings are successfully completed. Ensure that the vaulting window is appropriately sized to allow vaulting to complete.

4. Click **Add Domain Pair**. You can add multiple domain pairs.

> **Note:** This pairing connects the storage domains on the primary cluster and vault cluster that includes the vaulting window configuration. Data replication to the vault cluster occurs only during the defined vaulting window, when communication between the clusters is enabled.

5. **Optional**: Toggle on the **Data Transfer Throttle** if required.

   In **Throttle to** column, enter the throttling speed in Megabits per second (Mbps).
6. Click **Continue: Summary** to view the cluster pairing summary.
7. Click **Complete Pairing** to pair the cluster to vault cluster.

Create Protection Policy for Vault Cluster from Primary Cluster

To create a protection policy for the vault cluster from the primary cluster:

1. On the primary cluster, navigate to **Data Protection** > **Policies**.
2. Click **Create Policy** located at the top right of the page.
3. **Policy Name**: Specify a protection policy name. The name can contain the alphanumerics, underscores, hyphens, periods, and spaces. This field is required and can be changed later.
4. Specify when backups are captured:
   1. **Backup every xx**: Specify the minutes, hours, weeks, months, or years to set the frequency for how often backups are captured by the Protection Group. This defines the protection schedule for capturing backups.

      The policy schedule can be configured to run on specific days. From the **Every** drop-down, select **Week** and in the **On** field, select the days of the week you want to run the backup. For example, you can schedule a backup to run on Monday, Wednesday, and Friday, and not on Tuesday and Thursday.

      The policy schedule can be configured to run on specific dates as well (calendar-based scheduling). From the **Every** drop-down, select **Month**, and in the **On** field, select the **Date**. You can then choose the date of the month you want to run the backup. For example, you can schedule a backup to run on the 5th of every month.
5. Under **Primary Copy**, specify the following:
   1. **Keep On**: Select **Local** from the drop-down to keep the primary copy data on the Cohesity cluster.

If you are selecting any external targets, then this policy can be only used for performing CloudArchive Direct wherein the primary copy of the data is stored on the external targets. For more information, see CloudArchive Direct.

2. **Retain for**: Specify how many days, weeks, months, or years backups are retained on the Cohesity cluster before they are deleted.
    1. The **Retain** option can be set to a maximum value of 365000.
    2. Retentions at 7-day boundaries turn into weeks.
3. **Lock**: Specify how many days, weeks, months, or years the retained log backups should be locked. You cannot delete the snapshots during the specified period.

    > **Note:** This option is available only if you have enabled the DataLock option at the policy level.

6. Click **More Options** to configure the additional policy settings.
7. **DataLock**: Toggle on to lock the policy and any snapshots that belong to Protection Groups associated with the policy. DataLock is typically used for compliance and regulatory purposes. For more information, see DataLock.

    If you have enabled the **DataLock** option at the policy level, then you have the option to lock the backup retained on the Cohesity cluster. In the **Lock** option field available in the **Primary Copy** pane, specify how many days, weeks, months, or years the retained backups must be locked. You cannot delete the snapshots during the specified lock period.
8. Select **Add Vault** to add the vault cluster for the backups to the protection policy. Specify the following:
    1. **Transfer to**: Select the Vault cluster from the dropdown menu to transfer the data from the source cluster.
    2. **Every**: Specify the frequency of data transfer to the vault.
    3. **Retain for**: Specify the duration of the vaulted copy to be retained on the vault cluster.

> **Note:** Data transferred from the source cluster to the vault cluster is automatically locked using DataLock. This lock is permanently applied to vaulted snapshots, cannot be disabled, and remains active throughout the retention period. DataLock ensures immutability and compliance by preventing any modification or deletion of data during its lifecycle in the vault cluster.

9. **Optional**: Enable **Transfer only successful runs** if required.

   Transfer only successful runs: With this option, the data from the source cluster is transferred to the vault cluster only after the successful protection run.

10. If required, you can add additional policy settings. For more information, see Create or Edit a Standard Policy.

    > **Note:** Only the Data Security user can edit the vaulting protection policy.

11. Click **Create**.

Register a Source on Primary Cluster

Registering a source makes it eligible to be protected or backed up on the Cohesity cluster.

To register a source:

1. Navigate to **Data Protection** > **Sources**.
2. Click **Register** > select any source.

For more information on registering a source, see Register a Source.

Create a Protection Group on Primary Cluster

When you create a Protection Group, you can select an existing source, policy, or storage domain. You can also create them while creating the Protection Group. However, you might find it easier to create them prior to creating the Protection Group.

To create a protection group,

1. On the primary cluster, navigate to **Data Protection** > **Protection** and do one of the following:
   1. To create a Protection Group—Click **Protect** on the top-right of the page and then select the type of Protection Group.

2. To edit a Protection Group—Click the action icon (⋮) next to the Protection Group and select **Edit**.

2. If creating a new Protection Group, select **Protect** >select a source from the list.
3. In the **New Protection** pop-up, do one of the following:
    1. Protect the source by specifying a subset of options such as objects, protection group and policy by clicking the edit icon corresponding to the following options:
        1. **Add Objects**: Select the registered source or click **Register Source** to register a source. From the **Objects** list, select the volumes you want to back up.
        2. **Protection Group**: Specify a name for the Protection Group.
        3. **Policy**: Select an existing vault protection policy or click **Create Policy** to create a new protection policy. For more information, see Create Protection Policy for Vault Cluster from Primary Cluster.
        4. **Storage Domain**: Select the appropriate storage domain.

            > **Note:** This option is visible on the New Protection pop-up only if there is more than one storage domain.

            > **Important:** Select the storage domain used during pairing to ensure vaulting runs successfully.

        5. Click **Protect**.
    2. To protect the source by specifying all the options, click More Options and select the required settings.

For more information on creating a protection group, see Create a Protection Group.

Vaulting Status

You can view the vaulting status once the protection group is created from the primary cluster. The status can be viewed from the primary cluster and the vault cluster.

> **Note:** The vaulting status will appear in the vault cluster only after a successful protection run.

View Vaulting status from the Primary Cluster

To view the vaulting status from the primary cluster:

1. On the primary cluster, navigate to **Data Protection** > **Protection**.
2. Select the protection enabled source.
3. Click the **Vault** tab to see the vaulting status.

View Vaulting status from the Vault Cluster

To view the vaulting status from the vault cluster:

1. On the vault cluster, navigate to **Vault** > **Protection**.
2. Select the successful protection run.
3. Click the **Vault** tab to see the protection run details.

Recover from Vault Cluster

You can recover the sources that are vaulted to the vault cluster to the primary cluster or a newly specified location.

Refer to Considerations section before you initiate a recovery.

To recover the vaulted sources from the vault cluster:

1. On the vault cluster, navigate to **Data Protection** > **Recoveries**.
2. Click **Recover** located at the top right of the page.

For more information on the recovery, see Recovery.

To recover the files or folders of a source, refer to the recovery section of the specific source.

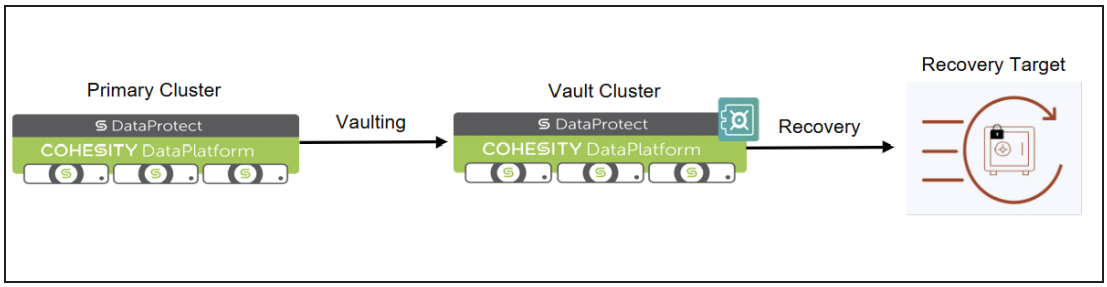
To manage a recovery, see Manage Recovery.

Supported Vaulting and Recovery Configurations

FortKnox Self-Managed supports multiple configurations for both vaulting and recovery workflows to enable deployment flexibility.

Configuration 1

The primary cluster vaults data to a designated vault cluster. All recovery operations are performed directly from the vault cluster.

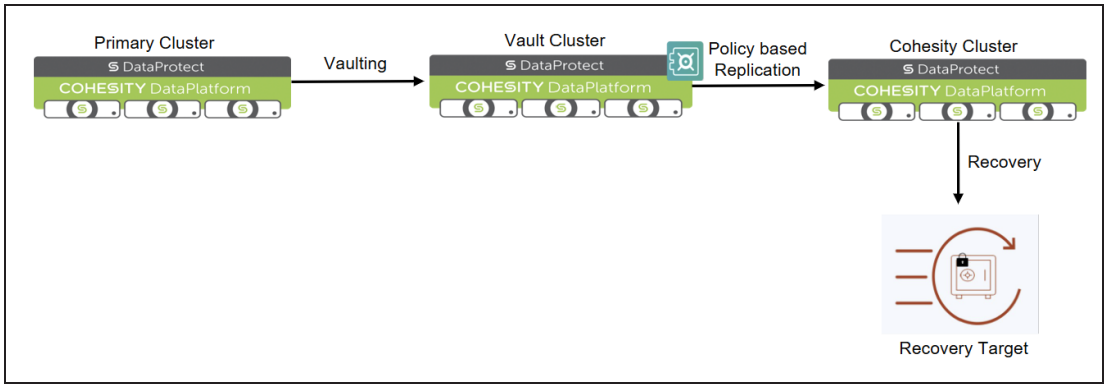


To vault the backup data directly from the primary cluster to the vault cluster:

1. From the vault cluster, initiate pairing with the primary cluster.
2. On the primary cluster,
    1. Create a vaulting policy. For more information, see Vaulting Policy.
    2. Configure a protection job and assign the vaulting policy to it. For more information, see Protection Group.

Configuration 2

The primary cluster vaults data to a designated vault cluster. The vault cluster then performs policy-based replication to a secondary Cohesity cluster, which is used for recovery operations. This workflow is supported through APIs. Data protection policies configured on the primary cluster control both vaulting and replication.



To vault and recover the backup data:

1. From the vault cluster, initiate remote cluster pairing with the secondary Cohesity cluster.
2. On the primary cluster,
    1. Use the API to configure a cascading policy that vaults the data to the vault cluster and then replicates from the vault cluster to the secondary Cohesity cluster.
    2. Provide the cluster ID and name for both the vault cluster and the secondary

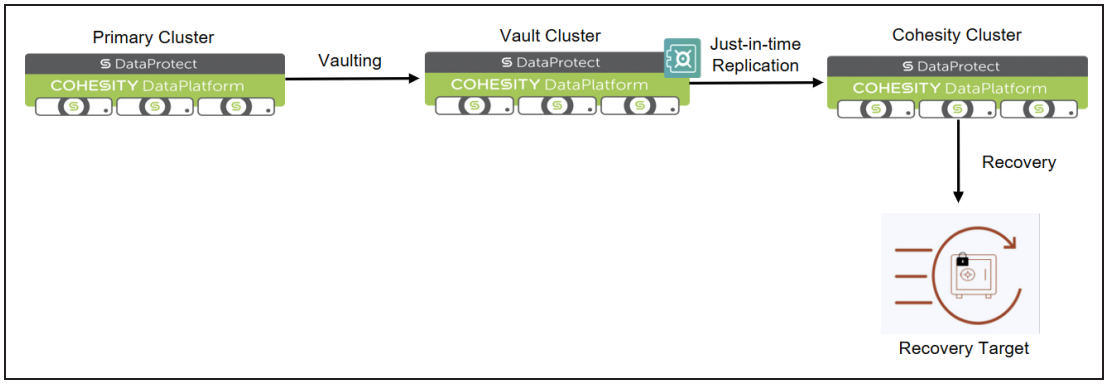
Cohesity cluster in the cascading policy.

3. Create and assign a protection job that uses this cascading policy.

For more information, see Cascaded Replication, Archival, and Vaulting Policy.

Configuration 3

The Primary cluster vaults data to a designated vault cluster. When recovery is needed, snapshots are manually replicated from the vault cluster to a secondary Cohesity cluster. This secondary cluster is used to perform recovery operations.

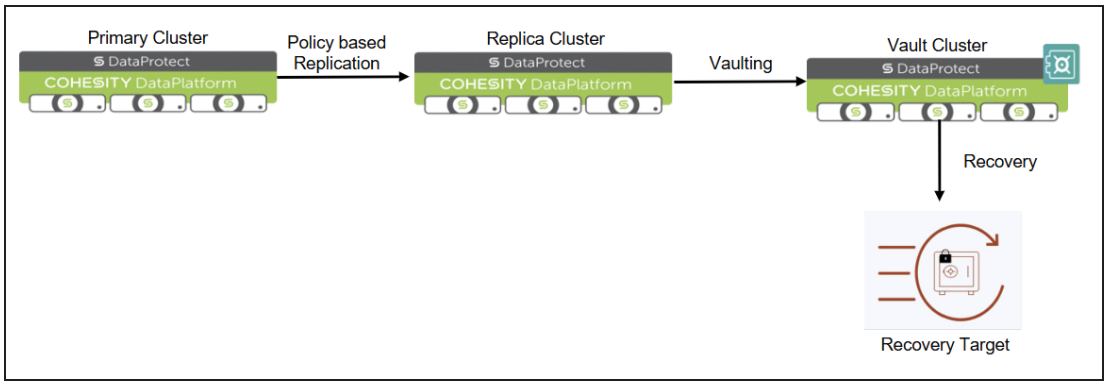


To perform just-in-time replication of snapshots to secondary Cohesity cluster:

1. On the vault cluster, navigate to **Vault** > **Protection**.
2. Click the action icon (⋮) next to the successful protection run and select **Edit**
3. Add the intermediate recovery cluster in **Replicate to** column as a new replication target for the specific snapshot and click **Save**.
4. On the intermediate recovery cluster,
    1. Navigate to **Data Protection** > **Protection**.
    2. Verify that the replication is successful.
5. Initiate recovery from the intermediate recovery cluster to the required recovery target.

Configuration 4

The primary cluster replicates data to a replica Cohesity cluster using policy-based replication. The replica cluster then vaults the replicated data to the vault cluster. This workflow is supported through APIs. Policies configured on the primary cluster control both replication and vaulting operations.



To replicate the backup data and recover:

1. From the vault cluster, initiate vault pairing with the Replica Cohesity cluster.
2. On the primary cluster,
    1. Use the API to configure a cascading policy that replicates the data to the replica Cohesity cluster and then vaults from the replica cluster to the vault cluster.
    2. Provide the cluster ID and name for both the replica cluster and the vault cluster in the cascading policy.
    3. Create and assign a protection job that uses this cascading policy.

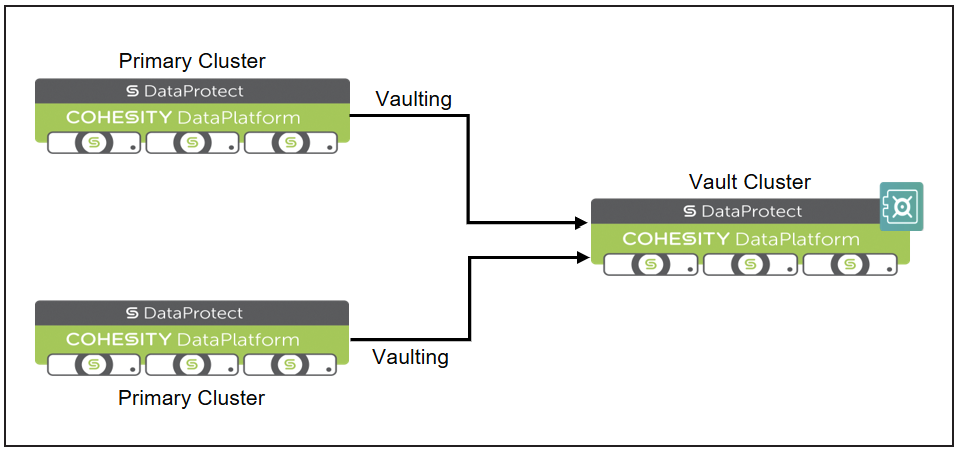
Limitation for Cascaded Policy

The Primary cluster UI does not display the vault cluster.

For more information, see Cascaded Replication, Archival, and Vaulting Policy.

Configuration 5

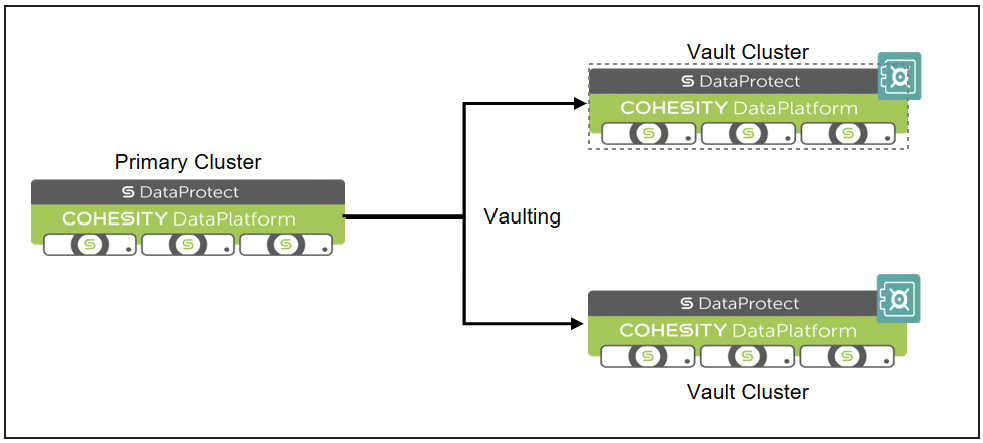
FortKnox Self-Managed supports multiple primary clusters vaulting to one vault cluster.



For more information, see Configuration 1.

Configuration 6

FortKnox Self-Managed supports one primary cluster vaulting to multiple vault clusters using different policies.



For more information, see Configuration 1.

Vaulting Scenario for Organizations

FortKnox Self-Managed supports the Organizations (multitenancy) feature. The multitenancy feature enables you to configure the multitenant environment on your Cohesity Platform and securely isolate each tenant in your environment. You can use a single Cohesity cluster to provide service to multiple tenants.

To configure FortKnox Self-Managed for Organizations:

1. **Enable Organizations**

   Enable the Organizations feature on both the primary and vault clusters. For more information, see Enable Organizations (Multitenancy) on a Cluster.

2. **Create Tenant Storage Domains**

   Create one or more storage domains for the tenant on both primary and vault clusters.

   > **Note:** Only Service Provider (SP) admin can create the storage domains.

3. **Establish Cluster Pairing**

   On the vault cluster, create a pairing between the primary and vault clusters.

   During the pairing process, map the tenant's storage domain on the primary cluster to the corresponding storage domain on the vault cluster.

4. **Create Vaulting Policy**

On the primary cluster, create a vaulting policy that references the vault cluster as the target.

> **Note:** Only Service Provider (SP) admin can create the vaulting policy.

5. **Assign Vaulting Policy to Tenant Organization**

   On the primary cluster, within the Service Provider management interface, assign the newly created vaulting policy to the tenant's Organization.

   > **Note:** Only Service Provider (SP) admin can assign vaulting policy to tenant organization.

6. **Create Protection Group**

   On the Primary cluster, create a protection group and select the storage domain designated for vaulting.

   > **Note:** Only Service Provider (SP) admin or Organization Admin can create protection group.

If the tenant requires changes to the vaulting window schedule, they must request the service provider to update the vault pairing configuration with the new time intervals.

For more information on end-to-end Organizations setup, see Organizations (Multitenancy)

Considerations

Refer to these considerations before deploying FortKnox Self-Managed to ensure proper configuration and compliance.

Vaulting Window

Cohesity limits the number of parallel tasks using a slot allocation algorithm. With the current implementation, vault replication slots are not released if vaulting does not finish before the vaulting window closes. The paused vaulting task holds the slot until the vaulting window opens again. This can lead to slot starvation for new vaulting or regular replication tasks, preventing them from running, and impacting cluster scalability.

As a workaround, Cohesity recommends that the vaulting window duration be long enough to allow vaulting to complete.

Agent-Based Recovery from Vault Cluster

To recover agented data sources from a vault cluster, perform a manual registration.

Follow the procedure documented in Generate and Upload Cluster Certificates to register the source with the vault.

This process enables successful recovery without requiring a Cohesity Agent reinstallation.

Inbound Connection Requirements for Certain Recoveries

Certain recovery operations require the recovery target to establish inbound connections to the vault cluster.

Modify firewall configurations to allow the required inbound traffic.

> **Note:** For vCenter VM recoveries, enable inbound NFS access to the vault cluster from the ESXi Host under firewall settings.

Node Addition and Removal

When a new node added or the existing node removed from the primary cluster, make sure to update the vault pairing configuration.

To update the pairing configuration:

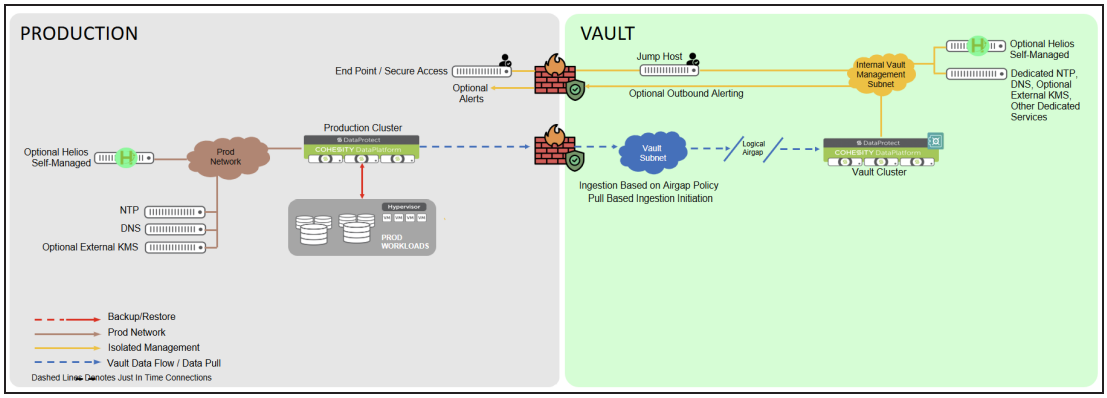
1. On the vault cluster, navigate to **Vault** > **Paired Clusters**.
2. Click the **Actions** menu (⋮) next to the paired cluster and select **Edit**.
3. Add/Remove the Node IP/VIP that was added/removed from the primary cluster.
4. Complete the cluster pairing procedure.

If a node is removed from the vault cluster, the vaulting process will get stuck and will need a restart of services on the primary cluster. Contact Cohesity Support for details.

Best Practices

This page outlines best practices for deploying and managing a Cohesity vault, focusing on physical and logical isolation, access control, firewall configuration, foundational services, and recovery strategies. Refer to the Prerequisites before configuring FortKnox Self-Managed.

Vault Deployment



Follow these best practices when deploying the vault.

Physical Isolation

- Deploy the vault in a physically isolated environment, separate from production systems.
- Use dedicated, locked cages or racks to enhance physical security.
- Avoid sharing physical hardware with production infrastructure.

Logical Isolation

- Place the vault in an isolated network protected by a firewall.
- Use separate network interfaces for management and vaulting traffic to prevent cross-contamination.

Vault Access and Management

- Limit access to a minimal number of authorized users.
- Enforce Least Privilege Access and Role-Based Access Control (RBAC).
- Allow management access only via a secure jump host within the isolated network.
- Physically disconnect IPMI ports to prevent out-of-band access.
- Do not register the vault with Cohesity managed Helios.

Vault Firewall Configuration

Block all inbound traffic to the vault network except for controlled access to the jump host.

Allow only the following outbound traffic from the vault:

Destination	Port	Protocol	Usage Notes
Primary cluster	23335	TCP	Required for vaulting scenario.
Primary cluster	23336	TCP	Required for vaulting scenario.

Restrict all other outbound traffic to essential services only.

Foundational Services

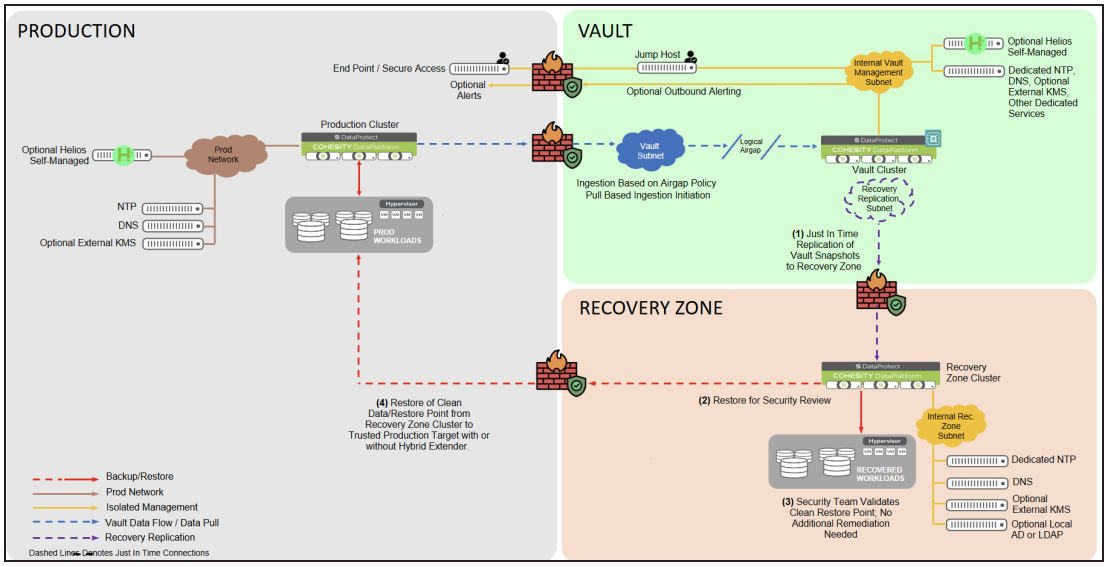
Do not share foundational services (e.g., NTP, DNS, AD/LDAP, MFA) between vault, production, and recovery zones.

Data Recovery Options

- While recovery directly from the vault is supported, it is not recommended.
- Replicate data from the vault to a Cohesity cluster in a Trusted Recovery Zone.
- Perform recovery from the Recovery Zone cluster back to production using one of the approved recovery patterns.

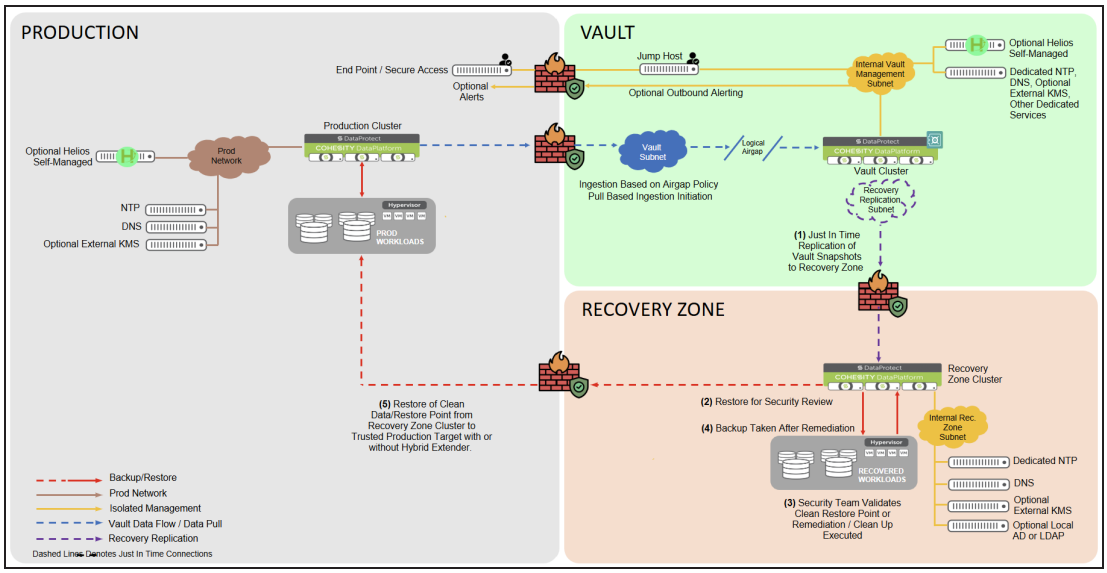
Recovery 1

Replicate Vault Snapshots to Recovery Zone, Restore in Recovery Zone, Validate Clean Restore Point, and Restore from Recovery Zone to Trusted Prod Target.



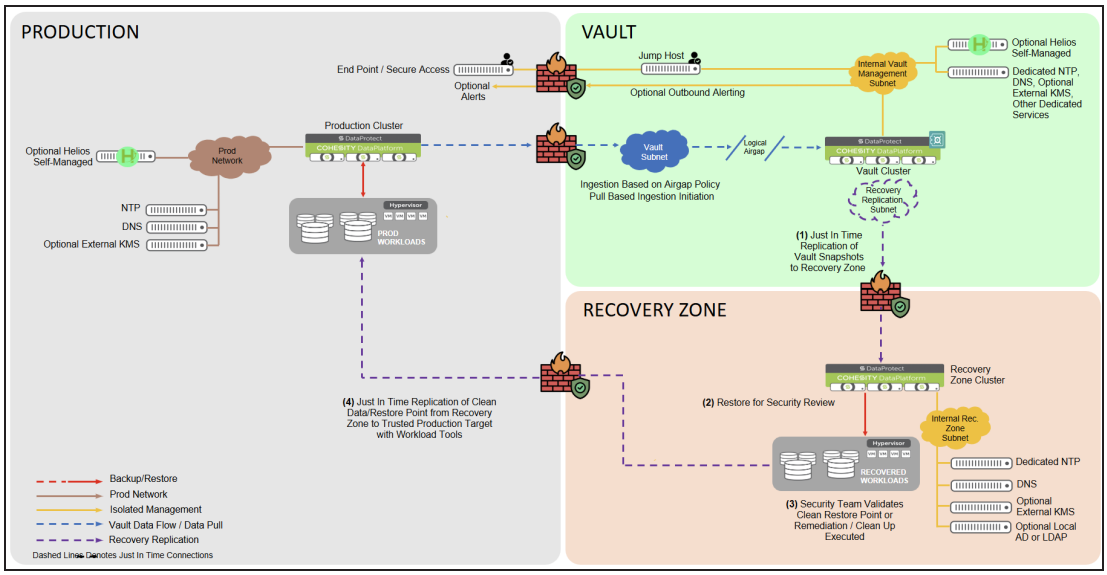
Recovery 2

Replicate Vault Snapshots to Recovery Zone, Restore in Recovery Zone, Validate Clean Restore Point, Backup to Recovery Zone Cluster, and Restore to Trusted Production Target.



Recovery 3

Replicate Snapshots to Recovery Zone, Validate Clean Restore Point, and Replicate Clean Workload Data to Trusted Target with Workload Tools.



Additional Best Practices

- Use physical clusters for all production vault deployments.
- Avoid using the vault as a Primary backup cluster, even though it is technically supported.
- Implement quorum-based approval via Helios Self-Managed for critical operations

(e.g., recovery, firewall changes).

- Use a dedicated Helios Self-Managed instance for vault operations.

Frequently Asked Questions

1. Can previously replicated data still be used for restore?

   Yes. Data replicated before switching to a vault remains fully available for restore operations. However, the cluster cannot be converted to a vault cluster unless storage domain encryption or software encryption at the cluster level is enabled.

2. Does existing replicated data expire?

   Yes. Replicated snapshots will expire according to their original retention policies.

3. Does transitioning to a vault policy or protection group require a new full backup?

   No. Once the replication cluster is converted to a vault target (removed as a replica and added as a vault target, and policies updated accordingly), the next vaulting run will transfer incremental data.

   > **Note:** Existing replicated snapshots are immutable if they were data-locked. If they were not data-locked, they are not immutable.

4. Are there version compatibility requirements between the primary backup cluster and FortKnox Self-Managed?

   Yes. The primary backup cluster must be running version 7.2.2_u2 or later to be compatible with FortKnox Self-Managed.

5. Does Proof of Concept (POC) require Multi-Factor Authentication (MFA)?

   Yes. MFA is required. You can use either email-based MFA or an authenticator app for verification.

6. Can data be vaulted from a FortKnox Self-Managed cluster to FortKnox SaaS?

   No. Vaulting from FortKnox Self-Managed to FortKnox SaaS is not supported.

7. Can CloudArchive be used for workloads in a FortKnox Self-Managed cluster?

   No. CloudArchive is not supported for workloads in FortKnox Self-Managed clusters.

8. Can the vault cluster also be used as a replication target?

   No. The vault cluster cannot be used as a replication target.

9. Does Helios Self-Managed require managing the vault cluster?

   No. Helios Self-Managed is optional and needed only for quorum controls. Vault cluster does not support SaaS.

10. What are the requirements when converting a primary cluster to a vault cluster?

Before converting a primary cluster to a vault cluster,

1. Enable Multi-Factor Authentication (MFA) for local users.
2. Encrypt either the entire cluster or all storage domains.
3. Enable node-to-node encryption across the cluster.
4. Configure the firewall to deny all traffic except for the "Application - Management" rule.
5. Remove any active policies for replication or cloud archival.

After conversion, you can change the firewall settings as they are no longer enforced.

Chapter 6: Organizations (Multitenancy)

Cohesity Platform cluster supports the multitenancy feature. The multitenancy feature enables you to configure the multitenant environment on your Cohesity Platform and securely isolate each tenant in your environment. You can use a single Cohesity cluster to provide service to multiple tenants. See the following topics for details:

- Service Providers (SPs) 758
- Large Enterprises 758
- Organization User Types 759
- Organizations Subfeatures 760
- Prerequisites and Considerations for Organizations 762
- Privileges for Service Provider Admin and Organization Admin 763
- Best Practices for Organizations 764
- Enable Organizations (Multitenancy) on a Cluster 765
- Add an Organization (Tenant) 766
- Infrastructure for Organizations 768
- Access Management for Organizations 779
- Users and Groups for Organizations 787
- Data Protection for Organizations 788
- Impersonate an Organization 791
- Deactivate an Organization 791
- Activate an Organization 792
- Delete an Organization 792
- CloudArchive and CloudTier for Organizations 793
- Replication for Organizations 794
- Reports and Chargeback for Organizations 794

Supported Multitenancy Workflows 798
Tenant-Level View Allowlist 1083

> **Note:**
> - In the context of Cohesity, the multitenancy feature is termed as Organizations. Each tenant on the Cohesity cluster is called an Organization.
> - Once the Organizations feature is enabled on a cluster, you cannot disable it.

You can configure the Organizations feature on the Cohesity cluster for the following environments:

- Service Providers (SPs)
- Large Enterprises

Service Providers (SPs)

As a service provider, you can use the Cohesity cluster to provide storage-related, data backup, data management services, etc. to your customers.

Cohesity Platform allows tenants to manage their organizations based on the privileges provided by you as a service provider. This allows organizations (tenants) to perform routine tasks without depending on you as the service provider.

You can provide the following services as a service provider:

- Backup as a Service (BaaS)
- Disaster Recovery as a Service (DRaaS)
- Filer as a Service (FaaS)

For more information on solutions, see the following documents:

- Backup as a Service Solution Guide
- Disaster Recovery as a Service (DRaaS) Solution Guide

Large Enterprises

Multitenancy is not just for service providers; it's also useful for large enterprises. Large enterprises can use multitenancy to isolate departments or business units as an individual tenant from each other for security and compliance reasons.

Organization User Types

In the Organization environment, we define the following user types for clarity of communication and understanding only. These user types may be different from jargon used elsewhere in the Cohesity documentation.

> **Note:** The following user types are used in Cohesity's Organizations (multitenancy) environment. These user types are not defined in the Cohesity Dashboard (UI).

Service Provider Administrator

A service provider is a company that provides IT services to its customers using the Cohesity cluster. A service provider administrator is typically a user with the default Administrator role.

> **Note:** Technically, the service provider administrator is the same as the **Cluster administrator**. We use the term **service provider administrator** in the context of the **Organization** feature, where the service provider manages multiple Organizations.

Organization Users

An Organization on the Cohesity cluster can have users and groups.

An Organization user with the Admin privilege is called the **Organization administrator** and users without the Admin privilege are called **Organization users**.

Organization Administrator

An Organization administrator can manage its own Organization in a multitenant environment. The Organization administrator role and its privileges are defined by the service provider administrator. The Organization administrator can create an Organization user or group. However, the Organization administrator cannot create or modify roles.

> **Note:** To add Active Directory as an Organization Admin, the AD domain's IP must be part of your assigned VLAN. Otherwise, please contact the Service Provider admin to add the AD domain to the cluster and assign it to your Organization. For Service Provider use cases, see Privileges for Service Provider Admin and Organization Admin.

Organization Users

An Organization user or group is created by the Organization administrator or it can be assigned to the Organization by a service provider administrator. The Organization administrator can only assign the inherited roles to a new Organization user or group.

The roles can be Viewer, Operator, or other custom roles.

Organizations Subfeatures

The following are some key subfeatures of the Organizations feature.

- A Service Provider Administrator can add Organizations and assign them the following Cohesity resources:
  - Storage Domain
  - View
  - AD, LDAP, SSO, or Keystone
  - Add Organization administrator, users, or groups
  - Objects
  - Policies and protection groups
  - VLAN(s)
- Organization users can log in to the Cohesity GUI for self-service access to their assets and services, in a manner that is securely isolated from other tenants. Cluster-level administrative capabilities are not available to Organization users.
- Organization administrators can configure Role-Based Access Control to control what is visible to tenant users.
- For data protection, each Organization owns private sources, protection jobs.

Storage efficiency

- As a service provider, you can also isolate data in Organizations from each other logically by assigning each Organization a storage domain, which creates separate, independent deduplication domains and encryption keys.
- As a service provider, you can alternatively configure Organizations to use the same storage domain for storage efficiency, which acts as a single deduplication domain. However, access is still secure and limited to each Organization. For more information, see Infrastructure for Organizations.

Network Isolation

- Service provider admins can isolate Organizations from each other by assigning VLAN.
- On each VLAN, service providers can assign cluster virtual IP addresses to each tenant.
- Alternatively, you can use Cohesity's Hybrid Extender to overcome IP address conflicts across the tenants. For more information, see Configure Network Settings for an Organization and Hybrid Extender

Impersonate Organizations

- Service providers can impersonate Organizations to preview and verify what their Organization administrator sees and helps Organizations diagnose and debug issues.
    - The Service provider administrator acquires tenant administrator privileges during impersonation.
    - The Service provider operator acquires tenant operator privileges during impersonation.
    - Service provider viewers will get tenant viewer privileges during impersonation.
- All actions performed during impersonation are audit-logged for security reasons. The audit logs are available to both service providers and Organizations. For more information. For more information, see Impersonate an Organization.

Backup and Restore

Cohesity provides efficient backup and restore workflows for service providers and Organizations and helps in managing large environments with multiple workloads using a single pane of glass. For more information, see Data Protection for Organizations.

Encryption

- Cohesity has a built-in key manager that generates keys and stores them internally on the SSDs in encrypted form.
- Data on the cluster is encrypted using a Data Encryption Key (DEK) and the DEK is in turn encrypted using a Key.
- Key Encryption Key (KEK). The encryption and decryption process is done within the Cohesity cluster and is transparent to all inbound and outbound protocols and applications, such as backup, archiving, and file services. Also, the keys are stored in a distributed fashion to be resilient in the rare event of a hardware failure.
- The default key rotation policy for KEK is 90 days, but the administrator can configure a different value.

Third-party Integration

Cohesity is based on an API-first architecture, valuing automation, consumable APIs, and self-service capabilities from the get-go. Users can enjoy error-free consistency and self-service manageability that extends the capabilities of individual applications and enables IT to spend less time with management, and more time with ambitious, value-oriented projects.

Supported automation frameworks include:

- VMware vCloud Director
- VMware vRealize Automation (vRA) and Orchestration (vRO)
- ServiceNow
- Python/Powershell SDK

Reports

- All Organizations can view their storage consumption report.
- As a service provider, you can view storage consumption reports by each tenant and generate custom reports. For more information, see Reports and Chargeback for Organizations.

Prerequisites and Considerations for Organizations

As a Cohesity cluster Administrator, you can enable multi-tenancy permanently for a cluster, add Organizations to the cluster, and assign resources and local users to the organization.

Prerequisites

- You must enable the Organizations feature to support multi-tenancy.
- Use VLANs to segregate traffic across different tenants. A VLAN should be assigned to each tenant. If it's not assigned, then the views in the tenant may become visible but not accessible to other tenants.

Considerations

- Once the Organizations feature is enabled on a cluster, you cannot disable it.
- Once an organization is created with a particular name/OrgID, the name/OrgID cannot be reused even after the org is deleted.

- If a single-tenant cluster is configured with remote access to a multi-tenant-enabled cluster, the Organizations page will not be available when accessing the multi-tenant cluster. The workaround is to enable multi-tenancy on the single tenancy cluster (it is not necessary to add any organizations.)
- Storage Consumed by Storage Domains: The Storage Consumed by Storage Domains report is available to the organization only if Storage Domain Sharing is disabled.
- View names must be unique. Two Organizations or service providers admin, or tenant cannot have two same view names.
- Users are assigned to the organization with specific roles by the service administrator. Cohesity does not allow an organization user to create a new user with a different role other than the organization's inherited roles.
    - For example, the service provider administrator creates two users with the "Viewer" and "Admin" roles and assigns them to the Organization. The organization administrator can now create a new user with either a "Viewer" or "Admin" role but cannot create a new user with a different role.
- No DNS per tenant. Global DNS must have stub zones for all tenant DNS.
- No multi-tenancy support for Marketplace Apps.
- If the **Enable for all Organizations** option is selected for a VLAN and the VLAN is assigned to an Organization in the OpenStack environment, the Swift clients cannot access Cohesity Swift Service through this shared VLAN.
- Organizations (tenants) do not have access to the Dashboard in the Cohesity UI.
- Replication to a source or remote cluster fails if the source or remote cluster has multi-tenancy enabled and VLAN assigned to the tenant. For more information, see the Replication stops sending data after upgrade to Cohesity release 6.4.1c and later KB article.
- To create a SmartFiles S3 View in a multi-tenant environment, log in to the Cohesity cluster as an Organization user. If you create the S3 View while impersonating an organization, the Service Provider administrator becomes the owner of the S3 View.

Privileges for Service Provider Admin and Organization Admin

The following table lists the privileges of the service provider admin that are distinct from those of the organization administrator.

Resource	Service Provider Administrator/Cluster Admin					Organization (Tenant) Administrator	
	Create	Assign	Unassign	Delete	Can be shared across tenants?	Add/Create	Delete
Storage Domain	Yes	Yes	No	Yes	Yes	No	No
View	Yes	Yes	No	Yes*	No	Yes	Yes
Full Source Tree	Yes	Yes	No	No	No	Yes	Yes
Partial Source Tree	Yes	Yes	Yes	NA	Yes	No	No
Protection Policy	Yes	Yes	Yes	Yes	Yes	No	No
Protection Job	Yes	Yes	No	No	No	Yes	Yes
VLAN	Yes	Yes	Yes	Yes	Yes	No	No
User/Group Management	Yes	Yes	Yes	Yes	No**	Yes	Yes

Note:

- * - Service provider administrator cannot delete a view assigned to an organization. But it can delete any unassigned views on the cluster.
- ** - Users cannot be shared across tenants. However, in the Single Sign-on (SSO) environment, groups can be shared.

Best Practices for Organizations

The following are best practices you can implement in Cohesity's Organizations (multitenancy) environment.

- To get better performance for VMware backups, use VMkernel ports (usually 10G) for backup instead of ESXi management (usually 1G) ports. For more information, see How to determine which vmkernel port is being used in a Cohesity VMware VM Backup in the Cohesity Knowledge Base.
- For a Hosted Backup solution with a shared, multitenant hypervisor, as a service provider, you should make sure the VLAN carrying the backup traffic has the Enable For All Organizations option enabled. This ensures the same backup network can be used for backing up different tenants' data.
- Use VLANs to segregate traffic across different tenants. Each tenant can be assigned a VLAN.
- Use different VPN tunnels for different tenants if the tenants are remote and accessing the Cohesity cluster over the Internet. This is important for secure self-service restores.
- Naming conventions in a multitenancy environment:
  - Create your naming convention for the Organization ID to work with 10 characters.
  - The Organization ID cannot be edited later. If the organization is deleted later, the Organization ID cannot be reused.
  - Use the same Organization ID across clusters.
- When replicating data between multitenant clusters, the same Organization ID and Storage Domain pairing must exist on both the transmitting and receiving clusters prior to running replication tasks.
- Follow the same practice when using CloudRetrieve; the same Organization ID and Storage Domains must exist on both clusters prior to running a CloudRetrieve download task.
- For service providers who are implementing a BaaS solution using Cohesity Data Cloud (Self-managed), Cohesity recommends that you segregate replication and backup traffic on the source cluster to avoid bandwidth issues. For more information, see Disaster Recovery as a Service (DRaaS) Solution Guide.
- Cohesity also recommends having a VPN connection between the source and DR clusters to set up replication across the clusters if the clusters are not using public IPs for replication communication.
- Alternatively, you can replicate over WAN without the need for a VPN connection.

Enable Organizations (Multitenancy) on a Cluster

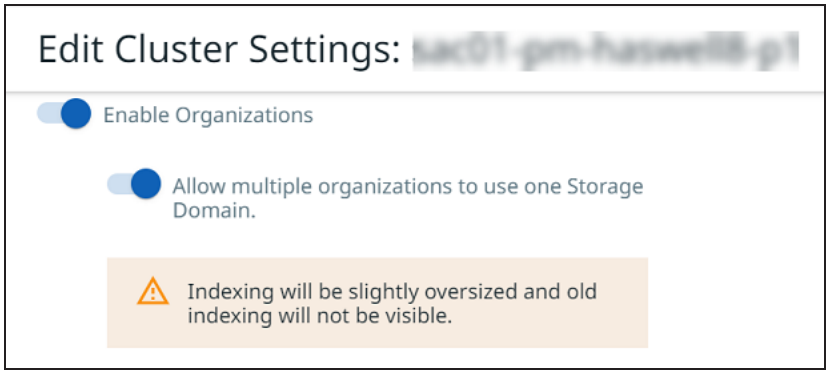
To use the Organizations feature and create Organizations, you must enable the feature. From the **Edit Cluster Settings** page, you can enable the feature.

> **Note:** You cannot disable the Organizations feature once it is enabled on a cluster.

After enabling the Organizations feature, you can add new Organizations from the **Access Management** page.

To enable the Organizations feature, complete the following steps:

1. In the Cohesity Dashboard, navigate to **Settings > Summary** and click **Configure**.
2. Toggle **Enable Organizations**.



> **Note:** Ignore the above warning on indexing as it is not actionable and does not indicate any issue when enabling Organizations on the cluster.

3. (Optional) Toggle on **Allow multiple Organization to use one Storage Domain**.

> **Note:** When you select this option, the storage consumption on the cluster reduces by providing Cohesity deduplication across all the Organizations using the storage domain. Organizations will be isolated from other Organizations whether this option is on or off.

4. Click **Save**.

Add an Organization (Tenant)

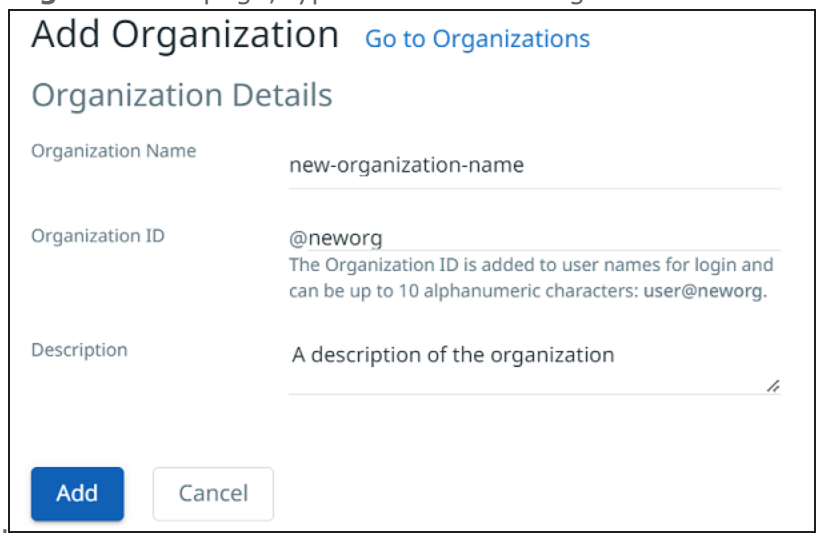
An Organization has a name and an organization ID. After you create an organization, you can edit and configure it according to your requirements. You can also deactivate or delete the Organization.

Prerequisite

The Organization feature is enabled. For information, see Enable Organizations (Multitenancy) on a Cluster.

To add an organization, complete the following steps:

1. In the Cohesity Dashboard, navigate to **Settings > Organizations** and click the **Add Organization** button on the top-right of the screen.
2. In the **Add Organization** page, type a name for an organization in the **Organization Name** field.



> **Note:** You can edit the Organization name after adding the Organization.

3. Type an ID for the Organization.
   - An identifier, up to ten alphanumeric characters, which is used as the suffix for all user names in the organization. For example, if you enter the ID abc123, user joe would log in to the cluster with the user name joe@abc123.
   - The Organization ID cannot be edited later. If the organization is deleted, the Organization ID cannot be reused.
   - Use the same Organization ID across clusters.

> **Note:** If you need to increase the number of characters in an Organization name, contact the Cohesity Support team.

4. (Optional)Type description for the organization.
5. Click **Add**.

   The **Edit Organization** page appears. You can configure your organization immediately after adding the Organization or editing the Organization later and configure it.

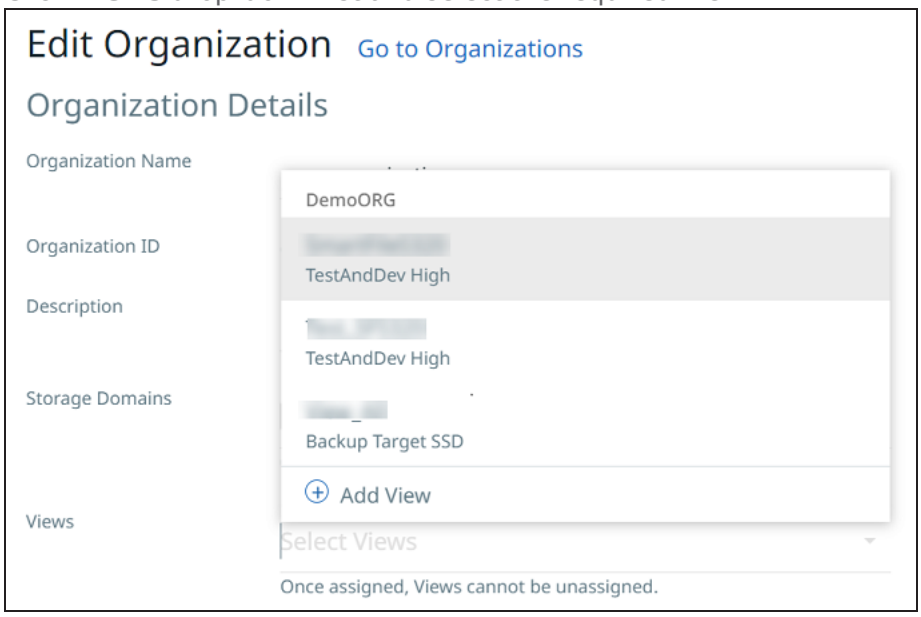
Infrastructure for Organizations

Assign a Storage Domain and View

You must assign a Storage Domain to the Organization for users in the Organization to use the Cohesity cluster.

> **Note:** Once you assign a storage domain to the Organization, you cannot unassign it. However, you can add multiple storage domains to the Organization.

1. In the Cohesity Dashboard, navigate to **Settings > Access Management**.
2. In the **Organizations** tab of the **Access Management** page, click ⋮ for the required Organization, and select **Edit**.
3. In the **Edit Organization** page, click the **Storage Domains** drop-down and select desired storage domains.
4. Click **Views** drop-down list and select the required View.



> **Note:** A View assigned to an Organization cannot be accessed or unassigned by the cluster admin. However, the **View** can be deleted by the Organization admin or by the cluster admin by impersonating the Organization.

5. Click **Save**.

Configure Network Settings for an Organization

The network settings for an Organization involves assigning VLANs (optional) and set service provider side NAT.

VLANs

To further isolate network traffic for the Organization, assign VLAN IDs. VLANs can be added and removed later. Use VLANs to segregate traffic across different tenants. If VLANs are used they must be assigned to tenants. Each tenant can be assigned a VLAN.

> **Note:** For a Hosted Backup solution with a shared hypervisor, as a service provider, you should make sure the VLAN carrying the backup traffic has the **Enable For All Organizations** option enabled. This ensures the same backup network can be used for backing up different tenants' data.

For more information, see Manage VLANs

IPs on the NAT

Specify the hostname or IP Address. The Hostname or Address(es) provided here corresponds to the public IPs on the NAT (in front of the Cohesity nodes) so that the Organizations can use these entries to reach out to the Cohesity nodes.

To assign VLAN to an Organization, complete the following steps:

1. In the Cohesity Dashboard, navigate to **Settings > Access Management**.
2. In the **Organizations** tab of the **Access Management** page, click ⋮ for the required Organization, and select **Edit**.
3. In the **Network Segment** section of the **Edit Organization** page, click **Assign VLANs**.
4. In the **Assign VLANs** page, select a **VLAN** and click **Assign**.
5. In the **Cohesity Node IP Range** field of the **Edit Organization** page, type hostname, or IP address.
6. Click **Save**.

Hybrid Extender

As a service provider, if you are serving multiple tenants (customers) in isolated networks with the same IP address ranges and subnets on the same Cohesity cluster, you may need to enable the Hybrid Extender.

Once the service provider administrator or cluster administrator enables the Hybrid Extender, the Organization (tenant) administrator can deploy and configure the Hybrid Extender.

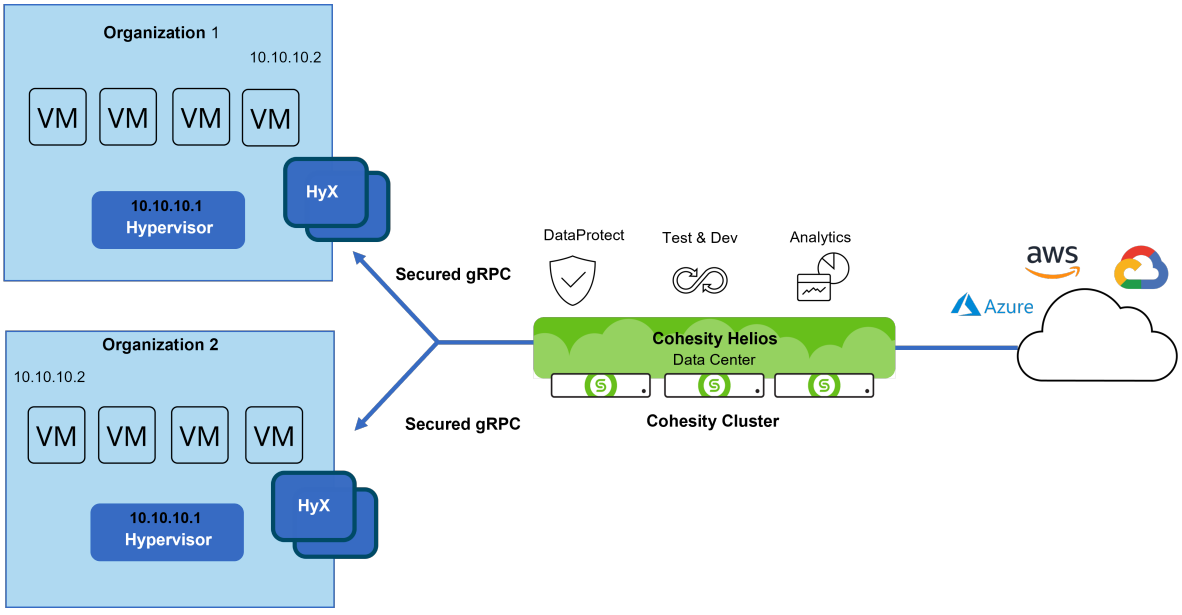
> **Note:** If you are upgrading the Cohesity cluster from one maintenance release to another maintenance release, you need not upgrade the Hybrid Extender. For example, if you are upgrading the Cohesity cluster from 7.2.1 to 7.2.2, you need not upgrade the Hybrid Extender. However, Cohesity recommends that the version of Cohesity cluster and the Hybrid Extender should be the same.

In a multitenant environment, if organizations are controlling the IP addressing for their virtualization hosts, virtual machines, physical servers, NAS servers, Active Directories, and other servers (collectively "tenant entities"), there is a possibility that the tenant entities' IP addresses overlap with each other. As a result, the Cohesity cluster will be unable to uniquely identify a given tenant entity using its IP address (Example: tenant A and tenant B might both have SQL Server VMs with identically the same IP address on their respective tenant private networks). To resolve this issue, you can deploy a Hybrid Extender VM on each organization to uniquely identify the virtual entities using the tuple of organization ID and virtual entity's IP address. The Hybrid Extender acts as a proxy VM between the organization and the Cohesity cluster and also provides source-side deduplication.

Hybrid Extender Support

Communication between the Hybrid Extender VM and the Cohesity cluster is over-secure gRPC and encrypted using mutual TLS. The Hybrid Extender VM handles all the outbound traffic from the Cohesity cluster to supported platforms (VMware vCenter, VMware ESXi, and to the "physical server", and the inbound traffic of VMware backup ingest traffic from VMware ESXi (or physical server) to Cohesity cluster.

For more information about the supported workflows, see Supported Multitenancy Workflows for Hybrid Extender.



Prerequisites

- Ensure that the Hybrid Extender option is enabled while creating the organization.
- (Default) Ensure port 29994 is open on the Hybrid Extender VM, and ports 11117 and 29991 are open on the Cohesity cluster.
- DNS configuration—The DNS configuration on your Hybrid Extender is used for general name resolution and to look up the domain controller to join the Cohesity cluster to the tenant AD. This is used during source registration for name resolution and mount-based restores/clones for data protection of MS-SQL server, Oracle, and so on.

  The following are the considerations for DNS configuration on Hybrid Extender:

  - When you assign an IP address using DHCP, the Hybrid Extender automatically gets the DNS configuration.
  - When you assign a static IP address, you must add the DNS in the Hybrid Extender VM by accessing the VM using SSH. You can access the Hybrid Extender VM and add your DNS in the `/etc/resolv.conf` file. For more information on the steps to edit the `/etc/resolv.conf` file, see Editing for Hybrid Extender VM. For any assistance, you may contact the Cohesity Technical Support team.
- Register the AD domain of the tenant and on the DNS server of the tenant, create DNS entries for the registered AD machine accounts with Hybrid Extender IPs. This ensures that the clients connected to the tenant network are able to access the views.
- Ensure that Network Time Protocol (NTP) is set up on the Hybrid Extender. For more information, see Set Up NTP Servers.

  If NTP is not setup:

  - RPC requests between the Hybrid Extender and the cluster can timeout.
  - If the time skew between the AD server and the Hybrid Extender is greater than five minutes, Kerberos authentication may fail.
  - Hybrid Extender may not be able to connect if the time lag between the Hybrid Extender and the cluster is extensive enough to invalidate TLS certificates.

Authentication

NFS—Hybrid Extender supports only LDAP group membership lookups.

SMB—Hybrid Extender supports the following authentication methods:

- NTLM authentication—Tenants can mount their shares using the server IP address or FQDN. The tenant must be registered with only one AD domain.
- Local user account—The Service Provider can create a local user account and assign this user to a tenant.

- Kerberos authentication.
- Anonymous users.

Considerations

- Hybrid extender supports source registration and backup only for Windows and Linux physical sources. AIX, HPUX, Solaris physical sources are not supported with hybrid extender.
- Currently, Cohesity does not support the auto-upgrade of the Hybrid Extender. Therefore, you must upgrade the Hybrid Extender after upgrading the Cohesity cluster from one major release to another major release. For example, if you are upgrading the Cohesity cluster from 6.5.1 to 6.6, use the Hybrid Extender version provided with 6.6.
- When you're upgrading to maintenance releases such as 6.5.1e, you need not upgrade the Hybrid Extender. However, Cohesity recommends that the version of Cohesity cluster and the Hybrid Extender to be same.
- If a tenant deploys multiple Hybrid Extender VMs, SMB and NFS sessions do not failover to the next available Hybrid Extender VM. Cohesity depends on the hypervisor that is hosting the Hybrid Extender VM to ensure high availability. If the hypervisor does not support high availability, I/O requests fail.
- Hybrid Extender does not support the following features:
  - S3
  - SMB Multichannel
  - Keystone
  - Kerberos client for NFS
  - SSO
  - NFS authentication

Hardware Requirements for Hybrid Extender VM

The default configuration is as mentioned below:

- **Memory**: 4GB RAM
- **Processor**: 4 vCPU

Enable Hybrid Extender

To enable the Hybrid Extender, complete the following steps:

1. In the Cohesity Dashboard, navigate to **Settings > Access Management**.
2. In the **Organizations** tab, click ⋮ for required organization, and select **Edit**.

3. In the **Network Segments** section of the **Edit Organization** page, toggle the **Hybrid Extender**.
4. Click **Save**.

Disable Hybrid Extender

Before you disable the Hybrid Extender, ensure that no protection or recovery job is running. After you disable the Hybrid Extender, the tenant network falls back to VLAN-based multitenancy. For information about assigning VLANs, see Configure Network Settings for an Organization.

To disable the Hybrid Extender, complete the following steps:

1. In the Cohesity Dashboard, select **Settings > Access Management**.
2. In the **Organizations** tab, click ⋮ for required organization, and select **Edit**.
3. In the **Network Segments** section of the **Edit Organization** page, turn off the **Hybrid Extender** option.
4. Click **Save**.

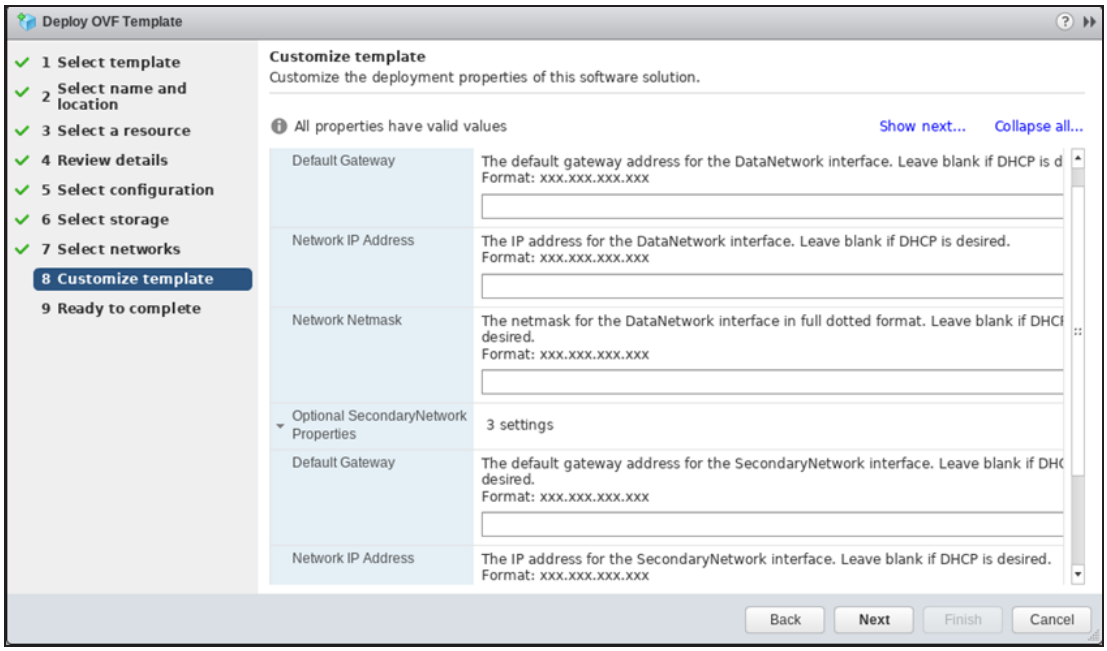
Support Two Interfaces on Hybrid Extender

Hybrid Extender can be configured with two interfaces so that it can simultaneously talk to a tenant's private network and an entity (Cohesity) outside of the private network. This feature eliminates the need for making network configuration changes (such as NAT mappings or changing firewall rules) for the Hybrid Extender interface to reach the Cohesity. Following are the two network interfaces:

- Primary interface (ens160)
- Secondary interface (ens192)

Configuring Two Interfaces

You can configure the Hybrid Extender using one or two network interfaces. Each network interface can be configured with DHCP or static IPs. DHCP is the default. Static IPs will be used only if you configure a static IP.



To use Hybrid Extender with one network interface:

1. Configure the first network interface with DHCP or static IPs.
2. Do not specify any configuration for the second network interface. This unused secondary interface will not affect user functionality.

To use Hybrid Extender with two network interfaces:

- Configure both network interfaces as required (using either DHCP or static IPs)

> **Note:**
> - By default, the primary interface is used to communicate with the Cohesity cluster and the secondary interface is used to communicate with entities in the tenant's internal network.
> - If the **Network IP Address** field value for an interface is left empty, Cohesity uses a DHCP server to configure the interface.
> - If network field values are provided as input, Cohesity uses those static values to configure the interface and fall back to DHCP if there is an issue with the values.
> - After deployment, you can remove the second interface manually from the VM if required.

Network Interfaces Combinations

- If you specify the network fields for both interfaces, the interfaces will come up with the specified static IP addresses.

- If you do not specify the network fields for both the interfaces, the interfaces will be automatically configured as DHCP.
- If you specify the network field only for the primary interface, the primary interface will come up with the static IP and the secondary interface is automatically configured as DHCP.
- If you specify the network field only for the secondary interface, the secondary interface will come up with the static IP and the primary interface is automatically configured as DHCP.

Use Cases

Use only Primary Interface

1. In the primary interface, provide an IP address if you want to use a static IP address or leave it blank to use DHCP.
2. Leave the secondary interface blank.

> **Note:**
> The secondary interface comes up with DHCP as you left the field blank. Remove the interface from the VM configuration or use the following command to bring down the secondary interface:
>
> ip link set dev ens192 down

Use the Secondary Interface to communicate with Cohesity Cluster

1. Configure both interfaces as required. For more details, see Network Interfaces Combinations.
2. Once the VM is up, create a **customer_settings.json** file in the data/bifrost directory. This file is used to override default interface behavior.
3. Explicitly mention the interface to be used for communication with the cluster and the interface to be used for internal tenant side communication (Note that explicitly mentioning both of these is important. If only one is mentioned, we will still use the default interfaces).

Sample **customer_settings.json** file:

```
{
"tenant_source_side_interface_name": "ens160",
"cohesity_side_interface_name": "ens192"
}
```

Deploy Hybrid Extender VM

1. In the Cohesity Dashboard, select **Settings > Access Management**.
2. In the **Organizations** tab, click ⋮ for required organization, and select **Edit**.
3. In **the Network Segments** section of the **Edit Organization** page, click **Add Hyx**.
4. On the **How to configure Hybrid Extender?** page, click the download button under **step 1(Download and provision the HyX)** to download the .ova file. You can also download the .ova file from MyCohesity portal.
5. Deploy this OVA file in your ESXi hypervisor as a virtual machine by following the instructions given on the ESXi console.
6. Go back to the **How to configure Hybrid Extender?** page and click the download button under **step 2 (Download the configuration file)**.
7. Go to http://<ip_address>:29994/upload and upload the configuration file you downloaded.

   > **Note:** Where <ip_address> is the IP address of the Hybrid Extender VM.

8. Refresh the Hybrid Extender page. The Hybrid extender VM will connect.

You can deploy more than one Hybrid Extender for each organization. If the backup adapter supports multi-streaming, then having multiple Hybrid Extenders per organization improves high availability, load balancing, and yields faster backups and restores.

- High availability—If one Hybrid Extender instance fails, the Cohesity cluster will retry backup, recovery, and clone workflows using a surviving Hybrid Extender.
- Load-balancing and throughput—When multi-streaming a backup or restore, different network flows may traverse different Hybrid Extenders to parallelize the task and speed the overall operation.

The configuration file you upload (steps 6 and 7) on each Hybrid Extender VM should be unique for each organization.

It is recommended to use a different config file for every Hybrid Extender but you may choose to reuse the same config file for deploying Hybrid Extenders of the same organization. However, for different organizations, use a different configuration file on different Hybrid Extender VMs.

Set Up NTP Servers

The tenant administrator must provide the NTP servers. To update the machine clock, execute the following command:

```
ntpdate -u <ntpserver>
```

Example: `ntpdate -u ntp.for.mydomain`

Using Non-Secure gRPC

Run these commands in Hybrid Extender to use non-secure gRPC:

1. `bifrost.sh stop>`
2. `bifrost.sh start --magneto_grpc_timeout_msecs=300000 --tcp_proxy_connector_ports=445:445,2049:2049,80:80,443:443,11117:11117,11113:11113`
3. `sudo firewall-cmd --add-port=11113/tcp --zone=public --permanent && sudo firewall-cmd --reload`

Recommendations

- Deploy multiple Hybrid Extender VMs to distribute client traffic and achieve high availability and increased throughput.
- Download a new configuration file from Cohesity Cluster every time you deploy a new Hybrid Extender VM.
- Cohesity recommends that you use the Hybrid Extender version provided with the Cohesity version to get access to the supported sources. For example, use the Hybrid Extender version provided with Cohesity 6.6.0a.
- Once the Hybrid Extender is connected, the backup and recovery communication between cluster and source will be proxied through the Hybrid Extender VM.
- If you are upgrading the Cohesity cluster, you must upgrade the Hybrid Extender. To upgrade the Hybrid Extender, you should first redeploy the new version and then decommission the existing version of the Hybrid Extender. After you upgrade a cluster, then the version of Hybrid Extender should be either the same as Cohesity cluster or it can remain in the previous version. However, Cohesity recommends that the Cohesity cluster version and the Hybrid Extender version should be the same. As an example, you can refer to the table below:

Cohesity Cluster Version	Hybrid Extender Version
6.6.0a	• 6.6.0 • 6.6.0a

Ports Used by Hybrid Extender

For more information about ports used by Hybrid Extender, see Hybrid Extender.

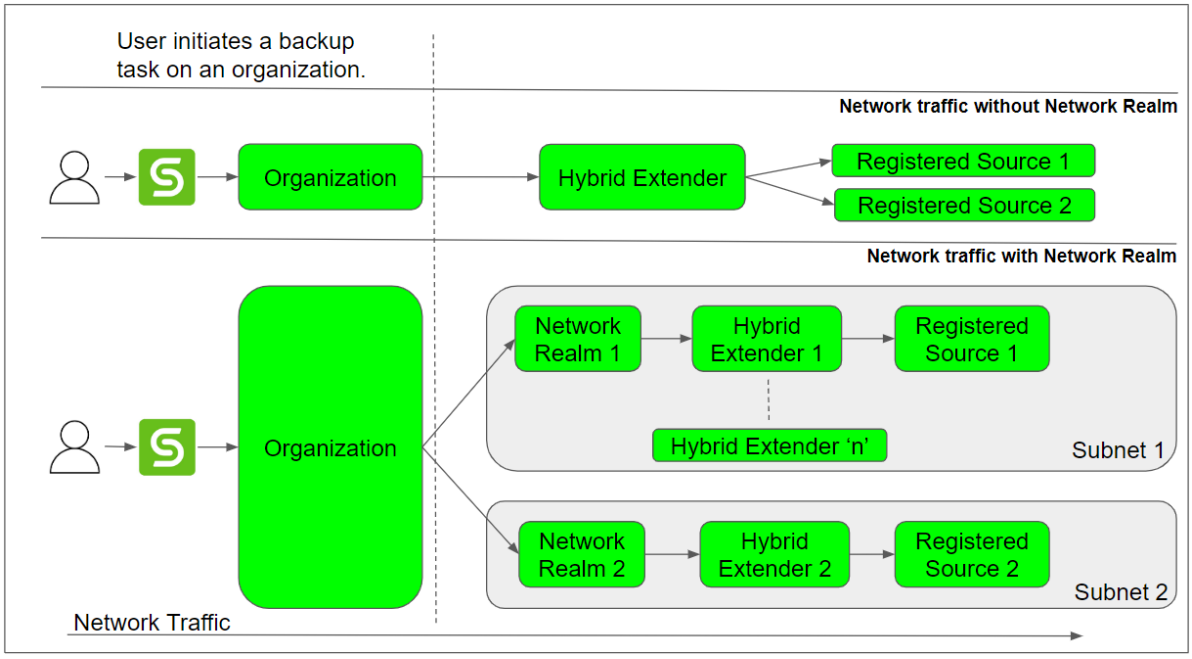
Network Realms for Multi-tenant Environments

Cohesity introduces Network Realms for multi-tenant environments. Network Realm ensures source-level selection in a multi-tenant environment, and allows you to create and manage multiple isolated networks within a tenant. On a Cohesity cluster, a source and a hybrid extender can be associated with a Network Realm to create an isolated network.

How it works?

When a backup task is initiated on a Cohesity cluster, it reaches out to the Hybrid Extender associated with the Network Realm for the source IP address. You can associate the source with the Network Realm during its registration and each source can be associated with only one Network Realm. However, you can associate multiple Hybrid Extenders with a Network Realm. The Network Realm maintains the list of registered sources on a Cohesity cluster to create isolated networks. An isolated network ensures that a task on a Cohesity cluster doesn't fail due to a mismatch of IP addresses from multiple sources.

> **Note:** You must have an **Admin** or **Super Admin** role or similar privileges in a custom role to create and manage Network Realms.



Technical Support for Hybrid Extender VM

Hybrid Extender now has a support channel that can be enabled to let Cohesity Technical Support engineers access it for troubleshooting. The login credentials for the Hybrid Extender will be needed for accessing it. The support channel can be enabled or disabled as an Organization admin or service provider admin impersonating the tenant. Contact the ***Cohesity Technical Support*** team for assistance.

Access Management for Organizations

Assign an Authentication Server

Assigning an authentication server enables Organization users to access the Organization securely.

You can assign one of the following authentication server types:

- Active Directory
- LDAP
- Keystone

Assign Active Directory

An entire AD domain can be dedicated to each Organization. Or An AD domain can be registered on the cluster by the Cohesity administrator user (in which case no AD domain is added to the Organization) and individual users/groups from that AD domain may be added to each Organization.

To assign an Active Directory, complete the following steps:

1. In the Cohesity Dashboard, navigate to **Settings > Access Management**.
2. In the **Organizations** tab of the **Access Management** page, click ⋮ for the required Organization, and select **Edit**.
3. In the **Edit Organization** page, click the **Assign AD/LDAP/Keystone** link.
4. In the Assign **AD/LDAP** page, click **Active Directory**.
5. Select one or more Active Directories from the list.
6. Click **Save**.

Assign LDAP

To assign an LDAP server to an Organization, complete the following steps:

1. In the Cohesity Dashboard, navigate to **Settings > Organizations**.
2. In the **Organizations** tab, click ⋮ for the required Organization, and select **Edit**.
3. In the **Edit Organization** page, click the **Assign AD/LDAP/Keystone** link.
4. In the **Assign AD/LDAP** page, click **LDAP**.
5. Select one or more **LDAP** providers from the list or create a new one.

> **Note:**
> - You can map the LDAP providers to the Active Directory domain so users can access the same files on the Cohesity cluster from both Windows and Linux systems.
> - An AD/LDAP that is assigned to an Organization cannot be assigned to another Organization.

6. Click **Save**.

Assign a Keystone Config

After you create an Organization on the Cohesity cluster, you must map a Keystone config to use the Cohesity Swift service in the Organization. For more information, see OpenStack Integration.

To assign a Keystone config to an Organization, complete the following steps:

1. In the Cohesity Dashboard, navigate to **Settings > Organizations**.
2. In the **Organizations** tab of the **Access Management** page, click ⋮ for the required organization, and select **Edit**.
3. In the **Edit Organization** page, click the **Assign AD/LDAP/Keystone** link.
4. In the **Assigning AD/LDAP** page, the **Keystone** tab displays the registered Keystone servers. Select one Keystone server and click **Assign**.
5. In the **Swift Roles** section of the **Edit Organization** page, click the pencil icon.
6. In **the Edit Default Swift** options, add or modify the required Swift roles and click **Save**

> **Note:** You can only add the roles defined on the OpenStack server.

7. (Optional)To further isolate network traffic for the organization, assign VLAN IDs.

> **Note:**
> - You can add or remove VLANs later.
> - All the swift requests whose tenancy cannot be determined will fail.

8. Click **Save**.

Single Sign-On for Organizations

An Organization in a multitenancy cluster can register an IDP and use it for single sign-on authorization within the Organization.

For information on SSO, see Single Sign-On (SSO).

You can configure Single Sign-On at two different levels on a Cohesity cluster with the Organizations feature is enabled:

- Single Sign-On at a Service Provider level.
- Single Sign-On at an Organization level.

To successfully sign in to the Cohesity cluster, after successful validation at IDP, at least one of the following must be true:

1. The user is registered as an SSO user on the Cohesity cluster.
2. The user is part of an SSO group that is registered on the Cohesity cluster.
3. A default role is available in the SSO configuration.
    1. If a default role is added to the SSO, then the user needn't be added to the cluster and all users will have default access to the cluster using the default role.
    2. If no default role is added to the cluster, then the user has to be added to the cluster with a particular role, and then only the user login to the cluster.

Single Sign-On at a Service Provider Level

When a Service Provider Administrator registers an SSO (IDP), the SSO is configured at the cluster level and it is not assigned to a specific Organization.

The following are a few points you should consider for Service Provider-level SSO:

- The Service Provider Administrator can create new SSO users and groups and assign roles in multiple Organizations.
- The Service Provider Administrator can configure multiple SSOs (IDPs) on the cluster. However, one SSO per tenant and one per service provider admin.
- The users and groups that are part of the SSO (IDP) configured on the cluster are authenticated through the same SSO (IDP).
- If a default role is assigned to the SSO, the role is applicable to all the SSO users and groups that are part of the SSO.
- If no default role is assigned to the SSO, the role that is assigned to the individual group or user is applicable.
- An SSO group can be assigned to multiple Organizations. If an SSO user is part of a group and that group is part of multiple Organizations, the user can access other Organizations by using the Switch Organization option in the Cohesity Dashboard and then manage more than one Organization based on the roles assigned to the group.

- A user who is a part of a group and the group is assigned to multiple Organizations can have different roles inside different Organizations.

For example, In the following configuration:

- **IDP**: Okta is configured at the Cohesity cluster level.
- **SSO Groups**: Group 1 with Admin role and Group 2 with Operator role are created on the Cohesity cluster and the same groups are present on the Okta IDP.
- **SSO User on Okta**: User1 is part of both Group 1 and Group 2 on the Okta IDP.
- **Organizations**: Org 1, Org 2, and Org 3 are created on the Cohesity cluster.
- Group 1 with the Admin role is assigned to Org 1 and Org 2.
- Group 2 with the Operator role is assigned to Org 3.

Now, when the User1 accesses the Cohesity cluster, the user can switch among Org1, Org2, and Org3. User1 inherits the role assigned to the group.

In this scenario, the User1 plays the role of the Admin for Org1 and Org2 and for Org 3 as an Operator.

- All the existing SSO users in the SSO of an Organization can be quickly onboard to Cohesity by configuring the SSO and registering groups on the Cohesity cluster.
- An Organization Admin can switch among multiple Organizations. The Service provider/tenant admin can only see the entities that belong to a logged-in Organization.

Single Sign-On at an Organization Level

When an Organization Administrator registers an SSO (IDP), the SSO is configured at the Organization level and is applicable only to that Organization.

The following are a few points you should consider for the Organization-level SSO:

- To manage the SSO configured at the Organization level, you must sign in to the Organization.
- When you sign in to the Organization with SSO configured at the Organization level, you are authenticated through the SSO installed on the Organization and you cannot switch to any other Organization.
- As an Organization user or administrator, depending on the role assigned, you can create new SSO users and groups, and assign roles to them within the Organization.
- All the existing SSO users in the SSO of an Organization can be quickly onboard to Cohesity by configuring the SSO and registering groups on the Cohesity cluster.

Configure SSO at an Organization Level

As an Organization Admin, you can sign in to the Organization and register an SSO specific to your Organization.

Prerequisites

- As the Organization admin, you must have the Admin role assigned or you should be part of an SSO group with the Admin role assigned.
- Add the Cohesity cluster as an application on your IDP.
- Get the SSO URL and certificate file.

To configure SSO at an Organization level, complete the following steps:

1. Access the Cohesity Dashboard.
2. On the **Sign in** page, click **Sign in with SSO** and click **Sign In**.
3. Slide the **Sign in to Organization** toggle button.
4. Type your Organization ID and click **Sign In**.
5. On the IDP login page, provide your username and password.
6. Click **Sign in**.
7. After signing in, click **Settings > Access Management**.
8. Click the **SSO** tab and click the **Configure SSO** button on the top-right of the screen.
9. Complete the SSO configuration steps.

Switch Organizations as an Organization Admin or User

If your role requires you to manage multiple Organizations, you can switch among multiple Organizations to perform Organization-specific operations.

Prerequisites

- Access the cluster as a Cohesity cluster admin and configure SSO (IDP) on the cluster.
- Create a group and add the required users to the group on your IDP. This allows users to become part of multiple Organizations.
- Add SSO group(s) on the cluster the same as the IDP group.
- Assign groups to multiple Organizations. For more information, see the Assign an SSO Group to Organizations.
- Add the Cohesity cluster as an application on your IDP

To switch to another Organization, complete the following steps:

1. Access the Cohesity Dashboard.
2. On the **Sign in** page, click **Sign in with SSO** and click **Sign In**.
3. On the IDP login page, provide your IDP username and password.
4. Click **Sign in**.
5. In the Cohesity Dashboard, click the user icon in the top-right corner and select **Switch**.
6. In the **Switch** window, select a required Organization from the list.

   Click **Switch**.

Assign an SSO Group to Organizations

Currently, a Cohesity user can be part of only one Organization. However, you can assign an SSO group to multiple Organizations. When you assign the group to multiple Organizations, a user that's part of the group can switch among the Organizations. However, the user inherits the role assigned to the group.

> **Note:** After assigning a group to multiple Organizations, users within that group can sign in to the Cohesity Dashboard and switch among the Organizations. All users have the same privileges that are assigned to the group.

To assign an SSO user or group to Organizations, complete the following steps:

1. Click **Settings > Organizations**.
2. On the **Organizations** page, click the button and select **Edit**.
3. On the **Edit Organization** page, click **Assign Users/Groups** of the **Users/Groups** section.
4. Select a required IDP domain from the drop-down list at the top of the page.
5. In the **Assign Users/Groups** window, select the groups from the list and click **Assign**.
6. Click **Save**.
7. Repeat steps 1 to 6 to assign the same group to a different Organization.

Sign in Using an Organization ID

Users of an Organization with SSO assigned can sign in using the Organization ID. When a user signs in using an Organization ID, the sign-in goes through the SSO assigned to the Organization. The user can access only the objects assigned to the Organization and the role assigned to the user/group. The user cannot switch to any other Organization.

Prerequisites

- Users must be part of the IDP.
- Add the Cohesity cluster as an application on your IDP.
- A default role must be assigned for the user/group that is signing in to the Cohesity cluster.
- You must know the Organization ID. Cohesity Admin or Service provider can provide the Organization ID.

To sign in using the Organization ID, complete the following steps:

1. Access the Cohesity Dashboard.
2. On the **Sign in** page, click **Sign in with SSO**.

3. On the **Single Sign-On** page, click **Sign in to Organization**.
4. Provide the organization ID and click Sign in.
5. In the IDP login page, provide your username and password.
6. Click **Sign in**.

Sign in as a Group User

A user who is part of a group can sign in to the Cohesity cluster and manage the Organizations.

Prerequisites

- A user must be part of the IDP and added to the required group.
- Add the Cohesity cluster as an application on your IDP.
- Create a group and add the desired user on the cluster and assign that group to all the desired Organizations.

After signing in, the group user can see all the Organizations assigned to the groups that the user is a member and perform admin role functions within those Organizations.

To sign in as a group user, complete the following steps:

1. Access the Cohesity Dashboard.
2. On the **Sign in** page, click **Sign in with SSO** and click **Sign In**.
3. On the IDP login page, provide your username and password.
4. Click **Sign in**.

Edit or Deactivate an SSO for an Organization

You can edit or deactivate an SSO for any Organization only after accessing the Organization. If you are the Service Provider, you can impersonate and edit the SSO and if you are an Organization user or admin, you can log in to the Organization and edit.

> **Note:** If you deactivate SSO, only the Organization admin or a user with Access Management privileges can reactivate it.

To edit or deactivate an SSO for any Organization, complete the following steps:

1. Access the Cohesity Dashboard.
2. On the **Sign in** page, click **Sign in with SSO** and click **Sign In**.
3. Slide the **Sign in to Organization** toggle button.
4. Type your Organization ID and click **Sign In**.
5. On the IDP login page, provide your username and password.
6. Click **Sign in**.

7. After signing in, click **Settings > Access Management**.
8. Click the **SSO** tab, click the action menu (⋮) and select either **Edit** or **Deactivate**.

Multi-factor Authentication for Organizations

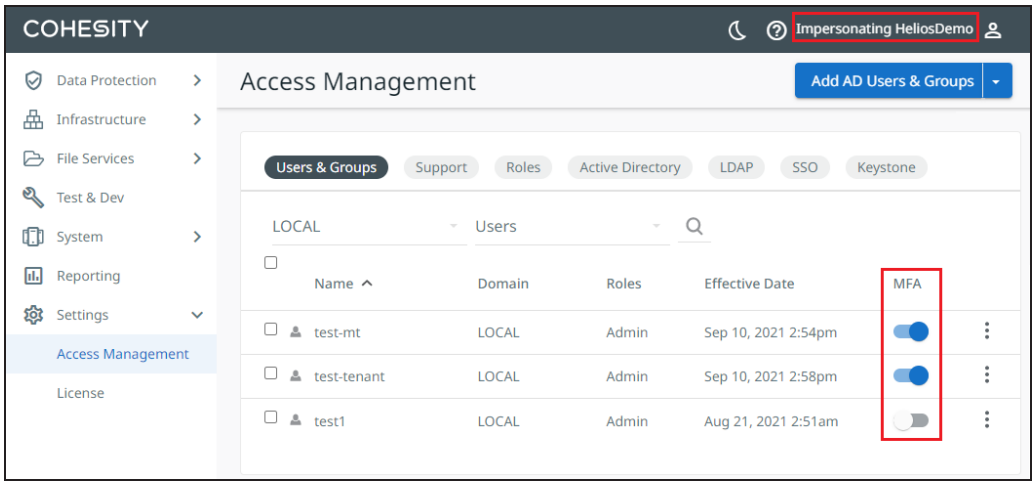
Multi-factor Authentication (MFA) is an additional layer of security used to verify the identity of a user. In a multitenant environment, the Cohesity supports MFA for local users. For more information about organization users, see Organization User Types.

A service provider administrator can enable or disable MFA at the cluster level. An Organization administrator can enable or disable MFA for user(s) in their organization.

To enable and set up MFA, follow the instructions in the Multi-factor Authentication for Local and Active Directory Users section.

To disable MFA for an Organization user, the service provider administrator or Organization administrator must complete the following steps:

1. In the Cohesity GUI, click the user icon ( ) in the upper-right corner and select **Impersonate**.
2. In the **Impersonate** dialog, select the required Organization from the list and click **Switch**.
3. Navigate to **Settings > Access Management** and click the **MFA** tab.
4. In the **MFA** column, turn off the toggle corresponding to the user:



5. Click **Disable**.
6. Click **Save**.

- Multi-factor Authentication for the Support User Account

Users and Groups for Organizations

Assign an Organization Administrator

After creating an Organization, you need to assign an Organization Administrator. The organization administrator can be a local user. You must provide the Administrator privileges for the user.

To assign an administrator to an organization, complete the following steps:

1. In the Cohesity Dashboard, navigate to **Settings > Access Management**.
2. In the **Organizations** tab of the **Access Management** page, click ⋮ for the required Organization and select **Edit**.
3. In the **Edit Organization** page, click the **Assign Users/Groups**.
4. In the **Assign Users/Groups** page, select the user that you want to assign as an Administrator.

   > **Note:** If you have created a user with Administrator privileges, you can create one by clicking the **Add User** link on the **Assign Users/Groups** screen. After creating the user, assign the same user.

5. Click **Assign**.
6. Click **Save**.

Assign Local or AD Users and Groups

You can assign local users, AD users and groups to an Organization. Select one or more users from the list or create new ones. You can also add the users later.

> **Note:** When logging in to the cluster, use the syntax as given below: Username: <user>@<Organization ID>

Points to Remember

- When you assign a user or group to the Organization, the assigned user or group can access the Cohesity cluster using the user name and tenant ID.
- Users in the Organization can see all the users and roles in the Organization, but they cannot create or delete users or roles.
- Restricted users currently cannot be assigned to Organizations. If a user with the Administrator role is assigned to an Organization, they will have reduced cluster-level privileges.
    - AD users/groups can be assigned to the Organization. To login to the cluster or to access Views via SMB, use the AD credentials.
    - Who can perform this task: Service Provider Administrator/Cluster Administrator.

  To assign AD or local users to an Organization, complete the following steps:

1. In the Cohesity Dashboard, navigate to **Settings > Access Management**.
2. In the **Organizations** tab of the **Access Management** page, click ⋮ for the required Organization and select **Edit**.
3. In the **Edit Organization** page, click **Assign Users/Groups**.
4. In the **Assign Users/Groups** page, select the required local or AD users or groups.
5. Click **Assign**.
6. Click **Save**.

Data Protection for Organizations

Assign Objects

Select the Sources to assign exclusively to the Organization.

Consider the following points for assigning objects:

- If you select a top-level node in the Object hierarchy, the entire Source is assigned to the Organization. The Organization becomes the owner and can manage the Source (unregister, edit, refresh, and protect it after the source is assigned to an Organization, the cluster administrator cannot edit or remove the source(read-only mode).
- If you select a sub-tree(VMware sources) in the Object hierarchy, only those Objects are assigned to the Organization. The Organization can protect and recover those Objects, but it cannot manage the Source. Conversely, the cluster administrator

cannot protect and recover those Objects, but can see and manage the Source. For more information, see Assigning Protection Sources to an Organization.

- Organizations can also register their own Sources after they log in to the cluster.

To assign an object to an Organization, complete the following steps:

1. In the Cohesity Dashboard, navigate to **Settings > Access Management**.
2. In the **Organizations** tab of the **Access Management** page, click ⋮ for the required Organization and select **Edit**
3. In the **Edit Organization** page, click the **Assign Objects** link.

   > **Note:** You can filter the objects or search the objects using the filter and search options.

4. In the **Assign Objects** page, select the required objects and click **Assign**.
5. Click **Save**.

Assigning VCD objects

Assigning Sub-Trees

In vCloud Director, you can assign the following vCD sub-trees to a Cohesity organization.

- vCD Organisation
- Organisation VDC
- vApp
- VMs

When an organization(tenant) a user accesses the organization, the user can see only the sources assigned to that organization ensuring isolation among the organizations.

> **Note:** If a sub-tree (like a VM folder, ESXi host, or ResourcePool) is assigned to an organization, there must be at least one VM in the sub-tree to properly determine permissions during VM recovery.

The organization user can perform all supported operations for the assigned VCD sources using tenant login and the Cohesity vCD plugin.

> **Note:** The sub-trees can be assigned to Cohesity organizations in all network configurations (i.e. default-subnet-based, VLAN-based, and Hybrid Extender-based).

Assigning Top-level VCD

Although rare, it is possible to assign a top-level node in the VCD hierarchy (in other words, an entire VCD instance) to an organization.

Note: This is not supported for Cohesity organizations using a Hybrid Extender, but is supported for Cohesity organizations using other network configurations (i.e. default-subnet-based, VLAN-based).

Assigning Existing Protection Groups to an Organization

- Assign the Protection Group's storage domain to the organization.
- Assign the protection source to the organization.
- Assign the Protection Group's protection policy to the organization.
- Assign the Protection Group to the organization.

> **Note:** When you assign an existing protection group that is created at the cluster-level to an organization(tenant) and if there is any backup run after assigning the protection group to the organization(tenant), it will result in reindexing of files and folders if there are any changes in them. After the reindex, only the organization (tenant) users can search for files and folders.

Assign Policies and Protection Groups

Protection Groups once assigned to Organization cannot be unassigned. When you assign a protection group, you can assign protection policy, storage domain, and source to a particular job.

1. In the Cohesity Dashboard, navigate to **Settings > Access Management**.
2. In the **Organizations** tab of the **Access Management** page, click ⋮ for the required Organization and select **Edit**
3. On the **Edit Organization** page, click **Assign Policies And Protection Groups**.
4. In the **Assign Policies And Protection Groups**, select a policy name, and click

Assign.

5. Click **Save**.

Impersonate an Organization

As a Service Provider or Cluster administrator, you can impersonate an Organization to verify what the Organization administrator will see in the cluster.

Actions performed when impersonating an Organization are logged and both the cluster administrator and Organization can see the audit entries by selecting **System > Audit Log.**

To impersonate an Organization administrator, complete the following steps:

1. In the Cohesity Dashboard, click the user icon ( ) in the top-right corner and select **Impersonate**

   > **Note:** To return to your own dashboard, click the user icon, and select **Switch Back**.

2. In the **Impersonate** screen, select the required Organization from the list and click **Switch**.

   > **Note:** Once you switch, the dashboard is refreshed to display what the Organization administrators will see (the top right corner of the dashboard indicates that you are impersonating the Organization administrator). You can impersonate multiple Organization administrators at the same time by opening the dashboard in different browser windows or tabs.

Deactivate an Organization

You can deactivate an Organization to stop access to the Organization.

> **Note:** Deactivating an Organization does not delete it. You can activate it back.

When an Organization is deactivated, its users cannot log in to the Cohesity Dashboard, future Protection Group runs are paused, and any replication runs will fail. Protection Groups that are currently in progress will complete.

To deactivate an Organization, complete the following steps:

1. In the Cohesity Dashboard, navigate to **Settings > Access Management**.
2. In the **Organizations** tab of the **Access Management** page, click ⋮ for the required Organization, and select **Deactivate**.
3. In **the Deactivate Tenant** screen, click the **Deactivate** button.

> **Note:** The Status column in the Organizations page changes to Inactive.

Activate an Organization

You can activate an Organization that is in the deactivated status.

To activate an Organization, complete the following steps:

1. In the Cohesity Dashboard, navigate to **Settings > Access Management**.
2. In the **Organizations** tab of the **Access Management** page, click ⋮ for the required Organization, and select **Activate**.
3. In the **Activate Tenant** screen, click the **Activate** button.

> **Note:** The Status column in the Organizations page changes to Active.

Delete an Organization

When you delete an Organization, all the resources and users for the Organization are permanently deleted from the Cohesity cluster.

Deleting an Organization deletes all the entities of the Organization, such as protection groups, protection sources, LDAP, remote targets, users, groups, and recovery targets. Once deleted the above entities will be completely lost. However, service providers can still impersonate a deleted Organization. This allows the service providers to remove any entity (that gets stuck while deletion) manually.

> **Note:**
> - Policies and Storage Domains of the Organization will retain their association with the tenant even if the tenant is deleted.
> - The Organization ID and name cannot be reused after the Organization is deleted.

To delete an Organization, complete the following steps:

1. In the Cohesity **Dashboard**, navigate to **Settings > Access Management**.
2. In the **Organizations** tab of the **Access Management** page, click ⋮ for the required Organization, and select **Delete**.
3. In the **Tenant Delete** screen, click the **Delete** button.

The status of the Organization in the Organizations page changes to **Marked for Deletion**. The deletion process is an asynchronous process. Once the Organization is completely deleted, the status changes to **Deleted**.

CloudArchive and CloudTier for Organizations

CloudArchive

Using the Cohesity, you can quickly archive data to multiple external targets such as:

- Public clouds
- Private clouds - S3-compatible device
- Any NAS-NFSv3 from storage vendors
- QStar managed tape libraries

As a service provider, you can register an external target and add the target to a policy that you can assign to an Organization for CloudArchive.

If you want your Organization Administrator to perform the Cloud Archive, you should create a protection policy with CloudArchive and assign the protection policy to the required Organization.

CloudTier

Cohesity CloudTier enables an additional storage tier where cold data can be stored. After you register supported existing cloud storage as a CloudTier target with the Cohesity cluster, you can enable CloudTier to move rarely used and inactive data to the cloud when HDD used capacity exceeds a set threshold (typically 80%).

As a service provider, you can enable the CloudTier setting in a storage domain.

> **Note:** If you plan to allow any CloudTier functionality, do not share a storage domain among Organizations. If you enable CloudTier, Cohesity recommends mapping each storage domain to a single Organization.

Replication for Organizations

The Replication feature in Cohesity enables the service providers to provide Disaster Recovery as a Service (DRaaS) solution to their tenants.

For more information about replication, see: About Replication.

Prerequisites

- The Organizations feature must be enabled on the source cluster or target cluster to use the replication feature in the Organizations (multitenancy) environment.
- The source and target cluster must be running Cohesity Data Cloud (Self-managed) version 6.1 or later for Organizations to use the replication feature.
- When replicating data between multitenancy-enabled Clusters, the same Organization ID and matching storage domain(s) must exist on both the transmitting and receiving Clusters prior to running replication tasks.
- When using replication, the same org ID should exist on the primary and DR clusters for the Organization.

Disaster Recovery for Organizations (Multitenancy)

As a service provider, you can implement replication in the Organizations (multitenancy) environment using your Cohesity cluster for your Organizations (tenants) and provide Disaster Recovery as a Service (DRaaS). You can implement DRaaS depending on the backup network topology implemented. DRaaS service enables Organizations (tenants) to recover data in the event of data loss.

Replication is the fundamental operation that makes any Disaster Recovery as a Service (DRaaS) solution possible. Cohesity's DRaaS refers to the approach of maintaining a regularly updated replica of Organizational backup data in another Cohesity cluster in the same or different locations for data retention and offsite storage. Cohesity leverages service providers' multi-tenant infrastructure wherein they replicate data from multiple customers on shared but logically isolated infrastructure.

For more information on implementing Disaster Recovery as a Service (DRaaS), see the solution document: Use Cohesity Multi-tenancy to Offer Disaster Recovery as a Service (DRaaS).

Reports and Chargeback for Organizations

Cohesity provides many built-in reports that help you with planning, charge-back, compliance, and more.

Some of the other benefits of Cohesity Reports include:

- Schedule and receive reports through emails.
- Filter reports based on type, operation, time frame, or tenant Organization.
- Integrate with third-party business intelligence tools.

Cohesity provides required reports for Service Providers and Organizations:

- Storage Consumed by Organizations
- Storage Consumed by Storage Domains Report(Only for tenants)
- Backup Summary
- Clone and Recover VM Tasks Summary
- Failed Objects
- Protected Objects Heatmap (since 6.5.1 only)
- Protection Runs Summary
- Protection Summary by Object Type
- Storage Consumed by Backups
- Storage Consumed by Organizations
- Unprotected/Protected VMs

Important Points to Consider When Using Reports for Organizations

The following are the important points you must consider when using Reports for organizations:

- You must use the **Physical Usage** tab from the **Storage Consumed by Organizations** report that is available in the **Service Provider login** for billing purposes. This report is computed every two days.
- Do not use the **Storage Consumed by Organizations** report in the **tenant login** for billing purposes.
- The **Storage Consumed by Domains Report** displays the most current space usage data. However, you notice a mismatch in data between the **Storage Consumed by Domains Report** and **Storage Consumed by Organizations** as the latter is computed every 2 days.
- Some of the UI labels in different reports have different UI label names for the same attribute. So, consider them as synonyms. For example, the **Raw used**, **Physical used**, **Storage Consumed** labels in different reports are synonyms. These labels are respectively used in the following reports:
    - Storage Consumed by Storage Domains report (Service Provider login)

- Storage Consumed by Organizations (Tenant login)
- Storage Consumed by Organizations (Service Provider login)

For more information on Reports, see Reports.

Chargeback

As a service provider, you can charge your tenants for storage consumption. You can charge based on the pre-deduplication or post-deduplication of storage consumption by a tenant. Cohesity provides you with required raw data in the form of reports for your billing purposes.

You can get the required data for chargeback from the following:

- Storage Consumed by Organizations report
- Custom report that you can generate using REST APIs

Built-in Reports

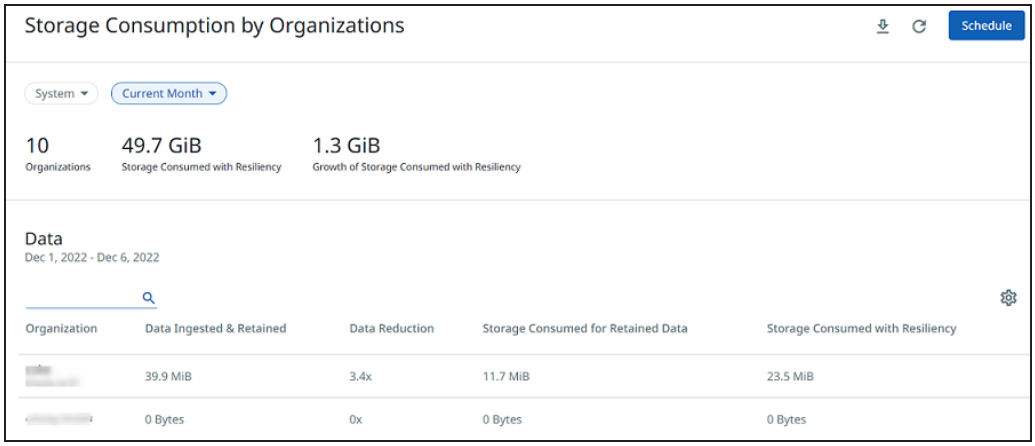
View Storage Consumed by Organizations Report

This report provides information about the Organizations consuming the most storage.

By default, the report displays all the Organizations in the cluster, but you can specify one or more in the Organizations field. For more information, Storage Consumed by Organizations

To view the report, complete the following steps:

1. Access the Cohesity **Dashboard**.
2. In the **Dashboard**, click **Reporting**.
3. In the **Reports** tab, click the **Select Report** drop-down and select **Storage Consumed by Organization**.



> **Note:** After selecting the **Storage Consumed by Organization** report, a report for all Organizations is displayed. However, you can apply filters and view reports that are specific to the storage domain and Organizations.

4. (Optional)Select the required **Storage Domain** from the dropdown.
5. (Optional)Select the required **Organizations** from the dropdown list.
6. (Optional) Click **Apply Filter**.
7. Click the **Physical Storage** or **Work Load** tabs to view the required details.

> **Note:** The Physical Storage tab displays the Top 3 Organizations Storage Consumed and the Work Load tab displays the Top 3 Organizations by Backup Data.

View Storage Consumed by Storage Domains Report

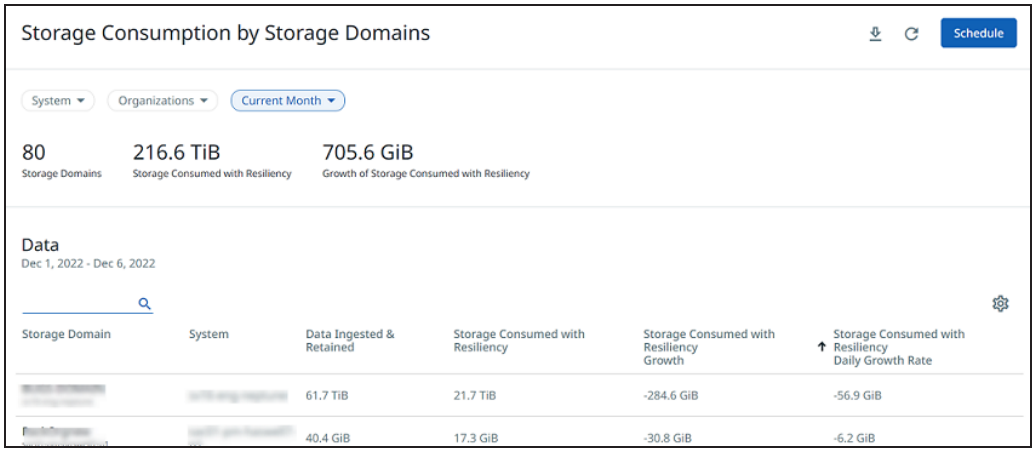
The Storage Consumed by Storage Domains report provides information about the Storage Domains that store the most logical data and raw data on the Cohesity cluster.

This report provides the following charts:

- Top <Num> Storage Domains by Storage Used—This chart lists up to ten Storage Domains that have stored the largest amount of data.
- Top <Num> Jobs by Logical Data Managed—This chart lists up to ten Storage Domains that have stored the largest amount of logical data from a Source.

To view the report, complete the following steps:

1. On the Cohesity Dashboard, click **Reporting**.
2. In the **Reports** tab, click the **Select Report** drop-down and select **Storage Consumed by Storage Domains**.



3. (Optional)Provide number of days to Calculate Growth Over Specified Days and click **Apply Filter**.

Custom Reports

The Custom Reporting Database is a new feature built into the platform using a PostgreSQL database. An internal service called Groot collects statistics and metrics from various internal platform services and populates data into Postgres. To generate reports, service providers write SQL statements with the schema Cohesity has published. For more information, Custom Reporting

> **Note:** The Custom Reports feature is not available for tenants.

Supported Multitenancy Workflows

This section lists the supported multitenancy workflows.

Protection Group and External Targets Workflows

- Virtual Server (VMs) and Physical Server Workflows
  - Protection Based Workflow
  - Archival Based Workflow
  - Replication Based Workflow
- Databases Workflows
  - Protection Based Workflow for MS SQL VM, FCI, and AG
  - Archival Based Workflow for MS SQL VM, FCI, and AG
  - Replication Based Workflow for MS SQL VM, FCI, and AG
  - Protection Based Workflow for MS SQL File-based, Volume-based, and Native Backup
  - Archival Based Workflow for MS SQL File-based, Volume-based, and Native Backup
  - Replication Based Workflow for MS SQL File-based, Volume-based, and Native Backup
  - Protection Based Workflow for Oracle, SAP HANA, and SAP Sybase ASE
  - Archival Based Workflow for Oracle, SAP HANA, and SAP Sybase ASE
  - Replication Based Workflow for Oracle, SAP HANA, and SAP Sybase ASE

- NAS Workflows
  - Protection Based Workflow
  - Archival Based Workflow
  - Replication Based Workflow
- Workflows for Views, Remote Adapters
  - Protection Based Workflows

The Cohesity admin can either assign the entire VMware source or the components of the VMware source to an organization.

The following table lists different granularity at which VMware components can be assigned as a source to an organization (especially applicable for service providers that provide hosted IaaS).

Source	Components
VMware vCenter	• Entire VC • VMware DC • ESXi cluster • ESXi host • Folders • Resource pools • VMs
VMware vCloud Director	• Entire vCD • vCD Org • Org vDC • vApp • VMs

Databases Workflows

Protection Based Workflow for MS SQL VM, FCI, and AG

Categories	Workflows	Sources		
		MS SQL VM	MS SQL FCI	MS SQL AG
REGISTRATION	Register a source	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Refresh object hierarchy	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Refresh Application registration	Yes using VM edit workflow	Supported (CA,TA)	Supported using Edit workflow for VM(CA,TA)
	Auto-protect new objects	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
BACKUP	Incremental backup with CBT	Yes as log-based incremental	Supported (CA,TA)	Supported (CA,TA)
	Full backup with CBT	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Incremental backup with SQL server differential	N/A	N/A	N/A
	Full backup without CBT	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Ability to run a log backup in parallel to a full backup.	N/A	N/A	N/A
	Backup, archive and replicate now	Supported at DB and server level both (CA,TA)	Supported at DB and server level both(CA,TA)	Supported at DB and server level both (CA,TA)
	CloudSpin to AWS and Azure	N/A	N/A	N/A

Categories	Workflows	Sources		
		MS SQL VM	MS SQL FCI	MS SQL AG
RECOVER	Recovering an entity in the Job Run	Supported (CA,TA)	Only DB and VM supported(CA,TA)	Only DB and VM supported (CA,TA)
	Recover an entire backup job run	Yes as crash-consistent VM not as SQL restore	No	Supported as Crash Consistent VM not as SQL Restore(CA,TA)
	Recover a SQL DB to the original server and instance	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Recover a SQL DB to the original server but a different instance	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Recover a SQL DB to a different server that has the same SQL version	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Recover DB to Alternate Instance with overwite	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Recover a SQL DB to a different server that has a different SQL version (Based on MS requirements)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Instant volume mount	Supported (CA,TA)	Supported (CA,TA)	Yes
	Crash-consistent recover for apps	Supported (CA,TA)	Supported (CA,TA)	Yes using IVM (physical)

Categories	Workflows	Sources		
		MS SQL VM	MS SQL FCI	MS SQL AG
CLONE	Clone an object of a job run	Supported (CA,TA)	Cloning DB from FCI to standalone server / node Supported. cloning db to fci instance not supported	Supported (CA,TA)
	Clone all the objects of a job run	Yes as crash-consistent VM, not as SQL clone	No	Supported as Crash Consistent VM not as SQL Clone(CA,TA)
	Clone db to FCI instance	N/A	N/A	N/A
	Crash-consistent recover for apps	Supported (CA,TA)	No	Supported using Instant volume mount (physical) (CA,TA)
DB Migration	SQL DB Migration without auto sync	N/A	N/A	N/A
	SQL DB Migration with auto sync	N/A	N/A	N/A
TEARDOWN	Tear down objects	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Tear down instant volume mount	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
CANCEL	Cancel a running job run	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Cancel a running clone or recover tasks	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)

Categories	Workflows	Sources		
		MS SQL VM	MS SQL FCI	MS SQL AG
DELETE SNAPSHOT	Delete a local snapshot of a job run	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
FILE RECOVERY	Search for files or folders	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Browse for a backed-up object	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Download files/folders	Supported (TA)	Supported (TA)	Supported (TA)
	Recover files	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Download a VMX file	Supported (TA)	N/A	Supported (TA)
VIRTUAL DISKS RECOVERY	Recover Virtual Disks	N/A	N/A	N/A
CONVERT AND DEPLOY	Register Azure source and clone VMs to Azure	N/A	N/A	N/A
	Register AWS source and clone VMs to AWS	N/A	N/A	N/A

Archival Based Workflow for MS SQL VM, FCI, and AG

Categories	Workflows	Sources		
		MS SQL VM	MS SQL FCI	MS SQL AG
ARCHIVAL	Archive an incremental backup	Supported (Not for log backup) (CA,TA)	Supported (Not for log backup) (CA,TA)	Supported (Not for log backup) (CA,TA)
	Archiving an incremental backup with SQL server differential	N/A	N/A	N/A
	Archive a full backup	Supported (Not for log backup) (CA,TA)	Supported (Not for log backup) (CA,TA)	Supported (Not for log backup) (CA,TA)
RECOVER	Recover a single object of a job run from an archive to a source	Supported (No Databases, Only Files) (CA,TA)	Supported (No Databases, Only Files) (CA,TA)	Supported (No Databases, Only Files) (CA,TA)
	Recover an entire backup job run from an archive to a source	No	No	No
	Instant volume mount from an archive	Not Supported for SQL (use VM or physical)(CA,TA)	Not Supported for SQL (use VM or physical)(CA,TA)	Not Supported for SQL (use VM or physical)(CA,TA)
	Crash-consistent recover for apps from an archive	Supported (No Databases, Only Files and VM) (CA,TA)	Supported (No Databases, Only Files)(CA,TA)	Supported (No Databases, Only Files and VM) (CA,TA)
DB Migration	SQL DB Migration without auto sync	N/A	N/A	N/A
	SQL DB Migration with auto sync	N/A	N/A	N/A

Categories	Workflows	Sources		
		MS SQL VM	MS SQL FCI	MS SQL AG
CLONE	Clone objects of a job run from an archive	No	No	No
	Clone all objects of a job run from an archive	No	No	No
	clone db to FCI	N/A	N/A	N/A
	Crash-consistent clone for apps from an archive	No	No	No
CANCEL	Cancel a running archival task	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Cancel a running clone or recover task that is retrieving from an archive	No	No	No
DELETE SNAPSHOT	Delete an archived snapshot of a job run from the external target	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)

Categories	Workflows	Sources		
		MS SQL VM	MS SQL FCI	MS SQL AG
FILE RECOVERY	Search for files or folders from an archive	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Browse for files or folders from an archive snapshot	No	No	No
	Download files and folders from an archive	Supported (TA)	Supported (TA)	Supported (TA)
	Recover files from an archive to a source (to the same and different sources)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Download n VMX file from an archive	N/A	N/A	N/A
VIRTUAL DISKS RECOVERY	Recover Virtual Disks	N/A	N/A	N/A
CLOUD RETRIEVE - SEARCH & RETRIEVE	Search for an object in an external target	Supported for volume based job (CA)	Supported for volume based job (CA)	Supported for volume based job (CA)
	Download metadata for all runs of a job	Supported for volume based job (CA)	Supported for volume based job (CA)	Supported for volume based job (CA)
	Download a snapshot (archived data) for a job run	Supported for volume based job (CA)	Supported for volume based job (CA)	Supported for volume based job (CA)

Categories	Workflows	Sources		
		MS SQL VM	MS SQL FCI	MS SQL AG
CLOUD RETRIEVE - CLONE	Clone objects of a job run from an archive	Supported for volume based job (CA,TA)	Supported for volume based job (CA,TA)	Supported for volume based job (CA,TA)
	Clone all objects of a job run from an archive	No	No	No
	clone DB to FCI	N/A	N/A	N/A
CLOUD RETRIEVE - RECOVER	Recover objects of a job run from an archive to a source	Supported for volume based job (CA,TA)	Supported for volume based job (CA,TA)	Supported for volume based job (CA,TA)
	Recover all objects of job run from an archive to a source	No	No	No
	Instant volume mount from an archive	Not Supported for SQL (use VM or physical, volume based)(CA,TA)	Not Supported for SQL (use VM or physical, volume based)(CA,TA)	Not Supported for SQL (use VM or physical, volume based)(CA,TA)

Categories	Workflows	Sources		
		MS SQL VM	MS SQL FCI	MS SQL AG
CLOUD RETRIEVE - FILE RECOVERY	Search files or folders from downloaded snapshot	Supported for volume based job (CA,TA)	Supported for volume based job (CA,TA)	Supported for volume based job (CA,TA)
	Search files or folders from the metadata of a retrieved job run	Supported for volume based job (CA,TA)	Supported for volume based job (CA,TA)	Supported for volume based job (CA,TA)
	Browse files or folders from a retrieved snapshot	Supported for volume based job (CA,TA)	Supported for volume based job (CA,TA)	Supported for volume based job (CA,TA)
	Browse files or folders from the metadata of a downloaded job run	Supported for volume based job (CA,TA)	Supported for volume based job (CA,TA)	Supported for volume based job (CA,TA)
	Download files and folders from an archive	Supported for volume based job (TA)	Supported for volume based job (TA)	Supported for volume based job (TA)
	Recover files from an archive to a source (to the same and different sources)	Supported for volume based job (CA,TA)	Supported for volume based job (CA,TA)	Supported for volume based job (CA,TA)
	Download a VMX file from an archive	N/A	N/A	N/A
CLOUD RETRIEVE - VIRTUAL DISKS RECOVERY	Recover Virtual Disks	N/A	N/A	N/A

Replication Based Workflow for MS SQL VM, FCI, and AG

Categories	Workflows	Sources		
		MS SQL VM	MS SQL FCI	MS SQL AG
REPLICATION	Replicate an incremental backup with CBT to a remote cluster	Supported as Log based incremental (CA,TA)	Supported as Log based incremental (CA,TA)	Supported as Log based incremental (CA,TA)
	Replicate an incremental backup with SQL server differential to a remote cluster	N/A	N/A	N/A
	Replicate a full backup with CBT to a remote cluster	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Replicate a full backup without CBT to a remote cluster	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
FAILOVER	Failover an inactive Job on a remote cluster	No	No	No

Categories	Workflows	Sources		
		MS SQL VM	MS SQL FCI	MS SQL AG
RECOVER	Recover a single object of a job run from a remote cluster	Supported (CA,TA)	Yes only for DBs & not full server for physical	Yes only for DBs & not full server for physical
	Recover an entire backup job run from a remote cluster	Yes as crash-consistent, not as SQL restore	No	No
	Recover a SQL DB from a remote cluster to another SQL server with the same SQL version	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Recover a SQL DB from a remote cluster to different SQL server with a different SQL version	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Instant volume mount of replicated data	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Crash-consistent recover for apps from a remote cluster	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
DB Migration	SQL DB Migration without auto sync	N/A	N/A	N/A
	SQL DB Migration with auto sync	N/A	N/A	N/A
CLONE	Clone an object of a job run from a remote cluster	Supported (CA,TA)	Supported (CA,TA)	Only DB and VM supported (CA,TA)
	Clone all objects of a job run from a remote cluster	Yes as crash-consistent VM, not as SQL clone	No	No
	clone db to FCI	N/A	N/A	N/A
	Crash-consistent clone for apps from a remote cluster	Supported (CA,TA)	No	Yes for DB and VM

Categories	Workflows	Sources		
		MS SQL VM	MS SQL FCI	MS SQL AG
TEARDOWN	Tear down object on a remote cluster	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Tear down instant volume mount on a remote cluster	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
CANCEL	Cancel a running replication task	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Cancel a clone or recover task on a remote cluster	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
DELETE SNAPSHOT	Delete replicated snapshot of a job run on a remote cluster	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
FILE RECOVERY	Search for files or folders on a remote cluster	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Browse for replicated object on a remote cluster	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Download replicated files and folders from a remote cluster	Supported (TA)	Supported (TA)	Supported (TA)
	Recover replicated files from a remote cluster	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Download a VMX file from a remote cluster	Supported (TA)	N/A	Supported but only VM(TA)
VIRTUAL DISKS RECOVERY	Recover Virtual Disks	N/A	N/A	N/A
CONVERT AND DEPLOY	Register Azure source and clone VMs to Azure	N/A	N/A	N/A
	Register AWS source and clone VMs to AWS	N/A	N/A	N/A

Categories	Workflows	Sources

	Browse files or folders from the metadata of a downloaded job run	Supported for volume based job (CA,TA)	N/A	N/A
	Download files and folders from an archive	Supported for volume based job (TA)	N/A	N/A
	Recover files from an archive to a source (to the same and different sources)	Supported for volume based job (CA,TA)	N/A	N/A
	Download a VMX file from an archive	N/A	N/A	N/A
CLOUD RETRIEVE - VIRTUAL DISKS RECOVERY	Recover Virtual Disks	N/A	N/A	N/A

Replication Based Workflow for MS SQL File-based, Volume-based, and Native Backup

Categories	Workflows	Sources		
		MS SQL Volume Based	MS SQL File Based	MS SQL Native
REPLICATION	Replicate an incremental backup with CBT to a remote cluster	Supported as Log based incremental (CA,TA)	Supported (CA,TA)	N/A
	Replicate an incremental backup with SQL server differential to a remote cluster	N/A	N/A	Supported (CA,TA)
	Replicate a full backup with CBT to a remote cluster	Supported (CA,TA)	Supported (CA,TA)	N/A
	Replicate a full backup without CBT to a remote cluster	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
FAILOVER	Failover an inactive Job on a remote cluster	No	No	No

Categories	Workflows	Sources		
		MS SQL Volume Based	MS SQL File Based	MS SQL Native
RECOVER	Recover a single object of a job run from a remote cluster	Yes only for DBs & not full server for physical	Yes	Yes
	Recover an entire backup job run from a remote cluster	No	No	No
	Recover a SQL DB from a remote cluster to another SQL server with the same SQL version	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Recover a SQL DB from a remote cluster to different SQL server with a different SQL version	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Instant volume mount of replicated data	Supported (CA,TA)	N/A	N/A
	Crash-consistent recover for apps from a remote cluster	No	No	No
DB Migration	SQL DB Migration without auto sync	N/A	N/A	N/A
	SQL DB Migration with auto sync	N/A	N/A	N/A
CLONE	Clone an object of a job run from a remote cluster	Supported (CA,TA)	Only DB is supported (CA,TA)	No
	Clone all objects of a job run from a remote cluster	No	No	No
	clone db to FCI	N/A	Supported (CA,TA)	N/A
	Crash-consistent clone for apps from a remote cluster	No	No	No

Categories	Workflows	Sources		
		MS SQL Volume Based	MS SQL File Based	MS SQL Native
TEARDOWN	Tear down object on a remote cluster	Supported (CA,TA)	Only DB is supported (CA,TA)	Only DB is supported (CA,TA)
	Tear down instant volume mount on a remote cluster	Supported (CA,TA)	N/A	N/A
CANCEL	Cancel a running replication task	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Cancel a clone or recover task on a remote cluster	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
DELETE SNAPSHOT	Delete replicated snapshot of a job run on a remote cluster	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
FILE RECOVERY	Search for files or folders on a remote cluster	Supported (CA,TA)	N/A	N/A
	Browse for replicated object on a remote cluster	Supported (CA,TA)	N/A	N/A
	Download replicated files and folders from a remote cluster	Supported (TA)	N/A	N/A
	Recover replicated files from a remote cluster	Supported (CA,TA)	N/A	N/A
	Download a VMX file from a remote cluster	N/A	N/A	N/A
VIRTUAL DISKS RECOVERY	Recover Virtual Disks	N/A	N/A	N/A

		Office 365
RECOVER	Recovering an entity in the Job Run	Supported (CA,TA)
	Recover an entire backup job run	Supported (CA,TA)
	Recover a SQL DB to the original server and instance	N/A
	Recover a SQL DB to the original server but a different instance	N/A
	Recover a SQL DB to a different server that has the same SQL version	N/A
	Recover a SQL DB to a different server that has a different SQL version (Based on MS requirements)	N/A
	Instant volume mount	N/A
	Crash-consistent recover for apps	N/A
CLONE	Clone an object of a job run	N/A
	Clone all the objects of a job run	N/A
	Clone db to FCI instance	N/A
	Crash-consistent recover for apps	N/A
DB Migration	SQL DB Migration without auto sync	N/A
	SQL DB Migration with auto sync	N/A
TEARDOWN	Tear down objects	N/A
	Tear down instant volume mount	N/A
CANCEL	Cancel a running job run	Supported (CA,TA)
	Cancel a running clone or recover tasks	Supported (Cloning is not supported) (CA,TA)

Categories	Workflows	Sources
		Office 365
DELETE SNAPSHOT	Delete a local snapshot of a job run	Supported (CA,TA)
FILE RECOVERY	Search for files or folders	Searching for Files/Folders, mails, and mailboxes Supported (CA,TA)
	Browse for a backed-up object	Supported (CA,TA) for Onedrive and SharePoint Not Supported for Outlook
	Download files/folders	Supported for SharePoint Not Supported for Outlook Only Files Suported for Onedrive; not Folders (TA)
	Recover files	Recovering Files/Folders, mails, and mailboxes supported (CA,TA)
	Download a VMX file	N/A
VIRTUAL DISKS RECOVERY	Recover Virtual Disks	N/A
CONVERT AND DEPLOY	Register Azure source and clone VMs to Azure	N/A
	Register AWS source and clone VMs to AWS	N/A

Archival Based Workflows

Categories	Workflows	Sources
		Office 365
ARCHIVAL	Archive an incremental backup	No
	Archiving an incremental backup with SQL server differential	N/A
	Archive a full backup	No
RECOVER	Recover a single object of a job run from an archive to a source	No
	Recover an entire backup job run from an archive to a source	No
	Instant volume mount from an archive	N/A
	Crash-consistent recover for apps from an archive	N/A
DB Migration	SQL DB Migration without auto sync	N/A
	SQL DB Migration with auto sync	N/A
CLONE	Clone objects of a job run from an archive	N/A
	Clone all objects of a job run from an archive	N/A
	clone db to FCI	N/A
	Crash-consistent clone for apps from an archive	N/A
CANCEL	Cancel a running archival task	No
	Cancel a running clone or recover task that is retrieving from an archive	No
DELETE SNAPSHOT	Delete an archived snapshot of a job run from the external target	No

Categories	Workflows	Sources
		Office 365
FILE RECOVERY	Search for files or folders from an archive	No
	Browse for files or folders from an archive snapshot	No
	Download files and folders from an archive	No
	Recover files from an archive to a source (to the same and different sources)	No
	Download n VMX file from an archive	N/A
VIRTUAL DISKS RECOVERY	Recover Virtual Disks	N/A
CLOUD RETRIEVE - SEARCH & RETRIEVE	Search for an object in an external target	No
	Download metadata for all runs of a job	No
	Download a snapshot (archived data) for a job run	No
CLOUD RETRIEVE - CLONE	Clone objects of a job run from an archive	No
	Clone all objects of a job run from an archive	No
	clone DB to FCI	N/A
CLOUD RETRIEVE - RECOVER	Recover objects of a job run from an archive to a source	No
	Recover all objects of job run from an archive to a source	No
	Instant volume mount from an archive	N/A

Categories	Workflows	Sources
		Office 365
CLOUD RETRIEVE - FILE RECOVERY	Search files or folders from downloaded snapshot	No
	Search files or folders from the metadata of a retrieved job run	No
	Browse files or folders from a retrieved snapshot	No
	Browse files or folders from the metadata of a downloaded job run	No
	Download files and folders from an archive	No
	Recover files from an archive to a source (to the same and different sources)	No
	Download a VMX file from an archive	N/A
CLOUD RETRIEVE - VIRTUAL DISKS RECOVERY	Recover Virtual Disks	N/A

Replication Based Workflows

Categories	Workflows	Sources
		Office 365
REPLICATION	Replicate an incremental backup with CBT to a remote cluster	Supported (CA,TA)
	Replicate an incremental backup with SQL server differential to a remote cluster	N/A
	Replicate a full backup with CBT to a remote cluster	N/A
	Replicate a full backup without CBT to a remote cluster	Supported (CA,TA)
FAILOVER	Failover an inactive Job on a remote cluster	No

Categories	Workflows	Sources
		Office 365
RECOVER	Recover a single object of a job run from a remote cluster	No
	Recover an entire backup job run from a remote cluster	No
	Recover a SQL DB from a remote cluster to another SQL server with the same SQL version	N/A
	Recover a SQL DB from a remote cluster to different SQL server with a different SQL version	N/A
	Instant volume mount of replicated data	N/A
	Crash-consistent recover for apps from a remote cluster	N/A
DB Migration	SQL DB Migration without auto sync	N/A
	SQL DB Migration with auto sync	N/A
CLONE	Clone an object of a job run from a remote cluster	N/A
	Clone all objects of a job run from a remote cluster	N/A
	clone db to FCI	N/A
	Crash-consistent clone for apps from a remote cluster	N/A
TEARDOWN	Tear down object on a remote cluster	N/A
	Tear down instant volume mount on a remote cluster	N/A
CANCEL	Cancel a running replication task	No
	Cancel a clone or recover task on a remote cluster	No
DELETE SNAPSHOT	Delete replicated snapshot of a job run on a remote cluster	No

Categories	Workflows	Sources
		Office 365
FILE RECOVERY	Search for files or folders on a remote cluster	No
	Browse for replicated object on a remote cluster	No
	Download replicated files and folders from a remote cluster	No
	Recover replicated files from a remote cluster	No
	Download a VMX file from a remote cluster	N/A
VIRTUAL DISKS RECOVERY	Recover Virtual Disks	N/A
CONVERT AND DEPLOY	Register Azure source and clone VMs to Azure	N/A
	Register AWS source and clone VMs to AWS	N/A
CLOUD REPLICATION	Create a snapshot in AWS and replicate to another region	N/A
	Create a snapshot in Azure and replicate to another region	N/A

AWS Cloud Workflows

Protection Based Workflows

Categories	Workflows	Sources		
		AWS Instances (Native Backup)	AWS Instances (CSM)	AWS RDS
REGISTRATION	Register a source	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Refresh object hierarchy	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Refresh Application registration	N/A	N/A	N/A
	Auto-protect new objects	Supported (CA,TA)	No	No
BACKUP	Incremental backup with CBT	Supported (CA,TA)	No	Supported(AWS does incremental backups)(CA,TA)
	Full backup with CBT	N/A	N/A	N/A
	Incremental backup with SQL server differential	N/A	N/A	N/A
	Full backup without CBT	N/A	N/A	N/A
	Ability to run a log backup in parallel to a full backup.	N/A	N/A	N/A
	Backup, archive and replicate now	Supported (CA,TA)	No	N/A
	CloudSpin to AWS and Azure	N/A	N/A	N/A

Categories	Workflows	Sources		
		AWS Instances (Native Backup)	AWS Instances (CSM)	AWS RDS
RECOVER	Recovering an entity in the Job Run	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Recover an entire backup job run	Supported (CA,TA)	Supported (CA,TA)	No
	Recover a SQL DB to the original server and instance	N/A	N/A	N/A
	Recover a SQL DB to the original server but a different instance	N/A	N/A	N/A
	Recover a SQL DB to a different server that has the same SQL version	N/A	N/A	N/A
	Recover DB to Alternate Instance with overwite	N/A	N/A	N/A
	Recover a SQL DB to a different server that has a different SQL version (Based on MS requirements)	N/A	N/A	N/A
	Instant volume mount	No	N/A	N/A
	Crash-consistent recover for apps	No	N/A	N/A
CLONE	Clone an object of a job run	No	N/A	N/A
	Clone all the objects of a job run	No	N/A	N/A
	Clone db to FCI instance	N/A	N/A	N/A
	Crash-consistent recover for apps	No	N/A	N/A

Categories	Workflows	Sources

Once enabled, disable Secure Archive at external target level	No	No
Perform search for CloudRetrieve operations	No	No
Download jobs (CloudRetrieve)	No	No
Download files/folders from archive	No	No
Download files/folders from archive for downloaded CloudRetrieve jobs	No	No
Recover files/folders to source	No	No
Recover files/folders to source from archive for downloaded CloudRetrieve jobs	No	No

GCP External Targets for CloudArchiveDirect

Workflows	External Targets	
	Google - Nearline	Google - Coldline
Enable/disable deduplication at external target level	No	No

Workflows	External Targets	
	Google - Nearline	Google - Coldline
Enable/disable incremental archive at external target level	No	No
Enable encryption at external target level	No	No
Once enabled, disable encryption at external target level	No	No
Enable/disable compression at external target level	No	No
Delete external target	No	No
Enable secure archive at external target level	No	No
Once enabled, disable Secure Archive at external target level	No	No
Perform search for CloudRetrieve operations	No	No
Download jobs (CloudRetrieve)	No	No
Download files/folders from archive	No	No
Download files/folders from archive for downloaded CloudRetrieve jobs	No	No
Recover files/folders to source	No	No
Recover files/folders to source from archive for downloaded CloudRetrieve jobs	No	No

Oracle External Targets for CloudArchiveDirect

Workflows	External Targets	
	Oracle Standard	Oracle Archive
Enable/disable deduplication at external target level	No	No
Enable/disable incremental archive at external target level	No	No
Enable encryption at external target level	No	No

Workflows	External Targets	
	Oracle Standard	Oracle Archive
Once enabled, disable encryption at external target level	No	No
Enable/disable compression at external target level	No	No
Delete external target	No	No
Enable secure archive at external target level	No	No
Once enabled, disable Secure Archive at external target level	No	No
Perform search for CloudRetrieve operations	No	No
Download jobs (CloudRetrieve)	No	No
Download files/folders from archive	No	No
Download files/folders from archive for downloaded CloudRetrieve jobs	No	No
Recover files/folders to source	No	No
Recover files/folders to source from archive for downloaded CloudRetrieve jobs	No	No

Microsoft Azure External Targets for CloudArchiveDirect

Workflows	External Targets			
	Azure Hot Blob	Azure Cool Blob	Azure Archive	Azure Gov
Enable/disable deduplication at external target level	No	No	No	No
Enable/disable incremental archive at external target level	No	No	No	No
Enable encryption at external target level	No	No	No	No
Once enabled, disable encryption at external target level	No	No	No	No
Enable/disable compression at external target level	No	No	No	No

Workflows	External Targets			
	Azure Hot Blob	Azure Cool Blob	Azure Archive	Azure Gov
Delete external target	No	No	No	No
Enable secure archive at external target level	No	No	No	No

Download files/folders from archive for downloaded CloudRetrieve jobs	No	No	No	No
Recover files/folders to source	No	No	No	No
Recover files/folders to source from archive for downloaded CloudRetrieve jobs	No	No	No	No

S3 - Compatible, NAS, Tape External Targets for CloudArchiveDirect

Workflows	External Targets		
	NAS	QStar Tape	S3 - Compatible (E.g., Cohesity)
Enable/disable deduplication at external target level	No	No	No
Enable/disable incremental archive at external target level	No	No	No
Enable encryption at external target level	No	No	No
Once enabled, disable encryption at external target level	No	No	No
Enable/disable compression at external target level	No	No	No

Workflows	External Targets		
	NAS	QStar Tape	S3 - Compatible (E.g., Cohesity)
Delete external target	No	No	No
Enable secure archive at external target level	No	No	No
Once enabled, disable Secure Archive at external target level	No	No	No
Perform search for CloudRetrieve operations	No	No	No
Download jobs (CloudRetrieve)	No	No	No
Download files/folders from archive	No	No	No
Download files/folders from archive for downloaded CloudRetrieve jobs	No	No	No
Recover files/folders to source	No	No	No
Recover files/folders to source from archive for downloaded CloudRetrieve jobs	No	No	No

Supported Workflow for NAS Tiering

NAS Tiering

Workflows	External Targets			
	Generic NAS - NFS	Generic NAS - SMB	Isilon - NFS	Isilon - SMB
Down-Tiering without leaving anything at source	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
Downtiering with leaving the symlink behind at the source	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
Orphan data delete	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)

Workflows	External Targets			
	Generic NAS - NFS	Generic NAS - SMB	Isilon - NFS	Isilon - SMB
Capacity Planner	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
Tiering Audit Log	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
Bucket Customization	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)

* = When all protocols are enabled, S3 is read-only mode and not
** = Yes for either SMB or NFS protocol

Supported Multitenancy Workflows for Hybrid Extender

This sections lists the supported multitenancy workflows for Hybrid Extender.

Protection Group and External Targets Workflows (Hybrid Extender)

- Virtual Server (VMs) and Physical Server Workflows (Hybrid Extender)
  - Protection Based Workflow
  - Archival Based Workflow
  - Replication Based Workflow
- Databases Workflows (Hybrid Extender)
  - Protection Based Workflow for MS SQL VM, FCI, and AG
  - Archival Based Workflow for MS SQL VM, FCI, and AG
  - Replication Based Workflow for MS SQL VM, FCI, and AG
  - Protection Based Workflow for MS SQL Volume-base, File-based, and Native Backup
  - Archival Based Workflow for MS SQL Volume-base, File-based, and Native Backup
  - Replication Based Workflow for MS SQL Volume-base, File-based, and Native Backup
  - Protection Based Workflow for Oracle, SAP HANA, and SAP Sybase ASE
  - Archival Based Workflow for Oracle, SAP HANA, and SAP Sybase ASE
  - Replication Based Workflow Oracle, SAP HANA, and SAP Sybase ASE

- NAS Workflows (Hybrid Extender)
  - Protection Based Workflow
  - Archival Based Workflow
  - Replication Based Workflow
- External Targets Using Hybrid Extender
  - AWS External Targets for CloudArchive - Standard
  - AWS External Targets for CloudArchive - C2S
  - AWS External Targets for CloudArchive - Gov
  - Microsoft Azure External Targets for CloudArchive
  - GCP External Targets for CloudArchive
  - Oracle External Targets for CloudArchive
  - S3 - Compatible, NAS, Tape External Targets for CloudArchive
- External Target for Incremental Forever Archival/CloudArchive Direct with Dedup (Hybrid Extender)
- External Target for Incremental Forever Archival/CloudArchive Direct without Dedup (Hybrid Extender)
  - AWS External Targets for CloudArchiveDirect - Standard
  - AWS External Targets for CloudArchiveDirect - C2S
  - AWS External Targets for CloudArchiveDirect - Gov
  - AWS External Targets for CloudArchiveDirect - GCP
  - AWS External Targets for CloudArchiveDirect - Oracle
  - AWS External Targets for CloudArchiveDirect - Azure
  - AWS External Targets for CloudArchiveDirect -S3 Compatible, NAS, Tape
- Supported Workflow for NAS Tiering (Hybrid Extender)

Legend for Charts Below:

Yes = Supported

No = Not Supported

N/A = Not Applicable

CA = Cluster Administrator

TA = Tenant Administrator

Create = Create for an Org

Delete = Delete from Cluster

Assign = Assign to an Org

Un-assign = Un-assign from an Org

Virtual Server (VMs) and Physical Server Workflows (Hybrid Extender)

Protection Based Workflow

Categories	Workflows	Sources				
		ESXi VM Servers	Physical Servers (Windows - Block Based)	Physical Servers (Windows - File Based)	Physical Servers (Linux - Block Based)	Physical Servers (Linux - File Based)
REGISTRATION	Register a source	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Refresh object hierarchy	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Refresh Application registration	N/A	N/A	N/A	N/A	N/A
	Auto-protect new objects	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	No

Categories	Workflows	Sources				
		ESXi VM Servers	Physical Servers (Windows - Block Based)	Physical Servers (Windows - File Based)	Physical Servers (Linux - Block Based)	Physical Servers (Linux - File Based)
BACKUP	Incremental backup with CBT	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	No	Supported (CA,TA)
	Full backup with CBT	N/A	Supported (CA,TA)	Supported (CA,TA)	No	Supported (CA,TA)
	Incremental backup with SQL server differential	N/A	N/A	N/A	N/A	N/A
	Full backup without CBT	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Ability to run a log backup in parallel to a full backup.	N/A	N/A	N/A	N/A	N/A
	Backup, archive and replicate now	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	CloudSpin to AWS and Azure	Supported (CA,TA)	N/A	N/A	N/A	N/A

Categories	Workflows	Sources				
		ESXi VM Servers	Physical Servers (Windows - Block Based)	Physical Servers (Windows - File Based)	Physical Servers (Linux - Block Based)	Physical Servers (Linux - File Based)
RECOVER	Recovering an entity in the Job Run	No	No	No	No	No
	Recover an entire backup job run	Supported (CA,TA)	No	No	No	No
	Recover a SQL DB to the original server and instance	N/A	N/A	N/A	N/A	N/A
	Recover a SQL DB to the original server but a different instance	N/A	N/A	N/A	N/A	N/A
	Recover a SQL DB to a different server that has the same SQL version	N/A	N/A	N/A	N/A	N/A
	Recover DB to Alternate Instance with overwite	N/A	N/A	N/A	N/A	N/A

Categories	Workflows	Sources				
		ESXi VM Servers	Physical Servers (Windows - Block Based)	Physical Servers (Windows - File Based)	Physical Servers (Linux - Block Based)	Physical Servers (Linux - File Based)
	Recover a SQL DB to a different server that has a different SQL version (Based on MS requirements)	N/A	N/A	N/A	N/A	N/A
	Instant volume mount	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	No
	Crash-consistent recover for apps	Supported (CA,TA)	No	No	No	No
CLONE	Clone an object of a job run	Supported (CA,TA)	No	No	No	No
	Clone all the objects of a job run	Supported (CA,TA)	No	No	No	No
	Clone db to FCI instance	N/A	N/A	N/A	N/A	N/A
	Crash-consistent recover for apps	Supported (CA,TA)	No	No	No	No

Categories	Workflows	Sources				
		ESXi VM Servers	Physical Servers (Windows - Block Based)	Physical Servers (Windows - File Based)	Physical Servers (Linux - Block Based)	Physical Servers (Linux - File Based)
DB Migration	SQL DB Migration without auto sync	N/A	N/A	N/A	N/A	N/A
	SQL DB Migration with auto sync	N/A	N/A	N/A	N/A	N/A
TEARDOWN	Tear down objects	Supported (CA,TA)	No	No	No	No
	Tear down instant volume mount	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	No
CANCEL	Cancel a running job run	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Cancel a running clone or recover tasks	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
DELETE SNAPSHOT	Delete a local snapshot of a job run	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)

Categories	Workflows	Sources				
		ESXi VM Servers	Physical Servers (Windows - Block Based)	Physical Servers (Windows - File Based)	Physical Servers (Linux - Block Based)	Physical Servers (Linux - File Based)
FILE RECOVERY	Search for files or folders	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Browse for a backed-up object	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Download files/folders	Supported (TA)	Supported (TA)	Supported (TA)	Supported (TA)	Supported (TA)
	Recover files	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Download a VMX file	Supported (TA)	N/A	N/A	N/A	N/A
VIRTUAL DISKS RECOVERY	Recover Virtual Disks	Supported (CA,TA)	N/A	N/A	N/A	N/A
CONVERT AND DEPLOY	Register Azure source and clone VMs to Azure	Supported (CA,TA)	N/A	N/A	N/A	N/A
	Register AWS source and clone VMs to AWS	Supported (CA,TA)	N/A	N/A	N/A	N/A

Archival Based Workflow

Categories	Workflows	Sources				
		ESXi VM Servers	Physical Servers (Windows - Block Based)	Physical Servers (Windows - File Based)	Physical Servers (Linux - Block Based)	Physical Servers (Linux - File Based)
ARCHIVAL	Archive an incremental backup	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Archiving an incremental backup with SQL server differential	N/A	N/A	N/A	N/A	N/A
	Archive a full backup	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)

Categories	Workflows	Sources				
		ESXi VM Servers	Physical Servers (Windows - Block Based)	Physical Servers (Windows - File Based)	Physical Servers (Linux - Block Based)	Physical Servers (Linux - File Based)
RECOVER	Recover a single object of a job run from an archive to a source	Supported (CA,TA)	No	No	No	No
	Recover an entire backup job run from an archive to a source	Supported (CA,TA)	No	No	No	No
	Instant volume mount from an archive	Supported (CA,TA)	Supported (CA,TA)	No	Supported (CA,TA)	No
	Crash-consistent recover for apps from an archive	Yes	No	No	No	No
DB Migration	SQL DB Migration without auto sync	N/A	N/A	N/A	N/A	N/A
	SQL DB Migration with auto sync	N/A	N/A	N/A	N/A	N/A

Categories	Workflows	Sources				
		ESXi VM Servers	Physical Servers (Windows - Block Based)	Physical Servers (Windows - File Based)	Physical Servers (Linux - Block Based)	Physical Servers (Linux - File Based)
CLONE	Clone objects of a job run from an archive	Supported (CA,TA)	No	No	No	No
	Clone all objects of a job run from an archive	Supported (CA,TA)	No	No	No	No
	clone db to FCI	N/A	N/A	N/A	N/A	N/A
	Crash-consistent clone for apps from an archive	Supported (CA,TA)	No	No	No	No
CANCEL	Cancel a running archival task	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Cancel a running clone or recover task that is retrieving from an archive	Supported (CA,TA)	No	No	No	No

Categories	Workflows	Sources				
		ESXi VM Servers	Physical Servers (Windows - Block Based)	Physical Servers (Windows - File Based)	Physical Servers (Linux - Block Based)	Physical Servers (Linux - File Based)
DELETE SNAPSHOT	Delete an archived snapshot of a job run from the external target	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
FILE RECOVERY	Search for files or folders from an archive	No	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)

NAS Workflows (Hybrid Extender)

Protection Based Workflow

Categories	Workflows	Sources			
		Generic NAS - NFS	Generic NAS - SMB	Isilon - NFS	Isilon - SMB
REGISTRATION	Register a source	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Refresh object hierarchy	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Refresh Application registration	N/A	N/A	N/A	N/A
	Auto-protect new objects	N/A	N/A	No	No
BACKUP	Incremental backup with CBT	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Full backup with CBT	N/A	N/A	N/A	N/A
	Incremental backup with SQL server differential	N/A	N/A	N/A	N/A
	Full backup without CBT	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Ability to run a log backup in parallel to a full backup.	N/A	N/A	N/A	N/A
	Backup, archive and replicate now	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	CloudSpin to AWS and Azure	N/A	N/A	N/A	N/A

Categories	Workflows	Sources			
		Generic NAS - NFS	Generic NAS - SMB	Isilon - NFS	Isilon - SMB
RECOVER	Recovering an entity in the Job Run	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Recover an entire backup job run	No	No	No	No
	Recover a SQL DB to the original server and instance	N/A	N/A	N/A	N/A
	Recover a SQL DB to the original server but a different instance	N/A	N/A	N/A	N/A
	Recover a SQL DB to a different server that has the same SQL version	N/A	N/A	N/A	N/A
	Recover DB to Alternate Instance with overwite	N/A	N/A	N/A	N/A
	Recover a SQL DB to a different server that has a different SQL version (Based on MS requirements)	N/A	N/A	N/A	N/A
	Instant volume mount	N/A	N/A	N/A	N/A
	Crash-consistent recover for apps	N/A	N/A	N/A	N/A

Categories	Workflows	Sources			
		Generic NAS - NFS	Generic NAS - SMB	Isilon - NFS	Isilon - SMB
CLONE	Clone an object of a job run	No	No	No	No
	Clone all the objects of a job run	No	No	No	No
	Clone db to FCI instance	N/A	N/A	N/A	N/A
	Crash-consistent recover for apps	N/A	N/A	N/A	N/A
DB Migration	SQL DB Migration without auto sync	N/A	N/A	N/A	N/A
	SQL DB Migration with auto sync	N/A	N/A	N/A	N/A
TEARDOWN	Tear down objects	N/A	N/A	N/A	N/A
	Tear down instant volume mount	N/A	N/A	N/A	N/A
CANCEL	Cancel a running job run	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
	Cancel a running clone or recover tasks	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
DELETE SNAPSHOT	Delete a local snapshot of a job run	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)

Categories	Workflows	Sources			
		Generic NAS - NFS	Generic NAS - SMB	Isilon - NFS	Isilon - SMB

Supported Workflow for NAS Tiering (Hybrid Extender)

NAS Tiering

Workflows	External Targets			
	Generic NAS - NFS	Generic NAS - SMB	Isilon - NFS	Isilon - SMB
Down-Tiering without leaving anything at source	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
Downtiering with leaving the symlink behind at the source	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
Orphan data delete	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
Capacity Planner	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
Tiering Audit Log	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)
Bucket Customization	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)	Supported (CA,TA)

Supported Cloud Spin and Other Workflows

This sections lists the supported Cloud Spin and other supported workflow:

- Cloud Spin Workflows
- **Other Supported Workflows**
  - Cohesity Data Cloud (Self-Managed)
  - User Interface
  - Replication
  - View Tenant-ID
  - Authentication
  - Authorization
  - Supported Cloud Spin and Other Workflows
  - RBAC

- Storage Domain Settings
- View Workflows

Legend for Charts Below:

Yes = Supported

No = Not Supported

N/A = Not Applicable

CA = Cluster Administrator

TA = Tenant Administrator

Create = Create for an Org

Delete = Delete from Cluster

Assign = Assign to an Org

Un-assign = Un-assign from an Org

Cloud Spin Workflows

AWS/AWS Gov Workflows

Workflows	VMware	OS Supported by VMware	HyperV 2016 VM Servers	HyperV 2012 VM Servers
Full cloud spin (Policy-based)	Supported (CA,TA)	Windows 10 Desktop Edition, Microsoft Windows Server 2012, Microsoft Windows Server 2016, and Microsoft Windows Server 2019, Windows Server 2022 CentOS 6.0+ 64-bit, 7.0 - 7.9 64-bit, 8.0 64-bit RHEL 6.7+ 64-bit, 7.0 - 7.9 64-bit, 8.0 - 8.2 64-bit SUSE Linux Enterprise Server 11 64 bit, 12 64 bit Ubuntu 14.x 64-bit, 16 64-bit, 18 64-bit, 20 64-bit OEL 5.11 - 5.8 64-bit, 6.x 64-bit, 7.0 - 7.9 64-bit Debian 6.0.0-6.0.8 64 bit, 7.0.0-7.8.0 64 bit, 8.0.0 64 bit Fedora Server 19-21 64 bit	No	No
Launch instance	Supported (CA,TA)		No	No
Tear-down launched instance (Full)	Supported (CA,TA)		No	No
Incremental Cloudspin (Policy-based)	Supported (CA,TA)		No	No
Launch instance (Incremental)	Supported (CA,TA)		No	No
Tear-down launched instance (Incremental)	Supported (CA,TA)		No	No
On-demand cloudspin / DR Failover from replication cluster	Supported (CA,TA)		No	No
Tear-down deployed instance	Supported (CA,TA)		No	No
DR Failback using Native Snapshot	Supported (CA,TA)		No	No
DR Failback to using Cohesity Protection Service	Supported (CA,TA)		No	No

Azure Workflows

Workflows	VMware	OS Supported by VMware	HyperV 2016 VM Servers	HyperV 2012 VM Servers	OS Supported by Hyper-V

Tenant-Level View Allowlist

In a multitenant environment, a tenant can add subnets to the allowlist and only the IP addresses within this subnet can access all the views of the tenant. This feature enables the tenant to manage all endpoints that have access to their views seamlessly.

Points to Note

- Tenant-level allowlist complements global allowlist and view-level allowlist.
- The tenant administrator must have the **Manage Cohesity Views** privilege. For more information, see Privileges for Service Provider Admin and Organization Admin.

To allowlist views at the tenant level, complete the following steps:

1. In the Cohesity Dashboard, click the user icon ( ) in the top-right corner and select **Impersonate**.
2. In the **Impersonate** pop-up window, select the required **Organization** and click **Switch**.
3. Select **File Services > Views > Global Settings**.
4. In the **Add Allowlist** pop-up window, enter a subnet IP in CIDR format (IPv4 - 10.0.0.0/24 or IPv6 - FE80:CD00::211E:729C/60).
5. Specify NFS and SMB permissions.
6. Specify whether NFS root squash must be enabled.
7. Optionally, enter a description for the allowlist.
8. Click **Add**.
9. Repeat the preceding steps for specifying additional subnets at the tenant level.

   For more information about adding subnets to allowlist, see Add Subnets to Allowlists.

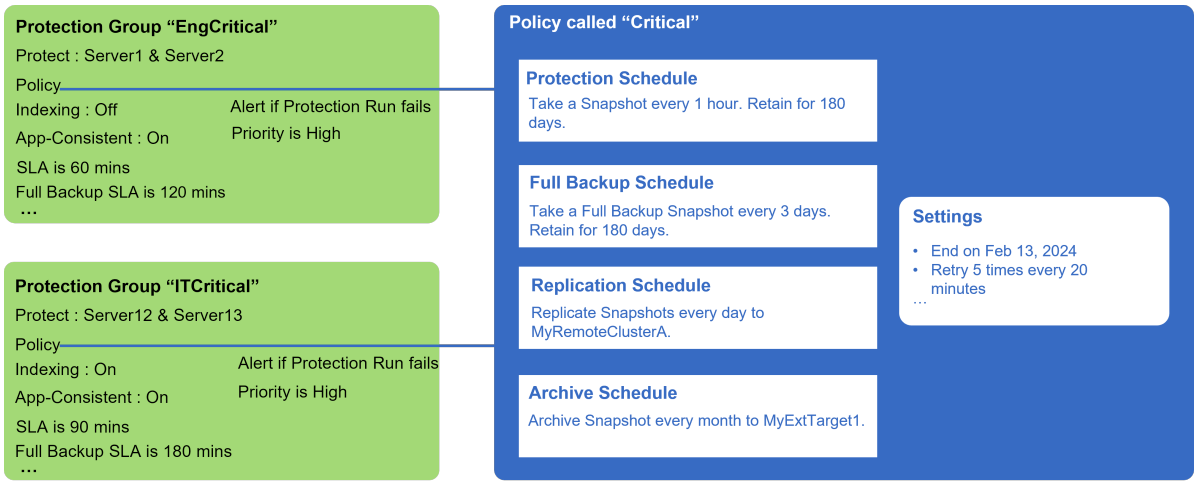
Chapter 7: Manage Protection Policy

A protection policy is a reusable set of settings that define how and when objects are protected, replicated and archived. You can select a standard policy to use when configuring a Protection Group. A Protection Group uses the schedules and settings defined in the policy to determine when and how backups are captured, archived or replicated.

For instructions on creating and managing policies, see Create or Edit a Standard Policy.

Some settings are defined in the Protection Group and some settings are defined in the policy. For example, for a Protection Group that protects servers, the schedule is defined at the policy level but indexing is defined at the Protection Group level as shown in the following figure.

Policies are reusable. You can define a single policy that is used by different Protection Groups as shown in the following figure.



Create or Edit a Standard Policy

A protection policy is a reusable set of settings that define how and when objects are protected, replicated and archived. You can select a standard policy to use when configuring

a Protection Group. A Protection Group uses the schedules and settings defined in the policy to determine when and how backups are captured, archived or replicated.

Use the default standard policies or create your own custom policies. Policies save time because you do not need to repetitively enter settings.

> **Note:** Policy creation and editing operations treat a month as having 31 days instead of 30 days, which was the definition in releases older than 6.8.1.

To create or edit a standard policy:

On the **Create Policy** page, select the target type and configure the advanced settings by clicking the respective icons from the floating menu when creating a policy.

On the **Create Policy** page you can change underlined numeric fields by over typing them or using the up and down arrow keys on your keyboard.

1. Navigate to **Data Protection > Policies**.
2. Click **Create Policy** located at the top right of the page..

   To edit an existing policy in the list, click the actions menu (⋮) and select **Edit** (✎).

   > **Note:** For Cohesity 6.6 and higher versions, the policy **Description** cannot be set or edited. For more details on how to edit the field, see the Unable to update the Description field in a Protection Policy KB article.

3. **Policy Name:** Specify a protection policy name. The name can contain alphanumerics, underscores, hyphens, periods, and spaces. This field is required and can be changed later.
4. Specify when backups are captured:
   - **Backup every xx**: Specify the minutes, hours, weeks, months, or years to set the frequency for how often backups are captured by the Protection Group. This defines the protection schedule for capturing backups.

     The policy schedule can be configured to run on specific days. From the **Every** drop-down, select **Week** and in the **On** field, select the days of the week you want to run the backup. For example, you can schedule a backup to run on Monday, Wednesday, and Friday, and not on Tuesday and Thursday.

> **Note:** The policy schedule can be configured to run on specific dates as well (calendar-based scheduling). From the **Every** drop-down, select **Month**, and in the **On** field, select the **Date**. You can then choose the date of the month you want to run the backup. For example, you can schedule a backup to run on the 5th of every month.

5. Under **Primary Copy**, specify the following:
   a. **Keep On**: Select **Local** from the drop-down to keep the primary copy data on the Cohesity cluster.

   > **Note:** If you are selecting any external targets, then this policy can be only used for performing CloudArchive Direct wherein the primary copy of the data is stored on the external targets. For more information, see CloudArchive Direct.

   b. **Retain for xx days**: Specify how many days, weeks, months, or years backups are retained on the Cohesity cluster before they are deleted.

   > **Note:**
   > - The **Retain** option can be set to a maximum value of 365000.
   > - Retentions at 7-day boundaries turn into weeks.

6. **Optional**: Enable **Data Movement** if required.

   Data Movement: With this option, you can move the data (downtier) from the selected AWS Standard Storage Tier to an AWS Archive Storage Tier target after a specified time period. Data Movement helps in space reclamation on the external target. You can select the S3 archive target in the **Move Data** section and set a time interval to transfer the data from the S3 standard tier to the S3 archive bucket. This interval can be defined in days, weeks, months, or years.

   > **Note:** As an AWS consideration, you cannot downtier from S3 Glacier to S3 Deep Archive. After downtiering to either S3 Glacier or S3 Deep Archive, you cannot perform any further downtiering.

7. Click **More Options** to configure the additional policy settings.

8. **DataLock:** Toggle on to lock the policy and any snapshots that belong to Protection Groups associated with the policy. DataLock is typically used for compliance and regulatory purposes. For more information, see DataLock.

   If you have enabled the **DataLock** option at the policy level, then you have the option to lock the backup retained on the Cohesity cluster. In the **Lock** option field available in the **Primary Copy** pane, specify how many days, weeks, months, or years the retained backups must be locked. You cannot delete the snapshots during the specified lock period.

9. **Periodic Full Backup**: Click the **Periodic Full Backup** icon from the floating menu to add a periodic full backup. You can schedule a policy to capture the periodic full backup for:

   - **Day** - Captures only the first successful run that started on that particular day.
   - **Week** - From the weekly calendar, select the required days of the week to run the backup.
   - **Month** - Use the **On** dropdown to select when the backup should run:
     - **First** - First selected day of the month.
     - **Second** - Second selected day of the month.
     - **Third** - Third selected day of the month.
     - **Fourth** - Fourth selected day of the month.
     - **Last** - Last selected day of the month.

       Then, choose the specific day of the week from the adjacent dropdown.
     - **Date** - From the pre-built calendar, select a required date for the backup.
   - **Year** - From the **On** dropdown, select one of the following:
     - **First Day** - First day of the year.
     - **Last Day** - Last day of the year.

   You can also schedule multiple periodic full backups with different frequencies and dates.

Note:

- The policy schedule can be configured to run on specific dates as well (calendar-based scheduling). From the **Every** drop-down, select **Month**, and in the **On** field, select the **Date**. You can then choose the date of the month you want to run the backup. For example, you can schedule a backup to run on the 5th of every month.
- If you specify multiple periodic full backup schedules for the same set of snapshots with different retention periods, the snapshots are retained for the longest specified period.
- Cohesity recommends a first full and incremental forever approach to back up all workloads (sources) with the exception for Oracle (SBT based backup) and SQL (VDI-based) where Cohesity recommends periodic full backups.

10. **Continuous Data Protection**: (*Applies only for VMware*) To achieve near zero RPO, click the **Continuous Data Protection** option floating menu and specify the time unit (hours) to capture and retain logs on the Cohesity cluster. This value defines the CDP schedule for capturing logs from the VMs.

    You can use this option to restore the VM applications to a point-in-time as opposed to periodic snapshots available with regular backups. For more information, see Cohesity CDP for VMware.

11. **Quiet Times:** Select this option from the **Backup Options** floating menu to add a quiet time. Quiet Times define time periods when new protection runs are not started. For example, you may want to configure hourly backups that run during weekdays but not on Saturday or Sunday. Quiet Times only prevent new protection runs from starting during the specified time period. Protection runs that started before the quiet time period are not affected and will continue to run. For example, if a protection run starts at 12:45 AM on Saturday morning and there is a weekend quiet time period that starts at 1 AM on Saturday morning, the protection run will continue to run past 1 AM. No new protection runs are started during the quiet times. Similarly, for jobs set on an interval basis, such as incremental jobs running every 6 hours, the job will start immediately after the Quiet Time ends. If the quiet time window ends 6 or more hours after the start time of a protection job, that run is skipped. For example, if jobs are scheduled at 6 AM, 12 PM, 6 PM, and 12 AM, and a Quiet Time is set from 11:30 AM to 1:30 PM, the job originally planned for noon will instead commence at 1:31 PM. Once the run commences at 1:31 PM, the next run will take place at 7:30 PM and not 6 PM (6 hours difference).

You can add multiple quiet times. For example, you could define a quiet time period for Saturday and Sunday and another quiet time period every morning from 9:00 AM to 11:00 AM. The quiet time window is considered based on the timezone specified in the protection group to which the protection policy is applied. For example, consider a policy defining a quiet time from 9 AM to 11 AM. There are two protection jobs: one in the IST timezone and the other in the PST timezone having the same policy. For the first job (in IST), protection runs will not be triggered during the 9 AM to 11 AM IST window. However, for the second job (in PST), protection runs can still be triggered because the 9 AM to 11 AM quiet time does not overlap with the same hours in the PST timezone, despite both jobs having the same policy.

> **Note:** If you update the Quiet Time periods in a policy for a running Protection Group, only new protection runs using the policy are affected and any existing Protection runs that have already started will use the original Quiet Time periods.

12. **Retry Options:** Select **Customize Retries** from the **Backup Options** floating menu to customize the retry settings for capturing snapshots. By default, the Cohesity cluster attempts to capture Snapshots three times before the protection run fails. The default time between retries is five minutes. You can optionally customize the number of retries and how long to wait between each attempt.
13. **BMR Backup (Physical Server)**: Select **BMR Backup** from the **Backup Options** floating menu to provide a backup schedule and retention period for Bare Machine Recovery (BMR) system data on a physical server.
    a. **Backup every xx**: Select the time unit for how often BMR backups are captured by the Protection Group.
    b. **Retain for xx days**: Specify how many days the BMR backups are retained on the Cohesity cluster before they are deleted.

       > **Note:** The **Retain** option can be set to a maximum value of 365000.

    c. **Lock**: Specify how many days, weeks, months, or years the retained BMR backups should be locked. You cannot delete the snapshots during the specified period.

> **Note:** This option is available only if you have enabled the **DataLock** option at the policy level.

14. **Log Backup (Databases):** Select **Log Backup** from the **Backup Options** floating menu to add a database logs schedule if you plan on restoring databases to a specific point in time between two full database server backups. If this policy has an archival schedule, this retention period also applies to the archived logs.

    For example, if you back up hourly at 5 minutes after the hour but you want the ability to restore a database to its state at 10:15 AM, specify a database logs schedule. The log backup saves all the transaction logs of all the databases so you can roll back to any point in time. Transaction logs are cumulative, so all the logs are backed up. When a database is added to a database server protected by Cohesity, its database logs are not backed up until a full database server backup has occurred.

    a. **Backup every xx:** Select the time unit for how often log backups are captured by the Protection Group.

    b. **Retain for xx days:** Specify how many days log backups are retained on the Cohesity cluster before they are deleted. If this policy has a Replication schedule, this retention period also applies to the logs replicated to the target cluster.

    > **Note:** The **Retain** option can be set to a maximum value of 365000.

    c. **Lock**: Specify how many days, weeks, months, or years the retained log backups should be locked. You cannot delete the snapshots during the specified period.

    > **Note:** This option is available only if you have enabled the **DataLock** option at the policy level.

    For SQL Protection Groups, if the log backups are configured in the Protection Group, all protection runs are replicated ignoring the set policy. For more information, see the Each SQL log backup run is replicated irrespective of policy KB article.

15. **Storage Array Snapshot**: Select **Storage Array Snapshot** from the **Backup Options** floating menu to provide a backup schedule and retention period for the Safeguarded snapshots for IBM Storage FlashSystem volume and volume groups. These are point-in-time cyber-resilient copies of IBM Storage FlashSystem volume groups.

    a. **Backup every xx**: Select the time unit for how often The Protection Group captures safeguarded snapshots.

    b. **Retain for xx days**: Specify how many days the Safeguarded snapshots are retained on the Cohesity cluster before they are deleted.

16. **Extended Retention**: Click the **Primary Copy** tile and select this option from the **Backup Options** floating menu to retain a subset of snapshots (backups) for longer than defined by the protection schedule.
    a. Specify when to take the first snapshot and how long to retain it. For more information, see Extended Retention.
    b. **Lock**: Specify how many days, weeks, months, or years the retained backups should be locked. You cannot delete the snapshots during the specified period.

    > **Note:** This option is available only if you have enabled the **DataLock** option at the policy level.

    c. **Full Backup Only**: Toggle on to apply this setting for full backup. By default, the toggle is off and extended retention will not be used.

    > **Note:** You can enable **Full Backup Only** when you have a periodic full schedule in the protection policy.

17. **Add Replication:** Select this option to replicate snapshots to another Cohesity cluster. The copied snapshots are stored in the storage domain of the remote cluster. (The storage domain, however, is specified in the Protection Group.) The replication schedule for copying Snapshots cannot be more often than the protection schedule for capturing Snapshots. For example if Snapshots are captured hourly, the Cohesity cluster cannot replicate them every 30 minutes but it can replicate them hourly or any value over one hour.

    > **Note:** For CloudArchive Direct, you should not add Replication.

    If database logs are backed up, they will also be replicated (there is not a separate replication schedule for logs). The retention period specified in the **Log Backup (Databases)** setting applies to both the source and target cluster.

    a. **Replicate to:** Select either a **Remote Cluster** or **AWS**.

    From the drop-down, select a cluster source to replicate snapshots. You can also select an AWS S3 storage source if you are backing up AWS VMs using the Cloud Snapshot Manager APIs of the cloud service.

    > **Note:** If you choose a remote cluster, use the **Replication Target** to specify the target cluster to copy the snapshots.

You can also register a new cluster to replicate to by selecting **Register Remote Cluster**. For detailed instructions, see Create a Connection to the Remote Cohesity Cluster.

b. **After every run:** Specify how often snapshots are replicated. The available replication schedule frequencies are:
   - **Hour**: Replicates the first successful run that started on that particular hour.
   - **Daily**: Replicates the first successful run that started on that particular day.
   - **Weekly**: From the weekly calendar, select the required days in a week. You can also set the replication schedule for n-number of weeks.
   - **Monthly**: Use the **On** dropdown to select the replication schedule:
     - **First** - First selected day of the month.
     - **Second** - Second selected day of the month.
     - **Third** - Third selected day of the month.
     - **Fourth** - Fourth selected day of the month.
     - **Last** - Last selected day of the month.

       Then, choose the specific day of the week from the adjacent dropdown.
     - **Date** - From the pre-built calendar, select the required date.
   - **Yearly**: From the **On** dropdown, select the available options:
     - **First Day** - First day of the year.
     - **Last Day** - Last day of the year.
     - **Date** - From the pre-built calendar, select a required date of the year.

> **Note:** Log backups are always replicated whenever a log backup run is finished irrespective of the replication schedule.

c. **Retain for xx days:**

   Full/Incremental Backups

   Specify how long the snapshots are retained on the remote cluster.

   The Retain option can be set to a maximum value of 365000.

   Log Backups

   Specify how long the log snapshots are retained on the external target.

The Retain option can be set to a maximum value of 365000.

> **Note:** All runs are replicated continuously as log backups require a continuous chain of backups.

d. **Lock**: Specify how many days, weeks, months, or years the retained snapshots should be locked. You cannot delete the snapshots during the specified period.

> **Note:** This option is available only if you have enabled the **DataLock** option at the policy level.

e. To add an additional replication schedule, repeat these steps. To replicate to multiple Cohesity clusters, create multiple replication schedules with different replication targets.

> **Important:** If you specify multiple replication schedules with the same replication target that replicate the same set of snapshots but with different retention periods, the snapshots are retained for the longest time period. For example if you define two replication schedules with the same replication target that retain the same set of snapshots but one schedule specifies a 90-day retention period and other schedule specifies a 180-day retention period, the set of snapshots are retained for 180 days.

For replication, the extended retention schedule is as follows:

- **Weekly**: The first successful run that started on a Sunday or later.
- **Monthly**: The first successful run that started on the first day of the month or later.
- **Yearly**: The first successful run that started on the first day of the year or later.

18. **Add Archival:** Select this option to add an archive schedule.
    a. **Archive to:** Select an existing external target. You can also register a new external target. For detailed instructions, see Register an External Target.
    b. **Archive only fully successful Runs:** Check this box if you want archive to occur only if the snapshots of all the objects protected by the Protection Group were created. If the creation of any snapshots fails, no snapshots are archived.

c. **Full Backup Only**: Toggle on to apply this setting for full backup. By default, the toggle is off and extended retention will not be used.

> **Note:** You can enable **Full Backup Only** when you have a periodic full schedule in the protection policy.

d. **Every #:** Specify the archive schedule for making copies of snapshots created by this Protection Group and storing them on a registered external target. (The storage domain, however, is specified in the Protection Group.) The archive schedule for copying snapshots cannot be more often than the protection schedule for capturing snapshots. For example if snapshots are captured daily, the Cohesity cluster cannot archive them hourly but it can archive them daily or any value less often than daily. The available archival schedule frequencies are:
   - **Hour** - Archives only the first successful run that started on that particular hour.
   - **Daily** - Archives only the first successful run that started on that particular day.
   - **Weekly** - From the weekly calendar, select the required days in a week. You can also set the archival schedule for n-number of weeks.
   - **Monthly** - Use the **On** dropdown to select the archival schedule:
     - **First** - First selected day of the month.
     - **Second** - Second selected day of the month.
     - **Third** - Third selected day of the month.
     - **Fourth** - Fourth selected day of the month.
     - **Last** - Last selected day of the month.

       Then, choose the specific day of the week from the adjacent dropdown.
     - **Date** - From the pre-built calendar, select the required date.
   - **Yearly** - From the **On** dropdown, select the required available options:
     - **First Day** - First day of the year.
     - **Last Day** - Last day of the year.
     - **Date** - From the pre-built calendar, select a required date of the year.

e. **Retain for xx days:**

   Full/Incremental Backups

   Specify how long the snapshots are retained on the external target.

> **Note:**
> - Cloud archive snapshots are expired per the retention policy. However, the garbage collection of the expired cloud archive snapshots happens in the background. The expired cloud archive snapshots will be garbage collected from the External Target once there are no active Cloud archive snapshots sharing data with them.
> - You cannot delete the latest archive snapshot as it might be needed in the future. However, if you still want to delete the archive snapshot, you must contact Cohesity Support.
> - The retention period is applicable only to the database backup and not the log backup.
> - The **Retain** option can be set to a maximum value of 365000.

Log Backups

Specify how long the log backup snapshots are retained on the external target.

> **Note:** The Retain option can be set to a maximum value of 365000.

You can add additional archive schedules.

> **Note:** If you specify multiple archive schedules with the same external target that archives the same set of snapshots with different retention periods, the snapshots are retained for the longest specified time period.

f. **Lock**: Specify how many days, weeks, months, or years the retained snapshots should be locked. You cannot delete the snapshots during the specified period.

> **Note:**
> - This option is available only if you have enabled the **DataLock** option at the policy level.
> - The DataLock duration must be less than or equal to the retention period.

g. To add an additional archival schedule, repeat these steps. To archive to multiple External Targets clusters, create multiple replication schedules with different External Targets.

> **Important:** If you specify multiple archival schedules with the same External Targets that archive the same set of snapshots but with different retention periods, the snapshots are retained for the longest time period. For example if you define two archival schedules with the same External Targets that retain the same set of snapshots but one schedule specifies a 90 day retention period and other schedule specifies a 180 day retention period, the set of snapshots are retained for 180 days.

For archival, the extended retention schedule is as follows:

- **Weekly**: The first successful run that started on a Sunday or later.
- **Monthly**: The first successful run that started on the first day of the month or later.
- **Yearly**: The first successful run that started on the first day of the year or later.

19. **Add CloudSpin:** Select this option to add a CloudSpin schedule. For more information, see Clone VMs to AWS Cloud Using CloudSpin.
    a. **CloudSpin to:** Select an existing cloud source or register a new cloud source. A cloud source is a cloud service instance where the snapshots are converted and copied **to**. For details about the different fields, see the appropriate source topic:
        - Register an Azure Cloud Source at Subscription Level
        - Register an AWS Cloud Source
    b. **After every run:** Specify how often snapshots are converted and copied to the cloud source.
    c. **Retain for xx days:** Specify how long the snapshots are retained on the cloud source.

> **Note:** The **Retain** option can be set to a maximum value of 365000.

    d. **Lock**: Specify how many days, weeks, months, or years the retained snapshots should be locked. You cannot delete the snapshots during the specified period.

> **Note:** This option is available only if you have enabled the **DataLock** option at the policy level.

e. **CloudSpin only fully successful Runs:** Check this box displays if you want converting and copying to occur only if the protection run successfully backs up all the protected objects, such as 10 out of 10 VMs. For example, if a protection run backs up only 7 out of 10 VMs, and this check box is selected, the protection run will not be converted and copied. If a protection run backs up only 7 out of 10 VMs, and this check box *is not* selected, the protection run can be converted and copied to a cloud source.

f. Specify the appropriate settings for the cloud service:

AWS

Select the Cloud Region in AWS where the VM should be copied to. For more information, see AWS Regions.

You can optionally add **Tags** to the resources by clicking **Add Tag**. These tags are key-value pairs that will be assigned to all the temporary and permanent resources created during Cloudspin. The maximum number of tags allowed is 40.

Azure

Resource Group—Select the Azure Resource Group where the converted VM image should be copied to.

Storage Account—Select an Azure Storage Account to use when copying the converted VM image.

Storage Container—Select an Azure Storage Container in the Storage Account to hold the converted VM image.

20. Click **Create**.

When editing an existing policy that is configured to capture backup snapshots on a minutes or hourly time schedule and you change the schedule to occur daily, weekly or monthly, you are prompted to specify a start time for each of the Protection Groups that use this policy.

The policy is immediately available to use in Protection Groups.

Note:

- For Cohesity 6.6 and higher versions, on NoSQL platforms, when you pause the backup job for a longer time than the retention period, the last successful snapshot will not be deleted even after the retention period expired on that snapshot.
- For Cohesity 6.6 and higher versions, the last snapshot is always retained on HDFS/HBase/Hive, MongoDB, Cassandra, and CouchBase platforms.

Considerations

- By default, all backups are incremental unless manually switched to Full. However, if no previous incremental backup exists for a specific object, a full backup will be automatically initiated, potentially generating warnings for certain applications.
- When scheduling a continuous backup policy, the protection run does not honor the start time.

  For example, specify a policy to capture the continuous backup at 9 AM every day with a periodicity of 7 hours.

Days	Description
Day 1	• First backup - 9 AM • Second backup - 4 PM (after 7 hours) • Third backup - 11 PM
Day 2	• First backup - 6 AM • Second backup - 1 PM In this example, on Day 2 the backup did not start at 9 AM.

Manage Policies

A standard policy must be associated with a Protection Group to protect objects.

Use the default standard policies or create your own custom policies. Policies save time because you do not need to repetitively enter settings. For more information, see Default Policies.

From the policy manager, you can create a new protection policy. For more information, see Create or Edit a Standard Policy.

You can also view policy settings, copy, edit and delete policies using the actions for each policy.

Column Name	Description / Action
Policy Name	Drill-down on this link to view the settings for the policy.
Organization	The name of the organization to which the policy belongs.
Backup	Snapshots are stored in the current (local) Cohesity cluster and there are one or more extended retention rules.
Replication	Snapshots are stored in the current (local) Cohesity cluster and are archived in the cloud.
Archive	Snapshots are stored in the current (local) Cohesity cluster and are archived in the cloud.
CloudSpin	Snapshots are stored in the current (local) Cohesity cluster and are archived in the cloud.
Actions	To manage an existing policy, click the actions menu (⋮) select one of the following options: • **Copy**( )–Create a new policy from an existing policy. • **Edit** ( )–Configure the settings of an existing policy. Follow the instructions provided in Create or Edit a Standard Policy. • **Delete** ( )–Delete this policy. If a Protection Group is based on a policy and the policy is deleted, the Protection Group keeps the original settings and is not deleted.

> **Note:** For jobs protecting servers, indexing is set at the Protection Group level.

Default Policies

The following default standard policies are provided:

- Gold
  - Take a snapshot every 4 hours and retain it for 7 days.
  - The first snapshot taken every day is retained for 90 days.
  - The first snapshot taken every week is retained for 365 days.
  - The first snapshot taken every month is retained for 1095 days.
  - Retry capturing snapshots 3 times every 5 minutes before reporting an error

- Silver
  - Take a snapshot every 12 hours and retain it for 14 days.
  - The first snapshot taken every day is retained for 90 days.
  - The first snapshot taken every week is retained for 365 days.
  - The first snapshot taken every month is retained for 730 days.
  - Retry capturing snapshots 3 times every 5 minutes before reporting an error
- Bronze
  - Take a snapshot every day and retain it for 30 days.
  - The first snapshot taken every week is retained for 90 days.
  - The first snapshot taken every month is retained for 365 days.
  - Retry capturing snapshots 3 times every 5 minutes before reporting an error
- Protect Once
  - Take a FULL snapshot and retain it for 14 days

> **Note:** Objects protected with the Protect Once policy are considered as unprotected if no other policy covers them. They may have valid snapshots but no ongoing protection.

> **Note:**
> Use the Protect Once policy only for a one-time activity, as Protection Groups using the Protect Once policy cannot be edited to remove or modify individual sources. This policy is intended to protect all included objects as a single unit.
>
> To make changes, consider the following options:
>
> - Wait for snapshots to expire, then delete and recreate the Protection Group.
> - Delete the Protection Group and all associated snapshots (if no longer needed).
> - Create a new Protection Group with the desired sources.

Customize Indexing

Toggle on **Indexing**, click **Add Inclusion** or **Add Exclusion** and enter a directory. Click the **X** to delete a directory from the list.

By default, the root directory (`/`) is included and entire file system is indexed. When a directory is indexed, its sub-directories are also indexed.

You can limit indexing to a specific set of files and directories to minimize the disk space used by the index. For example, you could add two additional rules to the first default rule:

- include `/`
- exclude `/var`
- include `/var/log`

In this example, all files in the `/` root directory are indexed except the files found in the `/var` directory. However, the files in the `/var/log` are indexed because there is an explicit include rule.

Include and Exclude Rules:

- Use forward slashes (/) for both Windows and Unix as the separator character.
- Do not specify the drive letter and colon in front of the directory path for Windows.
- Drive letters are allowed for Windows systems to limit the drives searched for a specified path.
- If **no drive** is specified then **all** drives for which the path is found are indexed.

Examples	Description
/C/Users	On Windows, include or exclude Users directory in C:\Users
/Users	On Windows, include or exclude Users directories in all drives, i.e. C:\Users, D:\Users.
/var/log	On Linux or Unix, include or exclude /var/log directory.

The default directory inclusion/exclusion list are as follows:

- include /
- exclude /$Recycle.Bin
- exclude /Windows
- exclude /Program Files
- exclude /Program Files (x86)
- exclude /ProgramData
- exclude /System Volume Information

- exclude /Users/*/AppData
- exclude /Recovery
- exclude /var
- exclude /usr
- exclude /sys
- exclude /proc
- exclude /lib
- exclude /grub
- exclude /grub2
- exclude /opt/splunk
- exclude /splunk

Excluding Pseudo Filesystems from Indexing

In a Linux operating system, specific filesystems, such as /sys, /proc, /dev, /run, /tmp, /dev/pts, and /dev/shm, are dynamically generated by the kernel during system boot. These filesystems are commonly referred to as 'pseudo filesystems' or 'virtual filesystems.' Their contents are unique to the system and temporary, meaning they do not persist beyond system reboots.

Due to their transient nature, Cohesity does not recommend indexing these pseudo filesystems. Attempting to index them not only lacks practical utility but may also result in inaccurate or inconsistent indexing outcomes.

Configure Pre & Post Scripts

Cohesity provides you the option to run user-defined scripts as a part of the Protection Group. When creating a Protection Group, you can configure:

- Pre Scripts: Scripts that will be executed before the protection run.
- Post Scripts: Scripts that will be executed after the protection run.
- Post Snapshot Scripts: Scripts that will be executed after the snapshot has been created on the source.

Supported Sources

You can run the Pre Script and Post Script for the following sources:

- Physical Servers
- Databases - MS SQL Server and Oracle Database
- NAS
- SAN

Depending on whether the Cohesity Agent is installed on the source, the settings required to configure the pre and post scripts in the Protection Group vary.

Configure Scripts for Sources with Agent Installed

Out of the supported sources for pre and post-scripts, physical servers and databases require Cohesity Agent to be installed on the source.

Following are the settings required for configuring the pre and post scripts for sources with Agent installed:

Pre-Script

- **Script Path**: Depending on the agents, specify the full path or name of the script as mentioned in the **Note** section below. A script matching the specified name must be available in the user_scripts directory found in the agent installation directory on the protected server. (See the table below for details about the directory path.) The script can be in any format, for example: shell script, batch file, executable (`.exe`), etc. The script must be configured with the permissions to allow execution (`+x`).

> **Note:**
> - For Physical servers, MS SQL server and Oracle, only the script name is required (provided the script is available in the `user_scripts` directory found in the agent installation directory).
> - For NAS and SAN sources, the absolute/full path to the script is required.
> - On Windows platforms, PowerShell, Python, or Perl scripts (any script that is not a .exe file) must be embedded within a .bat script before they are called.

> **Important:** Cohesity does not validate the content of the script and is not responsible for the content of the script or any actions done by the script. You must verify the script actions before a script or executable is run.

- **Script Params**: Optional field for passing one or more parameters to the script. All specified parameter values are passed as a single string to the script.
- **Timeout**: Optional field for specifying how long a script is allowed to execute before the Cohesity cluster stops the execution of the script. By default, the timeout is 15 minutes. If no value is specified, there is no timeout and the script is not stopped. This can cause a protection run to hang if the script never completes. The timeout is applied from the moment the script starts. For example, if the timeout is set to 15 minutes but the script takes 20 minutes to complete, it will be stopped after 15 minutes. Therefore, users should set the timeout based on the expected runtime of the script to avoid premature termination.
- **Continue Backup if script fails**: This toggle applies only to Pre-Scripts and is enabled by default. When this toggle is enabled, the Protection Group backs up the objects even if the Pre-Script fails. If this toggle is disabled and the Pre-Script fails, the backup is canceled but the Post-Script still runs.

Post-Script

- **Script Path**: Depending on the agents, specify the full path or name of the script as mentioned in the **Note** section below. A script matching the specified name must be available in the specified directory. The script can be in any format, such as a shell script or executable. The script must be configured with the permissions to allow execution (+x).

> **Note:**
> - For Physical servers, MS SQL server and Oracle, only the script name is required (provided the script is available in the user_scripts directory found in the agent installation directory).
> - For NAS and SAN sources, the absolute/full path to the script is required.
> - On Windows platforms, PowerShell, Python, or Perl scripts (any script that is not a .exe file) must be embedded within a .bat script before they are called.

> **Warning:** Cohesity does not validate the content of the script and is not responsible for the content of the script or any actions done by the script. You must verify the script actions before a script or executable is run.

- **Script Params**: Optional field for passing one or more parameters to the script. All specified parameter values are passed as a single string to the script.
- **Timeout**: Optional field for specifying how long a script is allowed to execute before the Cohesity cluster stops the execution of the script. By default, the timeout is 15 minutes. If no value is specified, there is no timeout and the script is not stopped. This can cause a protection run to hang if the script never completes. The timeout is applied from the moment the script starts. For example, if the timeout is set to 15 minutes but the script takes 20 minutes to complete, it will be stopped after 15 minutes. Therefore, users should set the timeout based on the expected runtime of the script to avoid premature termination.

When the post-script is enabled, it runs irrespective of the pre-script run status.

More about failures, cancellations and log files:

- If the backup is successful but the Pre-Script or Post-Script fails, a warning is issued with the script error. A script failure occurs for any of the following conditions:
  - script is not found in the expected location
  - script cannot be executed
  - script returns a failure return code of non-zero

  A script is successful when the return code is 0.
- If a Post-Script is configured, the script always executes even if the backup fails.
- If a protection run is canceled, all subsequent phases are canceled.
  - For example, if a protection run is canceled while the Pre-Script is running, the Pre-Script is canceled, then the backup task is canceled and then the Post-Script is canceled.
  - For example, if a protection run is canceled while the backup task is running, the backup task is canceled and then the Post-Script is canceled.
- Script execution log files can be found in the `user_script_logs` directory found in the agent log directory on the protected server. Both Stdout and Stderr from the script execution are recorded in the script log files. (See the table below for details about the directory path.)

Available Environment Variables

The Cohesity cluster populates the following environment variables with values before the Pre-Script or the Post-Script is run. You can use these environment variables in your script.

Variable Name	Available from Script	Description
`COHESITY_JOB_ID`	Pre-Script and Post-Script	Specifies the Cohesity id assigned to the Protection Group.
`COHESITY_JOB_NAME`	Pre-Script and Post-Script	Specifies the name of the Protection Group as displayed in the Cohesity Dashboard.
`COHESITY_BACKUP_TYPE`	Pre-Script and Post-Script	`kRegular` indicates an incremental (CBT) backup. Incremental backups utilizing CBT (if supported) are captured of the target protection objects. The first run of a kRegular schedule captures all the blocks. `kFull` indicates a full (no CBT) backup. A complete backup (all blocks) of the target protection objects are always captured and Change Block Tracking (CBT) is not utilized. `kLog` indicates a database log backup. Capture the database transaction logs to allow rolling back to a specific point in time. `kSystem` indicates a system backup. System backups are used to do bare metal recovery of the system to a specific point in time. (*Applies only to IBM*) `kStorageArraySnapshot` indicates storage array snapshot backup. This backup method creates point-in-time snapshots of data on a storage array, allowing for data protection and recovery without impacting the primary storage's performance.
`COHESITY_JOB_STATUS`	Post-Script	SUCCEEDED indicates the protection run ran successfully. ERRORED indicates the protection run reported an error.

> **Note:**
> To access an environment variable in PowerShell, use:`$env:<variable name>`.
>
> Example
>
> `Write-Host "COHESITY_BACKUP_HOST_ENTITY =" $env:COHESITY_BACKUP_HOST_ENTITY`

The following is a sample script for Linux

```
#!/bin/bash
echo "Hello...This is a sample script".
```

```
sleep 60
echo "Executing Script"
```

The following is a sample script for Windows

```
net start OracleOraDB12Home1TNSListener
net start OracleServiceMUC99
net start OracleServiceCATPRD
@oradim -startup -sid MUC99
@oradim -startup -sid CATPRD
```

Paths to User Scripts and Script Logs for Various Agents

Operating Systems	Directory Path Description	Path
Linux	Where Pre-Script and Post-Script must be stored to be found by the Cohesity cluster.	`INSTALL_DIR/user_scripts`
	Where the script execution logs are written by the Cohesity cluster when the script is run.	`INSTALL_DIR/logs/user_script_logs/`
	If the agent is installed using the `cohesityagent` user, the default `INSTALL_DIR` is...	`/home/cohesityagent/cohesityagent/`
	If the agent is installed using the `root` user, the default `INSTALL_DIR` is...	`/root/cohesityagent`
Windows	Where Pre-Script and Post-Script must be stored to be found by the Cohesity cluster.	`INSTALL_DIR\user_scripts`
	The default `INSTALL_DIR` is...	`C:\Program Files\Cohesity`
	Where the script execution logs are written by the Cohesity cluster when the script is run.	`C:\ProgramData\Cohesity\user_script_logs`
Solaris **AIX** **RHEL 5.x**	Where Pre-Script and Post-Script must be stored to be found by the Cohesity cluster.	`INSTALL_DIR/user_scripts`
	The default `INSTALL_DIR` is...	`/usr/local/cohesity/agent`
	Where the script execution logs are written by the Cohesity cluster when the script is run.	`LOG_DIR/user_script_logs`
	The default `LOG_DIR` is...	`/var/log/cohesity/agent`

Configure Scripts for Sources without Agent Installed

Out of the supported sources for pre and post-scripts, NAS and SAN sources do not require Cohesity Agent to be installed on the source.

Following are the settings required for configuring the pre and post scripts for sources without Agent installed:

- **Hostname or IP Address (Unix only)**: Specify either the hostname or the IP address of the remote Unix server where the script will run. (Only Unix is currently supported.)
- **Cluster SSH Public Key**: Click Copy Key to Clipboard to copy the entire string including the ssh-rsa string preceding the key, the public key and the username@cluster_name string after the key. Open the authorized_keys file (typically located in the ~/.ssh directory) and paste the entire string to the end of the file.
- **Username**: Specify the username on the remote Unix machine that will execute the script. The username must match the username specified in the authorized_keys file.

You can configure a Pre-Script, a Post-Script or both scripts.

Pre-Script

- **Script Path**: Depending on the agents, specify the full path or name of the script as mentioned in the **Note** section below. A script matching the specified name must be available in the specified directory. The script can be in any format, such as a shell script or executable. The script must be configured with the permissions to allow execution (+x).

> **Note:**
> - For Physical servers, MS SQL server and Oracle, only the script name is required (provided the script is available in the user_scripts directory found in the agent installation directory).
> - For NAS and SAN sources, the absolute/full path to the script is required.

> **Warning:** Cohesity does not validate the content of the script and is not responsible for the content of the script or any actions done by the script. You must verify the script actions before a script or executable is run.

- **Script Params**: Optional field for passing one or more parameters to the script. All specified parameter values are passed as a single string to the script.
- **Timeout**: Optional field for specifying how long a script is allowed to execute before the Cohesity cluster stops the execution of the script. By default, the timeout is 15 minutes. If no value is specified, there is no timeout and the script is not stopped. This can cause a protection run to hang if the script never completes. The timeout is applied from the moment the script starts. For example, if the timeout is set to 15 minutes but the script takes 20 minutes to complete, it will be stopped after 15 minutes. Therefore, users should set the timeout based on the expected runtime of the script to avoid premature termination.
- **Continue Backup if script fails**: This toggle applies only to Pre-Scripts and is enabled by default. When this toggle is enabled, the Protection Group backs up the objects even if the Pre-Script fails. If this toggle is disabled and the Pre-Script fails, the backup is canceled but the Post-Script still runs.

Post-Script

- **Script Path**: Depending on the agents, specify the full path or name of the script as mentioned in the **Note** section below. A script matching the specified name must be available in the specified directory. The script can be in any format, such as a shell script or executable. The script must be configured with the permissions to allow execution (+x).

  > **Note:**
  > - For Physical servers, MS SQL server and Oracle, only the script name is required (provided the script is available in the user_scripts directory found in the agent installation directory).
  > - For NAS and SAN sources, the absolute/full path to the script is required.

  > **Warning:** Cohesity does not validate the content of the script and is not responsible for the content of the script or any actions done by the script. You must verify the script actions before a script or executable is run.

- **Script Params**: Optional field for passing one or more parameters to the script. All specified parameter values are passed as a single string to the script.
- **Timeout**: Optional field for specifying how long a script is allowed to execute before the Cohesity cluster stops the execution of the script. By default, the timeout is 15 minutes. If no value is specified, there is no timeout and the script is not stopped. This can cause a protection run to hang if the script never completes.

The timeout is applied from the moment the script starts. For example, if the timeout is set to 15 minutes but the script takes 20 minutes to complete, it will be stopped after 15 minutes. Therefore, users should set the timeout based on the expected runtime of the script to avoid premature termination.

When the post-script is enabled, it runs irrespective of the pre-script run status.

More about failures, cancellations and log files:

- If the backup is successful but the Pre-Script or Post-Script fails, a warning is issued with the script error. A script failure occurs for any of the following conditions:
  - script is not found in the expected location
  - script cannot be executed
  - script returns a failure return code of non-zero

  A script is successful when the return code is 0.
- If a Post-Script is configured, the script always executes even if the backup fails.
- If a protection run is canceled, all subsequent phases are canceled.
  - For example, if a protection run is canceled while the Pre-Script is running, the Pre-Script is canceled, then the backup task is canceled and then the Post-Script is canceled.
  - For example, if a protection run is canceled while the backup task is running, the backup task is canceled and then the Post-Script is canceled.
- Script execution log files can be found in the `user_script_logs` directory found in the agent log directory on the protected server. Both Stdout and Stderr from the script execution are recorded in the script log files. (See the table below for details about the directory path.)

Available Environment Variables

The Cohesity cluster populates the following environment variables with values before the Pre-Script or the Post-Script is run. You can use these environment variables in your script.

Variable Name	Available from Script	Description
`COHESITY_JOB_ID`	Pre-Script and Post-Script	Specifies the Cohesity id assigned to the Protection Group.

Variable Name	Available from Script	Description
`COHESITY_JOB_NAME`	Pre-Script and Post-Script	Specifies the name of the Protection Group as displayed in the Cohesity Dashboard.
`COHESITY_BACKUP_TYPE`	Pre-Script and Post-Script	`kRegular` indicates an incremental (CBT) backup. Incremental backups utilizing CBT (if supported) are captured of the target protection objects. The first run of a kRegular schedule captures all the blocks. `kFull` indicates a full (no CBT) backup. A complete backup (all blocks) of the target protection objects are always captured and Change Block Tracking (CBT) is not utilized. `kLog` indicates a database log backup. Capture the database transaction logs to allow rolling back to a specific point in time. `kSystem` indicates a system backup. System backups are used to do bare metal recovery of the system to a specific point in time. (*Applies only to IBM*) `kStorageArraySnapshot` indicates storage array snapshot backup. This backup method creates point-in-time snapshots of data on a storage array, allowing for data protection and recovery without impacting the primary storage's performance.
`COHESITY_JOB_STATUS`	Post-Script	SUCCEEDED indicates the protection run ran successfully. ERRORED indicates the protection run reported an error.
`COHESITY_BACKUP_VOLUME_SNAPSHOT_SUFFIX`	Pre-Script	Contains the suffix Cohesity uses for creating the Pure Storage Volume snapshot.
COHESITY_BACKUP_GROUP_SNAPSHOT_SUFFIX	Post-Script	Contains the suffix Cohesity uses for creating the Pure Protection Group snapshot.

DataLock

DataLock is the Cohesity WORM (write once read many) feature that locks and retains files for compliance and regulatory purposes and to protect the files from accidental deletion.

DataLock enables your storage to be WORM-compliant to ensure the snapshot is not aged prematurely. When it is enabled, your data such as backups and archives cannot be deleted by anyone, including administrators, until the DataLock expires. This retention lock helps to prevent ransomware attacks on your clusters.

> **Note:** The contents of backups cannot be modified because of Cohesity SpanFS's immutable file system design.

The Cohesity Dashboard displays a lock ( ) icon to indicate DataLocked policies and snapshots.

Features of DataLock

- You can apply DataLock for each schedule (such as backup, extended retention, archive, and replication) defined in the Protection Policy.
- You can specify DataLock duration in days, weeks, months, or years for each schedule defined in the Protection Policy.

Considerations

- The DataLock expiry date:
  - Doesn't get extended if you extend the snapshot retention time of the runs that were created after the extension.
  - Gets extended if you extend the snapshot retention time of the runs that were created before the extension.
- Using DataLock with longer snapshot retention periods and for auto-protected sources can result in the cluster running out of space.
- DataLock retention must be less than or equal to backup retention.

Policy

The following table provides DataLock details when creating a protection policy by a user with a Data Security role (DSO) and a Non-Data Security role.

Workflow	Data Security	Non-Data Security
Create Policy	• DataLock is enabled by default when creating a protection policy, replication target, archival target, and CloudSpin. • Disable DataLock for backup, replication, archive, and CloudSpin. • Edit both backup retention and the Lock retention period.	• DataLock is enabled by default when creating a protection policy, replication target, archival target, and CloudSpin. • Disable DataLock for backup, replication, archive, and CloudSpin. • Edit both backup retention and the Lock retention period.
Edit Policy	• Able to edit the DataLock setting for backup, replication, archival, and CloudSpin. • You can add a new replication, archival or CloudSpin target, and to add DataLock for a target, click **Add DataLock**. • Able to edit both backup retention and the Lock retention period. • Delete targets irrespective of the DataLock setting.	• Unable to edit the DataLock setting for backup, replication, archival, and CloudSpin. • You can add a new replication, archival or CloudSpin target without DataLock because **Add DataLock** is disabled. • Unable to edit the Lock retention period but the backup retention can be modified. • Targets with DataLock enabled cannot be deleted.

Protection

The following table provides DataLock details when created by a user with a Data Security role (DSO) and a Non-Data Security role.

Workflow	Data Security	Non-Data Security
Run Now	• Able to edit the backup retention period. • Able to add a new target but the DataLock setting is not available. • If you want to specify DataLock for a new target it must be enabled when creating or editing the protection policy. • Delete existing targets irrespective of the DataLock setting.	• Able to edit the backup retention period. • Able to add a new target but the DataLock setting is not available. • If you want to specify DataLock for a new target it must be enabled when creating the protection policy. • Delete existing targets irrespective of the DataLock setting.

Workflow	Data Security	Non-Data Security
Edit Run	• Able to edit the backup retention period. • Able to add a new target but the DataLock setting is not available. If you want to add DataLock to a new target it must be enabled when creating or editing the protection policy. • Unable to delete existing targets. • Delete the DataLocked snapshot only if the Lock retention period expires or DataLock is disabled on the snapshot.	• Able to edit the backup retention period. • Able to add a new target but the DataLock setting is not available. If you want to add DataLock to a new target it must be enabled when creating the protection policy. • Unable to delete existing targets. • Delete the DataLocked snapshot if the Lock retention period expires or DataLock is disabled on the snapshot.

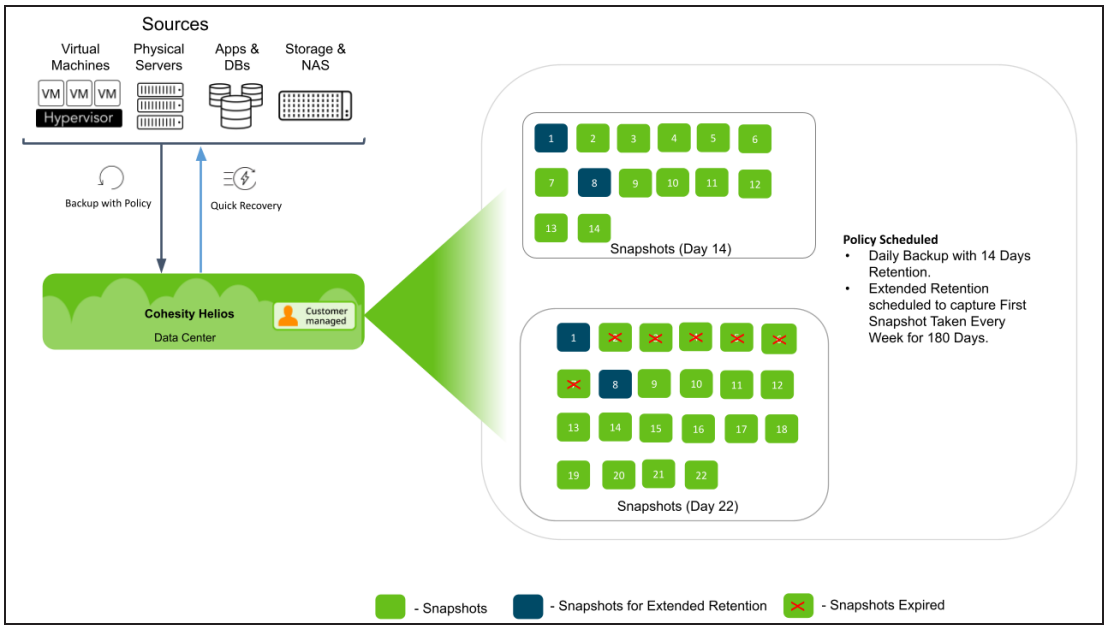
Upgrade

Upgraded Cluster	New Cluster
• No change to the existing system and user-created policies. • DataLock is enabled by default when creating a new policy. • You can disable DataLock on specific targets (Backup, Replication, Archival, and CloudSpin) when creating a new policy irrespective of the user's role.	• DataLock is enabled by default for both system policy and new policy created by a user. • You can disable DataLock on specific targets (Backup, Replication, Archival, and CloudSpin) when creating a new policy irrespective of the user's role.

Extended Retention

Snapshots selected for extended retention are retained for a longer time than defined in the protection schedule. You can retain the first snapshot of the backup run taken on the specified hours, every run, days, weeks, months, or years for a longer period of time.

> **Note:** The retention period can be set to a maximum value of 365000 days.



The table below lists the options available for protection policy and extended retention policy and the respective outcome.

Backup	Extended Retention	Description	Example
Every	Retain the First Snapshot taken every		

Backup	Extended Retention	Description	Example
Minutes	Run	The first snapshot captured after every run is retained for the specified number of days in the extended retention policy.	
	Hours	The first snapshot captured during the specified hour is retained for the number of days as mentioned in the extended retention policy. Every subsequent snapshot captured during the hour is retained for the number of days specified in the protection policy.	Define a protection policy that captures snapshots every 10 minutes and retains the snapshots for 14 days. Specify an extended retention policy to capture the first snapshot taken every hour and retain the snapshot for 28 days. **6:38PM** - The first backup starts. The snapshot captured is retained for an extended period of 28 days because this is the first snapshot in the hour 6PM - 7PM. **6:48PM** - The snapshot captured is retained for 14 days. **6:58PM** - The snapshot captured is retained for 14 days. **7:08PM** - The snapshot captured is retained for 28 days as this is the first snapshot in the hour 7PM - 8PM.

Backup	Extended Retention	Description	Example
	Days	The first snapshot captured on the specified day is retained for the number of days as mentioned in the extended retention policy. Every subsequent snapshot captured is retained for the number of days specified in the protection policy.	Define a protection policy that captures snapshots every 10 minutes and retains the snapshot for 14 days. Specify an extended retention policy to capture the first snapshot taken every day and retain it for 28 days. **6:30PM (Day 1)** - The first backup starts. The snapshot captured is retained for an extended period of 28 days because this is the first snapshot for Day 1. **6:40PM (Day 1)** - The snapshot captured is retained for 14 days. **11:50PM (Day 1)** - The snapshot captured is retained for 14 days. **12:00AM (Day 2)** - The snapshot captured is retained for an extended period of 28 days because this is the first snapshot for Day 2.

Backup	Extended Retention	Description	Example
	Weeks	The first snapshot captured during the specified week is retained for the number of days as mentioned in the extended retention policy. Every subsequent snapshot captured is retained for the number of days specified in the protection policy.	Define a protection policy that captures snapshots every 10 minutes and retains the snapshot for 14 days. Specify an extended retention policy to capture the first snapshot taken every week and retain the snapshot for 28 days. Assuming the week starts on Sunday: **Week 1, Sunday 6:30PM** - The snapshot captured is retained for 28 days. **Week 1, Thursday 8:30PM** - The snapshot captured is retained for 14 days. **Week 1, Saturday 11:50PM** - The snapshot captured is retained for 14 days. **Week 2, Sunday 12:00AM** - The snapshot captured is retained for 28 days.
	Months	The first snapshot captured during the specified month is retained for the number of days as mentioned in the extended retention policy. Every subsequent snapshot captured is retained for the number of days specified in the protection policy.	Define a protection policy that captures snapshots every 10 minutes and retains the snapshot for 14 days. Specify an extended retention policy to capture the first snapshot taken every month and retain the snapshot for 28 days. **January** - The first snapshot captured is retained for 28 days. Every subsequent snapshot captured in the month is retained for 14 days. **February** - The first snapshot captured is retained for 28 days. Every subsequent snapshot captured in the month is retained for 14 days.

Backup	Extended Retention	Description	Example
Days	Run	Cohesity recommends configuring the Extended Retention policy always more than the scheduled backup policy.	

Backup	Extended Retention	Description	Example
	Hours		

Backup	Extended Retention	Description	Example
	Days	The first snapshot captured during the specified day is retained for the number of days as mentioned in the extended retention policy. Every subsequent snapshot captured is retained for the number of days specified in the backup policy.	Define a backup policy that captures snapshots every day and retains the snapshot for 14 days. Specify an extended retention policy to capture the first snapshot taken every 2 days and retain the snapshot for 28 days. **7:00PM (Day 1)** - The first backup starts. The snapshot captured is retained for an extended period of 28 days. **7:00PM (Day 2)** - The snapshot captured is retained for 14 days. **7:00PM (Day 3)** - The snapshot captured is retained for an extended period of 28 days. **7.00PM (Day 4)** - The snapshot captured is retained for 14 days.
	Weeks	The first snapshot captured during the specified week is retained for the number of days as mentioned in the extended retention policy. Every subsequent snapshot captured is retained for the number of days specified in the backup policy.	Define a backup policy that captures every day and retains it for 14 days. Specify an extended retention policy to capture the first snapshot taken every week and retain the snapshot for 28 days. Assuming the week starts on Sunday: **Week 1, Sunday 6:30PM** - The snapshot captured is retained for 28 days. **Week 2, Sunday 6:30PM** - The snapshot captured is retained for 28 days.

Backup	Extended Retention	Description	Example
	Months	The first snapshot captured during the specified month is retained for the number of days as mentioned in the extended retention policy. Every subsequent snapshot captured is retained for the number of days specified in the backup policy.	Define a backup policy that captures snapshots every day and retains the snapshot for 14 days. Specify an extended retention policy to capture the first snapshot taken every month and retain the snapshot for 28 days. **January** - The first snapshot captured is retained for 28 days. Every subsequent snapshot captured in the month is retained for 14 days. **February** - The first snapshot captured is retained for 28 days. Every subsequent snapshot captured in the month is retained for 14 days.

Backup	Extended Retention	Description	Example
Week	Run	Cohesity recommends scheduling the Extended Retention policy always more than the scheduled backup policy.	

Backup	Extended Retention	Description	Example
	Hours		

Backup	Extended Retention	Description	Example
	Days		

Backup	Extended Retention	Description	Example
	Weeks	The first snapshot captured during the specified week is retained for the number of days as mentioned in the extended retention policy. Every subsequent snapshot captured is retained for the number of days specified in the backup policy.	Define a backup policy that captures snapshots every week and retains the snapshot for 14 days. Specify an extended retention policy to capture the first snapshot taken every two weeks and retain the snapshot for 28 days. Assuming the week starts on Sunday: **Week 1, Sunday 6:30PM** - The snapshot captured is retained for 28 days. **Week 2, Sunday 6:30PM** - The snapshot captured is retained for 14 days. **Week 3, Sunday 6:30PM** - The snapshot captured is retained for 28 days.

Backup	Extended Retention	Description	Example
	Months	The first snapshot captured during the specified week is retained for the number of days as mentioned in the extended retention policy. Every subsequent snapshot captured is retained for the number of days specified in the backup policy.	Define a backup policy that captures snapshots every week and retains the snapshot for 14 days. Specify an extended retention policy to capture the first snapshot taken every month and retain the snapshot for 28 days. Assuming the week starts on Sunday: **Week 1, Sunday 6:30PM** - The snapshot captured is retained for 28 days. **Week 2, Sunday 6:30PM** - The snapshot captured is retained for 14 days. **Week 3, Sunday 6:30PM** - The snapshot captured is retained for 14 days. **Week 4, Sunday 6:30PM** - The snapshot captured is retained for 14 days.

Backup	Extended Retention	Description	Example
Month	Run	Cohesity recommends scheduling the Extended Retention policy always more than the scheduled backup policy.	
	Hours		
	Days		
	Weeks		
	Months	The first snapshot captured during the specified month is retained for the number of days as mentioned in the extended retention policy. Every subsequent snapshot captured is retained for the number of days specified in the backup policy.	Define a backup policy that captures snapshots every month and retains the snapshot for 14 days. Specify an extended retention policy to capture the first snapshot taken every two months and retain the snapshot for 28 days. **January, February** - The first snapshot captured is retained for 28 days. Every subsequent snapshot captured in the month is retained for 14 days. **March, April** - The first snapshot captured is retained for 28 days.

You can create one or more extended schedules.
For example, you could define a protection schedule that captures snapshots every hour and retains them on the Cohesity cluster for 1 day. This protection schedule retains 24 sets of snapshots on a rotating basis, each hour a new set of snapshots are retained and the oldest set of snapshots is deleted.
If you want to retain a subset of these snapshots for a longer period of time, you could define an additional extended retention schedule to retain a single subset of snapshots daily for 90 days. This extended retention schedule retains 90 sets of snapshots on a rotating basis, each day a new set of snapshots are retained and the oldest set of snapshots is deleted.

> **Note:** If you specify multiple extended retention rules for the same set of snapshots with different retention periods, the snapshots are retained for the longest specified time period. For example if you define two extended retention rules that retain the same set of snapshots but one rule specifies a retention period of 90 days and another specifies a retention period of 180 days, the set of snapshots are retained for 180 days.

The extended retention schedule for backups is based on calendar-based scheduling for weekly, monthly, and yearly. For archive, replication, and CloudSpin; the extended retention schedule is as follows:

- **Weekly**: The first successful run that started on a Sunday or later.
- **Monthly**: The first successful run that started on the first day of the month or later.
- **Yearly**: The first successful run that started on the first day of the year or later.

For backup schedule, Cohesity allows you to set the day for weekly backup and any day of the week for monthly backup.

> **Note:** If a backup fails, the extended retention is applied to the next scheduled snapshot taken by the Cohesity cluster. However, if a manual backup was run in place of the failed backup after selecting "all objects" when selecting the VMs, extended retention is applied to the manual snapshot. For example, you've set the extended retention to be applied on the first snapshot on the first of every month. The scheduled backup on Feb 1st fails. After selecting all the objects (VMs), you run a manual backup successfully. The extended retention is applied to the snapshot of the manual backup.

Chapter 8: SmartFiles (File and Object Services)

This chapter includes the following topics:

- SmartFiles (File and Object Services) Overview 1132
- Ideal Use Cases for SmartFiles 1135
- Fundamentals of SmartFiles 1137
- Cohesity Views 1149
- File Shares (SMB) 1211
- Network File System (NFS) 1241
- Objects (S3) 1259
- SmartFiles Dashboard 1306
- OpenStack Integration 1323
- NAS Tiering 1338
- File Services Audit Logs 1361
- Antivirus Software to Protect Cluster Data 1370
- Access Management 1374

SmartFiles (File and Object Services) Overview

Cohesity SmartFiles is an enterprise-class, software-defined, data-centric, multiprotocol file and object solution for the enterprise that transcends traditional offerings in terms of manageability, scale, security, efficiency and multi-tiered data management. SmartFiles modernizes and simplifies data and application management by providing one platform for multiple workloads. It is a modern converged target for consolidating data silos and securely managing unstructured content and application data, including digital libraries, archives, rich media, video surveillance, big data, and backup data sets.

You can use Cohesity file and object services for the following use cases:

- **Backup targets**—Store backups from other products, such as Veeam. Reduce storage requirements with automatic deduplication and compression.
- **Home directories**—Create personal folders for Windows and Linux users. Use ID mapping to ensure consistent access control. Establish view user quotas and block certain file types. Create share aliases to simplify access.
- **Corporate file shares**— Store, access and share company files and documents. Lock and retain files for compliance and regulatory purposes.
- **Video and image stores**—Stream videos and store images of virtually any file size.
- **Archiving and tiering**—Archive infrequently used data to public clouds for long-term retention. Use cloud tiering for seamless capacity expansion into the cloud. Replicate into the cloud for disaster recovery and test/dev operations.
- **PACS images**—Store digital medical images for compliance and disaster recovery purposes. Use built-in antivirus software to protect against any viruses and ransomware. Lock and retain files for HIPAA compliance.
- **AWS S3 integration**—Use Cohesity cluster instead of S3 buckets.

Key Components

SmartFiles uses the following Cohesity cluster components:

- **Storage domains**—A named storage location on a cluster. When a cluster is created, it contains a default storage domain. You can create additional storage domains and customize them for the intended use case.

  When you create a storage domain, you define its options, including deduplication, compression, encryption, quotas, fault tolerance and erasure coding. Storage domains contain views.

- **Views**—A named storage location in a storage domain used for storing user data such as files, backup snapshots, objects and cloned VMs.

When you create a view, it inherits some options, like deduplication and compression, from its storage domain, but you can override them. You also define attributes such as access protocols, a Quality of Service policy, security settings, quotas, WORM (DataLock), file filtering and more.

Views are automatically assigned protocol-specific mount paths so they can be used as NFS exports and SMB shares.

Before a client system can mount a view, the client system's subnet must be added to the allowlist in the Cohesity cluster.

- **Allowlists**—Lists of subnets. Systems with IP addresses in those subnets can mount and access views. The Cohesity cluster supports global, view-level and share-level allowlists.

Supported Access Protocols

SmartFiles supports the following protocols for accessing views from client systems:

- NFS 3.0 and NFS 4.1—Mount a View Using NFS
- SMB 3.0 and SMB 2.x—Mount a View Using SMB
- AWS S3—Objects (S3)

Optimize for the Use Case

You can and should configure storage domains and views for the expected use case. For example, the data stored in a view can be written to faster SSD storage or slower, less expensive HDD storage, depending on the use case. The view's Quality of Service (QoS) policy determines the type of storage used and the latency factor in writing data to the view. The following use cases demonstrate why you might choose one QoS over another.

- **Videos**—Let's say you plan to store surveillance videos from security cameras that are continually streaming videos to a view. This workload entails sequential writes (recording the video) and sequential reads (video playback). Because this workload is not latency-sensitive, the data can be written to slower HDD storage. You can accomplish this by configuring the view with the appropriate QoS policy. In this case, you would use one of the Backup Target QoS policies.
- **Home directories**—Let's say you plan to set up home directories for university students to store their work in. This workload entails random reads and writes. Because this workload is latency-sensitive (students are actively accessing their work), the data should be written to faster SSD storage. In this case, you would use one of the TestAndDev QoS policies.

View and Storage Domain Options at a Glance

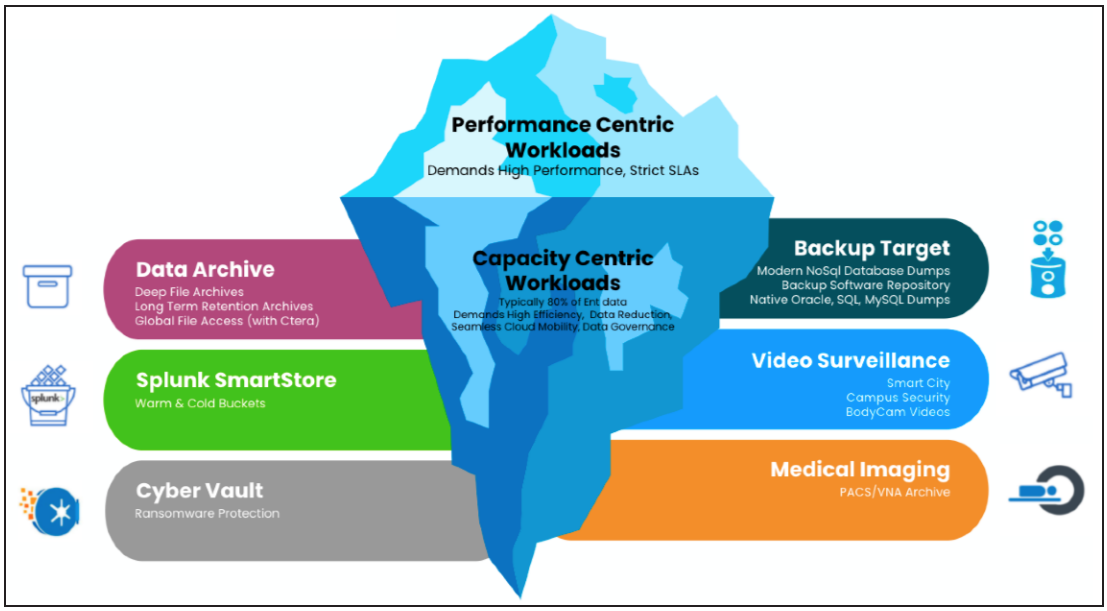
The following table lists configuration options and indicates whether the option is set at the view level or storage domain level.

Category	Option	Description	Setting
Storage efficiency	Deduplication	Eliminates redundant copies of data to reduce storage required on the Cohesity cluster.	Set for storage domain. Inherited by view and can be modified.
	Compression	Further reduces storage requirements with compression algorithms.	
Resiliency	Fault tolerance	Ensures organizations can continue conducting business in the event of a resource outage on the Cohesity cluster.	Storage domain
	Erasure coding	Ensures high availability by distributing data chunks across disks and nodes in the Cohesity cluster.	Storage domain
Security and compliance	Allowlists	Add subnets to allowlists so devices in those subnets can mount and access views using the NFS, SMB, or S3 protocol.	View
	Security styles (Native, Unified or NTFS)	Keep Linux and Windows permissions separate, or keep them in sync so when one changes, the other automatically changes. Or control NFS and SMB access by using the file's SMB ACL.	View
	Encryption	Encrypt data-at-rest and data-in-flight using the industry standard 256-bit Advanced Encryption Standard (AES) in Galois/Counter Mode. Cohesity cluster is also FIPS 140-2 compliant.	View
	Antivirus scanning	Use your choice of antivirus software to protect data on the Cohesity cluster.	View
	DataLock (WORM)	Enable long-term retention of files and prevent modification for compliance and regulatory purposes.	View
	File extension blocking	Allow or disallow certain file types in the view.	View

Category	Option	Description	Setting
Authentication and authorization	Active Directory	Authenticate SMB shares using Active Directory credentials.	View
	NTLM	Authenticate SMB shares based on NTMLv2, for clients that are not part of Active Directory. The clients may be part of Active Directory, but not able to use Kerberos, so they would fall back to using NTLM. Also, if a share is accessed, it would always use NTLM, as Kerberos requires using a Fully Qualified Domain Name (FQDN).	View
	LDAP	Authenticate NFS exports and SMB shares using LDAP credentials.	View
	Multi-protocol access	Automatically map permissions for multi-protocol views if the Cohesity cluster is joined to an Active Directory domain.	View
	RBAC	Create and manage custom Cohesity cluster administration roles for domain users and groups.	View
Quotas	Physical	Limit the physical data capacity for a storage domain.	Set for storage domain. Inherited by view and can be modified.
	Logical	Limit the logical data capacity of a view for users.	
Cold data	Cloud Tier	Automatically move cold, rarely accessed data to a cloud storage external target.	Storage domain
Performance	QoS policy	Optimize latency, throughput and priority of view I/O based on the expected workload.	View

Ideal Use Cases for SmartFiles

Cohesity SmartFiles is a software-defined, data-centric, multiprotocol file and object solution for the enterprise. The following image illustrates a few capacity-centric workloads which are ideal for SmartFiles:



There are dozens of capacity-centric workloads and use cases in which SmartFiles provides benefits. Amongst these use cases are:

- **Backup Target**—Includes the following workloads:
  - Backup software repository for applications such as Veeam Backup & Replication, Commvault Backup & Recovery, IBM Spectrum Protect, and NetBackup AdvancedDisk. For more information, see the following documents:
    - Use Cohesity for Your Veeam Backup Repository
    - Use Cohesity for Your Commvault Storage Libraries
    - Use Cohesity for Your IBM Spectrum Protect Storage Pools
    - Use Cohesity for Your NetBackup AdvancedDisk Storage
  - Database dumps for modern NoSQL applications such as Redis, CockroachDB, Vertica, and MongoDB.
  - Database dumps for traditional applications such as native MySQL, MS SQL, and Oracle SQL. For more information, see the following documents:
    - Streamline Microsoft SQL Server Native Backups with Cohesity
    - Best Practices for Oracle RMAN Backups on Cohesity Views
- **Data Archive**—Long-term retention for digital documents and audio and video files.
- **Splunk SmartStore**—Splunk SmartStore reduces overall cost of ownership by plugging into SmartFiles S3 views.
- **Video Surveillance**—Repository for surveillance videos captured using applications such as Milestone. Smart cities and campuses can use SmartFiles for storing videos.
- **Medical Imaging**—PACS archives and VNA archives.

- **Cyber Vault**—Long-term retention of data in an immutable format using Cohesity DataLock or S3 Object Lock and Legal Hold.

Fundamentals of SmartFiles

The following topics introduce you to key file and object services concepts:

About Deduplication

Deduplication eliminates redundant copies of data to reduce storage usage on the Cohesity cluster. Redundant data blocks are replaced with a pointer to the unique data copy, which ensures that only unique instances of data are transferred over the network and retained on storage media.

When you create a storage domain, you choose one of the following options:

- **Inline deduplication:** Data is deduplicated as it is written to the Cohesity cluster. Generally, Cohesity recommends inline deduplication. It is the default when creating a storage domain.
- **Post-process deduplication:** Data is deduplicated after it is written to the Cohesity cluster, which can improve the speed of I/O operations.
- **No deduplication:** Data is not deduplicated at all. You may want to disable deduplication if access speed is more important than conserving disk space, or if you are storing data that has already been deduplicated by another product.

Storage domains contain user-created views. The views inherit the deduplication setting from the storage domain. If inline deduplication is enabled for the storage domain, you can override it and always use post-process deduplication for the view.

> **Tip:** If the expected workload for a view is latency sensitive, Cohesity recommends post-process deduplication because it improves the speed of I/O operations to the view.

For more information about deduplication, see the white paper Cohesity Fault Tolerance — Data Integrity for Modern Web Scale Environments.

QoS Policies for Cohesity Views

You can assign a QoS policy to a view. A Cohesity view provides a storage location with NFS, SMB, and S3 mount paths in a storage domain on the Cohesity cluster. A QoS policy optimizes the view's performance in terms of throughput, IOPS, and latency for different workloads. The policies also let you prioritize I/O operations for certain views above others.

You need to assign the QoS policy to the view when creating the view. You can create a view using a predefined template or custom template. For more information, see:

- Create Views Using a Predefined Template
- Create Views Using a Custom Template

Predefined templates improve the performance and can also be used for different use cases and scenarios. Cohesity recommends creating a new view using a predefined template.

While creating a view, you can select a single category and the QoS policy defaults to the best optimization mode.

The table below lists the default QoS policies:

Category	Default QoS Policy
File Shares	Test And Dev High
Backup Target	Backup target High
Object Services	Test And Dev High

The following table lists the default properties for view templates. When you create a view using templates, these optimal settings for use cases are selected by default. For more information on view templates, see Cohesity Views.

View Category	View Template	Properties		
		Deduplication	Compression	Performance (QoS)

View Category	View Template	Properties		
File Shares	PACS Archive (Picture archiving and communication system)	No	No	Test And Dev High
	Multimedia	No	No	Test And Dev High
	Video	No	No	Backup Target High
	General Purpose Files	Yes	Yes	Test And Dev High
	Digital Archive	Yes	Yes	Test And Dev High
Backup Target	Commvault	Yes	Yes	Backup Target Commvault
	Veeam	Yes	Yes	Backup Target SSD
	General	Yes	Yes	Test And Dev High
	TSM	Yes	Yes	Test And Dev High
	Application Dumps (Oracle, SQL, SAP Hana)	Yes	Yes	Test And Dev High
Object Services	Containers	Yes	Yes	Test And Dev High
	General	Yes	Yes	Test And Dev High
	Splunk Smartstore	Yes	Yes	Test And Dev High
	Hadoop	Yes	Yes	Test And Dev High

There are two basic QoS policies, Test And Dev and Backup Target, and each has variants by storage media and priority.

QoS Policy	Optimized for I/O Workload Type	Priority ↓
Test And Dev	Mixed I/O workloads such as file shares. Best for writes and sequential single stream reads and writes. Recommended for Cohesity SmartFiles.	High
		Low
Backup Target	Best for sequential, multi-stream reads and writes. Recommended for Cohesity DataProtect and Cohesity Archive. Recommended for Cohesity SmartFiles when used as a backup target.	SSD
		High
		Low

Be sure to select an appropriate QoS policy for the view. By specifying a priority and the type of workload you expect, the Cohesity cluster can optimize how it processes data in regard to latency, throughput, and priority.

The following table lists the QoS policies in the decreasing order of QoS priority.

QoS Policy	Description
Journaled Sequential Dump	Use this policy for workloads that write large amounts of data sequentially to a very small number of files and do not keep many I/Os outstanding. By default data is written to the SSD and has the highest priority and low latency.
TestAndDev High	Use this policy for workloads that require lower I/O latency or do not keep many I/Os outstanding, as the I/Os are given higher priority compared to other QoS policies. Data is written to the SSD.
TestAndDev Low	The same as TestAndDev High, except that the I/Os with this QoS policy are given lower priority compared to I/Os with TestAndDev High when there is contention.
Backup Target CommVault	Use this policy to intelligently detect and exclude application-specific markers to achieve better deduplication when CommVault backup application is writing to a Cohesity View. Data is written to SSD and has the same priority and latency as TestAndDev High.
Backup Target Auto	*(Applicable only for Cohesity C6000 series)* Use this policy for workloads such as backups, which keep many I/Os outstanding. This policy distributes I/Os across SSDs and HDDs to achieve maximum performance based on the current usage. The priority for processing workload with this policy is lower than Journaled Sequential Dump, TestAndDev High, and Backup Target CommVault.

QoS Policy	Description
Backup Target SSD	Use this policy for workloads such as backups, which keep many I/Os outstanding, but in this case, Cohesity sends both sequential and random I/Os to SSD. The latency is lower than other Backup Target policies.The priority for processing workload with this policy is the same as Backup Target Auto.
Backup Target High	Use this policy for non-latency sensitive workloads such as backups, which keep many I/Os outstanding. Data is written to HDD and has higher latency compared to other QoS policies writing to a SSD The priority for processing workload with this policy is the same as Backup Target Auto.
Backup Target Low	The same as Backup Target High, except that the priority for processing workloads with this policy is lower than workloads with Backup Target Auto / High /SSD when there is contention.

Cohesity allows you to pin views to the SSD tier. For more information, see Pin Views to SSD.

In hybrid nodes that have both SSDs and HDDs, QoS policies use the storage media differently to optimize performance and life of the media. Many factors such as I/O block size and I/O pattern are considered. In general, Test And Dev uses SSDs for accelerating overall write performance. Backup Target often reads and writes directly from HDDs. For sequential reads, all QoS policies prefetch data intelligently into RAM and/or SSDs.

ID Mapping for Multi-Protocol Views

ID mapping maps Unix and Windows identifiers to provide consistent access control to files on shared storage, such as Cohesity views. Specifically, the Unix user and group IDs (UIDs/GIDs) are mapped to Windows user and group Security Identifiers (SIDs).

> **Tip:** ID mapping is used only for views that support both the NFS (Unix) and SMB (Windows) protocols *and* that have the Security Style set to either Unified or NTFS, as described later in this topic. ID mapping is irrelevant to views that support just one protocol.

You can use your organization's existing ID mapping in an external server or configure the Cohesity cluster to maintain internal ID mapping, as described in the following sections.

External Server ID Mapping

If the Cohesity cluster is joined to an Active Directory (AD) domain controller and your organization has existing ID mapping on any of the following servers, you can configure the Cohesity cluster to use that mapping for access to multi-protocol views. The administrator of the external server maintains the ID mapping.

- RFC2307 within AD
- SFU within AD
- Centrify
- LDAP

You can also configure fallback mapping in case the external server is not available.

Internal ID Mapping

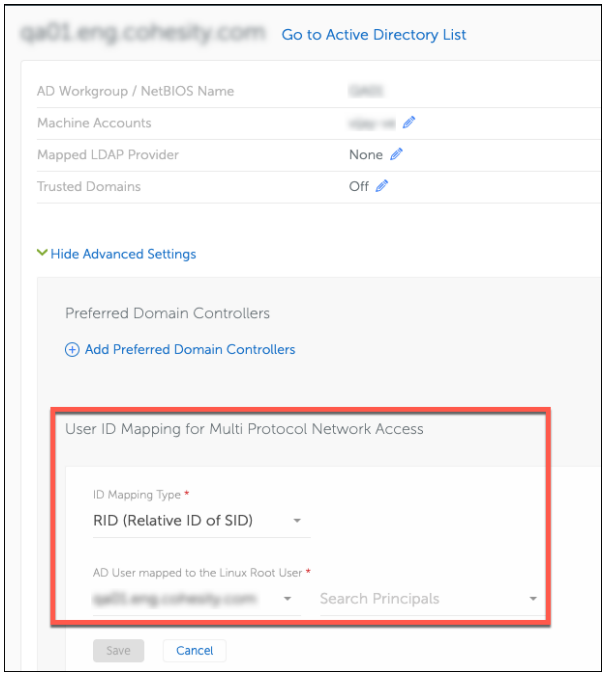
If the Cohesity cluster is joined to AD but your organization does not have an existing ID map, you can still configure the Cohesity cluster to use one of the following basic mapping types. The ID mapping will be stored internally on the Cohesity cluster.

- Fixed - A user-defined UID and GID are applied to all files created on the view.
- RID - The relative ID of the SID is used as the UID or GID.

Required Configuration for ID Mapping

To use ID mapping, do following in the Cohesity Dashboard:

- Configure a mapping type for the AD domain controller(s) on the Active Directory page. For more information, see Join Active Directory.



- Configure the following options for multi-protocol views. For information, see Create Views Using a Predefined Template.
  - **Read/Write Protocol** must be set to the required protocol (NFS, NFS v4.1 or SMB).

Optionally S3 access is selected. It is the default Read-Only Protocol. You can disable the access if you need it.

ID mapping is irrelevant if Read/Write Protocol or Read-Only Protocol is set to NFS only, SMB only or S3 only.

- **Security Style** must be set to Unified or NTFS.

  Unified means that Unix and Windows permissions are kept consistent; when one is changed, the other is automatically changed.

  NTFS means that access via SMB and NFS is controlled by the Windows ACL on the file/folder.

  ID mapping is irrelevant if Security Style is set to Native.

User and Directory Quotas for Views

In addition to the storage domain quotas, you can enable user quotas and/or directory quotas at the view level.

User Quotas

User quotas limit how much view capacity a user can use. After a view is created, you can set a default quota for all users and override the default for individual users.

> **Note:** If the view is used through both NFS and SMB, Cohesity strongly recommends using ID mapping to ensure accurate quota accounting. For more information, see ID Mapping for Multi-Protocol Views.

When a user reaches 85% of the quota, an alert (`UserExceededQuotaAlertLimit`) is triggered in the Cohesity cluster. If email notifications are configured for alerts, emails are also sent. To know more information, you can use the User Quotas.

Individual users will also receive an email if the Cohesity cluster joins an Active Directory domain and the user's email address is defined in the AD. NFS users will receive an email if they are mapped to an AD user whose email address is defined in the AD. Alert emails are sent to the addresses specified in the notification rule. AD users who wish to receive these emails must configure their email addresses in the notification rule. For more information about configuring alert notifications, see Configure Alert Notification Settings.

When the user reaches 100% of the quota, the (`UsersExceededQuota`) alert is triggered and the user cannot use additional capacity in the view until they reduce their usage or the quota is increased.

To enable user quotas:

1. Navigate to **SmartFiles > Views**.
2. On the **Views** page, click on a view name to navigate to the corresponding view details page.
3. Click the **Quotas** tab.
4. In the **User Quotas** section, turn on the **Enable** toggle. The default logical quota for all users and the alert threshold are displayed.
5. To change the default quota for all users, click the edit icon, select different values and click **Save**.
6. To override the default quota for an individual user:
    a. Click **Add**.
    b. In the **Add User Quota Override** dialog, select a local user, AD domain, or Unix user ID from the **Principal** drop-down.

       If the view's storage domain is mapped to an AD domain, you can select only that AD domain and its trusted domains.
    c. Enter an AD user or a Unix ID.
    d. Select different values for the **Quota Override**.
    e. Click **Add**.
    f. Repeat these steps to add additional user quota overrides.

You can also use the `iris_cli user-quotas` commands to manage user quotas. For example, you can change the default 85% alert threshold. For more information, see Using the Cohesity CLI and List of Cohesity CLI Commands.

Directory Quotas

Directory quotas limit the capacity of directories in a view. You can set different quotas for different directories. For example, you can set a quota on the parent directory /home/sales, and set different quotas on the sub-directories /home/sales/kane and /home/sales/reynolds.

If a quota is set on a parent directory, the data usage in any of its nested sub-directories contributes to the quota for the parent. So if the data usage for /kane is 20 GiB and /reynolds is 10 GiB, they contribute 30 GiB to the quota set for /home/sales.

If the view is replicated to another Cohesity cluster, the directory quotas are available on that Cohesity cluster.

When a directory reaches the alert threshold (by default, 90% of its quota), the `DirectoriesExceededQuota` alert is triggered in the Cohesity cluster but data can still be written to the directory.

When the directory reaches 100% of its quota, the `DirectoryExceededQuotaAlertLimit` alert is triggered and data cannot be written to the directory until files are deleted or the quota is increased.

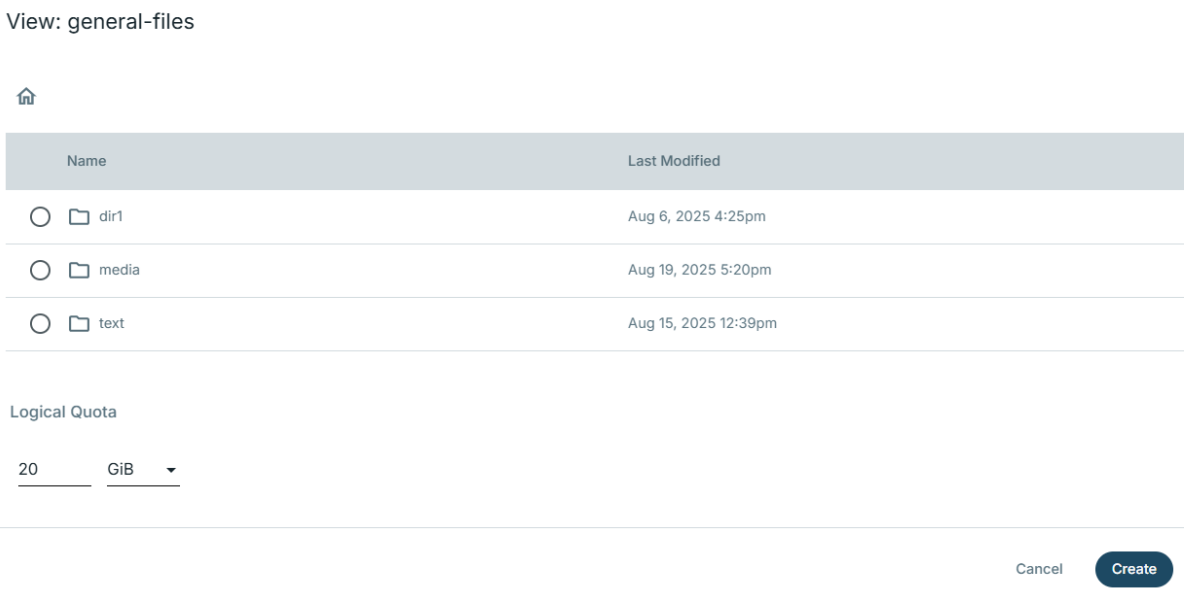
If email notifications are configured for alerts, emails are also sent.

Best Practices

- Enable directory quota at the time of directory creation. By doing so, you can ensure that the quota settings are in place from the beginning.
- After enabling the quota for a directory experiencing high IOPS, it is important to allow the current storage usage to be calculated before accessing the directory again. This allows the quota settings to be accurately applied and ensures proper management of storage usage within the directory.

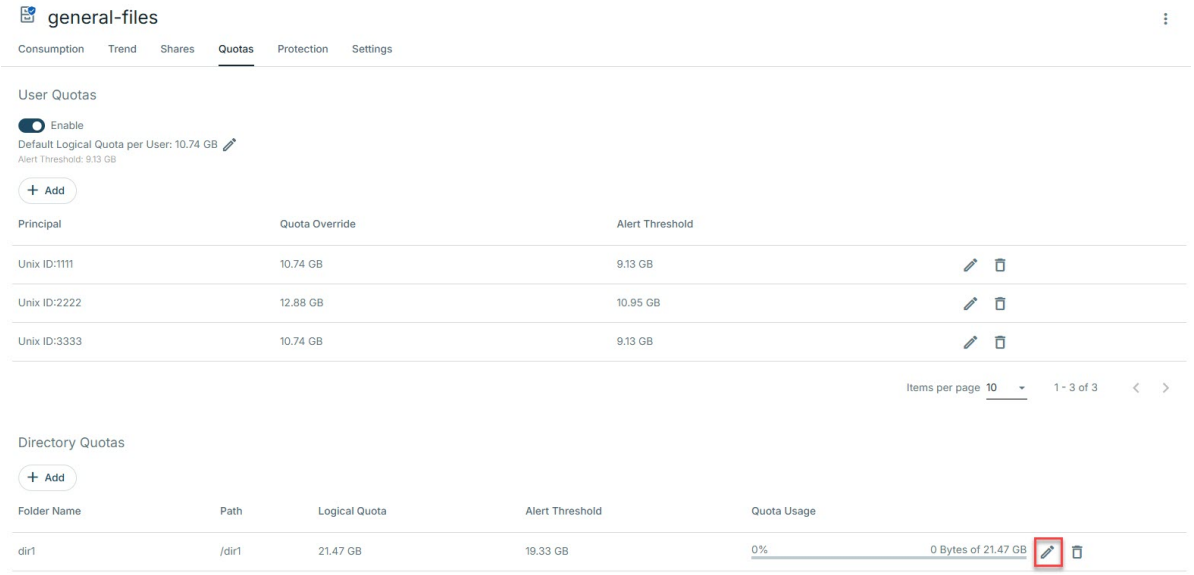
To enable directory quotas:

1. Navigate to **SmartFiles > Views**.
2. On the **Views** page, click on a view name to navigate to the corresponding view details page.
3. Click the **Quotas** tab.
4. In the **Directory Quotas** section, click **Add**. The directories in the view are displayed.
5. Click a directory folder and any sub-folders for which you want to set a quota.



6. Set the **Logical Quota** for the selected directory.

7. Click **Create**.
   The folder and its quota information is displayed.



8. By default, the alert threshold is 90% of the quota. To change it, click the edit icon.
9. In the **Alert Threshold** column, change the quota and/or unit of measure and click **Save**.
10. Repeat these steps for additional directories as needed.

To delete an existing directory quota, click the action icon ⋮ for the quota and select **Delete**.

File-level DataLock for NFS and SMB Views

DataLock is the Cohesity WORM (write once read many) feature that locks and retains files in a view for compliance and regulatory purposes.

This topic describes the file-level DataLock setting, which differs from the view-level DataLock setting available when cloning a view.

When you create a view, you can enable the **File DataLock** setting to make the files in the view immutable based on the following settings:

- whether files are automatically locked after a specified period of I/O inactivity, based on the last modified time stamp
- whether files are manually locked when users or applications change the file permissions to read only or change the last accessed time, for example, by using the following Linux and Windows commands.

  Using NFS:

```
chmod -w <filename>
```

```
touch -at YYYYMMDDhhmm.ss <filename>
```

Using SMB, from PowerShell:

```
# (dir filename).Attributes = "ReadOnly"
```

```
# (dir filename).LastAccessTime = "YYYY-MM-DD hh:mm:ss"
```

In addition to file system locking, the Cohesity REST API can be used to lock files, update time stamps and get file lock status. Contact your Cohesity account team for details on the REST API.

You can also set:

- a default retention period for locked files
- an overriding lock expiration date for files

For more information about the File DataLock settings, see File DataLock.

If File DataLock is enabled for a view, the files in the view are in one of the following states: unlocked, locked or lock expired. The following table lists the actions permitted for each state.

Permitted Action	Unlocked	Locked	Lock Expired
Change the file	yes	no	no
Delete the file	yes	no	yes

> **Note:** The File DataLock option is only applicable for NFS and SMB View types.

Snapshot Self-Service

The Snapshots Self Service option enables the users to retrieve files and folders from the backup snapshots without depending on the administrator for retrieval.

You can enable the snapshot self-service for Views supporting SMB/NFS protocols when creating or editing a View. For more information, see Create Views Using a Predefined Template.

When you enable the Self-service option on a View, a hidden snapshot directory is created and the backup snapshots are listed in the hidden directory.

Using the snapshots from the hidden snapshot directory, users can copy/restore the files or folders that may have been deleted accidentally or corrupted.

> **Note:** The Self-service option applies to the Views that are protected. You can set the Snapshot Self-service option on Views without protection job enabled. However, the snapshots directory will be empty without the backup snapshots.

For NFS and SMB Views, you need to enable the Enable Snapshot Directory option.

When you enable the option with default settings, a .snapshot directory is created for NFS Views, and ~snapshot directory is created for SMB Views. You can customize the Snapshot directory name for NFS and SMB.

NFS users/clients can access the .snapshot directory and SMB users/clients can access the ~snapshot directory and copy the required files or folders.

For NFS Views, the .snapshot directory may not be visible on the Linux server after being mounted. To navigate to the .snapshot directory, run the `cd .snapshot` command inside the mount path.

The snapshot retention period in the protected views depends on the protection policy.

> **Note:** When you are using a name of your choice for the snapshot directory name, ensure that it is a unique name. If the name of the snapshot directory is the same as one of the folders in your View, you will not be able to see the backup snapshots.

Show Previous Versions

The **Show Previous Versions** option is available for SMB Views. This is another option to restore files and folders.

> **Note:** When you upgrade from any previous versions to Cohesity 6.6 or later, by default, the **Show Previous versions** option is enabled with access to **Everyone**.

Restoring Files or Folders from Snapshots via NFS/SMB

To restore a file or folder:

1. Access your View.
2. Open the **.snapshot** (for NFS) or **~snapshot**(for SMB).
3. Select a Timestamp from which files or folders need to be restored and copy the required files or folders.

Restoring Files or Folders from Previous Versions via SMB

To restore a file or folder:

1. Mount the View and right-click a View and select **Properties**.
2. In the Properties window, click the **Previous Versions** tab and click the snapshot list.
3. From the list of Snapshots, select a timestamp.
4. The Snapshot opens in a new window listing all files.
5. You can copy the required files.

Cohesity Views

A Cohesity view provides a storage location with NFS, SMB, and S3 mount paths in a storage domain on the Cohesity cluster.

You can use the NFS protocol to mount the NFS mount path onto systems. You can mount the SMB mount path onto systems as an SMB share.

You can use the view to store data such as files, backup snapshots, and cloned VMs. Views can only be mounted on any machines specified in the allowlist subnets. A view can also act as a datastore during the VM cloning process and during VM recovery. You can select the SWIFT protocol and a create SWIFT-only view for OpenStack environments.

You can create a view for the following three categories:

- File Shares
- Backup Target
- Object Services

You can select the **Read/Write** protocol and, optionally, select the **Read-only** protocol.

You can create a Cohesity view only by using a template. The template can be a predefined template or a custom template. For more information, see:

- Create Views Using a Predefined Template
- Create Views Using a Custom Template

> **Note:** If you are using Kerberos (AD or MIT), you must create a view using the same storage domain that is mapped to AD/MIT-Kerberos + LDAP.

Navigate to the **SmartFiles > Views** page to perform the following actions:

- Create views using a predefined template or custom template.
- Create custom view templates.
- Manage share aliases—View and manage Cohesity-created shares and any user-created shares on the **Shares** tab. For more information, see Manage Share Aliases.
- Configure global settings—Enable Active Directory authentication for SMB shares.

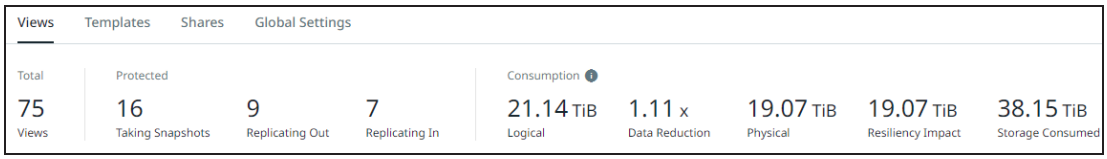
Specify subnets in the **Allowlist** that define ranges of IP addresses for systems that have privileges to access all views in the Cohesity cluster. For more information, see Add Subnets to Allowlists.

You can also clone a view, edit a view's settings, or delete a view.

The **Views** page also provides an overview of the views that have already been created. Views are grouped by storage domains. You can narrow the list by selecting a storage domain and/or typing part of a view name. To see a view's mount paths, click the view name.

Glance Bar

The glance bar provides a summary of the views:



The following details are displayed:

- **Total**—The total number of views.
- **Protected**
  - The number of views taking snapshots.
  - The number of views replicating data out of the cluster.
  - The number of views replicating data into the cluster.
- **Consumption**
  - **Logical**—Size of total unique logical data of active file system as residing on Cohesity. This does not count the space consumed by the Data Protection runs (i.e. snapshots) that may be protecting the active file system.
  - **Data Reduction**—The ratio of Data In to Data Written. This ratio reflects the data deduplication and data compression operations, and demonstrates the true power and value of the Cohesity.
  - **Physical**—This number reflects unique data written, before resiliency operations. This is the unique logical data has been reduced by data deduplication and data compression by Cohesity.
  - **Resiliency Impact**—The space required to honor resiliency settings (Erasure Coding / Replication Factor) in addition to the data written. For example, if the Data Written is 100 GB and resiliency setting is RF3, the Resiliency Impact is 200 GB. That is, to honor the resiliency setting, you will need an additional 200 GB on top of the 100 GB for the Data Written.

- **Storage Consumed**—The total size of data stored on the Cohesity file system after all operations on the data (data deduplication, data compression, and data resiliency) have been accounted for. This data can be stored either all locally or as a combination of local storage and in the Cloud Tier (if Cloud Tier is enabled). For example, if the Data Written is 100 GB and resiliency is set to RF3, leading to the need for an additional 200 GB of space, the resulting Storage Consumed is 300 GB. If the Data Written is 100 GB and resiliency is set to EC4:2, leading to the need for an additional 50 GB (as for every 4 data fragments, 2 parity fragments are added), the resulting storage consumed is 150 GB.

Views Table

The following table describes the columns on the **Views** page:

Column Name	Description / Action
View	The name of the view. Click on the view name to drill down and view the statistics and additional details.
Organization	The name of the organization that is associated with the view.
Protection	Displays the protection status.
Storage Domain	The name of the storage domain. Click on the storage domain name to drill-down and view the storage and performance statistics.
QoS Policy	The quality of service (QoS) specified for the view. By specifying a priority and the type of workload you expect, the Cohesity cluster can optimize how it processes data in regard to latency, throughput, and priority. For more information, see QoS Policies for Cohesity Views.

Column Name	Description / Action
Actions	To manage an existing view, select one of the following options: For a multitenant Cohesity cluster, you can only modify the objects that belong to your organization. • **Protect**–Create a Protection Group for the view. This action is available only for unprotected views. • **Clone** –Make a copy of the view. After cloning, the two versions of the data are unique. Changes made to the data in the new view are not replicated in the original view and changes made to the original view are not replicated in the new view. Data within a DataLock view is immutable. Follow the instructions provided in Clone a View. • **Mount Paths**–Copy the NFS, SMB, or S3 path to the clipboard. This path has to be used while mounting this view onto a local file system. For more information, see: • Mount a View Using NFS • Mount a View Using SMB **Note:** Multiple SMB paths are available if Active Directory has multiple account names; each machine account has its own path. Clicking this action copies the first SMB mount path in the list displayed on the View Details page. • **Edit**–Update the settings of a view. For more information, see Edit a View . • **Delete**–Delete the view. Deleting a view permanently deletes all the data stored on the view such as files or snapshots. If the view is used as a datastore for Cohesity cloned VMs, the VM files such as VMDK and VMX are also deleted. These cloned VMs can no longer run because these VMs can no longer access their VM files.

Filter Views Data

The **Views** page supports the following filters to pare down the data that you want to view in the table:

- **Organization**—Click the filter and select the organization from the list.
- **Category**—Click the filter and select the category: Backup Target, File Shares, or Object Services.
- **Protection Type**—Click the filter and select the protection type(s): Taking Snapshots, Replicating In, Replicating Out, or Archiving.
- **Protection Status**—Click the filter and select the protection status: Success, Warning, or Error.

Click **More Filters** to view the following filters:

- **Storage Domains**—Select the storage domain. You can also enter the name of the storage domain to filter by the storage domain name.
- **Protocol**—Select the protocol: NFS v3, NFS v4.1, SMB, S3, or SWIFT.
- **QoS Policy**—Select the QoS policy.

Hover over the search icon to view the **Search Views** search bar. Enter the name of the view to filter the views based on the name.

About Templates Tab

The **SmartFiles > Views** page includes a **Templates** tab. You can view the following details from the **Templates** tab:

- Number of total templates, predefined templates, and custom templates
- List of all predefined and custom templates

You can perform the following tasks from the **Templates** tab:

- Create a new custom template and modify existing custom templates
- Create a new Cohesity view
- Edit or delete custom templates

Cohesity supports creating customized view templates. While creating a view, you can configure settings according to your workloads and save these settings as a view template. You can use this customized template to create views. You can also edit or delete customized templates.

You can create a custom view template for the following categories:

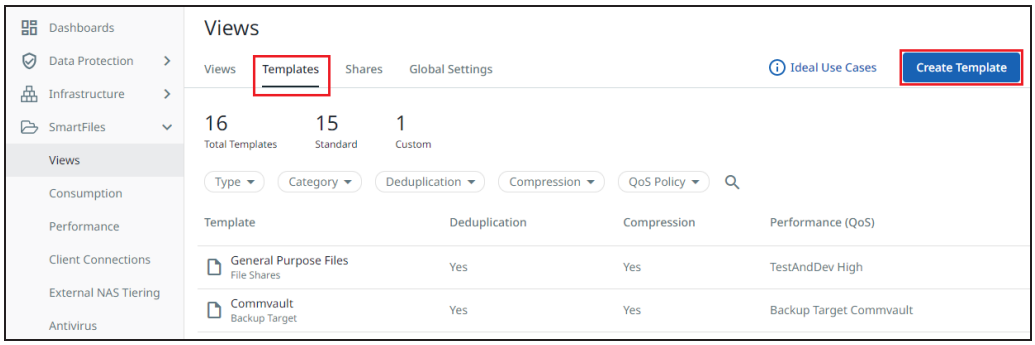
- File Shares
- Backup Target
- Object Services
- Archive Services

Create a Custom View Template

You can create a custom view template from the **SmartFiles > Views > Templates** tab or the **SmartFiles > Views > View Templates** side sheet.

To create a custom view template from the **Templates** tab:

1. Navigate to **SmartFiles > Views**.
2. On the **Views** page, go to the **Templates** tab.
3. Click **Create Template:**



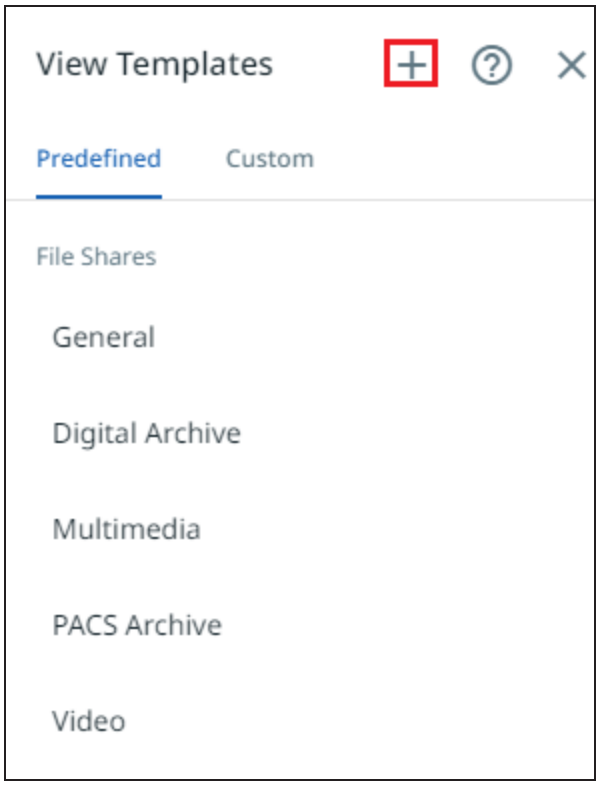
4. On the **Create View Template** dialog, complete the following:
    1. Enter a name for the template.
    2. Select a category:
        - File Shares
        - Backup Target
        - Object Services
        - Archive Services
    3. Create a new storage domain or select a storage domain from the list.

        > **Note:** Appropriate deduplication and compression settings are prepopulated while creating the storage domain.

    4. Based on the category that you selected, the custom template prepopulates a few default settings. You can update the settings based on your workload. Click **More Options** to update the default settings. For more information about the available options, see About Cohesity View Options.
5. Click **Create**.

To create a custom view template from the **View Templates** side sheet:

1. Navigate to **SmartFiles > Views**.
2. On the **Views** page, click **Create View**.
3. On the **View Templates** side sheet, click the **+** icon:



> **Note:** If no customized templates are created, you can also navigate to the **Custom** tab and click **Create Custom Template**.

4. On the **Create View Template** dialog, complete the following:
    1. Enter a name for the template.
    2. Select a category:
        - File Shares
        - Backup Target
        - Object Services
        - Archive Services
    3. Create a new storage domain or select a storage domain from the list.

        > **Note:** Appropriate deduplication and compression settings are prepopulated while creating the storage domain.

    4. Based on the category that you selected, the custom template prepopulates a few default settings. You can update the settings based on your workloads.

Click **More Options** to update the default settings. For more information about the available options, see About Cohesity View Options.

5. Click **Create**.

Create a View Template While Creating a View

To create a view template while creating a view:

1. Navigate to **SmartFiles > Views**.
2. On the **Views** page, click **Create View**.
3. On the **View Templates** side sheet, select a template.
4. Enter a name for the view.
5. Based on the template you selected, preconfigured settings are populated. Click **More Options** to update the settings. For more information about the available options, see About Cohesity View Options.
6. Click **Create View & Save as Template** to create the view and save the settings as a template:

7. On the **Template Name** dialog, enter the template name and click **Done**.

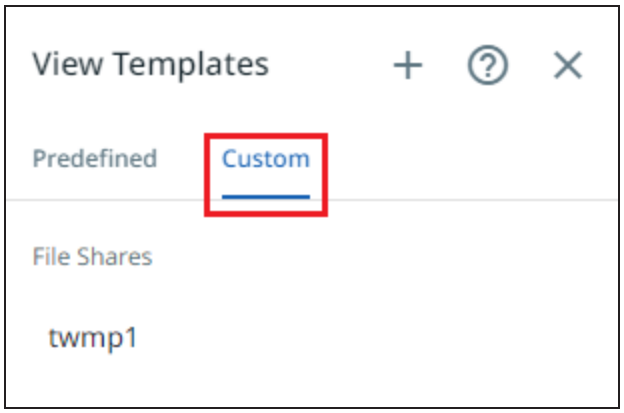
   The template is created.

View Custom Templates

To view custom templates from the **View Templates** side sheet:

1. Navigate to **SmartFiles > Views**.
2. On the **Views** page, click **Create View**.
3. On the **View Templates** side sheet, click the **Custom** tab.

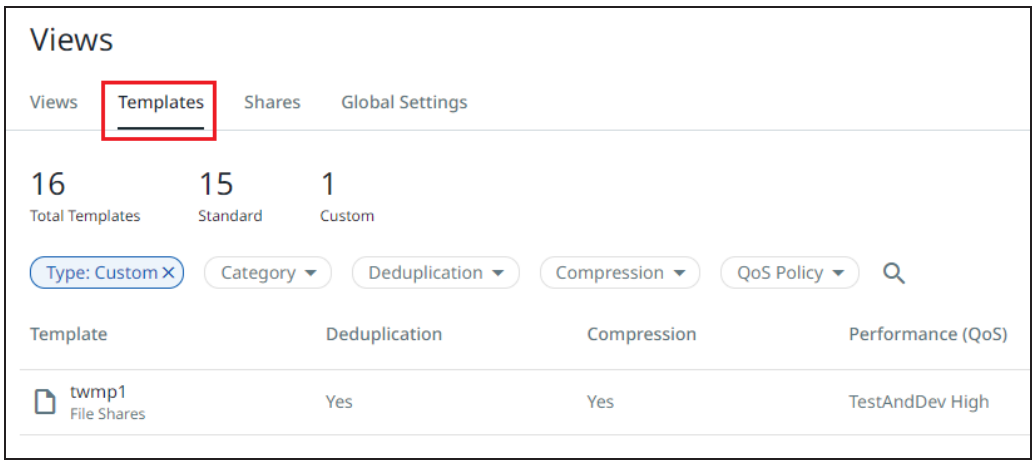
   All custom view templates are displayed:



To view custom templates from the **Templates** tab:

1. Navigate to **SmartFiles > Views**.
2. On the **Views** page, go to the **Templates** tab.
3. Click the **Type** filter and select **Custom**.

   All custom view templates are displayed:



Edit a Custom View Template

To edit a custom view template:

1. Navigate to **SmartFiles > Views** and do one of the following:
   - On the **Views** page, click **Create View**. On the **View Templates** side sheet, navigate to the **Custom** tab and hover over the custom template that you want to edit. Click ⋮ and select **Edit**.
   - On the **Views** page, go to the **Templates** tab. Click the **Type** filter and select **Custom**. Hover over the custom view template that you want to edit. Click ⋮ and select **Edit**.
2. On the **Edit View Template** page, update the settings as required.
3. Click **Update** to save the changes.

   The updated settings are applied only in views that are subsequently created from this template.

Delete a Custom View Template

To delete a custom view template:

1. Navigate to **SmartFiles > Views** and do one of the following:
   - On the **Views** page, click **Create View**. On the **View Templates** side sheet, navigate to the **Custom** tab and hover over the custom template that you want to delete. Click ⋮ and select **Delete**.

- On the **Views** page, go to the **Templates** tab. Click the **Type** filter and select **Custom**. Hover over the custom view template that you want to delete. Click ⋮ and select **Delete**.

2. On the **Delete Custom View Template?** dialog, click **Delete** to confirm.

Create Views Using a Predefined Template

You can create a view using predefined templates for different use cases and scenarios. Predefined templates are provided by Cohesity. Each category supports multiple templates. Templates have optimum preconfigured settings for a use case or scenario. You can select templates based on your requirements and create views faster. You can create views using a predefined template for the following categories:

- File Shares
- Backup Target
- Object Services
- Archive Services

Predefined templates and default properties for each predefined template are listed below.

Default Properties for Predefined Templates

The following table lists the default properties for predefined templates. When you create a view using predefined templates, these optimal settings for use cases are selected by default.

> **Note:** The view workflow suggests you create a new storage domain if there is no storage domain that exists with the necessary deduplication and compression settings based on the predefined template.

View Category	View Template	Properties		
		Deduplication	Compression	Performance (QoS)
File Shares	Multimedia	No	No	TestAndDev High
	Video	No	No	Backup Target High
	General Purpose Files	Yes	Yes	TestAndDev High

View Category	View Template	Properties		
Backup Target	Commvault	Yes	Yes	Backup Target Commvault
	Veeam	Yes	Yes	Backup Target SSD
	General	Yes	Yes	Backup Target High
	TSM	Yes	Yes	TestAndDev High
	Application Dumps (Oracle, SQL, SAP Hana)	Yes	Yes	TestAndDev High
Object Services	Containers	Yes	Yes	TestAndDev High
	General	Yes	Yes	TestAndDev High
	Splunk Smartstore	Yes	Yes	TestAndDev High
	Hadoop	Yes	Yes	TestAndDev High
Archive Services	General Archive	No	No	TestAndDev High

To create a view using a predefined view template:

1. Navigate to **SmartFiles > Views** and do one of the following:
   - On the **Views** page, click **Create View**. On the **View Templates** side sheet, navigate to the **Predefined** tab and select a predefined template.
   - On the **Views** page, go to the **Templates** tab. Click the **Type** filter and select **Predefined**. Hover over the predefined view template that you want to use, click ⋮, and select **Create View**.

   > **Note:** After you select the predefined template, you cannot modify the category.

2. Enter a name for the view.
3. Based on the template you selected, the predefined template populates optimum preconfigured settings. However, if you want to update the settings, click **More Options** and update the settings. For more information about the available options,

see About Cohesity View Options.

4. Click **Create** to create the view.

> **Note:** Click **Create View & Save as Template** to create the view and save the settings as a custom view template. On the **Template Name** dialog, enter the template name and click **Done**. The customized template is created.

Create Views Using a Custom Template

Cohesity supports creating customized view templates and using a customized template to create views. For more information, see About Templates Tab.

You can create a view using a custom template for the following categories:

- File Shares
- Backup Target
- Object Services
- Archive Services

To create a view using a custom template:

1. Navigate to **SmartFiles > Views** and do one of the following:
   - On the **Views** page, click **Create View**. On the **View Templates** side sheet, navigate to the **Custom** tab and select a custom template.
   - On the **Views** page, go to the **Templates** tab. Click the **Type** filter and select **Custom**. Hover over the custom view template that you want to use, click ⋮, and select **Create View**.

> **Note:** After you select the custom template, you cannot modify the category.

2. Enter a name for the view.
3. Based on the template you selected, the customized template populates preconfigured settings. However, if you want to update the settings, click **More Options** and update the settings. For more information about the available options, see About Cohesity View Options.
4. Click **Create** to create the view.

> **Note:** Click **Create View & Save as Template** to create the view and save the settings as a custom view template. On the **Template Name** dialog, enter the template name and click **Done**. The customized template is created.

About Cohesity View Options

Protection

Turn on the **Protection** toggle to specify the protection group and protection policy. If enabled, all views created using this template would use this protection group and adhere to the selected protection policy. In the policy, you can also define how the objects should be replicated.

- **Protection Group**—Use this option to protect objects as a group, or individually for granular level control. You can either create a new protection group or select an existing protection group from the drop-down list.
  - **New Group**—Enter a new group name. This will create a new protection group on the first use of the template.

    > **Note:** Ensure that you specify a group name that is not in use.

  - **Existing Group**—Select a protection group from the drop-down list.
- **Storage Domain**—Select a storage domain to be used during protection. You can also create a new storage domain.
- **Protection Policy**—Select a policy from the drop-down list. The policy is read-only. If you want to update the policy, go to the **Data Protection > Policies** page to edit the policy.

Storage Lifecycle Management Rules

You can reduce storage space utilization by managing the file timestamp attributes. You can define criteria for identifying aging files and specify actions to take upon meeting these conditions. By automating the deletion of aged files, storage lifecycle management ensures optimal performance and resource utilization, enabling you to reclaim valuable storage space.

> **Important:** Cohesity strongly recommends enabling **File Services** audit logs on Views on which storage lifecycle management is enabled.

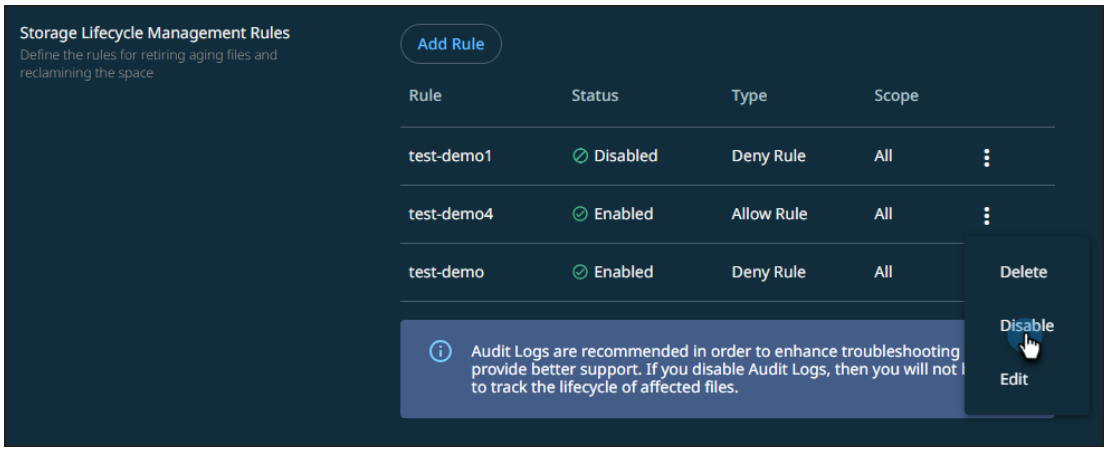
Click **No Lifecycle rules have been added yet** and click **Add Rule**:

In the **Add Storage Lifecycle Management Rule** dialog, do the following:

- **Name**—Enter a name for the rule.
- **Type**—Select one of the following:
  - **Allow Rule**—Files matching this rule are deleted.
  - **Deny Rule**—Files matching this rule are excluded from storage lifecycle management, even if the files match other rules.
- **Scope**—Select one of the following:
  - Select the **Apply to all files in the View** option to apply this storage lifecycle management rule on every file within the View.
  - Select the **Limit the scope of this rule using filters** option to limit the scope by using the following filters:
    - **Filter by File Extension**—Enter the file extension. For example, you can enter .pdf to restrict the scope to only PDFs stored in the View.
    - **Filter by Minimum File Size**—Specify the minimum file size limit.
    - **Filter by Maximum File Size**—Specify the maximum file size limit.
- **Aging Policy**—Select one of the following:
  - **Number of Days**—Specify the number of days.
  - **Date**—Select a date.
  - **None**—If you have selected the type as **Deny Rule**, choosing **None** ensures that the aging policy is not applied to the deny rule.

  To calculate aging, you can select Last Modification Time or Creation Time.
  - **Creation Time**—Refers to the timestamp when a file is initially created and saved to the storage medium.
  - **Last Modification Time**—Refers to the most recent timestamp when a file's data was modified. This timestamp updates whenever you modify the data in the file.

All the rules added are listed in the **Storage Lifecycle Management Rules** section.



The following details are displayed:

- **Name**
- **Status**: Enabled or disabled
- **Type**: Allow rule or deny rule
- **Scope**

Hover over the rule and click the vertical ellipsis to perform the following actions:

- **Delete**: Allows you to delete the rule
- **Enable** or **Disable**: Allows you to enable or disable the rule

  > **Note:** Only the rules that are enabled are considered during the execution of lifecycle management.

- **Edit**: Allows you to edit the rule

The tables below provide several examples of the aging policy:

- Allow Rule Examples
- Deny Rule Examples

Allow Rule Examples

Aging Policy	Description
	Files that have not been modified in the last **15** days are deleted.
	Files created more than **15** days ago are deleted.
	Files modified before **February 14, 2024**, are deleted.
	Files created before **February 14, 2024**, are deleted.

Deny Rule Examples

Aging Policy	Description
	PDF files are not deleted.
	Files modified within the last **20** days are not deleted.
	Files created within the last **20** days are not deleted.
	Files modified after **February 16, 2024**, are not deleted.
	Files created after **February 16, 2024**, are not deleted.

Important Points to Note

- When specifying file extensions, make sure to include the period (.) before the extension. For example, use ".pdf" instead of just "pdf".
- Regardless of the sensitivity of the View, file extensions are treated as case-insensitive and are handled the same way. For example, if a case-sensitive View contains files named f1.pdf, f2.PDF, and f3.Pdf, and a rule specifies to preserve only ".pDf" files, then all three files (f1.pdf, f2.PDF, and f3.Pdf) will be preserved.
- If a file meets the criteria for deletion based on a storage lifecycle management rule while it is open, the system still proceeds with deleting the file.
- Cohesity strongly recommends backing up Views on which storage lifecycle management is enabled. If any files are unintentionally deleted, you can recover them from the backup.
- The system honors **File DataLock** settings and storage lifecycle management rules are only applied to files that are not locked.
- If you replicate a View that includes storage lifecycle management rules, the rules are disabled since the View is read-only on the remote cluster. If you intend to use this View by cloning it, note that the storage lifecycle management rules will be present, but you must manually enable them on the View.

  > **Note:** If the remote cluster does not support Storage Lifecycle Management, the storage lifecycle management rules are not replicated to the remote cluster.

- When you archive and subsequently restore a View, the storage lifecycle management rules are not restored along with the View.
- When you clone a View, the storage lifecycle management rules associated with that View are also cloned and lifecycle actions are executed on this cloned View according to the rules.
- Users with the privilege to edit a View can add or update **Storage Lifecycle Management Rules** on that View.
- Storage lifecycle management rules applied to a View are executed on all eligible files within that View, regardless of the individual file's access permission settings.
- If you intend to enable **Storage Lifecycle Management Rules** on a View designated as a down-tiering target, Cohesity recommends not to enable lifecycle management on this target View if the down-tiering task uses the **Tier with symbolic links** option. Enabling lifecycle management under such circumstances may result in dangling symlinks on the primary source when files are deleted by lifecycle management on this target View. For more information about Symbolic Links, see Configure a Down-Tiering Task.

- By default, lifecycle job execution occurs across the cluster every seven days. During this process, the job identifies all Views governed by lifecycle policies and identifies files eligible for deletion according to the policy of each View. If a significant number of files are eligible for deletion, it may take multiple runs of the lifecycle job to remove them all. Cohesity focuses on prioritizing other critical workloads on the server; as a result, the job refrains from being more aggressive in deleting all files in a single run. Therefore, if a lifecycle job does not delete all files in one go, note that the subsequent job runs will eventually complete the task. Although Cohesity can schedule the lifecycle job to run daily, doing so would consume resources needed by active and higher-priority workloads on the Cohesity server. Hence, the default periodicity of once every seven days is maintained.

Lifecycle Management Details in Audit Logs

The **Cluster** audit logs feature captures all events that occur at the cluster level. To review storage lifecycle management details, you can download the CSV file from the **System > Audit Logs > Cluster** tab.

The following is an example of an audit log record:

```
filerLifecycleManagement:
  rules:
  - agingPolicy:
      agingCriteria: LastModificationTime
      days: 180
    fileFilter:
      fileExtensions:
      - .docx
      - .pdf
      fileSize:
        maxBytes: 1073741824
        minBytes: 1048576
    name: rule1
    status: Enabled
    type: Allow
```

The **File Services** audit logs feature allows you to capture and monitor events happening on your SMB and NFS Views. These logs document actions such as file deletions, last modification times, creation times, file sizes, and other pertinent details. Timestamps are included in these logs, enabling you to cross-reference with cluster audit logs and determine the most recently active storage lifecycle management rules.

The following is an example of a **File Services** audit log record:

```
{"Timestamp" : "2023-12-12T17:35:33.918Z", "RecordID" : "2cda:6b", "Protocol" : "SnapFS", "RequestType" :
"Delete ClientIP" : "10.14.52.77", "ViewName" : "test_view2", "Fsid" : 8817 ", "Result" : "Ok", "EntityType"
: "File", "EntityPath": "f_100kb_90day.pdf", "EntityInode" : 8035, "EntityModifyTimestamp" : "2023-09-12T01:
30:09.000Z", "InodeSizeBytes" : 102400, "SourceParentEntityInode" : 8815, "LCMRuleName" : "r1",
"EntityCreationTimestamp" : "2023-12-12T17:29:51.860Z"}
```

- `EntityPath` displays the name of the file that is being deleted.
- `LCMRuleName` displays the name of the storage lifecycle management rule.

Case Sensitive File or Folder Names

Turn on the **Case Sensitive File or Folder Names** toggle if you want the uppercase and lowercase version of the same letter in a file or folder name to be treated differently on the view. For example: `A` is different from `a`.

> **Note:** You cannot edit this setting after you create the view.

Performance

QoS Policy—Select the QOS policy. A QoS policy determines to which storage media data is written and the priority of I/O when contention occurs. For more information, see QoS Policies for Cohesity Views.

Pin View to SSD—Turn on the toggle to pin the view to the SSD tier so that critical data and data that has to be retrieved quickly are not downtiered to HDD or cloud. For more information, see Pin Views to SSD.

Security

Configure the security settings for the view. You can add and manage **Global IP Allowlist**, **Netgroup Allowlist**, and select **Security Style** for the view.

IP Allowlist

1. Select **Override Global IP Allowlist** to ignore the global IP allowlist and honor only specific entries provided in the view. Select **Extend Global IP Allowlist** to honor the global IP allowlist and the specific entries provided in the view.
2. Click **Add**.
3. In the **Add Allowlist** dialog, enter the subnet in CIDR format.
4. Select **NFS Permissions**, **SMB Permissions**, and **S3 Permissions**.
5. Select the **NFS Squash** option: **None**, **Root**, or **All**.
   For more information, see NFS Squashing.
6. Optionally, you can enter a description for the IP allowlist of the view.

Netgroup Allowlist

1. Select **Override Global Netgroup Allowlist** to ignore the global netgroup allowlist and honor only specific entries provided in the view. Select **Extend Global Netgroup Allowlist** to honor the global netgroup allowlist and the specific entries provided in the view.
2. Click **Add**.
3. In the **Netgroup Name** field, enter a name.
4. Select **NFS Permissions**.
5. Select the **NFS Squash** option: **None**, **Root**, or **All**.

For more information, see NFS Squashing.

6. Click **Add**.

Security Style

Select the **Security Style** for the view. This setting is available only if you select both NFS and SMB protocols.

- **Native**—Windows and Linux permissions are stored separately.
- **Unified**—Windows and Linux permissions are kept consistent such that when one changes, the other is modified automatically.
- **NTFS**—Access via SMB and NFS is controlled by an SMB ACL present on the file.

> **Note:** Permission mapping occurs only if the cluster has joined an Active Directory domain that has **User ID Mapping for Multi Protocol Network Access** enabled. For more information, see ID Mapping for Multi-Protocol Views.

Dedupe & Compression

Turn on the **Dedupe & Compression** toggle to always use post-processing, irrespective of the storage domain policy. This option is available only if deduplication and compression are enabled on the storage domain.

Logical Quota

Select one of the options to set the **Logical Quota** for the view:

- **Inherit from Storage Domain**
- Select **Override**, turn on the following toggles, and set the limit—**Logical Quota** or **Alert Threshold**

File DataLock

Turn on the **File DataLock** toggle to make the files in this view immutable based on the settings described below. File-level DataLock is typically used for compliance and regulatory purposes.

> **Important:** You can enable **File DataLock** only while creating the View. You cannot enable **File DataLock** on an existing View.

> **Note:** The **File DataLock** option is only applicable for NFS and SMB view types.

- **File DataLock Mode**—Select one of the following modes:
  - **Compliance**—Once File DataLock is enabled for the view, it cannot be disabled by anyone. However, a Cohesity user with the Data Security privilege can edit other DataLock settings. A user with the Data Security privilege can extend the override date into the future, but no one can shorten the date. Compliance mode means the view complies with SEC Rule 17a-4.
  - **Enterprise**—A Cohesity user with Admin privileges or Data Security privileges can rename the view, delete the view, extend or shorten the override date, switch to Compliance mode, and edit the File DataLock settings. This mode is useful for giving storage administrators additional control over the view.

    > **Note:**
    > - Apart from the local admins, Domain Admins also can delete files in a view with File DataLock enabled and operating in Enterprise Mode.
    > - Enterprise mode is supported on 6.4.1 and later clusters. If the view is replicated to a pre-6.4.1 cluster, Enterprise mode is automatically changed to Compliance mode. If the view is then replicated back to a 6.4.1 or later cluster, it retains the Compliance mode setting.

- **Default Lock Period**—Indicates the default time period that locked files remain locked if a user or application does not specify a default retention period. When the time period ends, files can be deleted but not changed.
  If you set the **Default Lock Period** to **Forever**, you cannot override it by enabling the **Override (Lock all files until a specific date)** option.
- **Autolock Files**—Indicates whether files are automatically locked after the specified period of I/O inactivity (based on the last modified timestamp).
  Override is supported only if **Autolock Files** is enabled. If **Autolock Files** is disabled, override cannot be used as legal hold.
- **Manually Lock Using**—By default, manual file locking occurs when a user or application sets the file's read-only attribute. Select one of the following:
  - **Read-Only**—Locks files when the file permission is set to read-only. For example, set the Windows file properties attribute or use the Linux `chmod` command.
  - **Future ATime**—Lock files when the last access time (**atime**) is set. For example, use Windows PowerShell commands or the Linux `touch` command.

  Auto lock and manual lock are not mutually exclusive. You can have both the options active at the same time.

- **Minimum Lock Period**: Optional. Indicate a minimum time for which the files remain locked if the user or application does not specify a default retention period.

  If an application or user locks the files for a default period and the application locks the files for a minimum period that is less than the default period, the request is silently rejected and the files remain locked as per the default retention period.

- **Maximum Lock Period**: Optional. Indicate a maximum time to ensure that a file's last access time cannot be set outside this period. A request to do so results in a permission denied error if the manual locking mode is **FutureATime**. Otherwise, the request will be silently rejected and the file will be locked for the default retention duration.

  This is useful for storage administrators to reclaim the storage space by specifying a maximum lock period after which the files can be either deleted or archived.

  > **Note:** By default, the **Maximum Lock Period** is set to **None** and cannot be edited if the **Default Lock Period** is **Forever**.

  The **Minimum Lock Period** and **Maximum Lock Period** fields are valid for both **FutureATime** and **Read-Only** manual lock.

- **Override (Lock all files until a specific date)**—Indicates whether the lock on files expires on a specific date. This setting is typically used for legal hold purposes. Files in a lock expired state cannot be deleted until this date.
  If the **Default Lock Period** is set to **Forever**, overriding only extends the period for the defined amount of time and does not actually override the files.

File Filtering

Turn on the **File Filtering** toggle if you want to block or allow files with specified file extensions from being written to this view. Select one of the following options:

- **Denied File Types**—If you want to specify a list of file extensions for files that are blocked from being written to this view. For example, if you specify a list with the `.exe` and `.dll` extensions, files with these extensions cannot be written to this view.
- **Allowed File Types**—If you want to specify a list of file extensions for files that are allowed to be written to this view. For example, if you specify a list with the `.cvs` and `.txt` extensions, only files with these extensions can be written to this view.

> **Note:** Special characters are not permitted in file extension names.

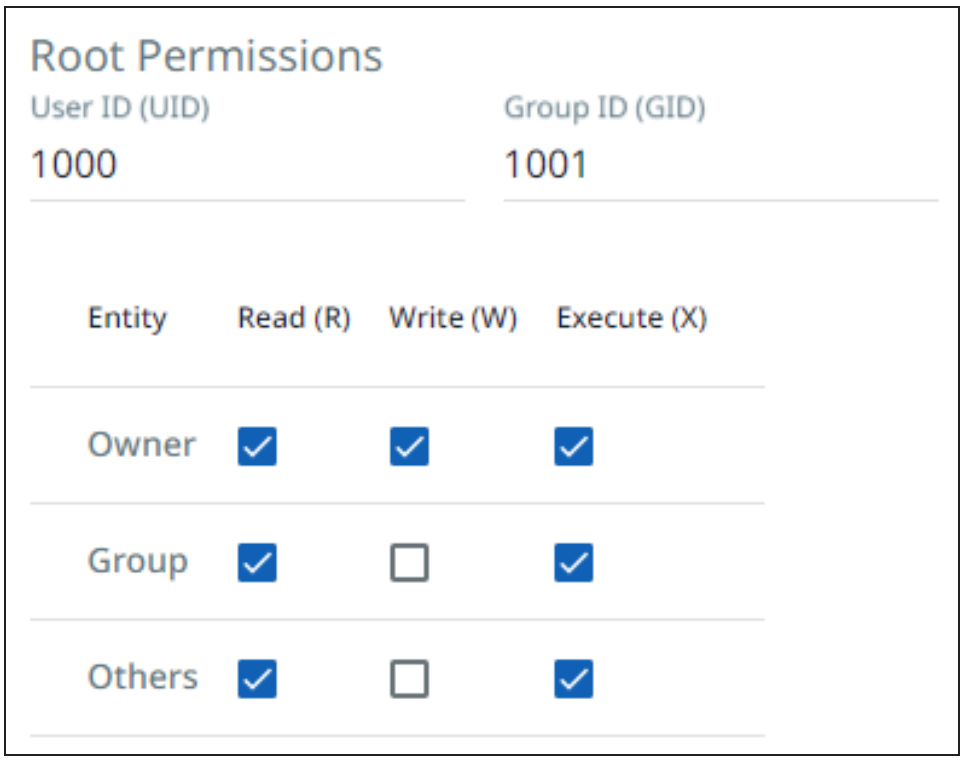
Enter file extensions separated with commas, spaces, tabs, or newlines and click **Add**.

NFS Options

You can control NFS access at the host IP, subnet, or netgroup level. The most restrictive permissions are applied.

- **Discoverable Shares**—When creating a Cohesity view, NFS shares are set as not discoverable by default. To change this default behavior, enable the **Discoverable Shares** toggle. Subsequently, you can see the discoverable shares in the `showmount` command output.
- **Root Permissions**—When creating a Cohesity view, the initial permissions are as follows:
  - Read, write, and execute permissions for the root user (UID=0)
  - Read and execute permissions for the group root (GID=0)
  - Read and execute permissions for others

  The Cohesity cluster administrator can set UID/GID for the root of the Cohesity view:



- Root Squash
- All Squash

Supported NFS Security Modes

Select at least one network authentication protocol:

- Unix Authentication
- Kerberos Authentication - Client needs to mount with sec=krb5.
- Kerberos Integrity - Client needs to mount with sec=krb5i.
- Kerberos Privacy - Client needs to mount with sec=krb5p.
  For more information, see NFS Security Modes for Kerberos Environments.

> **Note:** The authentication provider assigned to the storage domain is used for Kerberos authentication. For more information, see Kerberos.

SMB Options

Click the **SMB Options** to enable or disable the following SMB options:

- **Browsable Shares**—Turn on the toggle if you want shares of this view to be discoverable by the Windows `net view` command.

  Windows behavior prevents Cohesity SMB shares from being automatically discoverable. Use the `net view` command to probe the cluster explicitly using \\<Cluster-machine-account-name> or \\<Cluster-vip-FQDN> or \\<Cluster-VIP>.
- **Access Based Enumeration**—If this setting is enabled, then when a user browses an SMB share, only the files and folders that a user has privileges to access are displayed.
- **SMB Encryption**—Turn on the toggle to enable encryption. Turn on the **Enforce Encryption** toggle to disallow any SMB2 or SMB3 connections that do not have encryption enabled. Turn off the toggle to allow all connections.
- **Fast Durable Handles**—Turn on this toggle to improve performance, but continuous availability is lost. For more information, see Fast Durable Handles.
- **SMB Oplocks**—By default, the **SMB Oplocks** toggle is turned on when you create a view. If SMB Oplocks is enabled:
  - Client-side caching of read-ahead, write-behind, and lock information improves SMB share performance.
  - File and directory leasing also gets enabled on newer clients such as Windows 7 or later or Windows Server 2008 R2 or later. SMB leasing enables the client to cache file and directory metadata, which improves the overall file sharing performance.

    For more information, see SMB Oplocks.
- **Offline File Caching**—The SMB offline feature allows the SMB client to use files offline when the SMB clients are disconnected from the network. For more information, see SMB Offline.
- **NTFS Root Permissions**—For an SMB share, by default, everyone has full control permissions for the view. You can optionally define custom permissions for the view. Search for and select the principal (user or group) that you want to define permissions for. Select **Allow** or **Deny**. Then select the permissions and the folder/file level to apply them to. Click **Add**. Permissions adhere to the prescribed behavior of ACEs in a DACL. For more information, see Manage Access Using NTFS Permissions.

> **Note:** While editing a view, changes to the permissions apply only to new files and folders that are created after the change. Changes to permissions are not applied recursively to the view's existing files and folders.

If the view's storage domain is mapped to an AD domain, you can select only that AD domain and its trusted domains.

- **Share Level Permissions**—For an SMB share, you can optionally define custom permissions for the share. The share-level permissions are stored on the cluster as view metadata and are independent of the NTFS permissions.

  Search for and select the principal (user or group) that you want to define permissions for. Select **Allow** or **Deny**. Click **Add**. Permissions adhere to the prescribed behavior of ACEs in a DACL.

- **Super Users**—An SMB Super User is a privilege for AD users and groups, and local SMB users and groups. Select the AD domain and principal (user or group). Click **+** to add additional super users.

  A user with this privilege has complete access to view or share content overriding any assigned ACLs. However, the privilege cannot override the global allowlist and file-level data lock permissions. The privilege is set at the share-level for a view and not as NTFS root permissions. When the Super User privilege is assigned to a user for a specific view or share, the user has complete access to all the contents of the view or share. For more information, see SMB Super User.

> **Note:** The most restrictive permissions are applied. The permissions can be **Full Control**, **Modify**, **Read Only**, or **Super User**. For example, if NTFS permissions are Read and Write, but the share permission is Read, the Read permission is applied.

Snapshot Self-Service

Click **Snapshot Self-Service** and define the following to enable the users to retrieve files and folders from the backup snapshots without depending on the administrator for retrieval. For more information, see Snapshot Self-Service.

- In the **NFS Snapshot Options** section, turn on the **Enable snapshot directory** button. Optionally, you can specify a name for the snapshot directory.

  > **Note:** When you use a custom name for the snapshot directory name, ensure that the name is unique and is not present inside the view.

- In the **SMB Snapshot Options** section, you can turn on the **Show previous versions** and **Enable snapshot directory** buttons. Optionally, you can specify a name for the snapshot directory. Click **Add** and set the SMB snapshot access permissions.

  > **Note:** When you use a custom name for the snapshot directory name, ensure that the name is unique and is not present inside the view.

Antivirus

If antivirus software is installed on the Cohesity cluster, you can enable antivirus scanning on the view. For more information, see Antivirus Software to Protect Cluster Data.

Audit Logs

Turn on the **Audit Logs** toggle to enable audit logs. For more information, see File Services Audit Logs.

Description

Click **Description** and provide a description for the view.

Manage Access Using NTFS Permissions

You can use NTFS permissions to manage access to the files and folders that are stored in NTFS file systems. For an SMB share, by default, everyone has the **Full Control** permission level for the view. You can optionally define custom permissions for the view.

To define custom permissions for an SMB share, complete the following steps:

1. Navigate to **File Services > Views > All Views**.
2. On the **All Views** page, select **Create View > New View**.
3. Enter a name for the view.
4. Select one of the following categories:
   - **File Shares**
   - **Backup Target**
5. Click the **Read/Write Protocol** drop-down list and select **SMB**.
6. Click **More Options**.
7. Click **SMB Options**.
8. In the **NTFS Root Permissions** section, click **Add**.
9. In the **Add NTFS Root Permissions** pop-up window, do the following:

1. Select the AD domain from the drop-down list.
2. Select the Principal from the drop-down list. The list of users is displayed under the **Users** category. The list of groups is displayed under the **Groups** category.

   > **Note:** You can add local users and AD users to these built-in groups. For more information, see Users and Groups.

   Cohesity supports the following well-known local groups:

   - Administrators
   - Users
   - Guests
   - Power Users
   - Backup Operators

     For more information, see Supported Windows Well-Known SIDs.
3. Select the type of access:
   - Allow
   - Deny
4. Click the **Applies To** drop-down list and select one of the following:
   - This folder, subfolders, and files.
   - This folder and subfolders
   - This folder and files
   - This folder
   - Subfolders only
   - Files only
5. Select the permission level:
   - Full Control
   - Read & Write
   - Modify
   - Read Only
6. Click **Add**.

The permissions are added and the details are displayed in the Permissions table.

For more information about creating a view, see Create Views Using a Predefined Template.

To update NTFS permissions in an existing view, complete the following steps:

1. Navigate to **File Services > Views > All Views**.
2. On the **All Views** page, hover over the view that you want to edit, click the **More Options** icon, and select **Edit**.
3. On the **Edit View** page, click **SMB Options**, and update the permissions.
4. Click **Update**.

NFS Squashing

You can configure NFS root squash or all squash at the subnet, netgroup, or view level. Subnet/netgroup level squashing supersedes view-level squashing.

Root Squash

By default, root squashing is enabled on a Cohesity view and root user requests are processed as though it is made by the anonymous user (UID=65534). If you disable squashing, the root user on the client gets the same level of access to files as the root user on the Cohesity view. Root squashing allows the root user (UID=0) to be trusted by clients defined in a given allowlist.

All Squash

All squash maps all users, including root, to a defined UID/GID. The default UID used for squashing is 65534.

Edit a View

You can edit a View and modify the View its settings. Some of the View settings cannot be modified or updated.

To edit a View, complete the following steps:

1. Navigate to **SmartFiles > Views**.
2. In the **All Views** page, for the required View click the ⋮ icon and select **Edit**.
3. In the **Edit View** screen, modify the required View properties. For more information, see Cohesity Views.
4. Edit the required properties and click **Update**.

> **Note:** You cannot edit most of the properties of a view if the View is created using View templates and some of the View properties cannot be edited for any View type.

> **Important:** You cannot edit the **File DataLock** option. You can enable **File DataLock** only while creating the View.

Pin Views to SSD

Cohesity allows you to pin views to the SSD tier. This feature enables you to pin views to the SSD tier so that critical data and data that has to be retrieved quickly are not downtiered to HDD or cloud. You can do the following:

- Pin a view to an SSD when you create the view.
- Edit an existing view and pin the view. In this case, only the new data written after the view is pinned is retained on the SSD tier.
- Pin a view for an indefinite period of time. Select **Forever** if you want to set this option. The data resides on the SSD forever.
- Pin a view for a definite period from the time of its last access. You can select **Hours**, **Days**, **Months**, or **Years** and specify an appropriate number in the field. The view is pinned for the specified duration from its last access time. After the specified period, the data is automatically downtiered to HDD.
- Only the following QoS policies support pinning views:
  - Test And Dev High
  - Backup Target SSD

  For more information, see QoS Policies for Cohesity Views.
- Unpin a view from an SSD.

> **Note:** If the system has used the reserved SSD capacity, view pinning is not honored and the data is downtiered to HDD.

Pin a View to the SSD

To pin a view when creating a view, complete the following steps:

1. Navigate to **SmartFiles > Views > All Views**.
2. Click **Create** and select **View**.

3. In the **Create View** pop-up window, click **More Options**.
4. Click **Performance**:
5. From the **QoS Policy** drop-down list, select one of the following QoS policies:
    - **Test And Dev High**
    - **Backup Target SSD**
6. Enable the **Pin View to SSD** toggle button.
7. Select one of the following options to set the duration:
    - **Forever**—Pins the view forever. The data resides on the SSD forever.
    - **Hours**—Enter the number of hours for which the view should be pinned.
    - **Days**—Enter the number of days for which the view should be pinned.
    - **Months**—Enter the number of months for which the view should be pinned.
    - **Years**—Enter the number of years for which the view should be pinned.

    > **Note:** The view is pinned for the specified duration from its last access time.
8. Complete the other steps required to create a view. For more information, see Create Views Using a Predefined Template.
9. Click **Create**.

To pin an existing view, complete the following steps:

1. Navigate to **SmartFiles > Views > All Views**.
2. Hover over the view that has to be pinned to the SSD, click the **More Options** icon, and select **Edit**.
3. In the **Edit View** page, click **Performance**.
4. From the **QoS Policy** drop-down list, select one of the following QoS policies:
    - **Test And Dev High**
    - **Backup Target SSD**
5. Enable the **Pin View to SSD** toggle button.
6. Select one of the following options to set the duration:
    - **Forever**—Pins the view forever. The data resides on the SSD forever.
    - **Hours**—Enter the number of hours for which the view should be pinned.
    - **Days**—Enter the number of days for which the view should be pinned.
    - **Months**—Enter the number of months for which the view should be pinned.

- **Years**—Enter the number of years for which the view should be pinned.

> **Note:** The view is pinned for the specified duration from its last access time.

7. Click **Update**.

> **Note:** An algorithm runs in the background every 12 hours. When the pinning properties are updated on the view, only after the algorithm runs, the data is downtiered to HDD if it is cold (rarely accessed) for more than the specified duration.

Unpin a View from the SSD

You can unpin a view manually if the data is no longer required to be retrieved quickly. After you unpin the view, the data stored on the SSD is downtiered to HDD.

> **Note:** An algorithm runs in the background every 12 hours. After the view is unpinned, the next run of the algorithm clears the pinning properties, and the data is downtiered to HDD.

To unpin a view from the SSD, complete the following steps:

1. Navigate to **SmartFiles > Views > All Views**.
2. Hover over the view that has to be unpinned from the SSD, click the **More Options** icon, and select **Edit**.
3. In the **Edit View** page, click **Performance**.
4. Disable the **Pin View to SSD** toggle button.
5. Click **Update**.

Clone a View

You can make a clone of an existing view. After cloning, the two versions of the data are unique. Changes made to the data in the new view are not replicated in the original view and changes made to the original view are not replicated in the new view. Data within a DataLock view is immutable. You can also clone a view from a view Snapshot. For more information, see Clone a View From a Snapshot.

To clone a View:

1. Navigate to **SmartFiles > Views**.
2. Hover over the view that you want to clone, click ⋮ and select **Clone**.
3. Select the clone's **Purpose**.

   Select **Clone as DataLock View** if you want to clone a view as write once read many. Data within a DataLock view is immutable, and most view properties cannot be edited. (Note that view-level DataLock is different than file-level DataLock, as described in File-level DataLock for NFS and SMB Views.)
4. In the **Task Name** field, you can optionally change the default name for the clone task.
1. **View Name:** If you are creating or cloning a new view, specify a name for the view. Forward slashes (/) are not allowed in the view name.

   > **Important:** Renaming a view changes its default share name. Clients won't be able to mount the view unless they use the new share name. Clients using a share alias are not affected by the rename.

   For a DataLock view, select a date for lock expiration. During the lock period, data within the view cannot be edited by any user.

   During the lock period, users with Data Security privileges can delete the view (unless File DataLock is enabled for the view, in which case the view cannot be deleted), extend the lock period (it cannot be reduced) , add IPs in the allowlist and change the description. After the lock period expires, the view can be deleted by any user that has permission to delete it.
5. The Storage Domain is already selected. The new view is always created in the same storage domain as the original view.

   If the selected storage domain has Inline Deduplication enabled, an option appears that lets you override the default storage domain Inline Deduplication setting for the current view. Select this option if desired. Cohesity recommends enabling Inline Deduplication.

   If Inline Deduplication is on, deduplication occurs when the Cohesity cluster writes the data to the Cohesity View. If Inline Deduplication is off, deduplication occurs after the Cohesity cluster writes the data to the Cohesity View.

   For more information, see About Deduplication.

   1. **QoS Policy:** A QoS Policy determines to which storage media data is written and the priority of I/O when contention occurs. Select an appropriate QoS policy for the view. By specifying a priority and the type of workload you expect, the Cohesity cluster can optimize how it processes data in regard to latency,

throughput, and priority.

For details and recommendations, see QoS Policies for Cohesity Views.

2. To have privileges to mount and access a view, a system must be specified in the allowlist subnet. For more information, see Add Subnets to Allowlists.

6. Click **Continue**.

You can view the cloned Cohesity view on the **Test & Dev** page.

The view is ready to store data or act like a datastore during the VM recovery and VM cloning processes.

After cloning, the two versions of the data are unique. Changes made to the data in the new view are not replicated in the original view and changes made to the original view are not replicated in the new view. Data within a DataLock view is immutable.

Clone a View From a Snapshot

You can clone a view directly from a snapshot of the type view. This clone action creates a new view with a copy of the data captured in the snapshot. After cloning, the two versions of the data are unique. Changes made to the data in the new view are not replicated in the original view and changes made to the original view are not replicated in the new view. Data within a DataLock view is immutable.

You can clone a view from a snapshot created using any of the following actions:

- A snapshot captured directly from a view on the current Cohesity cluster.
- A snapshot located on a remote Cohesity cluster that was replicated (copied) from the Cohesity cluster that captured the snapshot.
  When the first Snapshot is replicated to the remote Cohesity cluster, a DR view is created on this remote Cohesity cluster. A DR view is a placeholder view that does not store data and cannot be cloned or mounted. You can use this DR view to access the replicated Snapshots using the Cohesity UI on the receiving (remote) Cohesity cluster. You can create a new view on the remote Cohesity cluster by cloning a replicated Snapshot associated with the DR view. In addition, when the first Snapshot is replicated to the remote Cohesity cluster, an Inactive Job is also created on the remote Cohesity cluster. You can use an Inactive Protection Group of type View to access the replicated Snapshots using the Cohesity UI on the remote Cohesity cluster that received the Snapshots. An Inactive Protection Group of type View is a placeholder Job and you cannot failover this type of Inactive Protection Group.

  While creating a Protection Group for a view, if you have enabled the option to create a view on the remote Cohesity cluster, then along with the snapshot, a view will be created on the remote Cohesity cluster from the latest snapshot during the first Protection Group run. The same view will be reused and will always point to the latest snapshot after every run

To learn more, see Protect Cohesity Views.

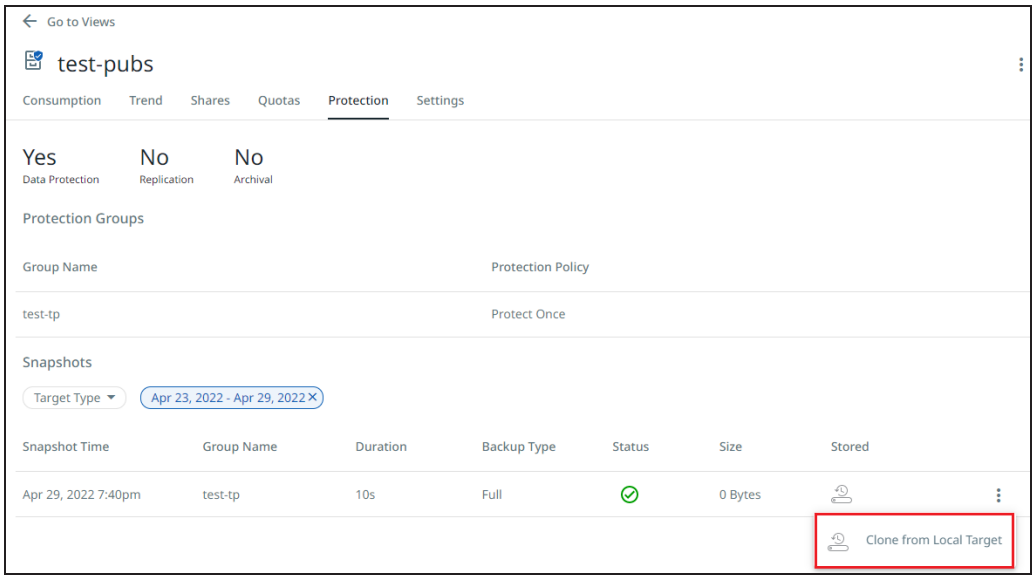
You can also clone a view directly from an existing view. For more information, see Clone a View.

To clone a view from a snapshot:

1. Navigate to **SmartFiles > Views**.
2. On the **Views** page, click on the view name that has been backed up into a snapshot that you want to clone.

   > **Note:** If you are on a Cohesity cluster with replicated snapshots that were captured on another Cohesity cluster, you can access the replicated snapshots from a special view created on the remote Cohesity cluster called a **DR View**. A DR view is a placeholder view that does not store data and cannot be cloned or mounted. You can use this DR view to access the replicated Snapshots using the Cohesity UI on the receiving (remote) Cohesity cluster. You can create a new view on the remote Cohesity cluster by cloning a replicated Snapshot associated with the DR view.

3. On the view details page, click the **Protection** tab.
4. Hover over the snapshot that you want to clone into a new view, click ⋮, and select **Clone from Local Target**



1. Select the clone's **Purpose**.

   Select **Clone as DataLock View** if you want to clone a view as write once read many. Data within a DataLock view is immutable, and most view properties

cannot be edited. (Note that view-level DataLock is different than file-level DataLock, as described in File-level DataLock for NFS and SMB Views.)

2. In the **Task Name** field, you can optionally change the default name for the clone task.
3. **View Name:** If you are creating or cloning a new view, specify a name for the view. Forward slashes (/) are not allowed in the view name.

   > **Important:** Renaming a view changes its default share name. Clients won't be able to mount the view unless they use the new share name. Clients using a share alias are not affected by the rename.

4. For a DataLock view, select a date for lock expiration. During the lock period, data within the view cannot be edited by any user.

   During the lock period, users with Data Security privileges can delete the view (unless File DataLock is enabled for the view, in which case the view cannot be deleted), extend the lock period (it cannot be reduced) , add IPs in the allowlist and change the description. After the lock period expires, the view can be deleted by any user that has permission to delete it.
5. The Storage Domain is preselected. The new view is created in the same Storage Domain as the cloned snapshot.

   If the selected storage domain has Inline Deduplication enabled, an option appears that lets you override the default storage domain Inline Deduplication setting for the current view. Select this option if desired. Cohesity recommends enabling Inline Deduplication.

   If Inline Deduplication is on, deduplication occurs when the Cohesity cluster writes the data to the Cohesity View. If Inline Deduplication is off, deduplication occurs after the Cohesity cluster writes the data to the Cohesity View.

   For more information, see About Deduplication.
6. **QoS Policy:** A QoS Policy determines to which storage media data is written and the priority of I/O when contention occurs. Select an appropriate QoS policy for the view. By specifying a priority and the type of workload you expect, the Cohesity cluster can optimize how it processes data in regard to latency, throughput, and priority.

   For details and recommendations, see QoS Policies for Cohesity Views.
7. To have privileges to mount and access a view, a system must be specified in the allowlist subnet. For more information, see Add Subnets to Allowlists.

5. Click **Continue**.

You can view the cloned Cohesity view on the **Test & Dev** page.

The view is ready to store data or act like a datastore during the VM recovery and VM cloning processes.

Clone the Contents of a Directory in a View

You can recursively clone (copy) the contents of a directory in a View to a new directory in the same View or a different View using the `view clone-directory` Cohesity CLI command.

Limitation

The default value for the maximum number of files in the source hierarchy that can be atomically cloned together is 8192. Contact Cohesity Support to increase the maximum number of files in the source hierarchy that can be atomically cloned together.

To copy the contents of a directory in a View:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. Clone the contents of a directory using the Cohesity CLI `view clone-directory` command:

   ```
   admin>view clone-directory destination-directory-name=<DestDirName>
   destination-directory-path=<DestPath> source-directory-
   path=<SourcePath>
   ```

   > **Tip:** You can use the CLI Help feature to view the `view clone-directory` options by entering the following command: `view clone-directory help`.

CLI Option	Placeholder Name	Example	Description
`destination-directory-name=`	**<DestDirName>**	`Dest`	Specify the name of the new directory where the source directory will be recursively copied, under the specified destination path. The new directory will be a child under the destination directory and must not already exist.
`destination-directory-path=`	**<DestPath>**	`/ViewDest`	Specify the directory path of the destination directory where the cloned directory will be created. You must start the path with a slash (`/`) and include the View name in the directory path. You can optionally preface the path with the Storage Domain name.

CLI Option	Placeholder Name	Example	Description
`source-directory-path=`	**<SourcePath>**	`/ViewSrc`	Specify the full path of the source directory to clone (or recursively copy) the contents from. You must start the path with a slash (`/`) and include the View name in the directory path. You can optionally preface the path with the Storage Domain name.

For example, the following directory structure and files exist prior to running the example CLI command:

- `/ViewSrc/test/file.txt`
- `/ViewSrc/test/src/text.txt`
- `/ViewDest`

The following example command is run:

```
view clone-directory destination-directory-name=Dest destination-directory-path=/ViewDest source-directory-path=/ViewSrc/test
```

After the above command is run, the following directories and files exist in the Views.

- `/ViewDest/Dest/file.txt`
- `/ViewDest/Dest/src/text.txt`
- `/ViewSrc/test/file.txt`
- `/ViewSrc/test/src/text.txt`

Protect Cohesity Views

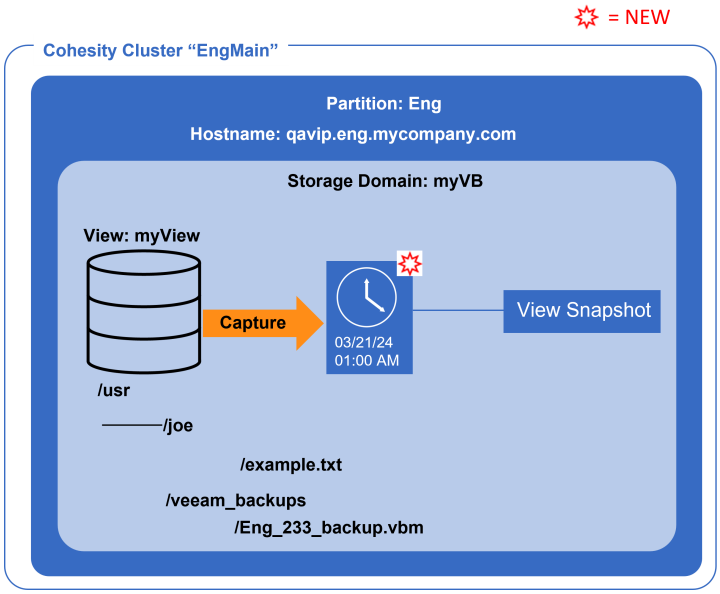
You can protect the data in a view by capturing snapshots of the view. A view Protection Group captures snapshots according to the protection schedule defined by the associated protection policy. Snapshots can be used as follows:

- The snapshot can be cloned into a new view that is stored in the same storage domain as the original snapshot. The new view contains the version of the files and directories as they were captured when the original snapshot was created.
- The snapshot can be replicated (copied) to another storage domain on a remote Cohesity cluster. The replication schedule is defined by the protection policy associated with the Protection Group.

Other backup products, such as Veeam, can store data in a view.

The steps below provide a sample scenario of how view snapshots are captured, cloned and replicated:

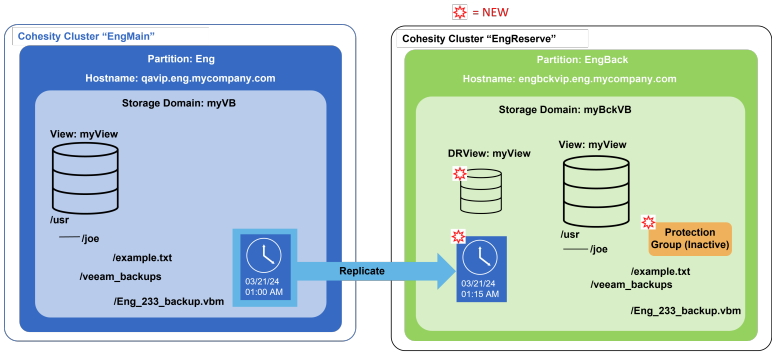
1. A view Protection Group captures a snapshot of all files and directories stored in a view. In this example, all the files and directories currently stored in the `myView` view are captured in the `3/21/24 01:00 AM` snapshot.



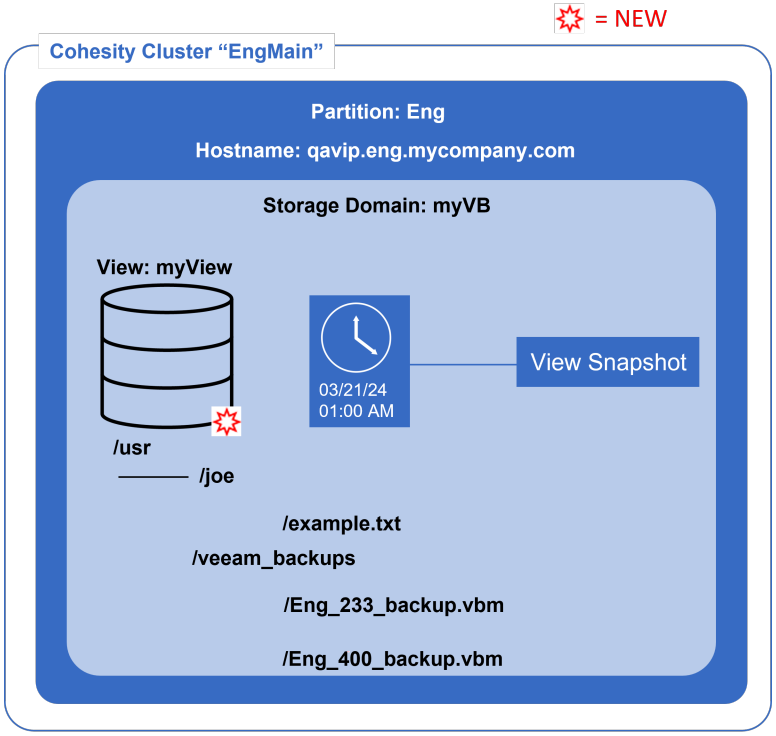
2. If a replication schedule is defined for protection policy associated with Protection Group that created the snapshot, then the following would be created on the remote Cohesity cluster ("EngReserve, below):
    - A copy of the snapshot is replicated from the Cohesity cluster capturing the snapshots ("EngMain", below)
    - A DR view is created when the first snapshot is replicated to the remote Cohesity cluster. A DR view is a placeholder view that does not store data and cannot be cloned or mounted. You can use this DR view to access the replicated

snapshots using the Cohesity UI on the receiving (remote) Cohesity cluster. You can create a new view on the remote Cohesity cluster by cloning a replicated snapshot associated with the DR view. In addition, when the first snapshot is replicated to the remote Cohesity cluster, an Inactive Job is also created on the remote Cohesity cluster.

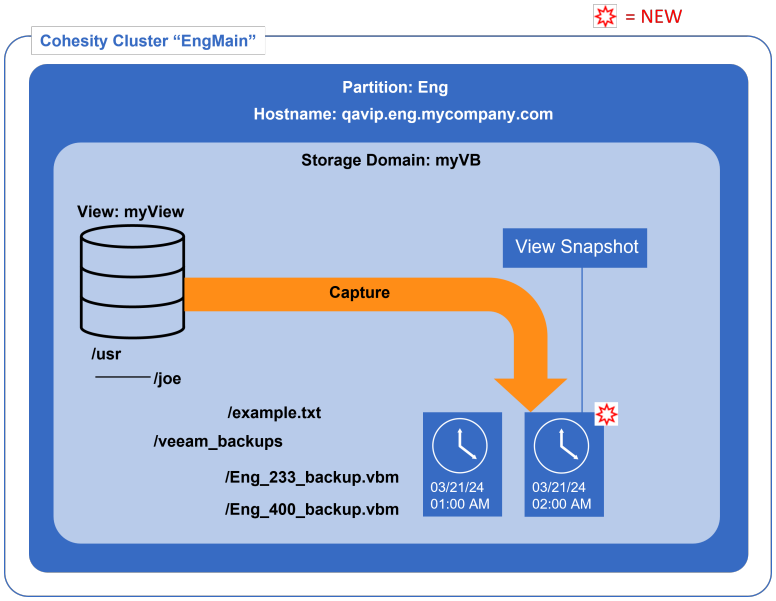
- A new view with Read-Only permission is created from the latest replicated snapshot (if you have enabled the option to create view on the remote Cohesity cluster). This view can have any user-specified name provided while creating Protection Group for a view and will always point to the latest replicated snapshot. If a disaster strikes, you can clone this view instead of the latest snapshot. However, if you want to restore a data set that is not the latest, then you must clone the view from the respective snapshot.



3. In the original `myView` view, a new file called `Eng_400_backup.vbm` is created at 1:30 AM.

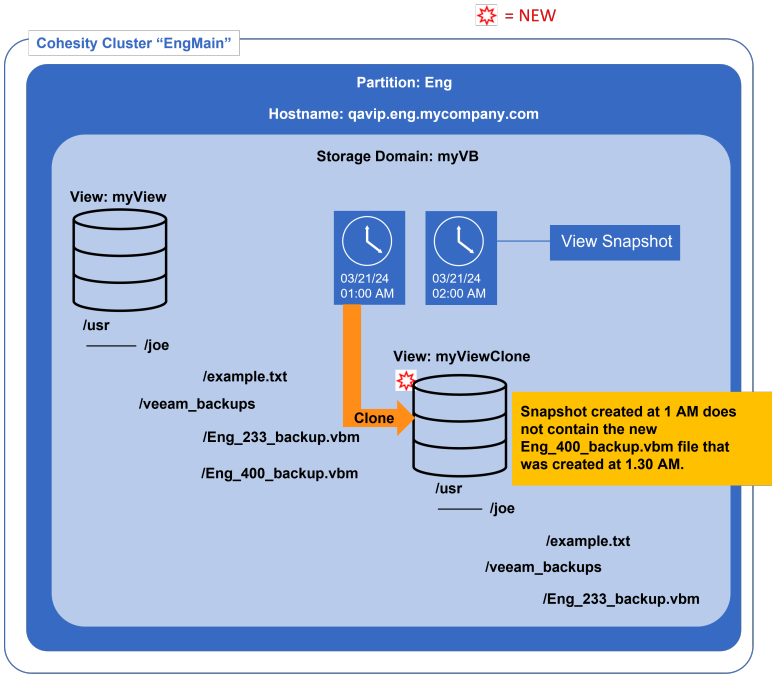


4. At 2:00 AM, a new view snapshot is captured. The 2:00 AM snapshot has captured the new file called `Eng_400_backup.vbm` but the original 1:00 AM snapshot does not have the file.

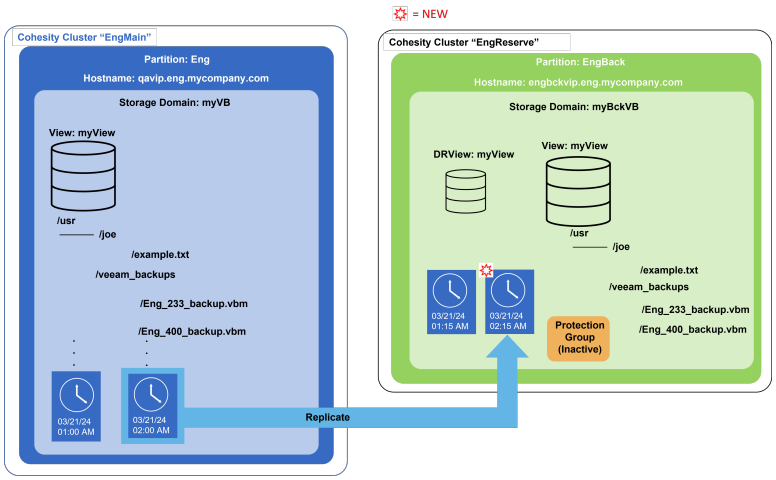


5. You clone the 1:00 AM snapshot in the capturing Cohesity cluster. A new view (called myViewClone) is created with the versions of the files and directories as originally captured by the 1:00 AM snapshot. The new view is always created in the same

Storage Domain as the original view. The new view (called myViewClone) does not contain the Eng_400_backup.vbm file.

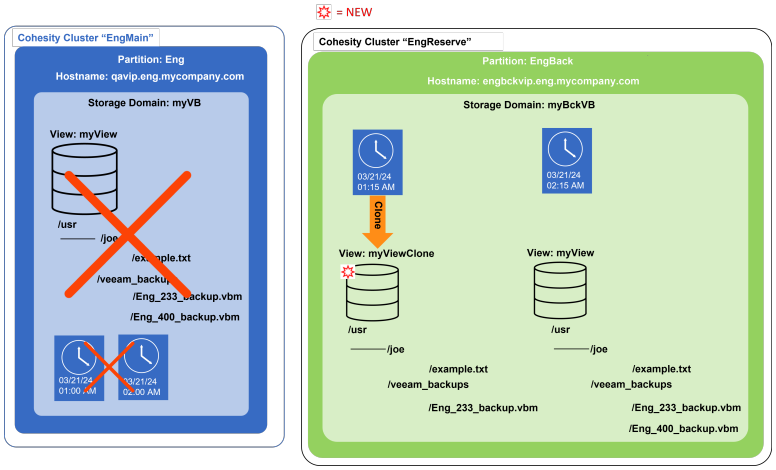


6. As defined by the replication schedule of the Job, along with the latest view a second copy of the snapshot is replicated to a remote Cohesity cluster at 2:15 AM. In this example, every snapshot captured on the Cohesity cluster ("EngMain", below) is replicated to the remote Cohesity cluster ("EngReserve", below).



7. If disaster strikes and the original view is no longer available, you can recover from the disaster by cloning the snapshot stored on the remote Cohesity cluster. When the View Snapshot is cloned, a new View is created that contains the version of the files and directories as they were captured when the Snapshot was created. In this example, since the new view created on the remote Cohesity cluster ("EngReserve",

below) was replicated from the second snapshot, the new view (called `myBckVM`) contains the `Eng_400_backup.vbm` file.



Add or Edit a Protection Group for a View

The Protection Group captures snapshots of views and snapshots of views are required for the following tasks:

- creating a new view from a view snapshot
- replicating snapshots
- archiving snapshots

The Cohesity cluster supports backing up the following entities stored in the view:

- ordinary files
- directories
- symbolic links
- hard links

These entities can be captured in a view snapshot and restored to a new view. The backup and recovery of the following special files is supported: pipes, block devices, sockets and character devices.

To create a Protection Group for a view:

1. Navigate to **Data Protection > Protection** and do one of the following:
   - To create a Protection Group—Click **Protect** on the top-right of the page and then select the type of Protection Group.
   - To edit a Protection Group—Click the action icon (⋮) next to the Protection Group and select **Edit**.
2. If creating a new job, select **Protect > Cohesity View**.

3. **Views:** Select the view that you want to protect and then click **Save Selection**. The list shows the Storage Domain that contains the view. View Snapshots are always stored in the same Storage Domain as the original view.
4. **Name:** Enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.
5. **Policy:** Select an existing protection policy or create a new one by selecting **New Policy**.
6. **Remote View**: This option is available only if the policy you selected has replication enabled. In the **Remote cluster** fields, enter a name for each view that will be created on the remote Cohesity cluster corresponding to the views on the primary Cohesity cluster. Ensure that the name provided for the views are unique and are not the same as any other view names on the remote Cohesity cluster. If the name provided is not unique, then on the remote Cohesity cluster, a new view will be create with"-1" appended to the provided name. In the next protection run, the views in the remote Cohesity cluster will be overwritten by the latest replicated snapshot of the view on the primary Cohesity cluster.
1. **End Date:** Optional. Toggle on and select the date when the Protection Group stops capturing snapshots. A protection run that starts prior to this date runs until completion even if it completes after this date.
7. **Start Time:** Indicates when the Protection Group should run. The current time is displayed by default but you can change it. Enter the hour and minutes or use the up and down arrows on your keyboard. Verify the AM or PM setting.

   The default time zone is the browser's time zone. You can change the time zone by selecting a different time zone.
8. **Indexing** :Indexing is enabled by default and is required for file recovery. Optionally customize by adding indexing rules. Type index text. Click **Add** under **Include** and **Exclude** fields to add more index terms.
9. **Priority:** Select a priority for the Protection Group execution. Cohesity supports concurrent backups, but if the number of Protection Groups exceeds the ability to process them, those with **High** priority are given the highest priority to execute, **Medium** the second-highest priority, and **Low** the lowest priority.
10. **Cancel Runs at Quiet Time Start:** Available only if the selected policy has at least one quiet time period. Toggle it on to specify that all currently executing protection runs should abort if a quiet time period specified for the Protection Group starts. By default this toggle is off, which means after a protection run starts, it continues to execute even when a quiet time period specified for this protection run starts. However, a new protection run will not start during a quiet time period.
11. **Alerts:** Optional. Select one or more of the following settings if you want Alerts to be created for the following triggers:

- **Success:** Create an Informational Alert when a Protection Group completes successfully. Emails are not sent when Informational Alerts are created.
- **Failure:** Create an Critical Alert if the Protection Group fails to complete. Emails are sent when Critical Alerts are created.

For more information about Alerts, see Alerts.

12. **Description:** Optional. Click the plus sign and enter a description for the Protection Group.
13. Click **Protect**.

    The Protection page is displayed and includes the new Protection Group.

Recover Files or Folders

You can now recover the files and folders of a view that has been protected. You can either recover the files and folder of a view to an alternate view or to the same view. This section describes how to perform the recovery of a view.

Considerations

- You can select only those views as targets that have the **Case Sensitive File or Folder Names** option same as the source view. For example, if the file of a view you selected for recovery has the **Case Sensitive File or Folder Names** option disabled, then from the **Select View** drop-down, you can select only those views having the **Case Sensitive File or Folder Names** option disabled.
- You can recover files or folders from a view having the **File DataLock** option enabled. However, you cannot recover files or folders to a view having the **File DataLock** option enabled.
- The target view and the source view must belong to the same storage domain.
- You can recover files or folders from an NFS view to an SMB view and vice-versa. However, symlinks will not be preserved for cross protocol recoveries.
- You can recover files or folders from an archive and replicated view.
- You cannot recover files or folders to a Read-only view.
- You cannot recover files or folders from an S3 view or to an S3 view.

Recover to the Original View

To recover files and folders to the original view:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** located at the top right of the page and then select **Cohesity View > Files or Folders**.
3. Select any one of the following options to search for the file or folder:

- **Files and Folders**: Allows you to search and recover files using file or folder names from any backup available on the Cohesity cluster.
- **Browse**: Allows you to search and recover files using the name of the view or Protection Group from any backup available on the Cohesity cluster.

If you select..	Then..
Files and Folders	1. Enter characters of the file name, path, or by specifying the wildcard character *. A list of items displays. You can optionally filter the search results by object type, source, object, Protection Group, Storage Domain, files only, or folders only. 2. From the list of search results, select the required files or folders to recover. 3. By default, the latest snapshot is selected for recovery. To recover from a different snapshot: 1. From the selected list, mouse over the snapshot, and then click the **edit** icon. The Edit recovery point page appears. 2. Select a date range and the snapshot point for recovery. **Note:** • If you have selected multiple files for recovery, then any files not present in the newly selected snapshot will not be recovered. • By default, the snapshot is recovered from the local cluster. You can also select the snapshot archived to the cloud (icon) by clicking this icon if available in the Location option. 3. When recovering from an archive, consider the following points: • The archive (external target) must be currently registered for the task to succeed. • (*Applies only for cloud archive incremental with periodic full*) Provisioned Capacity Units (PCU) are required for all file-level recoveries. Provisioned capacity ensures that your retrieval capacity for expedited retrievals is available when needed. Each unit of capacity guarantees that at least three expedited retrievals can be performed every five minutes and provides up to 150 MB/s of retrieval throughput. 4. Click **Select Recovery Point** and go to step 4.

If you select..	Then..
Browse	1. Enter the full or partial view or Protection Group name. You can by specify the wildcard character *. You can also optionally filter the search results by object type, source, object, Protection Group, Storage Domain. 2. From the list of search results, select the object whose files or folders are to be recovered. 3. By default, the latest snapshot is selected for recovery. To recover from a different snapshot, click the snapshots drop-down in the top-left corner and select the snapshot you need. 4. By default, only the files and folders that are indexed are displayed. To display all the available files and folders, toggle off the **Browse on Indexed Data** option. **Note:** • Changing the snapshot after selecting the items (files or folder) removes the selected items from the cart. • Enabling or disabling the **Browse on Indexed Data** option after selecting the items (files or folder) removes the selected items from the cart. • Deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process. 5. Once you select the files and folder to recover, select one of the following options: • **Download Files**: If you are recovering a single file, this option downloads the file to your browser's download folder. For all other selections, this creates a recovery task. When the task completes, from the Recoveries page, click the task name and then click **Download Files** to download the generated zip file. • **Next**: If you select this option, then continue with next step to configure the file recovery options. 6. After saving the selection, if you want to recover from a different snapshot or change the location from where the snapshot is recovered, perform the following steps: 1. From the selected list, mouse over the snapshot, and click the edit icon. The Edit recovery point page appears.

If you select..	Then..
	2. By default, only the snapshots that are indexed are displayed. To display all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. 3. Select a date range and the snapshot point for recovery. 4. By default, the snapshot is recovered from the local Cohesity cluster. You can also select a snapshot archived to the cloud (icon) by clicking this icon if available in the **Location** option. When recovering from an archive, consider the following points: • The archive (external target) must be currently registered for the task to succeed. • (*Applies only for cloud archive incremental with periodic full*) Provisioned Capacity Units (PCU) are required for all file-level recoveries. Provisioned capacity ensures that your retrieval capacity for expedited retrievals is available when needed. Each unit of capacity guarantees that at least three expedited retrievals can be performed every five minutes and provides up to 150 MB/s of retrieval throughput. 7. Click **Select Recovery Point** and go to step 4.

4. Once you select the files and folder to recover, select one of the following options:
   - **Next Recover Option**: If you select this option, then continue with the step 5 to configure the file recovery options.
   - **Download Files**: If you are recovering a single file, this option downloads the file to your browser's download folder. For all other selections, this creates a recover task. When the task is completed, from the Recoveries page, click the task name and then click **Download Files** to download the generated zip file.

     Character replacement explanation for : and \ in file and directory names in zip files

     If the original file or directory name contains a ':' , it is replaced with '_COLON_' in the archive.
     Example:
     - The original name is "a:b" then the archived name is "a_COLON_b"
     - The original name is "a:b:c" then the archived name is "a_COLON_b_COLON_c"

If the original file or directory name contains a '\', it is replaced with '_BACK_SLASH_' in the archive.
Example:

- The original name is "x\y" then the archived name is "x_BACK_SLASH_y"
- The original name is "x\y\z" then the archived name is "x_BACK_SLASH_y_BACK_SLASH_z"

5. From the **Recover To**, select **Original view** to recover the files or folders to the same view.
6. To recover to a different location in the original view, enable the **Recover to alternate path** option, and then provide the location to which the files or folders are to be recovered in the **Alternate Path** field. By default, the files and folders will be recovered to the original location.
7. Optional. Edit the default settings of the following **Recovery options**:
   - **Overwrite Existing File/Folder**: By default, this option is disabled to create the files and folders in the specified location. Any duplicate files are skipped. Enable this option to overwrite the existing files and folders.

     Consider this example, you are recovering a file, **1.txt** from the source view V1 to the root directory of the target view V2. If a file, **1.txt** already exists in the root directory of the target view V2, then the **Overwrite** behavior is as follows:

     - If the **Overwrite** option is enabled during recovery, the **1.txt** in the target view is overwritten with the data in the **1.txt** file of the source view V1.
     - If the **Overwrite** option is disabled during recovery, the **1.txt** in the target view V2 will not be overwritten with the data in the **1.txt** file of the source view V1.

     If **Overwrite** is enabled, recovering a file to the source when the file is in use may cause the open file to be overwritten. Whether overwriting occurs depends on the application using the file.
   - **Preserve File/Folder Attributes**: This option is not applicable for the file or folder recovery of a view.
   - **Continue on Error**: By default, this option is enabled to continue the recovery even if one of the objects encounters an error. Disable this option to discontinue the recovery task if one of the objects encounters an error.
   - **Cluster Interface**: By default, the **Auto Select** option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the **Interface Group** drop-down.
   - **Task Name**: Change the default name of the recovery task.

- **Save Success Files**: Enable this option to download the success logs for a recovery run.

8. Click **Recover**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Recover to an Alternate View

To recover files and folders to the alternate view:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** located at the upper-right corner of the page and select **Cohesity View > Files or Folders**.
3. Select any one of the following options to search for the file or folder:
   - **Files and Folders**: Allows you to search and recover files using file or folder names from any backup available on the Cohesity cluster.
   - **Browse**: Allows you to search and recover files using the name of the view or Protection Group from any backup available on the Cohesity cluster.

If you select..	Then..
Files and Folders	1. Enter characters of the file name, path, or specify the wildcard character *. A list of items is displayed. You can optionally filter the search results by object type, source, object, Protection Group, Storage Domain, files only, or folders only. 2. From the list of search results, select the required files or folders to recover. 3. By default, the latest snapshot is selected for recovery. To recover from a different snapshot: 1. From the selected list, mouse over the snapshot, and then click the **edit** icon. The Edit recovery point page appears. 2. Select a date range and the snapshot point for recovery. **Note:** • If you have selected multiple files for recovery, then any files not present in the newly selected snapshot will not be recovered. • By default, the snapshot is recovered from the local cluster. You can also select the snapshot archived to the cloud (icon) by clicking this icon if available in the Location option. 3. When recovering from an archive, consider the following points: • The archive (external target) must be currently registered for the task to succeed. • (*Applies only for cloud archive incremental with periodic full*) Provisioned Capacity Units (PCU) are required for all file-level recoveries. Provisioned capacity ensures that your retrieval capacity for expedited retrievals is available when needed. Each unit of capacity guarantees that at least three expedited retrievals can be performed every five minutes and provides up to 150 MB/s of retrieval throughput. 4. Click **Select Recovery Point** and go to step 4.

If you select..	Then..
Browse	1. Enter the full or partial view or Protection Group name. You can specify the wildcard character *. You can also optionally filter the search results by object type, source, object, Protection Group, or Storage Domain. 2. From the list of search results, select the object whose files or folders are to be recovered. 3. By default, the latest snapshot is selected for recovery. To recover from a different snapshot, click the snapshots drop-down in the top-left corner and select the snapshot you need. 4. By default, only the files and folders that are indexed are displayed. To display all the available files and folders, toggle off the B**rowse on Indexed Data** option. **Note:** • Changing the snapshot after selecting the items (files or folders) removes the selected items from the cart. • Enabling or disabling the **Browse on Indexed Data** option after selecting the items (files or folders) removes the selected items from the cart. • Deleted snapshots may be displayed as valid recovery points for a brief period until they are removed from the search index by a background process. 5. Once you select the files and folders to recover, select one of the following options: • **Download Files**: If you are recovering a single file, this option downloads the file to your browser's download folder. For all other selections, this creates a recovery task. When the task completes, from the Recoveries page, click the task name and then click **Download Files** to download the generated zip file. • **Next**: If you select this option, continue with the next step to configure the file recovery options. 6. After saving the selection, if you want to recover from a different snapshot or change the location from where the snapshot is recovered, perform the following steps: 1. From the selected list, mouse over the snapshot, and click the edit icon.

If you select..	Then..
	The Edit recovery point page appears. 2. By default, only the snapshots that are indexed are displayed. To display all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. 3. Select a date range and the snapshot point for recovery. 4. By default, the snapshot is recovered from the local Cohesity cluster. You can also select a snapshot archived to the cloud (icon) by clicking this icon if available in the **Location** option. When recovering from an archive, consider the following points: • The archive (external target) must be currently registered for the task to succeed. • (*Applies only for cloud archive incremental with periodic full*) Provisioned Capacity Units (PCU) are required for all file-level recoveries. Provisioned capacity ensures that your retrieval capacity for expedited retrievals is available when needed. Each unit of capacity guarantees that at least three expedited retrievals can be performed every five minutes and provides up to 150 MB/s of retrieval throughput. 7. Click **Select Recovery Point** and go to step 4.

4. Once you select the files and folders to recover, select one of the following options:
   - **Next Recover Option**: If you select this option, continue to step 5 to configure the file recovery options.
   - **Download Files**: If you are recovering a single file, this option downloads the file to your browser's download folder. For all other selections, this creates a recovery task. When the task completes, from the **Recoveries** page, click the task name and then click **Download Files** to download the generated zip file.

     Character replacement explanation for : and \ in file and directory names in zip files

     If the original file or directory name contains a ':', it is replaced with '_COLON_' in the archive.
     Example:
     - The original name is "a:b" then the archived name is "a_COLON_b"
     - The original name is "a:b:c" then the archived name is "a_COLON_b_COLON_c"

If the original file or directory name contains a '\', it is replaced with '_BACK_SLASH_' in the archive.
Example:

- The original name is "x\y" then the archived name is "x_BACK_SLASH_y"
- The original name is "x\y\z" then the archived name is "x_BACK_SLASH_y_BACK_SLASH_z"

5. From the **Recover To**, select **Alternate view** to recover the files or folders to a different view.
6. From the **Select View** drop-down list, select an existing view. You can also create a new view by clicking **Create View** from the **Select View** drop-down.

> **Note:**
> You can select only those views as targets that have the:
>
> - **Case Sensitive File or Folder Names** option same as the source view. For example, if the file of a view you selected for recovery has the **Case Sensitive File or Folder Names** option disabled, then from the **Select** View drop-down, you can select only those views having the C**ase Sensitive File or Folder Names** option disabled.
> - **File DataLock** option disabled.
> - Same storage domain as the source view.

7. In the **Path** field, enter the path where you want to recover the file or folder in the target view. If the path you specified does not exist in the target, then Cohesity will create the path you specified and recover the file and folder in that path.
8. Optional. Edit the default settings of the following **Recovery options**:
   - **Overwrite Existing File/Folder**: By default, this option is disabled to create the files and folders in the specified location. Any duplicate files are skipped. Enable this option to overwrite the existing files and folders.

     For example, you are recovering a file, **1.txt**, from the source view V1 to the root directory of the target view V2. If a file, **1.txt**, already exists in the root directory of the target view V2, then the **Overwrite** behavior is as follows:

     - If the **Overwrite** option is enabled during recovery, the **1.txt** in the target view is overwritten with the data in the **1.txt** file of the source view V1.
     - If the **Overwrite** option is disabled during recovery, the **1.txt** in the

target view V2 will not be overwritten with the data in the **1.txt** file of the source view V1.

If **Overwrite** is enabled, recovering a file to the source when the file is in use may cause the open file to be overwritten. Whether overwriting occurs depends on the application using the file.

- **Preserve File/Folder Attributes**: This option is not applicable for the file or folder recovery of a view.
- **Continue on Error**: By default, this option is enabled to continue the recovery even if one of the objects encounters an error. Disable this option to discontinue the recovery task if one of the objects encounters an error.
- **Cluster Interface**: By default, the **Auto Select** option is enabled, and the recovery task automatically selects the correct VLAN. If you disable this option, select a configured interface group from the **Interface Group** drop-down.
- **Task Name**: Change the default name of the recovery task.
- **Save Success Files**: Enable this option to download the success logs for a recovery run.

9. Click **Recover**.

   The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Restore Previous Versions of SMB Files and Folders

You can restore previous versions of files and folders that are in Cohesity-protected SMB Views. This feature enables you to perform the restore from the system where the Views are mounted and provides the same functionality as the Windows "Restore previous versions" function.

The snapshot to be restored is generated only when the backup task is performed on the SMB view.

> **Note:**
> - The file or folder you want to restore must have already been backed up by a previous View Snapshot on the Cohesity cluster.
> - The versions available for restore are determined by the snapshots stored in the Cohesity cluster. For example, if the retention period specified in the Protection Policy retains snapshots for only two days, then only the versions from the past two days are available for restore.

To restore a previous version:

1. On the system, right-click the file or folder that is under a backed up view and select **Restore previous versions**.
2. Click the **Previous Versions** tab.
3. Select the version you want to restore to and click **Restore**.

Lock or Unlock Cohesity View Configuration

You can now lock or unlock the configuration of a Cohesity view. The lock or unlock feature provides additional security checks on the view's configuration. Only users with the **Data Security** privilege can lock or unlock a view.

You can lock or unlock a Cohesity view using the Cohesity CLI only. For more information, see view for view-related CLI operations:

- view lock
- view unlock

When a view is locked, no users can perform configuration-related operations such as:

- Access the properties of the view
- Create, edit, or delete aliases of the view
- Enable or disable user or directory quotas

Overwrite a View

You can use the Cohesity CLI `view overwrite` command to overwrite a View with the contents of another View in the same Cohesity cluster. The target View becomes a clone of the source View. This is useful if you want to maintain a View on a remote Cohesity cluster (used for replication) that has information from the latest replication of the source View. For example, you might manually create a View on the remote Cohesity cluster and then overwrite that View with a View snapshot after each replication task runs.

To overwrite a View:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. Overwrite the target View with the source View contents by using the following Cohesity CLI command:

   ```
   admin>view overwrite source-view-name=<view1> target-view-name=<view2>
   ```

Delete a View

You can delete a View if you do not need the data in a View. When you delete a View permanently all data stored in the View such as files, Snapshots and Cloned VM files.

> **Note:** You cannot revert the View delete operation.

To delete a View, complete the following steps:

1. Navigate to **SmartFiles > Views**.
2. In the **All Views** page, for the required View click the ⋮ icon and select **Delete**.
3. In the Delete View screen, type **Yes** to confirm and click **Delete**.

Remote Views

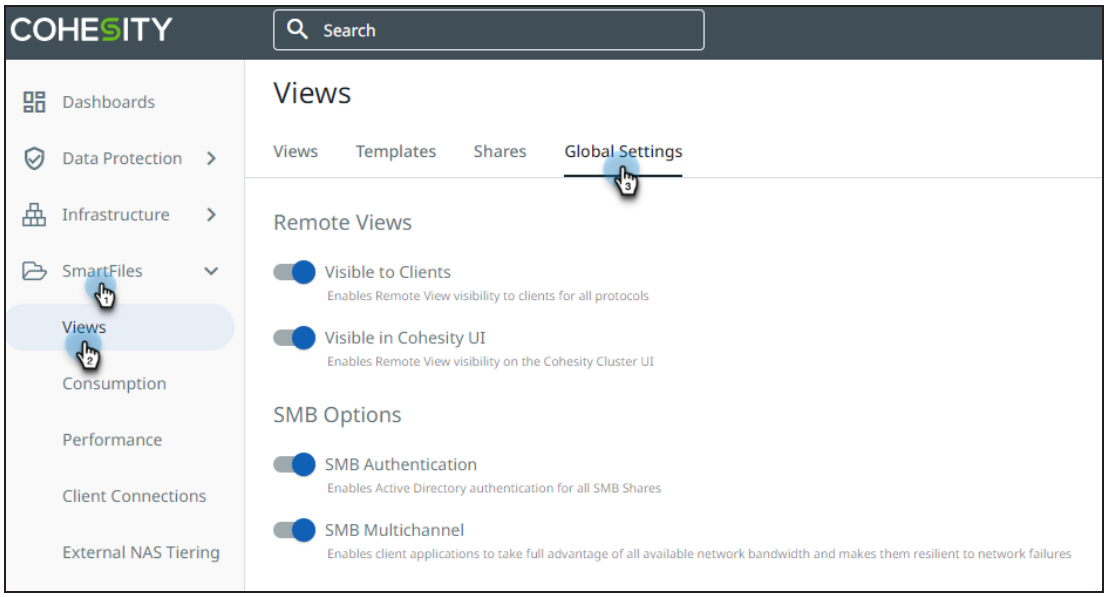
When a View is replicated from a source cluster to the target/remote cluster, a read-only View is automatically created on the target/remote cluster, which is also known as the Remote View. Remote Views are always read-only. By default, Remote Views are visible to clients and visible in the Cohesity GUI.

To disable Remote Views visibility on clients for all protocols:

1. Navigate to **SmartFiles > Views** and click the **Global Settings** tab.
2. Turn off the **Visible to Clients** toggle.

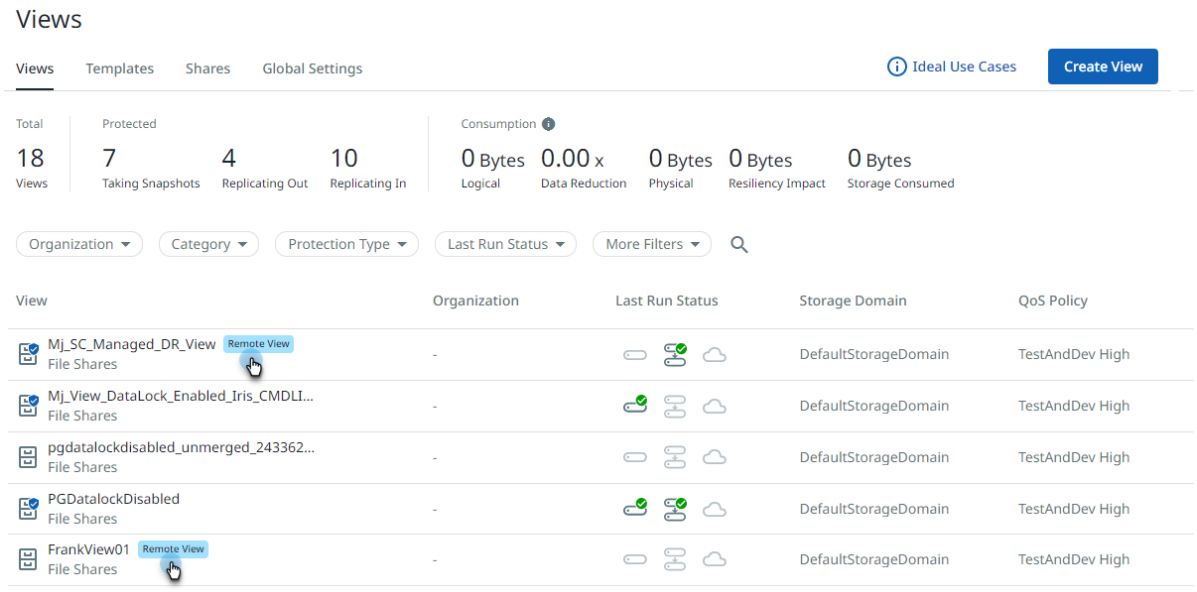
To disable Remote Views visibility on the Cohesity cluster GUI:

1. Navigate to **SmartFiles > Views** and click the **Global Settings** tab.
2. Turn off the **Visible in Cohesity UI** toggle.



If the **Visible to Clients** option is disabled, Remote Views are not visible to clients through Windows Explorer or the Linux/Unix `showmount` command. However, clients can still access the Remote Views through the direct mount path.

If the **Visible in Cohesity UI** option is enabled, the Remote View is displayed on the Views page. The **Remote View** label is displayed next to the view name:



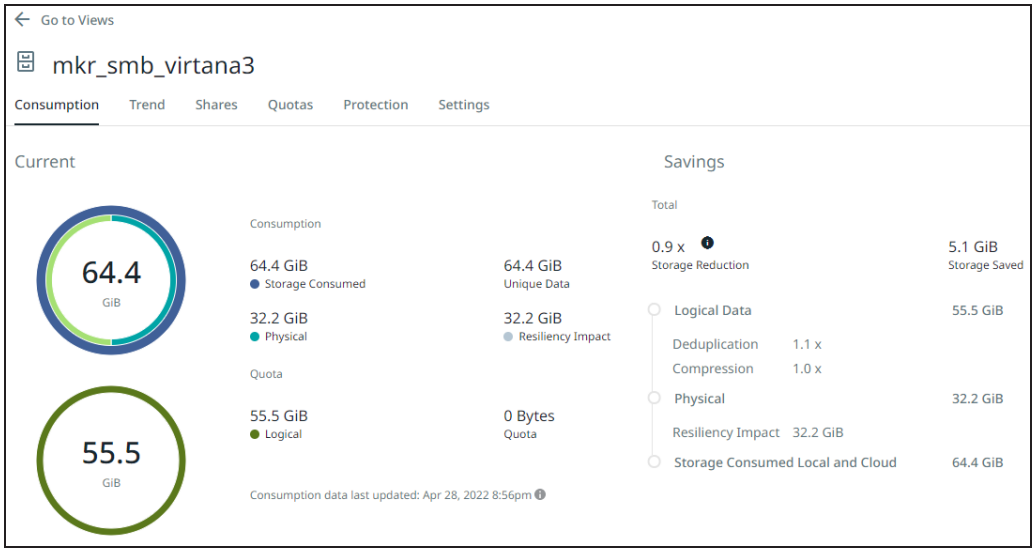
Consumption Details of a View

The view details page includes the **Consumption** tab, which displays the storage consumption and storage savings details for a specific Cohesity view.

To view the consumption details of a specific Cohesity view:

1. Navigate to **SmartFiles > Views**.
2. On the **Views** page, click on a view name to navigate to the corresponding view details page.

   The **Consumption** tab is displayed by default:



Related Topics

- Storage Statistics
- User and Directory Quotas for Views

Data Growth Trend of a View

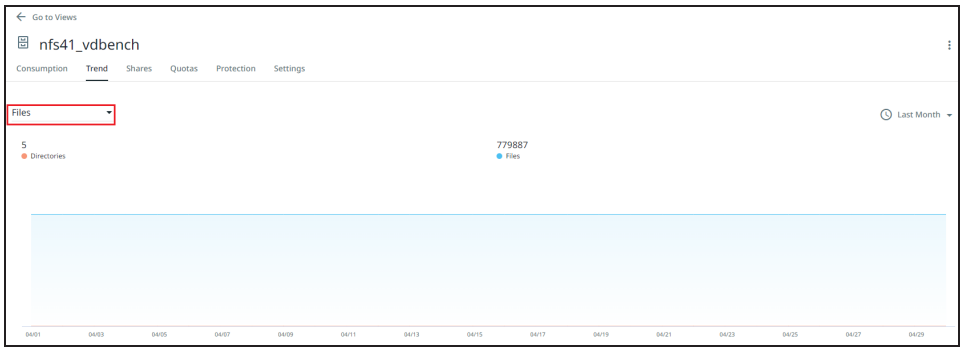
The view details page includes the **Trend** tab, which shows the data growth trend. The data is presented in a chart. You can customize the time period by selecting **Last Day**, **Last Week**, or **Last Month**. Turn on or off the **Storage Saved** or **Resiliency Impact** toggle to add or remove data from the chart.

To view the data growth trend of a specific Cohesity view:

1. Navigate to **SmartFiles > Views**.
2. On the **Views** page, click on a view name to navigate to the corresponding view details page.
3. Click the **Trend** tab and do one of the following:

- Select **Data** from the drop-down to view the data growth trend:

- Select **Files** from the drop-down to view the growth trend of directories and files:



Protection Details of a View

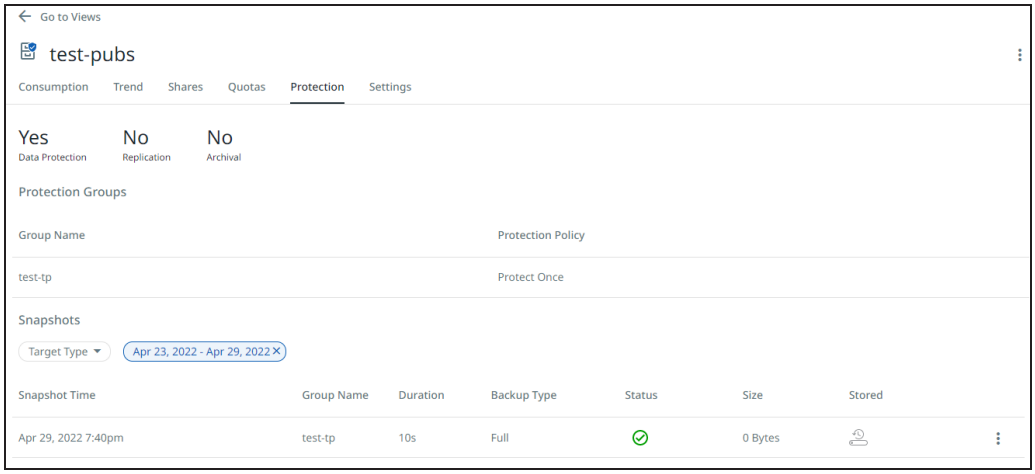
The view details page includes the **Protection** tab, which displays the protection details of the view. The following details are displayed:

- Data Protection status
- Replication status
- Archival status
- Protection group and protection policy details
- List of snapshots and snapshot details

To view the protection details of a specific Cohesity view:

1. Navigate to **SmartFiles > Views**.
2. On the **Views** page, click on a view name to navigate to the corresponding view details page.

3. Click the **Consumption** tab:



> **Note:** If the Cohesity view is not protected, a message is displayed. You can click **Create Protection Group** to protect the view. For more information, see Add or Edit a Protection Group for a View.

Cohesity View Details Page

The view details page includes the **Settings** tab, which displays all the details of the Cohesity view.

To view the details of a specific Cohesity view:

1. Navigate to **SmartFiles > Views**.
2. On the **Views** page, click on a view name to navigate to the corresponding view details page.
3. Click the **Settings** tab.

   The **View Details** section is displayed. All the details specific to the view are displayed. You can also navigate to the **File Services Audit Logs** page by clicking the **Manage Audit Logs** option.

File Shares (SMB)

The following topics provide guidance about using and managing file shares:

SMB Shares

Mounting and accessing views as SMB shares requires the following high level steps.

1. Review the information about optimizing storage domains and views for your use case.

   See SmartFiles (File and Object Services) Overview.

2. Create storage domains and views for your use case.

   See Create or Edit Storage Domains and Create Views Using a Predefined Template.

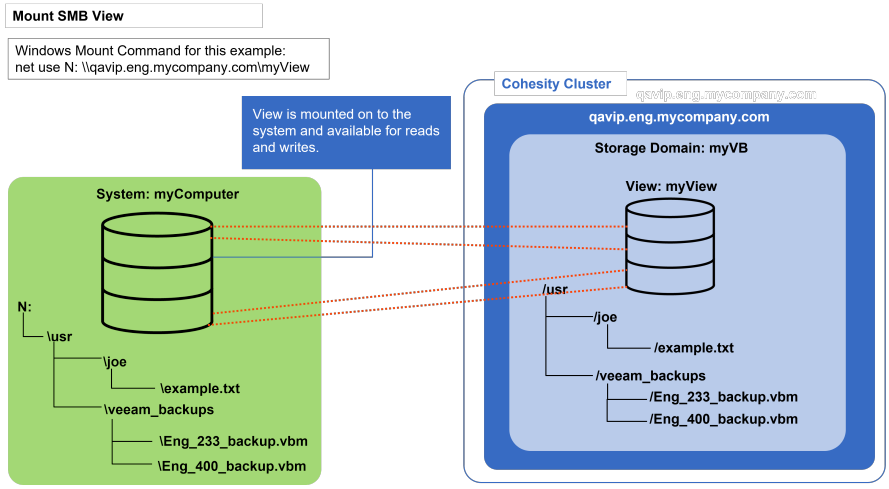
3. Add the client systems that will mount and access the views to the allowlist.

   See Add Subnets to Allowlists.

4. Mount the views to client systems so users and applications can store data in them.

   See Mount a View Using SMB.

Once the above steps are completed, you can use a view to store data such as files and directories. Other backup products, such as Veeam, can also store data in a view, as shown in the following figure.



SMB Features

The following SMB features are supported on the Cohesity cluster:

- SMB Oplocks
- Continuous Availability
- Fast Durable Handles
- SMB Offline
- SMB Multichannel

SMB Oplocks

The SMB Oplocks feature provides the capability for an SMB client to lock files and cache content locally. By caching the content on the client side, it improves the performance of read and write operations on the file and reduces the amount of network traffic required.

Enabling SMB Oplocks on a View also activates the file and directory leasing feature on newer clients, such as Windows 7 or later, or Windows Server 2008 R2 or later. This feature enhances performance by allowing the client to cache file and directory metadata.

The following table outlines the features utilized by the SMB client when the SMB Oplocks feature is enabled:

SMB Version	Clients	Feature Used
SMB 2.0	• Windows Vista or later • Windows Server 2008 • Mac OS X 10.9	The client uses the SMB2 oplocks feature
SMB 2.1	• Windows 7 or later • Windows Server 2008 R2	The client uses the SMB2 file leasing feature
SMB 3.0 (or later)	• Windows 8 or later • Windows Server 2012 or later	The client uses the SMB2 file and directory leasing feature

By default, the SMB Oplocks feature is enabled for a View, allowing the client to lock files and cache content locally for enhanced performance. However, it's important to note that enabling SMB Oplocks may introduce data inconsistency, as the data is cached locally on the client. If you prefer to ensure that the client commits writes to the SMB server synchronously, without caching the content locally, you have the option to disable the SMB Oplocks feature. This can be done by editing the View settings and modifying the **SMB Oplocks** option accordingly. For more information, see SMB Options.

Continuous Availability

Continuous Availability (CA) is a collection of features in SMB 3.0 protocol that aims to facilitate smooth failover in a clustered environment. Cohesity does not support all CA features.

Cohesity supports the Persistent Handles feature. By default, Persistent Handles is enabled on the Cohesity View, and the cluster node stores file handle operations on the disk. This allows SMB clients to reconnect to a different node in case of a node failure and seamlessly continue their operations with the same file handle. The Persistent Handles feature primarily pertains to the SMB 3.0 protocol and this can have an impact on SMB 2 clients.

By leveraging the Persistent Handles feature, Cohesity provides enhanced availability and seamless failover capabilities within a clustered environment, ensuring continuous access to data even in the event of a node failure.

> **Note:** If you enable the **Fast Durable Handles** option on a View, the Continuous Availability feature gets disabled.

Fast Durable Handles

The Fast Durable Handles option is designed to enhance performance for SMB clients by improving I/O operations, metadata operations, file listing, and more. It offers improved resiliency against service restarts of the Cohesity data service and short network failures. However, it's important to note that Fast Durable Handles might not be able to handle more significant events such as node failures or crashes of the SMB server service.

> **Note:** By default, when creating a View, the Fast Durable Handles feature is disabled. Enabling this feature for a View results in the Continuous Availability feature being disabled for that View.

You can enable the Fast Durable Handles feature for applications that can tolerate I/O failures and would benefit from faster performance on the client side. This feature is particularly useful for applications like Microsoft Office App or scenarios involving bulk changes of permissions.

> **Note:** If you enable or disable the **Fast Durable Handles** option for a View, it is necessary to unmap and then remap the SMB share associated with that View.

SMB Offline

The SMB Offline feature enables SMB clients to access and work with files even when they are disconnected from the network. By default, this feature is disabled, which means no caching is performed. However, you have the option to enable it on a per-View basis during the View creation process, and you can also modify it later for existing Views.

When the **Offline File Caching** option is enabled during View creation, the manual caching option is also enabled. If the **Offline File Caching** option is not enabled, manual caching is not enabled, ensuring that no offline access or caching is performed for that View.

SMB Multichannel

The SMB multichannel feature, available with the SMB 3.0 protocol, is supported at the cluster level. It enables SMB clients to utilize multiple network connections concurrently for read and write operations between the client and server. This capability enhances the throughput and performance of SMB communication by leveraging multiple network paths.

By leveraging SMB multichannel, users can experience improved data transfer speeds and optimized network utilization, resulting in enhanced performance during file transfers and data access. For information on enabling or disabling SMB Multichannel, see Enable or Disable SMB Multichannel.

Prerequisites for using SMB Multichannel

- Windows 8 or a later version, Windows Server 2012, or Windows Server 2012 R2 is required on both server and client.
- Both the server and client must be running on the SMB 3.0 protocol.
- The Windows Server must have a minimum of two network interfaces or the Receive Side Scaling (RSS) feature must be enabled.
- One or more network adapters should be configured using NIC teaming

Limitation

The option to advertise multiple IP addresses on the cluster is not supported.

Client Authentication Workflow with SMB Encryption Enabled

The following is the workflow for clients to authenticate to Cohesity when SMB encryption is enabled:

1. SMB Client reaches the Domain Controller and self-identifies using credentials.
2. SMB Client asks for ticket to service (Cohesity).
3. Domain Controller checks if SMB Client with the above credentials has access to the requested service. If accessible, the Domain Controller sends the ticket to SMB Client which only the service provider (Cohesity) can decode.
4. SMB Client sends this ticket in the SMB SessionSetup request.
5. Cohesity decodes this ticket. If successful, Cohesity sends *Success* in response to SessionSetup.
6. SMB Client sends TreeConnect request to connect to the specific View.
    - If SMB encryption is forced on the SMB Client, TreeConnect and all the following SMB commands will be encrypted by the SMB Client. The SMB2 specification SMB Server replies with the encrypted message to the encrypted request.
    - If SMB encryption is set to be forced from Cohesity (on View settings) above TreeConnect request as well as TreeConnect response will not be signed but in the TreeConnect response Cohesity will notify the SMB Client that the following messages for this View must be encrypted. Hence, the SMB Client must start encryption of all messages following TreeConnect.

> **Note:** The above workflow is not specific to Cohesity, except forced encryption setting on View. Cohesity follows the standard Kerberos/SMB/Encryption pattern.

Considerations

- For SMB, the maximum path length is tailored to the SMB clients that connect to Cohesity since the client machine controls the session to the SMB share. For more details, see Maximum Path Length Limitation.

SMB Super User

An SMB Super User is a privilege for AD users and groups, and local SMB users and groups. A user with this privilege has complete access to view or share content overriding any assigned ACLs. However, the privilege cannot override the global allowlist and file-level data lock permissions.

The SMB Super User privilege is helpful when you have migrated data from a different source storage to the Cohesity cluster. The privilege allows a user to access and set appropriate permissions on the migrated data.

If the SMB identity of an NFS user is given the Super User permissions, then the NFS user gets full access to the view when the view security style is set to unified or NTFS.

You can assign the SMB Super User privilege to a user when creating a view or share. You can also edit a view or share and assign the privilege. The privilege is set at the share level for a view and not as NTFS root permissions. When the Super User privilege is assigned to a user for a specific view or share, the user has complete access to all the contents of the view or share.

> **Note:** You can assign this privilege only from the Cohesity Dashboard.

A user with the Super User privilege cannot access files that are quarantined by an antivirus feature enabled on a view.

The SMB Super User privilege is replicated or archived when you replicate or archive the view or share.

Limitation:

The SMB Super User privileges that are set for shares (view-aliases) will not be effective for the mapped NFS identities for unified and NTFS security style views.

Best Practices for SMB Shares

Consider the following best practices when using views as SMB shares.

- For SMB client 2.x (Windows 7 and Windows Vista), set the HKLM\System\CurrentControlSet\Services\LanmanWorkstation\Parameters\DisableLargeMtu registry key value to 0 (zero) to enable 1 MB writes. Leaving the registry value at 1 (one) limits the size to 64 KB.
- If the SQL Server service runs as a non-regular user account (system or service account), it fails to write to an SMB share. To allow these accounts to write to an SMB

share, give the SQL server's domain machine account at least "Modify" access to the directory's ACL.

- The client's IP addresses must be within the global allowlist or View-level allowlist and use the correct subnet mask for allowlist entry.
- Ensure the LDAP server is reachable.
- Transitive trusts should be enabled if a user is part of an AD domain that requires transitive trusts.
- If you are using AD, add the cluster to the AD domain before creating a View.
- To improve performance when copying a lot of small files from a Cohesity SMB share, enable prefetching on the cluster. To enable prefetching on the cluster, contact Cohesity Support.

Add Subnets to Allowlists

Before you can mount and access a view, ensure the IP address of the system that is mounting the view is specified in a subnet that has been added to an allowlist.

Cohesity supports the following types of allowlists:

- **Global Allowlist**—The global allowlist applies to all views on the Cohesity cluster, but is overridden by a view allowlist or view share allowlist, if they exist.
- **View Allowlist**—Only the systems with IP addresses in the subnets listed in the view's allowlist have privileges to access and mount this view.

Update the Global Allowlist

To add a subnet to the Cohesity cluster's global allowlist:

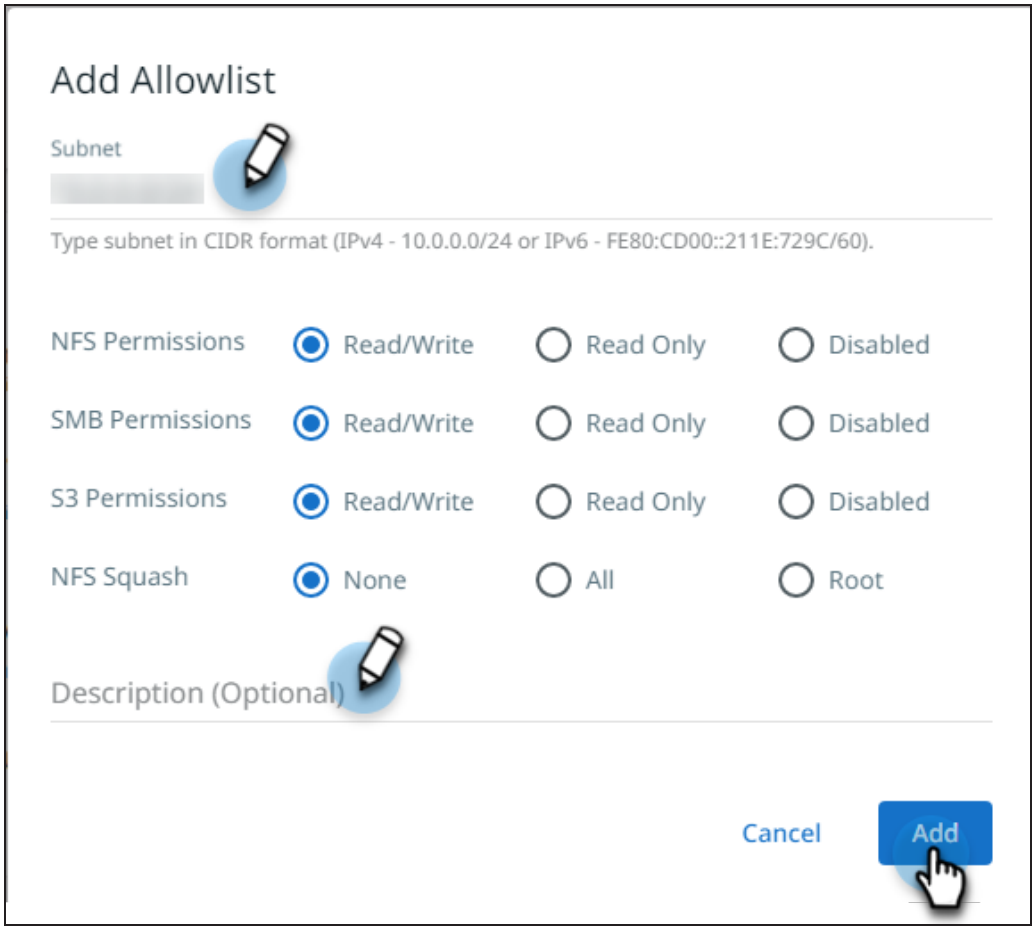
1. Navigate to **SmartFiles > Views**.
2. Click the **Global Settings** tab.
3. In the **Global Subnet Allowlist** section, click **Add**.
4. In the **Add Allowlist** dialog, enter a Subnet IP in CIDR format (IPv4 - 10.0.0.0/24 or IPv6 - FE80:CD00::211E:729C/60).

   > **Note:** CIDR prefix values are allowed from 0 to 32.

5. Select any or all permissions as required.

   > **Important:** By default, the ability to set **S3 Permissions** for restricting access to specific subnets is disabled. To limit S3-based access to specific subnets, review the How To Enable SmartFiles S3 View Allowlisting KB article.

6. Select **NFS Root Squash** as applicable.
7. In the **Description** field, enter a description for the allowlist.
8. Click **Add**:



9. Repeat the preceding steps for specifying additional subnets in the global allowlist.

Update a View Allowlist

To add a subnet to an existing view's allowlist:

1. Navigate to **SmartFiles > Views**.
2. Locate the required View in the list, click the ⋮, and select **Edit** ( ).
3. In Advanced settings, click **Edit** for the Security category.
4. **Override Global IP Allowlist:** Turn on **Override Global IP Allowlist** if you want to specify a custom list for this view. Only the systems with IP addresses in the subnets listed in the view's allowlist have privileges to access and mount this view. If you enable the **Override Global IP Allowlist** toggle, the machines listed in the subnets of the global Cohesity cluster allowlist cannot access or mount this view unless the IP address of the machine is also listed in the View's Allowlist.

Extend Global IP Allowlist: Allows you to extend the Global IP Allowlist.

To add subnets to the allowlist of this view:

a. Under **IP Allowlist**, select: **Override Global IP Allowlist** or **Extend Global IP Allowlist**.
b. Click **Add**.
c. In the **Add Allowlist** screen, type subnet in CIDR format.
d. Select any or all permissions as required.
e. Select **NFS Squash** options.

The **NFS all squash** option is like NFS Root Squash. However, for given IP addresses, all users are mapped to the All Squash User/Group configured in the view. The default All Squash User for all views is "nobody".

> **Note:** If the **Override Global Allowlist** toggle is off, this view can only be accessed and mounted by systems specified by the global Cohesity cluster allowlist.

5. Click **Update View**.

For more information on global settings for each protocol, see the following topics:

- Global Settings for NFS
- Global Settings for SMB

Global Settings for SMB

In addition to the settings provided in Add Subnets to Allowlists, the following settings are specific to SMB.

- Update a Share Allowlist
- Disable SMB Authentication
- Enable or Disable SMB Multichannel

Cohesity supports the following types of allowlists:

Share Allowlist—If a view has a share allowlist, only the systems with IP addresses in the subnets listed in the share allowlist have privileges to mount and access the folders and subfolders in the share.

You can add a share allowlist only to views that support the SMB protocol. The share allowlist is only in effect during SMB access. If the view supports both the SMB and other protocols, then access to the other protocols is subject to the view allowlist, if present, or the global allowlist.

> **Note:** When adding a single host IP address to an allowlist, the netmask must be 255.255.255.255.

After the Cohesity cluster is upgraded to 6.6.0c, note the following:

Existing NFS or SMB view—IP restriction is retained. If you access an existing NFS or SMB view using the S3 protocol, the request fails if the existing allowlist does not include the IP address of S3 clients. Before or after the upgrade, ensure to add the IP address or subnet at the view level if the NFS or SMB view is accessed using the S3 protocol.

Update a Share Allowlist

You can add an SMB share allowlist when creating or editing a share. For more information, see Manage Share Aliases.

Disable SMB Authentication

You can disable Active Directory authentication for SMB shares if you want users' AD credentials to be used only for logging on to the Cohesity cluster.

1. Navigate to **SmartFiles > Views**.
2. Click the **Global Settings** tab.
3. Turn off the **SMB Authentication** toggle.
4. In the **Disable SMB Authentication** screen, click **Disable**.

A message appears at the bottom of the screen confirming the change.

Enable or Disable SMB Multichannel

The SMB Multichannel feature is enabled by default and you may not need to disable it for any performance or networking problem. If you disable the feature, the performance and the reliability of the SMB3 protocol might reduce.

For more information about SMB Multichannel, see SMB Multichannel.

Prerequisites for using SMB multichannel:

- Windows 8 or later, Windows Server 2012 R2, Windows Server 2012 or higher on both server and client.
- Server and client must be on SMB 3.0.
- The Windows Server must have a minimum of two network interfaces or Receive side scaling (RSS) feature is enabled.
- One or more network adapters are configured using NIC teaming.
- Assign additional VIPs to each node for improved performance of SMB multichannel.

To disable or enable the SMB Multichannel feature:

1. Navigate to **File Services**> **Views**.
2. Click the **Global Settings** tab.
3. Under the **SMB Options** section, complete the following steps:
    1. Turn off the **SMB Multichannel** toggle.
    2. In the **Disable SMB Multichannel** screen, click **Disable**.

> **Note:** Turn on the **SMB Multichannel** toggle to enable SMB Multichannel. The confirmation message is displayed at the bottom of the screen.

Mount a View Using SMB

Before you can store data on a view, you have to mount it as an SMB share on your Windows system.

Prerequisites

- The view to be mounted must be enabled for the SMB protocol.
- The system that will mount the view must be in a subnet in a Cohesity allowlist. Otherwise, the system will not have privileges to mount and access the view.

Considerations

- Keeping with the industry standard of change notification for SMB shares, recursive change notifications are not sent due to their effect on process load and network traffic.
- Filenames that contain UTF-16 character codes ranging from U+D800 to U+DFFF are not allowed in Cohesity SMB shares.
- For Linux clients that are members of AD, using "client max protocol = SMB2" in the [global] section of /etc/samba/smb.conf is not supported. Use "client max protocol = SMB3".
- Cohesity SMB shares do not support alternate data streams.
- You can add Cohesity SMB shares as a Microsoft Distributed File System (DFS) target, but note that SmartFiles does not support any additional features or functionalities provided by Microsoft DFS.
- Windows behavior prevents Cohesity SMB shares from being automatically discoverable. Use the `net view` command to probe the cluster explicitly using \\<Cluster-machine-account-name> or \\<Cluster-vip-FQDN> or \\<Cluster-VIP>.

Mount a View

1. In the Cohesity Dashboard, copy the view mount path:
   a. Select **SmartFiles > Views**.
   b. Browse for the view in the list.
   c. Click the **Mount Paths** icon of SMB.
   d. In the **Mount Paths** screen, click the copy icon for SMB mount path and click **Close**.
2. On the Windows machines, mount the view as an SMB share using the mount path copied previously. You can use OS commands or utilities.

   For example, you can use the Windows command prompt to run the following command:

   ```
   net use <Drive Letter>: \\<View Mount Path>
   ```

   Example:

   ```
   net use N: \\qavip.eng.mycompany.com\myView
   ```

   If using Windows PowerShell, you do not have to mount the view. You can change the directory directly to a UNC path as long as your Windows login has privileges for the remote share. For example, you can do the following:

   ```
   cd \\<View Mount Path>
   ```

   The mounted file system is available to store data.

   If you want to use a Cohesity SMB share as a target for backup applications such as Veeam or CommVault, ensure you provide the UNC path to the target, for example:

   ```
   \\Hostname_or_VIP\myView
   ```

3. **Important:** At this point, the Cohesity root share does not have any default permissions or Access Control Entries (ACEs). The Windows administrator must apply these permissions before the share is ready for use.
   a. On the Windows machines, right-click the share root and go to **Properties > Security**.
   b. ACEs are applied only if the Administrator specifically adds ACEs to the share. A warning is displayed asking the logged-on user to assign ACEs to the share root.

Share Based Backup Using Remote VSS

Cohesity supports shadow copy creation for SMB views through Remote VSS (Volume Shadow Copy Service). With Remote VSS, you can take the application consistent shadow copies for applications that store data and configuration files on shares.

A shadow copy of the data represents a copy of the data in the share taken at a particular instant in time. A set of one or more of these shadow copies is collectively called as a

Shadow copy set. Each shadow copy and shadow copy set is represented with a unique GUID.

Create Backup Using Remote VSS

The generic steps to take a backup using Remote VSS are as follows:

1. Prepare for Shadow Copy.
    - The VSS client running on the application first collects information about what shares must be included while taking a shadow copy set. A shadow copy refers to one share location.
2. Create Shadow Copy.
    - Cohesity creates a clone of every view share in the shadow copy set.
    - Once the shadow copy is created, the clone of the shadow copy set is exposed.
3. Recovery of Shadow Copy set.
    - During the creation of shadow copy, if there are any modifications being done to the files that are being cloned, the VSS application must update these copies so that the shadow copy set is in a consistent state.
    - If auto recovery is enabled, then read/write permissions to that share must be set.
    - After recovery, all created clones are updated with read-only permissions.
4. Optional: Delete Shadow Copy.
    - The shadow copy can be deleted in the future if no more is required.

List Active SMB Connections and File Opens

You can use the Cohesity CLI to list active SMB connections and file opens for views.

List Active SMB Connections

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

    Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

    ```
    ./iris_cli -server 172.16.3.101 -username=admin
    ```

2. List the active SMB connections for Views by using the Cohesity CLI `view list-smb-connections` command:

    ```
    admin>view list-smb-connections
    ```

> **Tip:** You can also use the CLI Help feature to view the `view list-smb-connections` options by entering the following command: `view list-smb-connections help`.

CLI Option	Example	Description
`names=`	`ViewName1,ViewName2`	Optional. Specify a comma separated list of View names. The active SMB connections for these Views are displayed.

List Active SMB File Opens

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. List the active SMB file opens by using the Cohesity CLI `view list-smb-file-opens` command:

   ```
   admin>view list-smb-file-opens
   ```

   > **Tip:** You can also use the CLI Help feature to view the `view list-smb-file-opens` options by entering the following command: `view list-smb-file-opens help`.

CLI Option	Example	Description
`cookie=`	`string`	Optional. Copy and paste the cookie returned from a previous command's output to get the next set of entries in the output. A cookie is included at the end of the output if there are additional entries to display. For example, if you specify `page-count=10` and there are still more entries to display, include the cookie in the command and run it again to display the next set of entries. If this option is not specified, the command always outputs the first set of entries.
`file-path=`	`FilePath`	Optional. Specify the file path to an SMB file relative to the SMB mount path. The active SMB file opens for this file are displayed. If this option is not specified, the command outputs all file paths that have file opens.

CLI Option	Example	Description
`name=`	`ViewName`	Optional. Specify the name of the View. The active SMB file opens for this View are displayed. If this option is not specified, the command outputs all open file paths in all Views in the Cohesity cluster.
`page-count=`	`10`	Optional. Specify the number of entries you want the output to display. This limits the number of entries in the command output. If this option is not specified, the command outputs a maximum of 1000 entries or the number of file opens, whichever is smaller.

Supported Windows Well-Known SIDs

Starting with Cohesity 6.5.1, Cohesity added support for the following Windows well-known security identifier (SIDs) groups. For more information on SIDs, Well-known-security-identifiers-in-windows-operating-systems.

SID	Name
S-1-5-32-544	Administrators
S-1-5-32-545	Users
S-1-5-32-546	Guests
S-1-5-32-547	Power Users
S-1-5-32-548	Account Operators
S-1-5-32-549	Server Operators
S-1-5-32-550	Print Operators
S-1-5-32-551	Backup Operators
S-1-5-32-552	Replicators
S-1-5-32-582	Storage Replica Administrators

> **Note:** These supported SID groups are Windows SMB-specific groups and these are different from Cohesity inbuilt roles.

A Windows Administrator can assign any of the supported SID groups to a Cohesity share mounted on Windows Server or use the Microsoft Management Console (MMC) console to grant or deny access for the assigned SID group.

Once the supported SID group is assigned to the Cohesity share by the Windows Administrator, you can see the SID group name in the View properties under the NTFS root permissions of the Cohesity Dashboard.

For example, if you grant Read/Write permissions for the Backup Operators group to a View, the View Settings in the Cohesity Dashboard displays the group name (**File Services**>**Views**>(click the View name)**Settings**> **SMB Options**> **NTFS Root permissions**).

Limitation

You cannot assign these SID group roles to a View from the Cohesity Dashboard.

Microsoft Management Console (MMC) Integration

You can use the Shared Folders Microsoft Management Console (MMC) snap-in on Microsoft Windows clients to perform basic configuration and management actions for SMB shares on a Cohesity cluster.

Set up a Windows Client to Manage SMB Shares on Cohesity

Before you can manage Cohesity SMB shares, you must map a drive on the Windows client where MMC will be used to a Cohesity share.

When mapping, ensure you do the following:

- Add the Cohesity cluster to an Active Directory domain.
- Use the FQDN of the Cohesity cluster. For example: \\MyCluster.cohesity.com\

  Where, *MyCluster* is the machine account used to add the Cohesity cluster to the Active Directory domain. For more information, see Active Directory.

  The VIP of the Cohesity cluster is also supported but using the FQDN is recommended.
- The user logged into the Windows client must be a domain administrator or must have the Full Control permission on the share.
- For a View, the **Shares are Browsable** option must be toggled on for the shares to be discoverable by the Windows `net view` command. For more information, see Create a View.

Supported Actions Using MMC

- List Shares
- Get/set Share Permissions
- List Sessions
- List Active Open Files
- Close Active Open Files

- Create a Share
- Stop Sharing a View Alias

List Shares

1. Open the Shared Folders MMC snap-in:
   a. Click **Start > Run**.
   b. Type fsmgmt.msc and click **OK**.

      Shared Folders MMC snap-in opens.
2. Connect to the Cohesity cluster that has the SMB shares:
   a. Click **Action > Connect to another computer**.
   b. Type the FQDN of the Cohesity cluster. For example: MyCluster.cohesity.com
   c. Click **OK**.
3. In the left pane, click **Shares**. The right pane lists all SMB shares.

Get/set Share Permissions

1. Open the Shared Folders MMC snap-in:
   a. Click **Start > Run**.
   b. Type fsmgmt.msc and click **OK**.

      Shared Folders MMC snap-in opens.
2. Connect to the Cohesity cluster that has the SMB shares:
   a. Click **Action > Connect to another computer**.
   b. Type the FQDN of the Cohesity cluster. For example: MyCluster.cohesity.com
   c. Click **OK**.
3. In the left pane, click **Shares**. The right pane lists all SMB shares.
4. In the right pane, right-click the desired share and then click **Properties**.
5. To get the permissions a user or group has for the share:

   On the Share Permissions tab, click the desired user name or the group name. The permissions are displayed in the 'Permissions for' section.
6. To set the permissions a user or a group has for the share:

   On the Security tab, click the desired user name or the group name and then click **Edit**.

   > **Note:** Changes affect the SMB share only, not the ACL in the file system of the exported directory.

List Sessions

1. Open the Shared Folders MMC snap-in:
   a. Click **Start > Run**.
   b. Type fsmgmt.msc and click **OK**.
   Shared Folders MMC snap-in opens.
2. Connect to the Cohesity cluster that has the SMB shares:
   a. Click **Action > Connect to another computer**.
   b. Type the FQDN of the Cohesity cluster. For example: MyCluster.cohesity.com
   c. Click **OK**.
3. In the left pane, click **Sessions**. The right pane lists all active sessions to SMB shares.

List Active Open Files

1. Open the Shared Folders MMC snap-in:
   a. Click **Start > Run**.
   b. Type fsmgmt.msc and click **OK**.
   Shared Folders MMC snap-in opens.
2. Connect to the Cohesity cluster that has the SMB shares:
   a. Click **Action > Connect to another computer**.
   b. Type the FQDN of the Cohesity cluster. For example: MyCluster.cohesity.com
   c. Click **OK**.
3. In the left pane, click **Open Files**. The right pane lists all open files.

Close Active Open Files

1. Open the Shared Folders MMC snap-in:
   a. Click **Start > Run**.
   b. Type fsmgmt.msc and click **OK**.
   Shared Folders MMC snap-in opens.
2. Connect to the Cohesity cluster that has the SMB shares:
   a. Click **Action > Connect to another computer**.
   b. Type the FQDN of the Cohesity cluster. For example: MyCluster.cohesity.com
   c. Click **OK**.
3. In the left pane, click **Open Files**. The right pane lists all open files.
4. In the right pane, right-click the desired file and then click **Close Open File**.

Create a Share

You can create a View or a View alias.

1. Open the Shared Folders MMC snap-in:
   a. Click **Start > Run**.
   b. Type fsmgmt.msc and click **OK**.

      Shared Folders MMC snap-in opens.
2. Connect to the Cohesity cluster that has the SMB shares:
   a. Click **Action > Connect to another computer**.
   b. Type the FQDN of the Cohesity cluster. For example: MyCluster.cohesity.com
   c. Click **OK**.
3. Right-click **Shares** and select **New Share**.

   When the Shared Folder wizard opens, click **Next**.
4. **Folder path:** Enter a Storage Domain name and/or a View name or a folder path in a View. These must already exist on the Cohesity cluster.

   To create a View in the Storage Domain on the Cluster, for example, enter `c:\<storage-domain-name>`

   To create a View alias on the Cluster, for example, enter `c:\<storage-domain-name>\<view-name>\<view-path>`

   > **Note:** Using the Browse option to create a share is not supported.
5. **Share name:** Enter the `<share-name>`, which is either the View name or View alias name that will be created. This is based on the Folder path.
6. Select permissions and click **Finish**.

Stop Sharing a View Alias

> **Note:** Stopping sharing for a View in the Cluster is not supported.

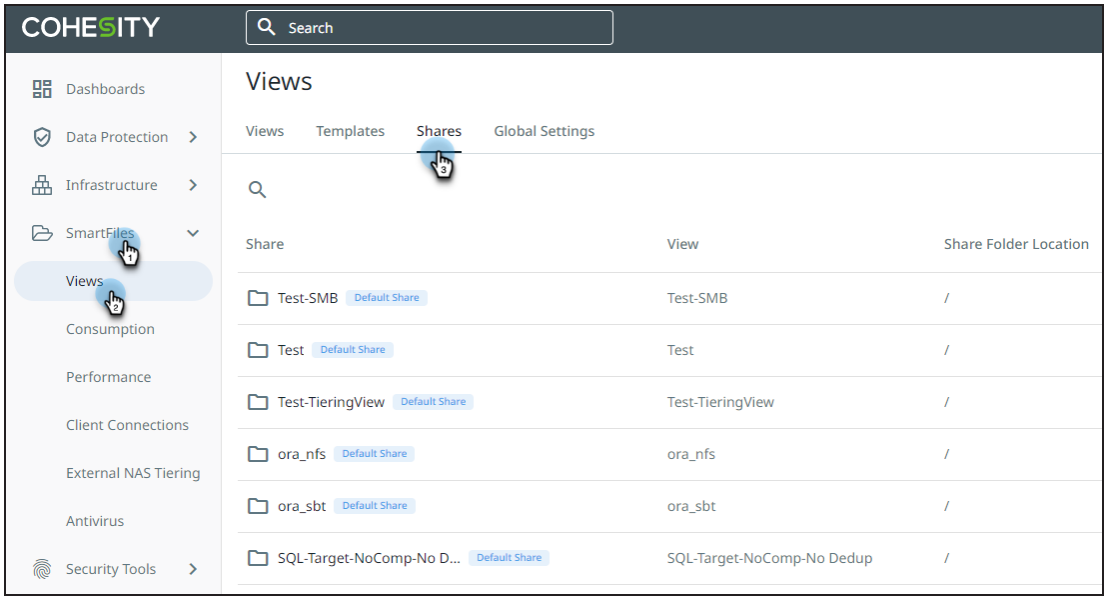
1. Open the Shared Folders MMC snap-in:
   a. Click **Start > Run**.
   b. Type fsmgmt.msc and click **OK**.

      Shared Folders MMC snap-in opens.
2. Connect to the Cohesity cluster that has the SMB shares:
   a. Click **Action > Connect to another computer**.
   b. Type the FQDN of the Cohesity cluster. For example: MyCluster.cohesity.com
   c. Click **OK**.

3. Click **Shares**.
4. Right-click the View alias you want to stop sharing and click **Stop Sharing**.

Manage Share Aliases

A share is used to mount a View on a user's system. Cohesity automatically creates a default share name for each View in the cluster, using the View name as the share name. If a View is renamed, the default share name reflects the new name. The default share name provides access to the root View. To see a list of shares in the Cohesity cluster, navigate to **SmartFiles > Views** and click the **Shares** tab:



You can manually create a share alias to an existing folder in a View. Users can then use the alias to access the folder without providing (or even knowing) the full path to it. This allows you to expose only that folder and its files and sub-folders. The user does not see the parent folders.

Using an alias can shorten the path used in the mount command. Also, unlike the default share name, the alias does not change if the View is renamed.

Consider a View that contains nested folders as shown below:

```
viewName
       dirOne
              dirTwo
                     dirThree
```

For example, you can assign a share name of `Three` to the `\dirOne\dirTwo\dirThree` path and then use the share name as follows:

- Windows: `net use V: \\vip.eng.mycompany.com\Three`
- Linux: `mount -t nfs vip.eng.mycompany.com:/Three mnt`

You can create multiple shares for different folders in Views. Share names must be unique within the Cohesity cluster.

> **Note:** If a share name refers to a folder that gets deleted, the share will be discoverable but you cannot mount it until you recreate the folder.

Create a Share

1. Navigate to **SmartFiles > Views**.
2. On the **Views** page, click on a view name to navigate to the corresponding view details page.
3. Click the **Shares** tab.
4. Click **Create Share**:

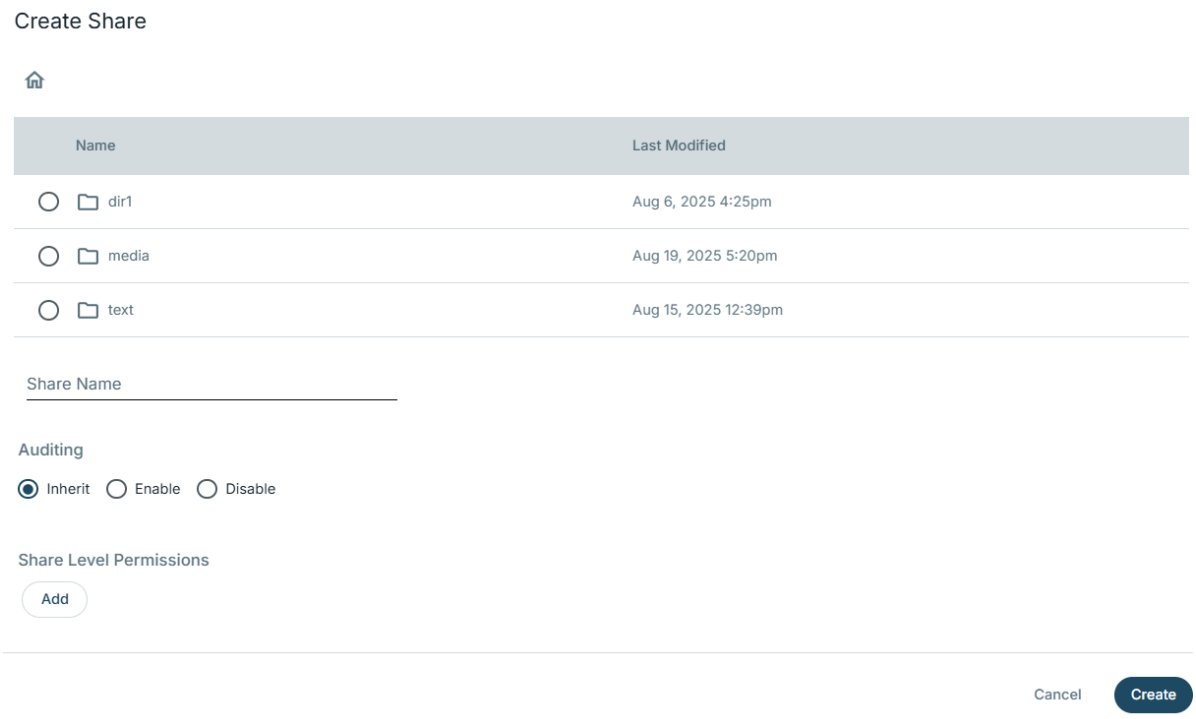
   The root/folder and any sub-folders in the View are displayed.

5. **Share Name**—Displays a modifiable name, based on the final folder in the path. Change the name as needed. The name must be unique within the Cohesity cluster.

   Auditing—If auditing is enabled on the View, share-level auditing is automatically enabled.

   By default, **Inherit** is selected.

   For user-created shares, you can override the View-level setting. You can enable or disable auditing on a share. If you enable auditing on a share, the share is audited even if auditing is disabled on the View. If you disable auditing on a share, the share is not audited even if auditing is enabled on the View:



> **Note:** You cannot modify the auditing setting of the default share from the share details page. To modify the auditing setting of the default share, edit the View and update the setting. For more information, see Enable or Disable Audit Logs for Views.

6. **Share Level Permissions**—For an SMB share, you can optionally define custom permissions for the share. The share-level permissions are stored on the cluster as view metadata and are independent of the NTFS permissions.

   Search for and select the principal (user or group) that you want to define permissions for. Select **Allow** or **Deny**. Click **Add**. Permissions adhere to the prescribed behavior of ACEs in a DACL.

7. **Super Users**—An SMB Super User is a privilege for AD users and groups, and local SMB users and groups. Select the AD domain and principal (user or group). Click + to add additional super users.

   A user with this privilege has complete access to view or share content overriding any assigned ACLs. However, the privilege cannot override the global allowlist and file-level data lock permissions. The privilege is set at the share level for a View and not as NTFS root permissions. When the Super User privilege is assigned to a user for a specific View or share, the user has complete access to all the contents of the View or share. For more information, see SMB Super User.

> **Note:** The most restrictive permissions are applied. The permissions can be **Full Control**, **Modify**, **Read Only**, or **Super User**. For example, if NTFS permissions are Read and Write, but the share permission is Read, the Read permission is applied.

8. **Override Global Allowlist**—Available only if the View supports the SMB protocol. Turn on the toggle if you want to create an allowlist for the share and override the Cohesity cluster's global allowlist.

   Click **Add Allowlist** and enter a subnet IP and subnet mask to specify a range of systems that have access to the share. Select the SMB permissions and enter an optional description. Click **Add**.

9. Click **Create Share**.

Edit a Share

You can change the global allowlist overrides for SMB views and share permissions for a share.

1. Navigate to **SmartFiles > Views** and click the **Shares** tab.
2. Click the share name you want to change.
3. Modify the share-level permissions and/or global allowlist overrides.

Delete a Share

You can delete a user-created share. You cannot delete a Cohesity-created share (the **Folder** column on the **Shares** tab contains only a forward slash / for these shares).

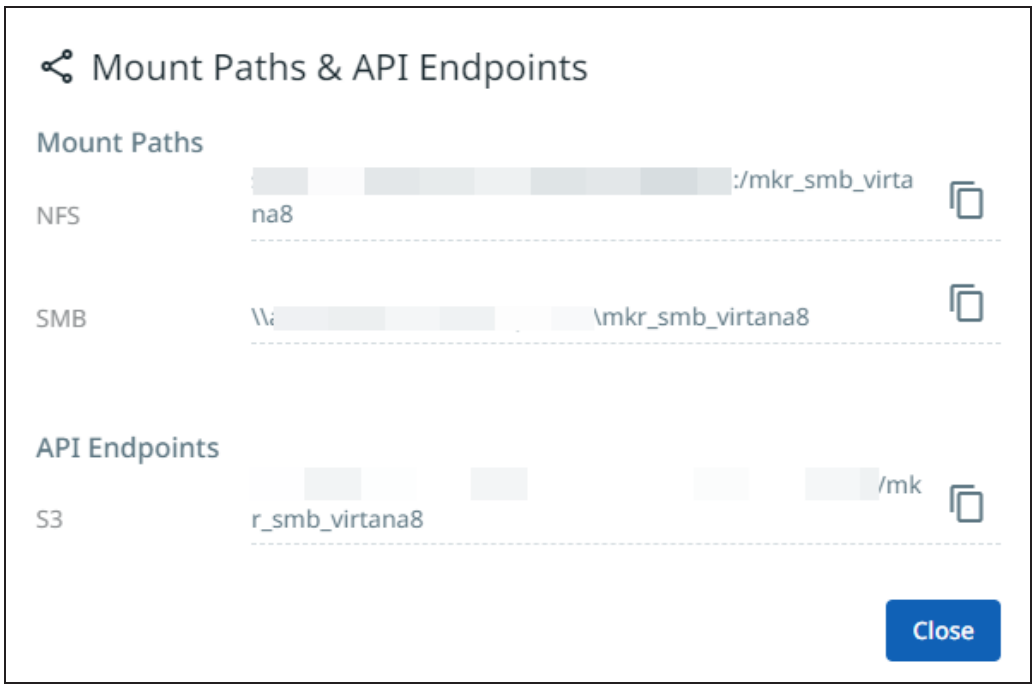
1. Navigate to **SmartFiles > Views** and click the **Shares** tab.
2. In the **Shares & Mount Paths** section, hover over the share that you want to delete and click the delete icon.
3. Confirm the deletion.

Mount Paths & API Endpoints

To view mount paths and API endpoints:

1. Navigate to **SmartFiles > Views**.
2. On the **Views** page, click on a view name to navigate to the corresponding view details page.
3. Click the **Shares** tab.
4. In the **Shares & Mount Paths** section, click corresponding to the share name to

view the **Mount Paths & API Endpoints** dialog:



Troubleshooting File Share Issues

Use the following information to troubleshoot file share issues.

Error: Could not Mount Datastore on any Host

Symptom: Attempting to mount a view results in the error:

```
Could not mount datastore on any host [additional details: NFS mount
<FQDN>:<NFS Path> failed: The mount request was denied by the NFS server.
Check that the export exists and that the client is permitted to mount it.
```

Cause: A configuration error in the global or view allowlist.

Resolution: Perform the following actions:

- Ensure that the subnet of the host is included as a part of the subnets in allowlist for the view.
- Disable the **Access Based Enumeration** option for the view. If Access Based Enumeration is enabled, then when a user browses an SMB share, only the files and folders that a user has privilege to access are displayed.
- After configuring the global allowlist, ensure that the hostname of the Cohesity cluster is successfully resolved. DNS resolution errors will be reported as:

  ```
  Could not mount datastore on any host [additional details: Operation
  failed, diagnostics report: Unable to resolve hostname '<FQDN>']
  ```

To resolve this issue in a VMware environment, add the DNS server that can resolve the FQDN using the following command:

```
esxcli network ip dns server add  --server=<DNS Server IP>
```

Error: Skipped Backing Up {folder name}

Symptom: Protecting a physical server via SMB shares to a Cohesity view fails with the error:

```
Skipped backing up {folder name} due to: Failed to create a new connection
to 10.1.0.33/G$, error msg: smbc_wrapper_cli_full_connection failed: NT_
STATUS_IO_TIMEOUT
```

Cause: This error is expected if the option **Skip Files on Errors** is enabled in the Protection Group. The option is enabled by default and lets the Protection Group continue to run even if it encounters errors on files, such as permissions errors. The Protection Group attempts to protect the files on the next protection run.

Resolution: Disable the **Skip Files on Errors** option (note that any error on a file will cause the Protection Group to fail.) For more information, see Protect NAS.

Error: [kInvalidRequest]: Diff streamer could not visit any entity successfully

Symptom: Any of the following:

- After creating a NAS Protection Group to protect CIFS/SMB shares, the Protection Group fails with the error:

  ```
  [kInvalidRequest]: Diff streamer could not visit any entity
  successfully
  ```

- When registering a NAS source, clicking the **Register** button after entering the SMB user credentials may fail with the error:

  ```
  HTTP POST - Authorization failed
  ```

Cause: Typically an authentication failure. Specific reasons include:

- Credentials recently changed.
- Credentials were entered with an invalid syntax. For example, the Cohesity Dashboard expects domain\user syntax, but accepts user@domain. The format user@domain results in several different issues when attempting to back up and must be avoided.
- Management traffic traverses a 1G interface, and the domain controller is not reachable from this interface.
- Domain account is being used to register the source for a Cohesity cluster which has not been registered with a domain.
- A NAS Protection Group is running on Windows 2003, which supports SMBv1. A mismatch of SMB versions may be occurring.

- The Active Directory server configuration may need to be changed. For example, trusted domains may need to be set to 0. Refer to Cohesity knowledge base article Slow or no Cohesity Dashboard login when authenticating with Active Directory domains.

Resolution: Perform the following actions:

Update the credentials:

1. In the Cohesity Dashboard, select **Data Protection > Sources**.
2. Find the source in the list, click the Actions Menu ⋮ and select **Edit**.
3. Select the Edit icon next to the Protection Group.
4. Re-enter the username and password.
5. Click **Save**.

If a log message similar to the following is reported, investigate an SMB version mismatch.

```
E0514 00:34:59.163116  8201 file_backup_base_op.cc:3938] backup_1296951_
1/task_1296954Skipping backup of entity  due to error: [kInvalidRequest]:
Failed to get metadata for path , error msg: Failed to open: NT_STATUS_
INVALID_PARAMETER
```

Use the following command syntax to mount an SMB share manually to test the connection. Adjust the value in the `vers` field, as required.

```
/usr/bin/sudo USER=<username> /usr/bin/timeout --signal=SIGINT --kill-after-
r=1s 10s /usr/bin/mount -t cifs -o vers=1.0,soft,intr,user_xat-
tr,domain=<domain>,ro <share_path> <mount_path>
```

Error: nfs: server {server name} not responding, still trying

Symptom: The following error occurs when you connect to the Cohesity cluster with the NFS Client:

```
nfs: server {server name} not responding, still trying
```

Cause: The timeout value between the NFS Client and the Cohesity cluster is set too low.

Resolution: Increase the timeout value in the NFS client using the `timeo` mount option. For more information about NFS mount options, see the NFS Linux man page.

Some files are not displayed in the view

Symptom: The Windows NFS client does not display all the files in a view.

Cause: The view supports only the SMB protocol.

Resolution: Perform the following actions:

1. In the Cohesity Dashboard, select **SmartFiles > Views** .
2. Find the view in the list, click the Actions Menu ⋮ and select **Edit**.

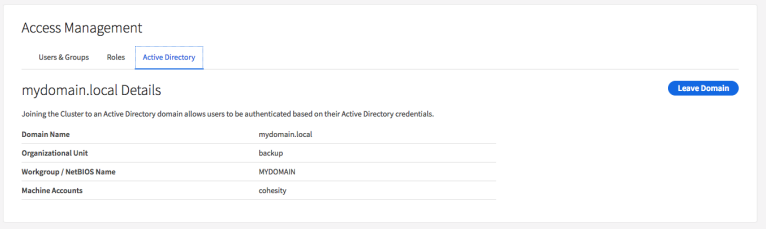
3. Click **Show Advanced Settings** and select **All** from **View Protocol**.
4. Enable **Shares are Browsable**. If disabled, the shares will be hidden.
5. Disable **Access Based Enumeration for SMB**. If the Access Based Enumeration is enabled, then when a user browses an SMB share, only the files and folders that a user has privileges to access are displayed.
6. Click **Update View** to save the changes.

Error: Path not found

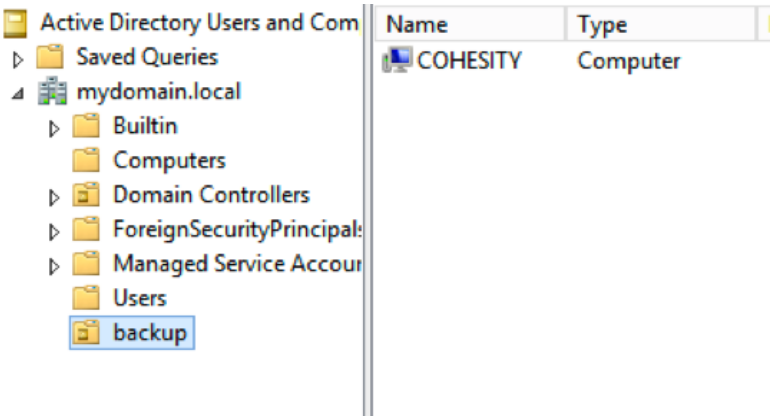
Symptom: The error `path not found` occurs when attempting to browse an SMB share for a view. Recovery tasks also fail.

Cause: When a Cohesity cluster is joined to an Active Directory, Cohesity SMB views use the computer name. This name is different from the Cohesity cluster name and what is configured in DNS. This difference will cause a "`path not found`" error and cause recovery tasks to fail.

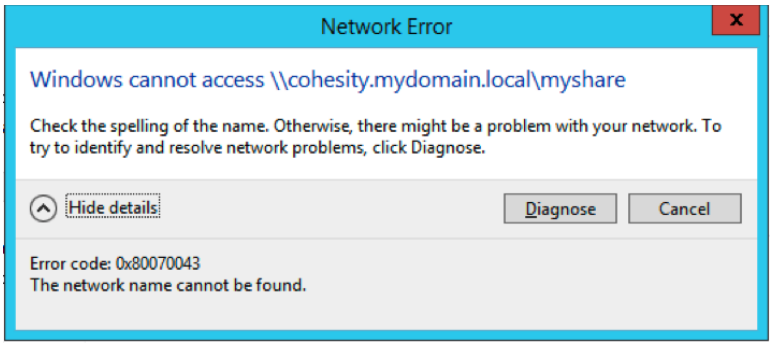
For example, in the following figure, the machine account name for the Cohesity cluster is Cohesity (in the Cohesity Dashboard, select **Settings > Access Management** and click the **Active Directory** tab).



Looking at the Active Directory, the computer account will be created with the name Cohesity.



Since a DNS entry does not exist, the following network error will be returned. You can verify it by browsing `IP\\server name IP\share name`.



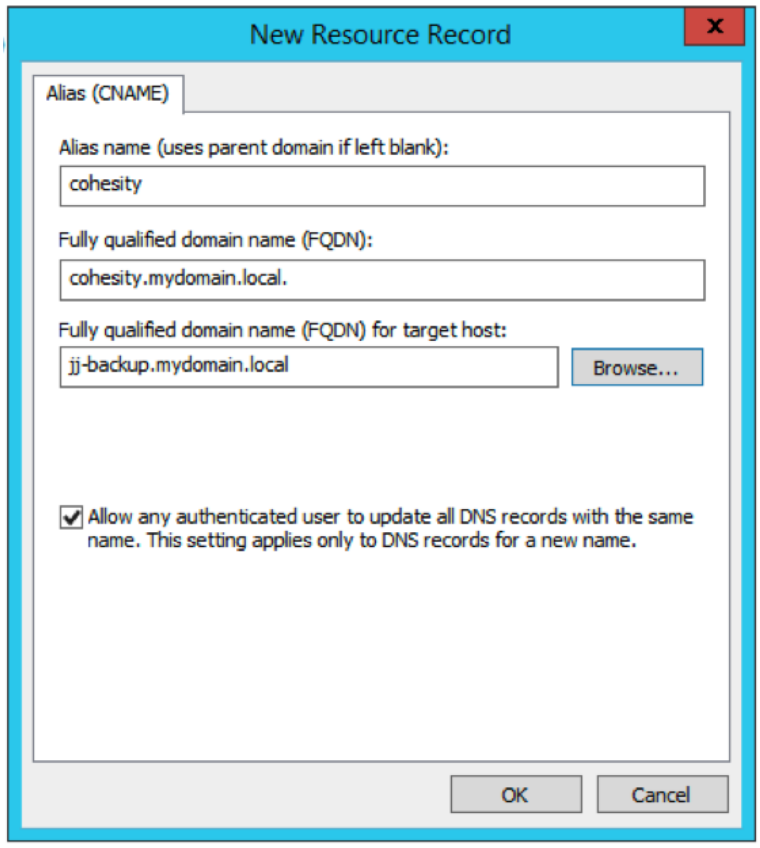
Attempting to ping Cohesity cluster or use `nslookup` on Cohesity cluster will fail.

```
C:\Users\Administrator&gt;nslookup cohesity.mydomain.local
Server:  UnKnown
Address:  ::1
```

Resolution: Perform one of the following actions:

- Create a DNS CNAME for resolving the machine account. From Windows DNS, right-click the new record, and then select the **CNAME** option.

  For example, in the following figure, the Cohesity cluster is **jj-backup** and has a DNS record. If no DNS record exists for the cluster's IP address, create a new A record and use the IP address of the cluster.



- Leave the domain AD (in the Cohesity Dashboard, select **Settings > Access Management > Active Directory** and click **Leave Domain**) and rejoin using a machine account that resolves in DNS.

  After the domain join completes, verify the Cohesity cluster with the `ping` and `nslookup` commands, and then test browsing a view via SMB.

Error: mount error(13): Permission denied

Symptom: Accessing an SMB share results in the error `mount error(13): Permission denied`, for example:

```
mount //app99/userdata to /home_cohesity_data/magneto/tmp/nas_mnt/source_
cohesity-3313822519568060-585114 failed: mount error(13): Permission denied
Refer to the mount.cifs(8) manual page (e.g. man mount.cifs)
```

Cause: The user credentials for the account accessing the SMB share may have changed.

Resolution: Update the Cohesity cluster with the new credentials.

Error: Windows cannot access {filename}

Issue: The "Enter network credentials" prompt is displayed on every mount or access attempt and the following error message is displayed:

```
Windows cannot access {filename}
You do not have permissions to access {filename}
```

Cause: The error is probably due to any of the following reasons:

- Client's IP address is not within the global allowlist.
- Access-Based Enumeration (ABE) is enabled
- AD group credentials are incorrect
- The LDAP server is unreachable

To confirm the IP address that is being denied, SSH to a node and run the following command:

```
grep -r <ip address> ~/logs/bridge_exec.*INFO*
```

Workaround: Depending on the root cause, use one of the following workarounds:

- Reconfigure the global allowlist to include the client's IP address, or override the global allowlist within the View configuration. For more information, see Add Subnets to Allowlists.
- Disable the **Access-Based Enumeration** option. For more information see, Create Views Using a Predefined Template.
- Refer to the Slow Cohesity Dashboard logins when authenticating with Active Directory domains KB article for guidance on how to troubleshoot an unreachable LDAP server.

Collect Information for SMB Troubleshooting

If you are unable to resolve an issue and need to contact Support, Cohesity recommends collecting the following information to assist Support with troubleshooting:

- Bridge logs: Search for LDAP errors. For information on capturing bridge logs, see Capture Logs.

  For example, `logs/bridge_exec.WARNING:E0525 12:33:20.113982 53125 ldap_request_executor.cc:165] Failed to acquire kerberos credentials for account: COHESITY$@TESTORG..ORG`

- Packet traces between the Cohesity cluster and the client: Use Wireshark to capture the traces on the client or use the `tcpdump` command on the cluster Node CLI.
  - Time of failure
  - Client IP file name and user name
  - Map using the IP address and not the fully qualified domain name to control the Node
- Packet traces between the Cohesity cluster and the domain controller for debugging authentication issues: Use the `tcpdump` command on the cluster Node CLI.
  - To capture only the SMB traffic on a Node:

    ```
    sudo tcpdump -i bond0 -w file.pcap -s 0 tcp port 445
    ```

Cohesity recommends capturing packet traces without any port filters for a short duration in order to capture SMB, LDAP, Kerberos, and DNS to domain controller traffic.

- To limit the capture to a single client, specify the IP address of the client in the command:

```
sudo tcpdump -i bond0 -w file.pcap host <client-ip>
```

- Client information:
  - Client OS version
  - Other applications, such as anti-virus software, installed on the client.
- The UNC path.
- Owner of the file and any ACLs applied permissions
- Group membership of the user.

Network File System (NFS)

Cohesity cluster supports the Network File System (NFS) protocol. You can create an NFS view and mount it on NFS clients using the NFS protocol.

When you mount an NFS view on NFS clients, the clients need to authenticate and authorize before they access the view on the Cohesity cluster. The Cohesity cluster authenticates the credentials against configured AD Kerberos or MIT Kerberos and authorizes using LDAP.

For more information on multiprotocol access, see ID Mapping for Multi-Protocol Views.

> **Note:** Cohesity recommends using a Linux client with kernel version 4.x or higher.

Supported NFS Versions

The following NFS versions are supported on the Cohesity cluster:

- NFSv3
- NFSv4.1

Considerations for using NFSv4.1 Protocol

The following are the considerations when using NFSv4.1:

- You must select the NFSv4.1 protocol option when creating a view using the Cohesity GUI to access the view over NFSv4.1.
- Both the NFS client and server must support NFSv4.1 to access an NFSv4.1 view

- You can create an NFSv3.0 and NFSv4.1 view with Kerberos and without Kerberos environments.
- In a Kerberos environment, NFS users of client machines should have corresponding accounts in both LDAP and KDC.
- LOCKT operations are not supported with NFSv4.1.
- Cohesity supports the pseudo file system, which allows you to mount the root directory. However, for security reasons, Cohesity does not support the `ls` operation after you mount the root directory.

Support for NFSv4.1 ACLs

An Access Control List (ACL) is a list of permissions associated with a file or directory. NFSv4.1 supports adding ACLs for a named user and special principals. Cohesity supports ACLs only on NFSv4.1 native views.

Example NFSv4.1 ACL

The following is an example of the NFSv4.1 ACL:

```
A:d:user@nfsdomain.org:rxtncy
```

The following section describes the example NFSv4.1 ACL:

- `A` is the ACE type and denotes Allow. This ACL allows the user or a group to perform actions requiring permissions.
- `d` is the inheritance flag and denotes that newly created subdirectories will inherit the ACE.
- `user@nfsdomain.org` is the ACE principal and denotes the named user or one of the following special principals:
  - OWNER@
  - GROUP@
  - EVERYONE@
- `rxtncy` are the permissions this ACE is allowing. You can specify one or more permissions.

Default NFSv4.1 ACL Behavior

By default, NFSv4.1 ACL denies any action if permission is not explicitly granted by an Allow ACE.

If a principal is attempting to perform an action over NFSv4.1 and if this action requires one or more permissions, an access check is performed. If an NFSv4.1 ACL is present, the system evaluates every ACE until a match is detected or until the end of the ACL. If every requisite permission is granted by Allow ACE(s) and is not forbidden by Deny ACE(s), the principal is allowed access. If any permission is denied by a Deny ACE, the system does not proceed with the evaluation, and the principal is denied access.

During the access check, if any permission is explicitly allowed or denied once, subsequent ACEs in the ACL cannot modify this permission.

NFSv4.1 ACL Limitations

- NFSv4.1 ACLs are not supported on unified views.
- POSIX ACLs are not supported on NFSv4 views.
- NFSv4.1 ACLs cannot be enforced on NFSv3 views.

NFS Security Modes for Kerberos Environments

The NFS security modes are available while creating a view with NFS protocol (NFSv3 or NFSv4.1). The security modes are applicable in a Kerberos environment.

The NFS security modes provide security to the data over the wire.

> **Note:** LDAP is a must for Kerberos (AD and MIT). However, if the security mode is Unix authentication (sec=sys) you do not need to have LDAP.

When you mount an NFS view on a client in the Kerberos environment, you must use one of the selected security modes.

The following NFS security modes are supported on the Cohesity cluster.

NFS Security Mode	Description
Unix Authentication	No support for authentication, NFS connections are authorized at a high level based on the Cohesity cluster configured subnets. For more information, see Mount a View Using NFS
Kerberos Authentication	Mount a view on a client using sec=krb5. Kerberos Authentication (krb5) supports only identity verification.
Kerberos Integrity	Mount a view on a client using sec=krb5i Kerberos Integrity (krb5i) supports data integrity services along with identity verification.
Kerberos Privacy	Mount a view on a client using sec=krb5p Kerberos Privacy (krb5p) supports data privacy along with integrity services and identity verification.

> **Note:** Unix authentication is the lowest security mode and krb5p is the highest security mode.

Considerations when Selecting NFS Security Modes

The following is a list of considerations you should consider for NFS security modes:

- By default, 'Unix Authentication' is selected when creating a view. However, you can choose the required security modes.
- You can only mount a view by using the selected security modes.

  For example, you selected Unix Authentication and Kerberos Privacy, so while mounting a view on a client, you can use any one of them.

  If you try to mount with other NFS security modes, the Cohesity cluster does not allow you to mount.

Prevent NFSv4.1 Client ID Collision

NFSv4.1 requires clients to identify themselves to servers with a unique string. File open and lock state shared between one client and one server is associated with this identity. To support robust NFSv4.1 state recovery and transparent state migration, this identity string must not change across client reboots.

If the hostname used by an NFSv4.1 client collides, the client is unable to mount over NFSv4.1. Hostname collision leads to client ID collision.

To prevent NFSv4.1 client ID collision, the NFS administrator must do the following:

1. Resolve hostname conflict.
2. Use the `nfs4_unique_id` parameter in the NFS client configuration.

   The `nfs4_unique_id` boot parameter specifies a unique string that can be used instead of the node name of a system when an NFS client identifies itself to a server. If the node name of the system is not unique, or it changes, its `nfs4_unique_id` remains the same, preventing collision with other clients or loss of state during NFS reboot recovery or transparent state migration.

NFSv 4.1 Unsupported Features

Cohesity does not support the following NFSv4.1 features:

- pNFS (Parallel NFS)
- Delegations - File and directory
- Volatile filehandle

> **Note:** Writing files larger than 1TB on Cohesity Views using the NFSv4.1 protocol may fail with the 'file too large' error. For more information, see the KB article.

NFS Exports

Mounting and accessing views as NFS exports requires the following high level steps.

1. Review the information about optimizing storage domains and views for your use case.

   See SmartFiles (File and Object Services) Overview.

2. Create storage domains and views for your use case.

   See Create or Edit Storage Domains and Create Views Using a Predefined Template.

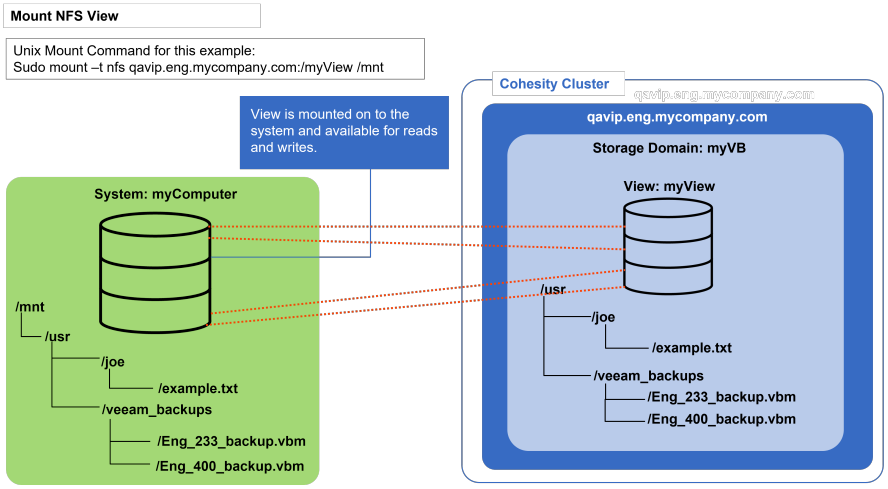
3. Add the systems that will mount and access views to the allowlist.

   See Add Subnets to Allowlists.

4. Mount the views to systems so users and applications can store data in them.

   See Mount a View Using NFS.

Once the above steps are completed, you can use a view to store data such as files and directories. Other backup products, such as Veeam, can also store data in a view, as shown in the following figure.



Add Subnets to Allowlists

Before you can mount and access a view, ensure the IP address of the system that is mounting the view is specified in a subnet that has been added to an allowlist.

Cohesity supports the following types of allowlists:

- **Global Allowlist**—The global allowlist applies to all views on the Cohesity cluster, but is overridden by a view allowlist or view share allowlist, if they exist.
- **View Allowlist**—Only the systems with IP addresses in the subnets listed in the view's allowlist have privileges to access and mount this view.

Update the Global Allowlist

To add a subnet to the Cohesity cluster's global allowlist:

1. Navigate to **SmartFiles > Views**.
2. Click the **Global Settings** tab.
3. In the **Global Subnet Allowlist** section, click **Add**.
4. In the **Add Allowlist** dialog, enter a Subnet IP in CIDR format (IPv4 - 10.0.0.0/24 or IPv6 - FE80:CD00::211E:729C/60).

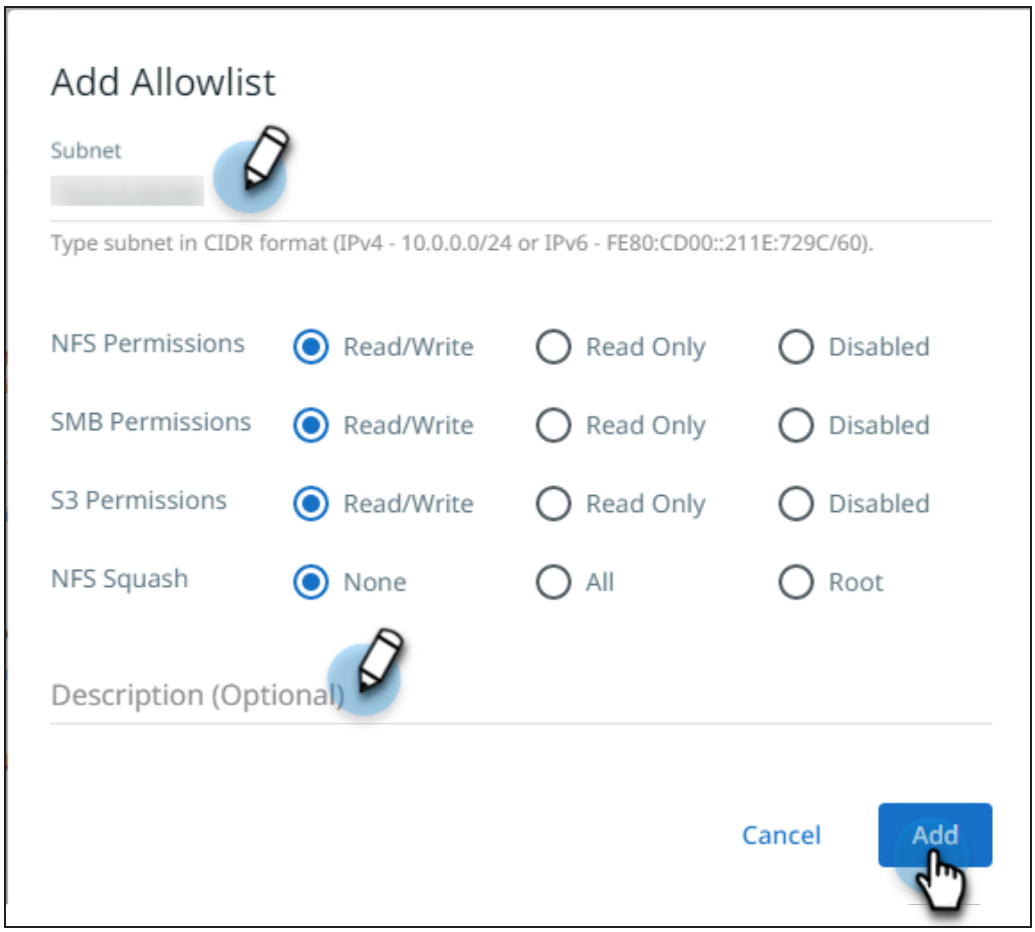
   > **Note:** CIDR prefix values are allowed from 0 to 32.

5. Select any or all permissions as required.

   > **Important:** By default, the ability to set **S3 Permissions** for restricting access to specific subnets is disabled. To limit S3-based access to specific subnets, review the How To Enable SmartFiles S3 View Allowlisting KB article.

6. Select **NFS Root Squash** as applicable.
7. In the **Description** field, enter a description for the allowlist.

8. Click **Add**:



9. Repeat the preceding steps for specifying additional subnets in the global allowlist.

Update a View Allowlist

To add a subnet to an existing view's allowlist:

1. Navigate to **SmartFiles > Views**.
2. Locate the required View in the list, click the ⋮, and select **Edit** ( ).
3. In Advanced settings, click **Edit** for the Security category.
4. **Override Global IP Allowlist:** Turn on **Override Global IP Allowlist** if you want to specify a custom list for this view. Only the systems with IP addresses in the subnets listed in the view's allowlist have privileges to access and mount this view. If you enable the **Override Global IP Allowlist** toggle, the machines listed in the subnets of the global Cohesity cluster allowlist cannot access or mount this view unless the IP address of the machine is also listed in the View's Allowlist.

   Extend Global IP Allowlist: Allows you to extend the Global IP Allowlist.

   To add subnets to the allowlist of this view:

a. Under **IP Allowlist**, select: **Override Global IP Allowlist** or **Extend Global IP Allowlist**.
b. Click **Add**.
c. In the **Add Allowlist** screen, type subnet in CIDR format.
d. Select any or all permissions as required.
e. Select **NFS Squash** options.

The **NFS all squash** option is like NFS Root Squash. However, for given IP addresses, all users are mapped to the All Squash User/Group configured in the view. The default All Squash User for all views is "nobody".

> **Note:** If the **Override Global Allowlist** toggle is off, this view can only be accessed and mounted by systems specified by the global Cohesity cluster allowlist.

5. Click **Update View**.

For more information on global settings for each protocol, see the following topics:

- Global Settings for NFS
- Global Settings for SMB

Global Settings for NFS

In addition to the settings provided in Add Subnets to Allowlists, you can allowlist Netgroup that have permissions to all views.

After the Cohesity cluster is upgraded to 6.6.0c, note the following:

Existing NFS or SMB view—IP restriction is retained. If you access an existing NFS or SMB view using the S3 protocol, the request fails if the existing allowlist does not include the IP address of S3 clients. Before or after the upgrade, ensure to add the IP address or subnet at the view level if the NFS or SMB view is accessed using the S3 protocol.

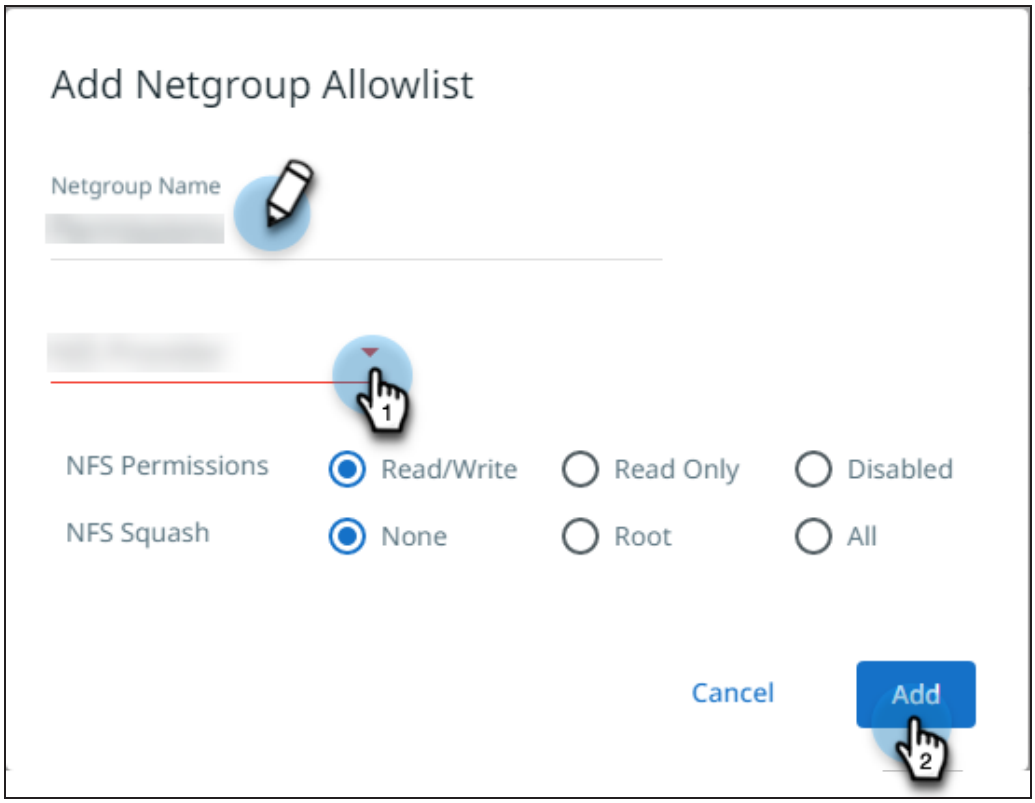
Global Netgroup Allowlist

You can allowlist Netgroup that has permissions to all views.

Perform the following steps on the Cohesity cluster to allowlist Netgroup:

1. Navigate to **SmartFiles > Views**.
2. Click the **Global Settings** tab.
3. In the **Global Netgroup Allowlist** section, click **Add** and do the following:
    1. In the **Netgroup Name** field, enter a name.
    2. Select **NFS Permissions** (Read/Write, Read Only or Disabled).

3. Select **NFS Squash** permissions (None, Root, All).
4. Click **Add**.



Mount a View Using NFS

Before storing data on a view, you have to mount it using NFS export on your Windows or Linux system.

Prerequisites

- The view must support the NFS protocol.
- The client system that will mount the view must be in a subnet in a Cohesity allowlist. Otherwise, the system will not have privileges to mount and access the view.
- Firewall port 2049 must be open for NFS operations on the Cohesity cluster. Port 2049 is the default port. You can change it as described Change the NFS Firewall Port.
- When mounting a view on a Windows system using NFS, the view must be browseable from NFS.

Considerations:

- NFS mount names and names of files contained in the mount support ASCII and UTF-8 character codes only.

- When data is deleted from a view, it may take up to a day for the disk space to become available again and visible from utilities such as `df`.
- To register an Oracle RAC or a RAC node as a physical server, the "host" command must be executed on each of the nodes of that RAC.
- Cohesity recommends using a Linux client with kernel version 4.x or higher.
- NFSv4.1 limitation:
    - LOCKT operations are not supported.

If you mount a view on a Windows system using NFS, you can read files from the mounted drive but not write to the view. To resolve this issue, change the UID and GID in the Windows Registry, as described in Mount a View with NFS protocol on Windows. (This issue does not apply if the view is mounted on Windows using SMB.)

NFS client mount parameters

The NFS mount options depend on the workload and the application. There is no standard recommendations for the mount options.

The following table lists the recommendations for NFS client mount parameters for file shares and backup target workloads in different operating systems.

NFSv3 mount parameters

Host	Recommended NFS Mount Parameters
Linux	**For Backup Target workload**: rw,relatime,vers=3,rsize=1048576,wsize=1048576,namlen=255,hard,proto=tcp,timeo=600,retrans=2,sec=sys,mountvers=3,mountproto=tcp,local_lock=none **For File Shares workload**: rw,relatime,vers=3,rsize=32768,wsize=32768,namlen=255,hard,proto=tcp,timeo=600,retrans=2,sec=sys,mountvers=3,mountproto=tcp,local_lock=none
UNIX (AIX / HP-UX / Solaris)	**For both File Shares & Backup Target workload**: bg,hard,intr,rsize=32768,wsize=32768,vers=3,proto=tcp,sec=sys,rw,acdirmax=30

Different versions of a host operating system can have different default NFS mount options.

The NFS mount options depend on the workload and the type and version of the host operating systems and applications. The mount parameters also vary based on various

backup and restore operations and the deployment specifications. For example, Oracle deployment type, version and the workflow.

The following table lists the NFS client mount parameters while using Cohesity as the **Oracle Backup Target**.

Host	Deployment type	Version	Default mount options	Full/Incremental Backup	Log Backup	Overwrite Restore	Alternate Restore	Clone
Linux	RAC	12c	rw,relatime,vers=3,rsize=1048576,wsize=1048576,namlen=255,hard,proto=tcp,timeo=600,retrans=2,sec=sys,mountvers=3,mountproto=tcp,local_lock=none					noac,local_lock=all
		11g		noac				
	Standalone	12c						local_lock=all
UNIX (AIX/HP-UX/Solaris)	RAC	12c	bg,hard,intr,rsize=32768,wsize=32768,vers=3,proto=tcp,sec=sys,rw,acdirmax=30			noac		noac,local_lock=all
		11g		noac				
	Standalone	12c						local_lock=all
		11g						

The following table lists the NFS client mount parameters while using Cohesity as a **Backup Storage Target** for the backup applications such as **CommVault** or **Veeam**.

Host	Mount Parameters
CommVault/ Veeam	noatime,vers=3,proto=tcp,rsize=1048576,wsize=1048576,timeo=10000,hard,intr,nolock

Mount a View with NFS Protocol

Perform the following steps to copy the view mount path:

1. In the Cohesity Dashboard, navigate to **File Services** > **Views** > **All Views**.
2. Browse for the view in the list
3. Click the Mount Paths icon of NFS.
4. In the Mount Paths screen, click the copy icon for **NFS mount path** and click **Close**.

For more information, see the following topics:

- Mount a View with NFS protocol using UNC Path
- Mount a View with NFS protocol on Linux/Unix
- Mount a View with NFS protocol on Windows
- Mount a View with Kerberos-Based NFS

Mount a View with NFS protocol using UNC Path

Some applications may require the NFS storage target in UNC path format.

For Example, while using Cohesity as a backup target for Veeam or CommVault, the View can be accessed with NFS protocol using the UNC Path in the below format:

```
\\<Cohesity_Cluster_Hostname_or_VIP>\<NFS_View_Name>
```

Mount a View with NFS protocol on Windows

> **Note:** If you are mounting a View on Windows using NFS, then you must disable NLM. To disable NLM, contact Cohesity Support.

To mount a view with NFS protocol on Windows:

1. On the Windows system, as the administrator, change the UID and GID in the Windows Registry. Otherwise, you will be able to read files from the mounted drive, but not write to the view. (This step is not applicable when mounting a Windows view using SMB.)
    a. In the Windows Start menu, start the Registry Editor by searching for `regedit` and clicking it.
    b. Navigate to the following path: `HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\ClientForNFS\CurrentVersion\Default`

c. Right-click `Default` and select **New** > **DWord (32-bit) Value**.
d. Enter `AnonymousUid` for the name and leave the value as `0`.
e. Right-click `Default` and select **New** > **DWord (32-bit) Value** again.
f. Enter `AnonymousGid` for the name and leave the value as `0`.
g. Reboot the Windows system.

2. Install the NFS Client on your Windows system.
3. Mount the View with NFS protocol on the Windows client using the mount command.

   Sample Command:

   ```
   mount -o mtype=hard fileaccess=777 nolock <Cohesity_Cluster_Hostname_or_VIP>:/<NFS_View_Name> <Windows_Drive_Letter>
   ```

   Example:

   ```
   mount -o mtype=hard fileaccess=777 nolock host.example.com:/NFS1
   ```

4. Verify the mounted NFS file systems with the `mount` command.

   ```
   C:\Users\Administrator&gt;mount
   Local   Remote                                  Properties
   ----------------------------------------------------------------------
   ---
   z:      \\host.example.com\NFS1                 UID=0, GID=0
                                                   rsize=1048576,
   wsize=1048576
                                                   mount=hard, timeout=10.0
                                                   retry=1, locking=no
                                                   fileaccess=777, lang-ANSI
                                                   casesensitive=no, sec=sys
   ```

Mount a View with NFS protocol on Linux/Unix

To mount a view with NFS protocol on Linux or Unix:

1. Install the `nfs-common` and `rpcbind` modules on the Linux/Unix client, if they are not already installed:
2. Create a directory to mount the share.
3. Mount the NFS volume using the `mount` command.
   - Specify the NFS version in the options parameter `vers` while mounting the view. For example, if you are mounting an NFSv4.1 View, specify `vers=4.1`. If you are mounting an NFSv3 View, specify `vers=3`.

   Sample Command (for File Services workload)

```
mount -t nfs -o
rw,relatime,vers=3,rsize=32768,wsize=32768,namlen=255,hard,proto=tcp,t
imeo=600,retrans=2,sec=sys,mountvers=3,mountproto=tcp,local_lock=none
<Cohesity_Cluster_Hostname_or_VIP>:/<NFS_View_Name> <View Mount Path>
```

Example:

```
mount -t nfs -o
rw,relatime,vers=3,rsize=32768,wsize=32768,namlen=255,hard,proto=tcp,t
imeo=600,retrans=2,sec=sys,mountvers=3,mountproto=tcp,local_lock=none
host.example.com:/NFS1 /home/user/nfsdir
```

4. Make NFS mounts persist across reboots (Make an entry in the `/etc/fstab` file. Steps may vary depending upon the Host Operating system).

For more information on the NFS client mount parameters, see NFS client mount parameters.

Mount a View with Kerberos-Based NFS

You can mount both NFS v3.0 and NFS v4.1 versions Views.

Prerequisites

- Before mounting a Kerberos-based view, configure the NFS client. For more information, see Configure Unix client for Mounting Kerberos Based View.
- The View must support the NFSv3.0 or NFSv4.1 protocol.
- The client system that will mount the View must be in a subnet in a Cohesity allowlist. Otherwise, the system will not have privileges to mount and access the view.
- Firewall port 2049 must be open for NFS operations on the Cohesity cluster. Port 2049 is the default port. You can change it as described Change the NFS Firewall Port.
- When mounting a view on a Windows system using NFS, the view must be browsable from NFS.

To mount a view with the Kerberos-based NFS, complete the following steps:

1. Install the `nfs-common` and `rpcbind` modules on the Kerberos client, if they are not already installed:
2. Create a directory to mount the share.
3. Mount the NFS volume using the mount command.
   - While mounting a view, specify the NFS version in the options parameter `vers`. For example, if you mount an NFSv4.1 View, specify `vers=4.1` and if you mount an NFSv3 View, specify `vers=3`.

   Sample Command (for File Services workload)

```
mount -t nfs -o
rw,relatime,vers=4.1,rsize=32768,wsize=32768,namlen=255,hard,proto=tcp
,timeo=600,retrans=2,sec=krb5,mountvers=4.1,mountproto=tcp,local_
lock=none <Cohesity_Cluster_Hostname_or_VIP>:/<NFS_View_Name> <View
Mount Path>
```

Example:

```
mount -t nfs -o
rw,relatime,vers=4.1,rsize=32768,wsize=32768,namlen=255,hard,proto=tcp
,timeo=600,retrans=2,sec=krb5,mountvers=4.1,mountproto=tcp,local_
lock=none host.example.com:/NFS1 /home/user/nfsdir
```

> **Note:** If you have selected specific NFS security modes for a View, you must use the same security modes when mounting a Kerberosed-based View. For example, if you have selected krb5i as the NFS security mode when creating a View, you must use the same.

4. Make NFS mounts persist across reboots (Usually done by making an entry in `/etc/fstab` file. Steps may vary depending upon the Host Operating system).

For more information on the NFS client mount parameters, see NFS client mount parameters.

List Active NFS Connections

To list active NFS connections for views:

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. List the active NFS connections for views by using the Cohesity CLI `view list-nfs-connections` command:

   ```
   admin>view list-nfs-connections
   ```

   > **Tip:** You can also use the CLI Help feature to view the `view list-nfs-connections` options by entering the following command: `view list-nfs-connections help`.

CLI Option	Example	Description
`names=`	`ViewName1,ViewName2`	Optional. Specify a comma separated list of view names. The active NFS connections for these views are displayed.

NLM Locking over NFS

File-level locking mechanisms are supported to restrict access to a file or portion of a file stored on the server to only one user or process at a time. Users can specify the byte range to lock or specify the entire file on the server to be locked. System administrator can use iris_cli commands for listing and clearing locks acquired on a file. Locks can be cleared from iris_cli if the client crashes while holding a lock for a file on the server.

NLM Locks are of two types: Shared or Exclusive.

- When a Shared or a Read lock is used, it prevents other users or processes from requesting a **write** lock to the file or a specific byte range of the file. The shared lock can be used by multiple users.
- Exclusive or Write Locks provides **exclusive** access for editing the file contents. When the exclusive lock is used, then no other user or process can lock that part of the file.
- Asynchronous NLM lock/unlock requests for files are not supported. For example, the client will not get a callback from the server in response to a lock/unlock request for a file.

View the NLM Locks

CLI Option	Description
view list-nlm-locks name=*<name>* file-path=*<file_path>*	To view the list of all the NLM locks based on the view and the filepath.
view list-nlm-locks name=*<name>* file-path=*<file_path>* verbose=true	To list all ranges locked for a file by all clients.
view clear-nlm-locks client-id=*<id>*	To clear all the existing NLM locks held by the client.

Change the NFS Firewall Port

NFS operations on the cluster use firewall port number 2049 by default. The following procedure explains how to change the port number.

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. Change the Bridge service port to the desired port. To change the Bridge service port, contact Cohesity Support.
3. Add a new firewall port profile by using the following command. This procedure uses the profile name `new-nfs-1`, but you can change it.

   ```
   iris_cli firewall-profile add name=new-nfs-1 ports=<new_port>/tcp
   force=true
   ```

   Example:

   ```
   [cohesity@node-1 ~]$ iris_cli firewall-profile add name=new-nfs-1
   ports=60001/tcp force=true
   Success: Successfully added firewall profile.
   ```

4. Activate the attachment by using the following command:

   ```
   iris_cli firewall-profile activate profile-name=new-nfs-1 interface-
   groups=intf_group1 action=allow
   ```

   Example:

   ```
   [cohesity@node-1 ~]$ iris_cli firewall-profile activate profile-
   name=new-nfs-1 interface-groups=intf_group1 action=allow
   Success: Successfully activated the profile.
   ```

5. From the shell prompt, add the IPV4 rule by using the following command:

   ```
   sudo firewall-cmd --direct --add-rule ipv4 filter INPUT 0 -m tcp -p tcp
   --dport <new_port> -j ACCEPT
   ```

   Example:

   ```
   [cohesity@node-1 ~]$ sudo firewall-cmd --direct --add-rule ipv4 filter
   INPUT 0 -m tcp -p tcp --dport 60001 -j ACCEPT
   success
   ```

6. Add the IPV6 rule by using the following command:

   ```
   sudo firewall-cmd --direct --add-rule ipv6 filter INPUT 0 -m tcp -p tcp
   --dport <new_port> -j ACCEPT
   ```

   Example:

```
[cohesity@node-1 ~]$ sudo firewall-cmd --direct --add-rule ipv6 filter
INPUT 0 -m tcp -p tcp --dport 60001 -j ACCEPT
success
```

7. Make the IPV4 rule permanent by using the following command:

```
sudo firewall-cmd --permanent --direct --add-rule ipv4 filter INPUT 0 -
m tcp -p tcp --dport <new_port> -j ACCEPT
```

Example:

```
[cohesity@node-1 ~]$ sudo firewall-cmd --permanent --direct --add-rule
ipv4 filter INPUT 0 -m tcp -p tcp --dport 60001 -j ACCEPT
success
```

8. Make the IPV6 rule permanent by using the following command:

```
sudo firewall-cmd --permanent --direct --add-rule ipv6 filter INPUT 0 -
m tcp -p tcp --dport <new_port> -j ACCEPT
```

Example:

```
[cohesity@node-1 ~]$ sudo firewall-cmd --permanent --direct --add-rule
ipv6 filter INPUT 0 -m tcp -p tcp --dport 60001 -j ACCEPT
success
```

9. Verify the port number changed in iptables by using the following command:

```
sudo iptables -nvL | grep <new_port>
```

Example:

```
[cohesity@node-1 ~]$ sudo iptables -nvL | grep 60001
    0     0 ACCEPT     tcp  --  *      *       0.0.0.0/0
0.0.0.0/0           tcp dpt:60001
```

10. Verify the port number changed in direct.xml by using the following command:

```
sudo grep <new_port> /etc/firewalld/direct.xml
```

Example:

```
[cohesity@node-1 ~]$ sudo grep 60001 /etc/firewalld/direct.xml
  <rule priority="0" table="filter" ipv="ipv4" chain="INPUT">-m tcp -p
tcp --dport 60001 -j ACCEPT</rule>
  <rule priority="0" table="filter" ipv="ipv6" chain="INPUT">-m tcp -p
tcp --dport 60001 -j ACCEPT</rule>
```

11. Restart the Bridge service by using the following command:

```
[cohesity@node-1 ~]$ iris_cli cluster restart-services service-
names=bridge
```

Objects (S3)

On a Cohesity cluster, you can create a SmartFiles S3 View. S3 Views are similar to Amazon S3 buckets. S3-compatible clients can use the S3 View to store and retrieve objects. As SmartFiles S3 manages data as objects, you can access files as S3 objects.

> **Tip:** You can use SmartFiles to automatically archive or tier data from a Cohesity cluster to Amazon S3 buckets. For these use cases, register an existing Amazon S3 bucket as an external target on the Cohesity cluster; Cohesity S3 Views are not required. For more information, see About Cloud Archival and About Cloud Tier.

> **Note:** Cohesity supports transferring payload in multiple Chunks (Chunked Upload) when using AWS Signature Version 4.

Prerequisite

- Firewall port 3000 (TCP, incoming to Cohesity cluster) must be open to support S3 protocol access to the views on the Cohesity cluster.

Considerations

- You must use one of the following accounts to create an S3 View:
  - A local Cohesity user.
  - An Active Directory user that was explicitly added to the Cohesity cluster and assigned a role. This user does not rely on an AD group for access to the Cohesity cluster.

  > **Important:**
  > You cannot create an S3 View using one of the following accounts:
  >
  > - An AD user that has Cohesity cluster access through an Active Directory group only
  > - An SSO user
  > - A Helios user

- To create a SmartFiles S3 View in a multi-tenant environment, log in to the Cohesity cluster as an Organization user. If you create the S3 View while impersonating an organization, the Service Provider administrator becomes the owner of the S3 View.

- Access Control Lists (ACLs) can be set on a bucket using the AWS CLI.
- You cannot use NFS to mount newly created S3 Views. However, if there are existing S3 Views that were configured to use NFS, you can mount such S3 Views using NFS.
- The maximum number of versions allowed per S3 object is 500,000.
- Cohesity recommends excluding any unsupported header(s) from your requests. By doing so, you can prevent any potential unintended consequences that may arise from using unsupported headers.

Get Started

The main steps for creating and using a view as a bucket are:

1. Sign in to the Cohesity cluster as a local user or an Active Directory user that was explicitly added to the Cohesity cluster and assigned a role.

   This step is required to establish ownership of your S3 view (bucket).

2. Retrieve your Cohesity S3 access keys from the Cohesity Dashboard and store them in your preferred location. For more information, see Manage Cohesity S3 Access Keys.

   The keys were automatically generated when your user account was created on the Cohesity cluster.

3. Create a view that supports the S3 protocol.

   You will be the owner of the view and will need your S3 access keys to access it through the S3 API and AWS CLI.

4. Optionally, install the AWS CLI so you can interact with the view, for example, to list buckets or objects. For more information, see Use the AWS CLI on Cohesity S3.

Create an S3 View

You can create an S3 View using a predefined template or a custom template.

You can create an S3 View using predefined templates for different use cases and scenarios. Predefined templates are provided by Cohesity. Cohesity provides the following predefined templates for **Object Services**:

- General
- Containers
- Hadoop
- Splunk SmartStore

To create a View using a predefined View template:

1. Navigate to **SmartFiles > Views** and do one of the following on the **Views** page:
   - Click **Create View**. On the **View Templates** side sheet, navigate to the **Predefined** tab and select a predefined template.
   - Go to the **Templates** tab. Click the **Type** filter and select **Predefined**. Click the **Category** filter and select **Object Services**. Hover over the predefined template that you want to use, click the Actions menu (⋮), and select **Create View**.
2. Enter a name for the View.
3. Based on the template you selected, the predefined template populates optimum preconfigured settings. However, if you want to update the settings, click **More Options** and update the settings. For more information about the available options, see S3 View Options.
4. Click **Create** to create the View.

Cohesity supports creating customized View templates and using a customized template to create S3 Views. For more information, see About Templates Tab.

To create an S3 View using a custom template:

1. Navigate to **SmartFiles > Views** and do one of the following on the **Views** page:
   - Click **Create View**. On the **View Templates** side sheet, navigate to the **Custom** tab and select a custom template.
   - Go to the **Templates** tab. Click the **Type** filter and select **Custom**. Click the **Category** filter and select **Object Services**. Hover over the custom template that you want to use, click the Actions menu (⋮), and select **Create View**.
2. Enter a name for the View.
3. Based on the template you selected, the custom template populates preconfigured settings. However, if you want to update the settings, click **More Options** and update the settings. For more information about the available options, see S3 View Options.
4. Click **Create** to create the View.

S3 View Options

Storage Domain

A storage domain is a named storage location on the Cohesity cluster. A storage domain defines the policy for configurations such as deduplication, compression, erasure coding, and encryption.

Select a storage domain from the list or click **Add Storage Domain** and create a new storage domain. During a Protection Group Run, the Cohesity cluster stores the snapshots of the S3 View in this storage domain.

Bucket Policy

A bucket policy provides access to the objects stored in the bucket. It's important to note that bucket policies do not apply to objects owned by other accounts.

To add a bucket policy, click **Add Policy** and input the desired bucket policy in the provided text area.

The following is an example of the bucket policy:

```
{
"Version": "2012-10-17",
"Statement": [
{
"Sid": "AllowUser2ToWriteObject",
"Effect": "Allow",
"Principal": {
"CanonicalUser": [
"USER2@LOCAL@"
]
},
"Action": [
"s3:PutObject"
],
"Resource": "arn:aws:s3:::BUCKET-NAME/*"
},
{
"Sid": "AllowUser2ToGetObjectOnlyWhenTagsHavePublicSecurity",
"Effect": "Allow",
"Principal": {
"CanonicalUser": [
"USER2@LOCAL@"
]
},
"Action": [
"s3:GetObject"
],
"Resource": "arn:aws:s3:::BUCKET-NAME/*",
"Condition": {
"StringEquals": {
"s3:ExistingObjectTag/security": "public"
}
}
}
]
}
```

After adding a policy, you can click **Remove Policy** if you wish to delete a policy.

Bucket Owner

A bucket owner has certain permissions and control over the bucket and its contents. You can only add a local Cohesity user as a bucket owner. By default, the currently logged-in user is set as the bucket owner. You can designate a local user as the bucket owner by selecting the user from the User drop-down list.

> **Note:** You cannot change the bucket owner once the S3 View is created.

ACLs

S3 Access Control Lists (ACLs) allow you to regulate access to both buckets and objects. ACLs are applied to the buckets. ACLs determine the users or groups that are granted

access. ACL permissions can only be granted to a local Cohesity user or one of the following S3 predefined groups:

- Authenticated Users group
- All Users group
- Log Delivery group

To add an ACL:

1. Click **Add ACL**.
2. Select a local Cohesity user or an S3 predefined group.
3. Select the bucket ACLs as necessary.
4. Click **Add**.

You can also edit or delete ACLs. To do so, click the vertical ellipsis corresponding to the user or group you wish to modify or remove and click **Edit** or **Delete** accordingly.

Object Keys

Cohesity S3 stores data based on Object Key patterns. When creating an S3 View, consider the object keys that you are most likely to store in the View, and choose the best pattern for optimal performance. You cannot edit object keys after the View is created.

Object Key Pattern—Select one of the following:

- **Object ID**: Object keys are mapped to internal object IDs.

  Important:
  - By default, **Object ID** is selected as the **Object Key Pattern**.
  - Cohesity recommends using Object ID as the Object Key Pattern to obtain better performance and scalability for the following operations:
    - `PutObject`
    - `ListObjects`
    - `ListObjectVersions`
  - Cohesity recommends using the Object ID as the Object Key Pattern for S3 views that are used as external targets.
  - If the **Object Key Pattern** of the S3 View is **Object ID**:
    - You cannot access the S3 View through SMB or NFS protocol.
    - Indexing is not supported and you cannot perform file-level recovery.
    - You can replicate the S3 View only if the remote cluster is running Cohesity cluster version 7.0. If the remote cluster is running an earlier version, replication fails.
    - You must use the **Incremental Forever** archival format while archiving the S3 View. You cannot archive the S3 View using the **Incremental with Periodic Full** format.
    - You can archive the S3 View to an external target that is registered on a Cohesity cluster running a version prior to 7.0. However, you can restore the S3 View only if the external target is registered on a Cohesity cluster that runs 7.0. If the external target is registered on a Cohesity cluster running a version prior to 7.0, restore fails.

- **Flat**: Optimal if most object keys are not organized hierarchically.

  If you create an S3 View using S3 API, by default, a Flat > Structured > Short View is created.

- **Flat Key Type**: Select one of the following:
  - **Random**: Optimal for object keys that are auto-generated, for example, MD5 hashes or UUIDs.
  - **Structured**: Optimal for object keys that use some structured pattern, like a date/time stamp. If most keys are less than 30 characters long, select Short. Otherwise, select Long.

  The Flat key pattern is supported on 6.4 and later Cohesity clusters. You cannot replicate the View to, or restore it from an archive on, a pre-6.4 Cohesity cluster.
- **Hierarchical**: Optimal if most object keys are organized in a logical hierarchy using '/' as a separator. Cohesity does not recommend using the **Hierarchical** View for latency-sensitive workloads.

> **Note:** Even though you choose a particular pattern, you can still store objects that have keys with a different pattern.

Read/Write Protocol

Select one of the following protocols:

- If you need read/write access to the View, select **S3**.
- Select **SWIFT** to create a Swift-only View that provides storage space for authorized Keystone users. The Swift-only View is tagged to a Project within a Domain. Only authorized Keystone users can access Swift-only Views. For more information, see Create a Swift-Only View.

> **Note:** If you select SWIFT, you cannot use **Object ID** as the **Object Key Pattern**. You can use **Flat** or **Hierarchical**.

Versioning

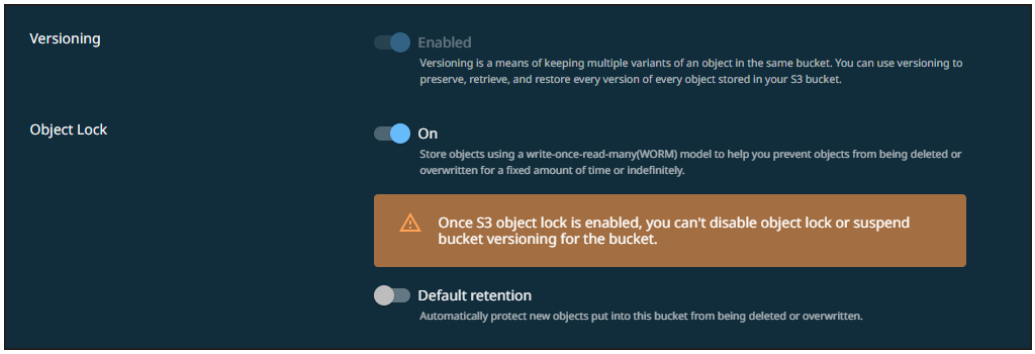
Click the **Versioning** section and turn on the toggle to keep multiple variants of an object in the same bucket. You can use versioning to preserve, retrieve, and restore every version of every object stored in your S3 bucket.

After you enable S3 Object Lock, the **Versioning** toggle is automatically turned on and you cannot disable Object Lock or suspend versioning on the bucket.

S3 Object Lock

Before proceeding, review the S3 Object Lock section.

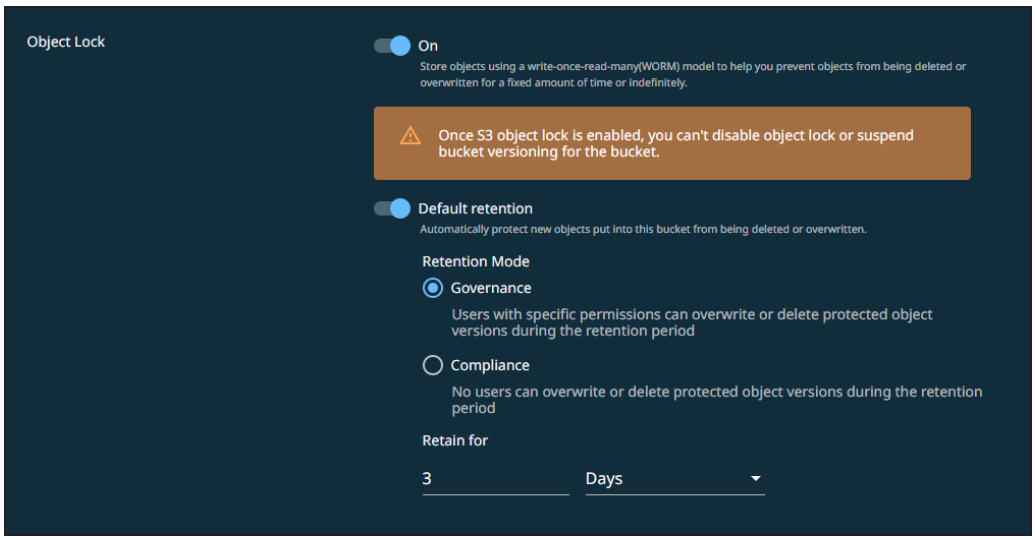
1. Click the **S3 Object Lock** section and turn on the toggle:



> **Note:** After you enable S3 Object Lock, the **Versioning** toggle is automatically turned on and you cannot disable Object Lock or suspend versioning on the bucket.

2. Turn on the **Default Retention** toggle and select one of the following retention modes to automatically protect new objects put into this bucket from being deleted or overwritten:
   1. **Governance**—Users with specific permissions can overwrite or delete protected object versions during the retention period.
   2. **Compliance**—No user can overwrite or delete protected object versions during the retention period.

   Select either **Days** or **Years** from the drop-down menu and enter the number of days or years to set the retention:



Lifecycle Management Rules

Before proceeding, review the S3 Lifecycle section.

1. Click the **Lifecycle Management Rules** section and click **Add Rule**.
2. In the **Add Lifecycle Management Rule** dialog, set up the rule.
3. Enter the name of the rule.
4. Select the **Rule Scope**:
    - Click **Apply to all objects in the bucket** to apply this rule to all objects in the bucket.
    - Click **Limit the scope of this rule using one or more filters** to limit the scope of this rule by adding one or more filters:
        - Enter a prefix to limit the scope of this rule to a single prefix.
        - Optionally, click **Add Object Tag** and add a key and value to apply the Lifecycle Management rule to a subset of objects that has all the tags specified in the rule. If an object has additional tags specified, the rule is still applied. For more information about object tags, see S3 Object Tags.
5. Select at least one rule action:
    - Select **Expire current versions of objects** and specify the number of days to expire objects identified in the rule.
    - Select **Permanently delete noncurrent versions of objects** and specify the number of days. Specify the number of days an object remains noncurrent before Cohesity executes the deletion process. Cohesity calculates this duration based on the time elapsed since the creation of its successor version, determining the object's noncurrent status.
    - Select **Remove expired object delete markers** to remove delete markers of expired objects. Cohesity will remove a delete marker only if there are no noncurrent versions associated with it.
    - Select **Delete incomplete multipart uploads** and specify the number of days to expire incomplete multipart uploads identified in the rule. Parts associated with these multipart uploads are deleted.
6. Click **Add**.

Protection

You can back up and recover S3 Views using local snapshots. Turn on the **Protection** toggle to specify the protection group and protection policy. If enabled, this S3 View uses this protection group and adheres to the selected protection policy. In the policy, you can also define how the objects should be replicated.

- **Protection Group**—Use this option to protect objects as a group, or individually for granular level control. You can either create a new protection group or select an existing protection group from the drop-down list.

  - **New Group**—Enter a new group name. This creates a new protection group when the View is created. Ensure that you specify a group name that is not in use.
  - **Existing Group**—Select a protection group from the drop-down list.
- **Storage Domain**—Select a storage domain to be used during protection. You can also create a new storage domain.
- **Protection Policy**—Select a policy from the drop-down list. The policy is read-only. If you want to update the policy, go to the **Data Protection > Policies** page to edit the policy.

Case Sensitive File or Folder Names

Turn on the **Case Sensitive File or Folder Names** toggle if you want the uppercase and lowercase versions of the same letter in a file or folder name to be treated differently on the View. For example, **A** is different from **a**.

> **Note:** You cannot edit this setting after you create the View.

Performance

- **QoS Policy**—Select the QoS policy. A QoS policy determines to which storage media data is written and the priority of I/O when contention occurs. For more information, see QoS Policies for Cohesity Views.
- **Pin View to SSD**—Turn on the toggle to pin the View to the SSD tier so that critical data and data that have to be retrieved quickly are not down-tiered to HDD or cloud. For more information, see Pin Views to SSD.

Security

Configure the security settings for the View. You can add and manage IP Allowlist for the S3 View:

1. Select **Override Global IP Allowlist** to ignore the global IP Allowlist and honor only specific entries provided in the View. Select **Extend Global IP Allowlist** to honor the global IP Allowlist and the specific entries provided in the View.
2. Click **Add**.
3. In the **Add Allowlist** dialog, enter the subnet in CIDR format.
4. Select **S3 Permissions**.
5. Optionally, you can enter a description for the IP Allowlist of the View.

Dedupe & Compression

Turn on the **Dedupe & Compression** toggle to always use post-processing, irrespective of the storage domain policy. This option is available only if deduplication and compression are enabled on the storage domain.

Logical Quota

Select one of the options to set the **Logical Quota** for the View:

- Inherit from storage domain
- Select **Override**, turn on the following options, and set the limit:
  - Logical Quota
  - Alert Threshold

> **Note:** Alert threshold must be less than logical quota.

Alert threshold notifies the System Administrator in advance and prevents system capacities from being exhausted without notification.

File Filtering

Turn on the **File Filtering** toggle if you want to block or allow files with specified file extensions from being written to this View. Select one of the following file filtering methods:

- **Denied File Types**—If you want to specify a list of file extensions for files that are blocked from being written to this View. For example, if you specify a list with the .exe and .dll extensions, files with these extensions cannot be written to this View.
- **Allowed File Types**—If you want to specify a list of file extensions for files that are allowed to be written to this View. For example, if you specify a list with the .cvs and .txt extensions, only files with these extensions can be written to this View.

  Enter file extensions separated with commas, spaces, tabs, or newlines, and click **Add**.

Audit Logs

Turn on the **Audit Logs** toggle to enable audit logs. For more information, see File Services Audit Logs.

Description

Click **Description** and provide a description for the S3 View.

Manage Cohesity S3 Access Keys

Cohesity automatically generates Cohesity S3 access keys for all users created by using the Cohesity Dashboard. Users can see their own keys, generate a new key and copy it to the clipboard as described below.

Admin users who have the **Manage Users** privilege can generate keys for other users but cannot see or copy those keys to the clipboard. Note that when generating a new key, anyone using the old key will lose access until they retrieve and use the newly generated key.

Get the Access Key Using the Cohesity Dashboard

1. Navigate to **Settings > Access Management**.
2. Click your user name in the list of users and groups.
3. Optionally, click **Show Key** to display your key.
4. Click the copy icon next to the **Access Key ID** and paste the key from your clipboard to a secure location to use later.
5. Click the copy icon next to the **Secret Access Key** and paste it to a secure location to use later.

> **Tip:** To generate a new secret access key, click the refresh icon and respond to the confirmation prompt.

Get the Access Key Using the Cohesity CLI

You can also get the access key information by using the following command in the Cohesity CLI:

```
admin>user ls
USER NAME                     : admin
ROLES                         : COHESITY_ADMIN
DOMAIN                        : LOCAL
CREATION TIME                 : Sunday, 26-Mar-17 20:00:39 PDT
LAST UPDATED TIME             : Thursday, 30-Mar-17 09:37:13 PDT
EFFECTIVE START TIME          : Sunday, 26-Mar-17 20:00:39 PDT
EMAIL ADDRESS                 : admin@abc.com
S3 ACCOUNT ID                 : admin@LOCAL
S3 ACCESS KEY ID              : yQ5iFakef0exyvDRJGRuF0bfd/sIMag50YiTb4UIrfU=
S3 SECRET ACCESS KEY          : T+VIuvkdltrgFakes9PjHrgaaODMF5rJjnt3452113o=
```

Allow S3 Buckets on the Cohesity cluster

> **Note:** This task is required only if you will be using the S3 API to create S3 views on the Cohesity cluster. This task is not necessary if you use the Cohesity Dashboard to create the views.

Create or edit a storage domain on the Cohesity cluster that allows S3 buckets. Even though S3 clients are not aware of storage domains, views in the Cohesity cluster must be created within a storage domain.

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. Create a storage domain that allows S3 buckets by using the Cohesity CLI `sd create` command:

   ```
   admin>sd create name=S3StorageDomain s3-buckets-allowed=true
   ```

   > **Note:**
   > It is mandatory to mention either the cluster-partition-id or the cluster-partition-name in the storage domain creation command.
   >
   > - Example command for storage domain creation using cluster-partition-id:
   >   admin@127.0.0.1> sd create name=S3StorageDomain s3-buckets-allowed=true cluster-partition-id=*32*
   > - Example command for storage domain creation using cluster-partition-name:
   >   admin@127.0.0.1> sd create name=S3StorageDomain s3-buckets-allowed=true cluster-partition-name=*DefaultPartition*

   Or edit an existing storage domain to allow S3 buckets using the `sd edit` command:

   ```
   admin>sd edit name=S3StorageDomain s3-buckets-allowed=true
   ```

   > **Note:** If multiple storage domains on the Cohesity cluster allow S3 buckets, Cohesity creates an S3 bucket in a random storage domain.

3. Create a view inside a storage domain that allows S3 buckets by using the Cohesity CLI `view create` command:

   ```
   admin>view create name=<viewName> storage-domain-
   name=<StorageDomainName>
   ```

   By default, all views are created with support for all protocols, but S3 access is read-only. If you want to disable NFS and SMB access to a view, use this command:

```
admin>view create name=<viewName> storage-domain-
name=<StorageDomainName> protocol=S3 view-category=ObjectServices
```

Creating a view with `protocol=S3` means the view does not support NFS or SMB access.

Use the AWS CLI on Cohesity S3

You can use the AWS CLI to interact with buckets (S3 protocol views) on the Cohesity cluster.

1. Download and install AWS CLI.
2. Refer to the S3 commands set.

   Cohesity cluster S3 support is detailed here.
3. Run the following command:

   ```
   aws configure
   ```

   and provide the access key and secret access key.
4. For the endpoint, use <Hostname or IP Address>:3000

   where Hostname or IP Address is available from a Cluster > Networking > VIPS page in the Cohesity Dashboard.

   For example: myCohesity.myCompany.com:3000
5. Cohesity supports both Signature Version 2 and Version 4, but recommends Version 4. Amazon has deprecated Version 2.

   The AWS CLI uses Version 4 by default for S3. To use Version 2, run the following command to configure it:

   ```
   aws configure set default.s3.signature_version s3
   ```

   To switch back to Version 4, run the following command:

   ```
   aws configure set default.s3.signature_version s3v4
   ```

Commands to List Buckets and Objects

> **Tip:** The commands below assume the Cohesity cluster has a valid SSL certificate installed. If the Cohesity cluster has the default self-signed certificate, add the `--no-verify-ssl` option to the commands.

Sample command to list buckets:

```
aws --endpoint-url https://<cluster_ip or hostname>:3000  s3api list-buckets
```

Sample command to list objects in a bucket:

```
aws --endpoint-url https://<cluster_ip or hostname>:3000  s3api list-objects-v2 --bucket=<bucket_name>
```

Manage S3 Server Certificate

The Cohesity S3 server shares the certificate with the Cohesity cluster. The default certificate is auto-generated and self-signed. To get the SSL certificate details of the cluster, execute the following command:

```
iris_cli cluster list-ssl-cert-details
```

For more information about Cohesity CLI, see Using the Cohesity CLI.

For more information about managing SSL certificates and the procedure to update the default certificate, see Update SSL Certificates Using Cohesity CA or Customer CA certificate.

Cohesity recommends using the AWS CLI to access the Cohesity S3 server without disabling certificate verification. Use the `--ca-bundle` option to specify the path of the certificate file in your host. The following is an example:

```
aws s3api put-object --bucket hello --endpoint-url https://example.com:3000 --key tmp --body myfile --profile 10.2.195.1 --ca-bundle cabundle.pem
```

For more information, see the *AWS CLI Configuration Variables* section in the AWS CLI Command Reference Guide.

If you have replaced the default certificate and if the new certificate has a certificate chain, you must combine all the certificates in this certificate hierarchy into one file and specify the path of this file in the `--ca-bundle` option.

> **Note:**
> The content in the combined certificate should be in the following order:
>
> 1. Server certificate
> 2. Intermediate certificates
> 3. Root certificate

Supported S3 APIs

Cohesity supports the following S3 APIs:

API	Required Permissions
CreateBucket	The user must have the **Manage Cohesity Views** privilege assigned to their role to perform this operation. No additional S3 permissions are required.
DeleteBucket	s3:DeleteBucket
DeleteBucketOwnershipControls	s3:PutBucketOwnershipControls
DeleteBucketPolicy	s3:DeleteBucketPolicy
GetBucketAcl	s3:GetBucketAcl
GetBucketLifecycleConfiguration	s3:GetLifecycleConfiguration
GetBucketOwnershipControls	s3:GetBucketOwnershipControls
GetBucketPolicy	s3:GetBucketPolicy
GetBucketVersioning	s3:GetBucketVersioning
HeadBucket	s3:ListBucket
ListBuckets	No additional S3 permissions are required.
PutBucketAcl	s3:PutBucketAcl
PutBucketLifecycleConfiguration	s3:PutLifecycleConfiguration
PutBucketOwnershipControls	s3:PutBucketOwnershipControls
PutBucketPolicy	s3:PutBucketPolicy
PutBucketVersioning	s3:PutBucketVersioning
DeleteBucketLifecycle	s3:DeleteBucketLifecycleConfiguration
CopyObject	• s3:PutObject • s3:GetObject • s3:GetObjectVersion

API	Required Permissions
DeleteObject	• s3:BypassGovernanceRetention • s3:DeleteObject • s3:DeleteObjectVersion
DeleteObjects	• s3:BypassGovernanceRetention • s3:DeleteObject • s3:DeleteObjectVersion
DeleteObjectTagging	• s3:DeleteObjectTagging • s3:DeleteObjectVersionTagging
GetObject	• s3:GetObject • s3:GetObjectVersion • s3:GetObjectTagging • s3:GetObjectVersionTagging • s3:GetObjectLegalHold • s3:GetObjectRetention

Supported S3 API Headers

This page provides a list of the S3 headers that are supported by Cohesity.

> **Note:** If unsupported headers are included in a request, they will be ignored.

Request Headers

Cohesity supports the following request headers:

- Authorization
- Content-Length
- Content-MD5
- Date
- Expect
- Host
- Range
- User-Agent—Ignored
- x-amz-bucket-object-lock-enabled
- x-amz-bypass-governance-retention
- x-amz-content-sha256
- x-amz-copy-source
- x-amz-copy-source-if-match
- x-amz-copy-source-if-modified-since
- x-amz-copy-source-if-none-match
- x-amz-copy-source-if-unmodified-since
- x-amz-copy-source-range
- x-amz-date
- x-amz-meta-*
- x-amz-object-lock-legal-hold
- x-amz-object-lock-mode
- x-amz-object-lock-retain-until-date
- x-amz-security-token—Ignored
- x-amz-tagging
- x-amz-tagging-directive

Response Headers

Cohesity supports the following response headers:

- Connection
- Content-Length
- Content-MD5
- Date
- ETag
- Server
- x-amz-abort-date
- x-amz-abort-rule-id
- x-amz-copy-source-version-id
- x-amz-delete-marker
- x-amz-expiration
- x-amz-object-lock-legal-hold
- x-amz-object-lock-mode
- x-amz-object-lock-retain-until-date
- x-amz-tagging-count
- x-amz-version-id

S3 Object Lock

On a Cohesity cluster, you can create a Cohesity view and use it as an Amazon S3 bucket. S3-compatible clients can use the view for object storage. S3 Object Lock enables you to store objects using a write-once-read-many (WORM) model. Cohesity supports S3 Object Lock, so you can prevent objects from being deleted or overwritten for a fixed amount of time or indefinitely.

You can enable Object Lock on new or existing SmartFiles S3 views. Cohesity recommends that you enable Object Lock when you create a new view. If you enable Object Lock on an existing SmartFiles S3 view, Object Lock does not implicitly protect objects that were created before the lock was enabled on the view. To protect objects that were created before the lock was enabled, use the `PutObjectRetention` or `PutObjectLegalHold` APIs and explicitly enable Object Lock on these objects.

> **Note:** If you enable Object Lock on a view, versioning is automatically enabled for the view and you cannot suspend versioning.

Object Lock uses versioning so multiple variants of an object are available in the same bucket. Even if the bucket owner deletes an object in a versioning-enabled bucket, the object version is protected and you can restore any version of the object stored in the

bucket. From a security perspective, Object Lock provides an extra layer of protection against object version changes, inadvertent deletion, and malicious modification of data.

In AWS, a policy defines permissions. You can associate a policy with an identity or resource. To restrict access to SmartFiles S3 views, you can attach resource-based policies so that you can specify who has access and what actions they can perform.

For more information about Object Lock, versioning, and policies, see Amazon S3 User Guide.

Retention Period

A retention period is a fixed period of time during which an object remains locked. During this period, the object is WORM-protected and cannot be overwritten or deleted. To add a retention period:

- Object Lock must be enabled on the bucket that contains the object
- The user must have the `s3:PutObjectRetention` permission

Retention Modes

Object Lock provides two retention modes: governance and compliance. Consider the following points before you choose the retention mode:

- Governance mode—You cannot overwrite or delete an object version or alter its lock settings unless you have special permissions. The bucket owner or a user granted permissions through S3 Bucket Policy can modify the retention period or delete the object using the `bypass-governance-retention` parameter in the request.

  Note:
  - When a user with adequate permissions executes a `DeleteObject` operation in a versioning-enabled bucket, a unique version delete marker is generated, safeguarding the previous version. To permanently delete a particular version, you can invoke the `DeleteObject` operation and provide the specific `VersionId`.
  - To view all versions of an object, execute the `ListObjectVersions` operation. The response includes all accessible versions within the S3 system.

    For more information about S3 versioning and deleting object versions, see Amazon S3 User Guide.

- Compliance mode—No user can overwrite or delete a protected object version. If an object is locked in compliance mode, you cannot change the retention mode or shorten the retention period.

Legal Hold

A legal hold prevents an object version from being overwritten or deleted. The legal hold provides the same protection as a retention period, but it has no expiration date. The legal hold remains in place until you explicitly remove it. To place or remove legal holds:

- Object Lock must be enabled on the bucket that contains the object
- The user must have the `s3:PutObjectLegalHold` permission

Important Points to Note

- If you enable Object Lock on a view, you can delete the view only if the view does not contain any objects.
- If you enable Object Lock, you cannot disable Object Lock or suspend versioning on the bucket.
- If Object Lock is enabled on a view, you can clone or replicate the view to a Cohesity cluster only if the remote cluster supports Object Lock. If the remote cluster does not support Object Lock, Cohesity recommends you upgrade the cluster to a version that supports the Object Lock feature.

Support for New Amazon S3 APIs

Cohesity introduces support for the following Amazon S3 APIs:

- GetObjectLockConfiguration
- PutObjectLockConfiguration
- GetObjectLegalHold
- PutObjectLegalHold
- PutObjectRetention
- GetObjectRetention

Cohesity enhances support for the following Amazon S3 APIs:

- CreateBucket—Support for the `x-amz-bucket-object-lock-enabled` request header.
- PutBucketVersioning
- PutObject—Support for the following request headers:
  - `x-amz-object-lock-mode`
  - `x-amz-object-lock-retain-until-date`
  - `x-amz-object-lock-legal-hold`
- GetObject—Support for the `VersionId` parameter and the following response headers:

    - `x-amz-object-lock-mode`
    - `x-amz-object-lock-retain-until-date`
    - `x-amz-object-lock-legal-hold`
- HeadObject—Support for the `VersionId` parameter and the following response headers:
    - `x-amz-object-lock-mode`
    - `x-amz-object-lock-retain-until-date`
    - `x-amz-object-lock-legal-hold`
- DeleteObject—Support for the `x-amz-bypass-governance-retention` request header.
- CreateMultipartUpload—Support for the following request headers:
    - `x-amz-object-lock-mode`
    - `x-amz-object-lock-retain-until-date`
    - `x-amz-object-lock-legal-hold`

  For more information about these APIs, see Amazon S3 API Reference.

Enable Object Lock From the Cohesity Cluster GUI

From the Cohesity Cluster GUI, you can enable Object Lock and Versioning on new or existing SmartFiles S3 views. If you enable Object Lock, versioning is automatically enabled for the view and you cannot suspend versioning.

To enable S3 Object Lock:

1. Navigate to **SmartFiles > Views**.
2. On the **Views** page:
    - Click **Create View** and proceed to the next step.
    - If it is an existing S3 view, click the Actions menu (⋮) and select **Edit** to edit the view. Proceed to Step 5.
3. Select a predefined template or custom template. Ensure that you select one of the following from the **Object Services** category to create an S3 view:
    - General
    - Containers
    - Hadoop
    - Splunk SmartStore
4. Click **More Options**.
5. Click the **S3 Object Lock** section and turn on the toggle.

> **Note:** After you enable S3 Object Lock, the **Versioning** toggle is automatically turned on and you cannot disable Object Lock or suspend versioning on the bucket.

6. Turn on the **Default Retention** toggle and select one of the following retention modes to automatically protect new objects put into this bucket from being deleted or overwritten:
   1. **Governance**—Users with specific permissions can overwrite or delete protected object versions during the retention period.
   2. **Compliance**—No user can overwrite or delete protected object versions during the retention period.

   Select either **Days** or **Years** from the drop-down menu and enter the number of days or years to set the retention.

For detailed instructions about creating an S3 View, see Create an S3 View.

Enable Object Lock Using AWS CLI

Ensure that the following prerequisites are met:

- Install curl on a Linux host which has connectivity with the Cohesity cluster.
- Install AWS CLI on the Linux host.
- AWS access key ID and secret access key of the user who is creating the bucket.

To enable Object Lock using AWS CLI, execute the following command:

```
aws s3api put-object-lock-configuration --endpoint-url https://cluster-fqdn-or-ip-address:3000 --bucket "bucket-name" --object-lock-configuration '{"ObjectLockEnabled": "Enabled"}' --no-verify-ssl --profile profile-name
```

View Object Lock Status

To determine whether Object Lock is enabled on a view, navigate to **SmartFiles > Views**. On the **Views** page, a lock symbol is displayed next to the view name if Object Lock is enabled.

The following figure shows a view on which Object Lock is enabled:

S3 Lifecycle

Cohesity supports configuring the lifecycle of your S3 objects so that they are stored cost-effectively throughout their lifecycle. S3 Lifecycle configuration includes a set of rules that define actions applicable to a specified group of objects. You can enable lifecycle management on new or existing S3 Views.

AWS S3 supports two types of actions:

- Transition actions—Define when objects transition to another S3 storage class.

  > **Note:** Cohesity does not support transition actions.

- Expiration actions—Define when objects should expire. Cohesity supports expiration actions and deletes expired objects on your behalf.

You can organize S3 objects using prefixes or tags. A prefix value enables you to group similar objects together in a bucket. You can create multiple S3 Lifecycle configuration rules for a bucket and apply a rule to a subset of objects.

Lifecycle Configuration

The S3 Lifecycle configuration is specified as XML and consists of a set of predefined rules. Each rule can include the following elements:

- **ID**—Uniquely identifies a rule. If you do not specify an ID in the Lifecycle configuration, Cohesity S3 automatically generates a unique identifier.
- **Status**—Indicates whether the rule is enabled or not.
- **Filter**—Identifies a subset of objects on which the rule should be applied. You can filter objects by prefixes or tags. This is an optional element and can be specified if required.
- **Actions**—Specifies a set of actions that must be applied to the filtered objects. Cohesity supports two expiration actions.

  For more information, see Expiration Actions.

The following is a sample lifecycle configuration using AWS CLI:

```
aws s3api put-bucket-lifecycle-configuration --bucket <view_name> --endpoint-url https://<host_name>:3000 --
no-verify-ssl --lifecycle-configuration \
'{
 "Rules":[
   {
     "ID":"id0",
     "Status":"Enabled",
     "Filter":{
       "Prefix":"obj"
     },
     "Expiration":{
       "Days":1
     }
   },
   {
     "ID":"id1",
     "Status":"Enabled",
     "Filter":{
       "Prefix":"mpu"
     },
     "AbortIncompleteMultipartUpload":{
       "DaysAfterInitiation":1
     }
   }
 ]
}'
```

Expiration Actions

Cohesity enables you to define when objects should expire. Cohesity supports the following three expiration actions:

- **Expiration**—Expires the objects identified in the rule. Objects are deleted at midnight UTC. You can configure one of the following parameters for this action:
  - **Days**—Specify the number of days after which the object should expire. Lifetime is measured from the object's creation time. Lifetime is calculated by adding the number of days specified to the object's creation time and rounding off the resulting time to midnight UTC of the next day. The following is an example:

    - Number of days specified—2
    - Object creation time—1/20/2022 11:30 AM UTC

      The object is deleted at midnight UTC on 1/23/2022
  - **Date**—Specify the date on which the object should expire.
  - **ExpiredObjectDeleteMarker**—Indicates if Cohesity will remove a delete marker without any noncurrent versions. When enabled, the delete marker expires; when disabled, no action is taken. You cannot specify this option with Days or Date in a Lifecycle Expiration Policy.
- **NoncurrentVersionExpiration**—Specifies when noncurrent object versions expire. Once it has expired, Cohesity permanently deletes the noncurrent object versions. You can set this lifecycle configuration action on a versioning-enabled View or a versioning-suspended View to delete noncurrent object versions after a set period in the object's lifecycle.
  - **NoncurrentDays**—Specifies the number of days an object is noncurrent. Once this specified period elapses, Cohesity automatically deletes the noncurrent object versions from the View.
- **AbortIncompleteMultipartUpload**—Manages the lifecycle of incomplete multipart uploads.
  - **DaysAfterInitiation**—Specify the number of days after initiation of multipart uploads Cohesity can abort these incomplete multipart uploads.

Support for Upgrade, Archive, and Replication

Expiration actions are also supported on existing Cohesity SmartFiles S3 views. If you have successfully upgraded to a version that supports S3 Lifecycle, you can configure these actions on views created in a previous version, for example, 6.5.1.

If S3 Lifecycle is enabled on a view and if the view is replicated to or archived and restored to another cluster that does not support S3 Lifecycle, the lifecycle configuration does not take effect. After the cluster is upgraded to a version supporting the S3 Lifecycle feature, the lifecycle configuration takes effect.

Add Lifecycle Management Rules From the Cohesity Cluster GUI

From the Cohesity cluster GUI, you can add Lifecycle Management rules on new or existing SmartFiles S3 views.

To add Lifecycle Management rules:

1. Navigate to **SmartFiles > Views**.
2. On the **Views** page:

- Click **Create View** and proceed to the next step.
- If it is an existing S3 view, click the Actions menu (⋮) and select **Edit** to edit the view. Proceed to **Step 5**.

3. Select a predefined template or custom template. Ensure that you select one of the following from the **Object Services** category to create an S3 view:
   - General
   - Containers
   - Hadoop
   - Splunk SmartStore
4. Click **More Options**.
5. Click the **Lifecycle Management Rules** section and click **Add Rule**.
6. In the **Add Lifecycle Management Rule** dialog, set up the rule.
7. Enter the name of the rule.
8. Select the **Rule Scope**:
   - Click **Apply to all objects in the bucket** to apply this rule to all objects in the bucket.
   - Click **Limit the scope of this rule using one or more filters** to limit the scope of this rule by adding one or more filters:
     - Enter a prefix to limit the scope of this rule to a single prefix.
     - Optionally, click **Add Object Tag** and add a key and value to apply the Lifecycle Management rule to a subset of objects that has all the tags specified in the rule. If an object has additional tags specified, the rule is still applied. For more information about object tags, see S3 Object Tags.
9. Select at least one rule action:
   - Select **Expire current versions of objects** and specify the number of days to expire objects identified in the rule.
   - Select **Permanently delete noncurrent versions of objects** and specify the number of days. Specify the number of days an object remains noncurrent before Cohesity executes the deletion process. Cohesity calculates this duration based on the time elapsed since the creation of its successor version, determining the object's noncurrent status.
   - Select **Remove expired object delete markers** to remove delete markers of expired objects. Cohesity will remove a delete marker only if there are no noncurrent versions associated with it.
   - Select **Delete incomplete multipart uploads** and specify the number of days

to expire incomplete multipart uploads identified in the rule. Parts associated with these multipart uploads are deleted.

10. Click **Add**.

Supported S3 APIs and Response Headers

Cohesity introduces support for the following S3 Lifecycle APIs:

- PutBucketLifecycleConfiguration

  Cohesity also supports the PutBucketLifecycle API.
- GetBucketLifecycleConfiguration
- DeleteBucketLifecycle

The following APIs now support the `x-amz-expiration` response header:

- PutObject
- CopyObject
- CompleteMultipartUpload
- GetObject
- HeadObject

The following APIs now support the `x-amz-abort-date` and `x-amz-abort-rule-id` response headers:

- CreateMultipartUpload
- ListParts

For more information about these APIs, see Amazon S3 API Reference documentation.

S3 Bucket Ownership Controls

To store data in Amazon S3, you must create a bucket and upload data to that bucket as objects. An object consists of file data and any metadata that describes the file. An AWS S3 bucket is a container for objects. By default, the object creator owns the object and can manage access through Access Control Lists (ACLs). However, as a bucket owner, you can use buckets to manage access to all objects in the bucket. You can disable ACLs on the S3 bucket and take ownership of all the objects in the bucket. You can use policies to control access to your data.

On a SmartFiles S3 View, you can use one of the modes to manage access on objects:

- **ObjectWriter**—This is the default mode of operation and remains in effect if object ownership controls are not configured on the bucket. The object creator automatically becomes the owner and remains the owner of the object.
- **BucketOwnerPreferred**—This mode is similar to **ObjectWriter** with the exception that the bucket owner becomes the object owner when the object is created with the `bucket-owner-full-control` canned ACL. Enabling or disabling this mode does not change the ownership of existing objects.
- **BucketOwnerEnforced**—This mode disables the ACLs on the bucket and objects. All existing objects/MPUs start being owned by the bucket owner. The owner of the object/MPU metadata does not change. If the mode is disabled, the previous owners start owning the objects/MPUs again. When enabled, all the new objects/MPUs are owned by the bucket owner. Ownership of these newly created objects/MPUs does not change when the mode is disabled. No canned ACLs `except bucket-owner-full-control` are allowed while creating the object/MPU. The grant specification is allowed only if it translates to full control for the bucket owner. This mode can be enabled only when the bucket is privately owned by the bucket owner and does not have any other grants. When this mode is enabled, bucket and object ACLs cannot be updated.

Support for Amazon S3 APIs

Cohesity introduces support for the following Amazon S3 APIs:

- PutBucketOwnershipControls
- GetBucketOwnershipControls
- DeleteBucketOwnershipControls

For more information about these APIs, see Amazon S3 API Reference.

Example Usage

To set bucket ownership controls, execute the following command:

```
aws --endpoint-url https://<cluster_ip or hostname>:3000 s3api put-bucket-ownership-controls --bucket <test-bucket> --ownership-controls='{"Rules": [{"ObjectOwnership": "BucketOwnerPreferred"}]}'  --profile aws
```

To verify whether bucket ownership controls are set, execute the following command:

```
aws --endpoint-url https://<cluster_ip or hostname>:3000 s3api get-bucket-ownership-controls --bucket <test-bucket> --profile aws
```

The following is a sample response:

```
{
    "OwnershipControls": {
        "Rules": [
            {
                "ObjectOwnership": "BucketOwnerPreferred"
            }
        ]
    }
```

```
}
```

To delete bucket ownership controls, execute the following command:

```
aws --endpoint-url https://<cluster_ip or hostname>:3000 s3api delete-bucket-ownership-controls --bucket <test-bucket> --profile aws
```

To verify whether bucket ownership controls are deleted, execute the following command:

```
aws --endpoint-url https://<cluster_ip or hostname>:3000 s3api get-bucket-ownership-controls --bucket <test-bucket> --profile aws
```

If bucket ownership controls are deleted, the following error message is displayed:

```
An error occurred (OwnershipControlsNotFoundError) when calling the GetBucketOwnershipControls operation: The bucket ownership controls were not found.
```

S3 Bucket Policy

To store data in Amazon S3, you must create a bucket and upload data to that bucket as objects. An object consists of file data and any metadata that describes the file. An S3 bucket is a container for objects. By default, only the creator can access the bucket or object. You can use a resource-based policy or an ACL to grant other users access to the bucket or object:

- If the policy is attached to a resource such as an S3 bucket, it is called a resource-based policy.
- An ACL is a list of grants identifying the grantees and the permissions granted. You can use ACLs to grant basic read/write permissions to other users.

Benefits of Using Bucket Policy

A bucket policy provides the following benefits over an ACL:

- ACL is restricted to a specific resource. For example, a bucket owner can grant access to a specific object by storing the ACL in the metadata of that object. If the owner wants to grant permissions to a set of objects having the prefix `log_`, the owner has to grant permissions using ACL for each object. This can be cumbersome. You can use a bucket policy and grant permissions to all objects having the prefix `log_`.
- You can use a bucket policy to grant permissions for certain bucket subresources such as `lifecycle` and `versioning`. You cannot use ACL to grant permissions for these

subresources.

- In a bucket policy, you can specify conditions, which permit the users to perform actions only if those conditions are met. For example, you can allow a user to list objects in a bucket only if the value of the `max-keys` parameter is less than 10.

Elements of a Bucket Policy

Bucket policy uses access policy language to define access permissions and specify conditions. The access policy is JSON-based and contains the following elements:

- Principals
- Resources
- Actions
- Effect
- Conditions

Principals

Cohesity S3 supports the following principals:

- Canonical user
- Anonymous user

Resources

You can use one of the following formats:

- `arn:aws:s3:::bucket_name/key_name`—AWS S3 uses Amazon Resource Name (ARN) to identify a resource.
- `urn:csf:s3:::bucket_name/key_name`—Cohesity S3 uses this format to identify a resource.

Actions

A set of predefined operations for each resource. Each action corresponds to a specific S3 operation such as `s3:PutObject` or `s3:PutObjectAcl`.

Effect

You can use one of the following values for the Effect element:

- `Allow`
- `Deny`

The default value is `Deny`.

Conditions

You can specify the conditions for a policy using this element. A `Condition` element can contain multiple conditions and each condition can contain multiple key-value pairs.

Cohesity S3 supports the following condition operators:

- String—`StringEquals`, `StringEqualsIgnoreCase`, `StringNotEquals`, and `StringNotEqualsIgnoreCase`.
- Numeric—`NumericEquals`, `NumericNotEquals`, `NumericLessThan`, `NumericLessThanEquals`, `NumericGreaterThan`, and `NumericGreaterThanEquals`.
- If a condition has multiple keys or values, you can use the `ForAllValues` or `ForAnyValue operator`.
- You can add the `IfExists` operator to the end of any condition operator name except the `Null` condition.

Cohesity S3 supports the following condition keys:

Condition Key	Description	Type
`s3:ExistincgObjectTag/<tag-key>`	Filters access by existing object tag key and value	String
`s3:RequestObjectTagKeys`	Filters access by the tag keys to be added to objects	ArrayOfString
`s3:RequestObjectTag/<tag-key>`	Filters access by the tag keys and values to be added to objects	String
`s3:max-keys`	Filters access by the maximum number of keys returned in a `ListBucket` request	Numeric
`s3:prefix`	Filters access by key name prefix	String
`s3:delimiter`	Filters access by the delimiter parameter	String
`s3:x-amz-acl`	Filters access by canned ACL in the request's `x-amz-acl` header	String

The following table lists the supported actions and the corresponding condition keys:

Action	Supported Condition Keys
ListBucket	• s3:prefix • s3:max-keys • s3:delimiter
ListBucketVersions	• s3:prefix • s3:max-keys • s3:delimiter
PutObject	• s3:x-amz-acl • s3:RequestObjectTagKeys • s3:RequestObjectTag/<tag-key>
PutObjectAcl	• s3:x-amz-acl • s3:ExistingObjectTag/<tag-key>
PutObjectVersionAcl	• s3:x-amz-acl • s3:ExistingObjectTag/<tag-key>
DeleteObjectTagging	• s3:ExistingObjectTag/<tag-key>
DeleteObjectVersionTagging	• s3:ExistingObjectTag/<tag-key>
GetObject	• s3:ExistingObjectTag/<tag-key>
GetObjectVersion	• s3:ExistingObjectTag/<tag-key>
GetObjectAcl	• s3:ExistingObjectTag/<tag-key>

Action	Supported Condition Keys
GetObjectTagging	• s3:ExistingObjectTag/<tag-key>
GetObjectVersionAcl	• s3:ExistingObjectTag/<tag-key>
GetObjectVersionTagging	• s3:ExistingObjectTag/<tag-key>
PutObjectTagging	• s3:ExistingObjectTag/<tag-key> • s3:RequestObjectTagKeys • s3:RequestObjectTag/<tag-key>
PutObjectVersionTagging	• s3:ExistingObjectTag/<tag-key> • s3:RequestObjectTagKeys • s3:RequestObjectTag/<tag-key>
BypassGovernanceRetention	• s3:RequestObjectTagKeys • s3:RequestObjectTag/<tag-key>

Example of an S3 Bucket Policy

The following is a sample S3 bucket policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowUser2ToWriteObject",
      "Effect": "Allow",
      "Principal": {
        "CanonicalUser": [
          "USER2@LOCAL@"
        ]
      },
      "Action": [
        "s3:PutObject"
      ],
      "Resource": "arn:aws:s3:::BUCKET-NAME/*"
    },
    {
      "Sid": "AllowUser2ToGetObjectOnlyWhenTagsHavePublicSecurity",
```

```
      "Effect": "Allow",
      "Principal": {
        "CanonicalUser": [
          "USER2@LOCAL@"
        ]
      },
      "Action": [
        "s3:GetObject"
      ],
      "Resource": "arn:aws:s3:::BUCKET-NAME/*",
      "Condition": {
        "StringEquals": {
          "s3:ExistingObjectTag/security": "public"
        }
      }
    }
  ]
}
```

Support for Amazon S3 APIs

Cohesity introduces support for the following Amazon S3 APIs:

- PutBucketPolicy
- GetBucketPolicy
- DeleteBucketPolicy

For more information about these APIs, see Amazon S3 API Reference.

Related Topics

- Supported S3 APIs
- Supported S3 API Headers

S3 Object Tags

Cohesity supports S3 object tagging. Object tags are unique key-value pairs that are applied to individual S3 objects. You can create, update, or delete object tags at any time during the lifetime of an S3 object. You can use object tags to categorize storage. For example, you can add details such as data owners and users, business unit names, media types, data format, or security classification.

Considerations

- You can add up to 10 tags for each object.
- Tag keys must be unique within each object.
- A tag key can be up to 128 Unicode characters in length.
- A tag value can be up to 256 Unicode characters in length.
- Keys and values are case-sensitive.

Support for Amazon S3 APIs

Cohesity introduces support for the following Amazon S3 APIs:

- PutObjectTagging
- GetObjectTagging
- DeleteObjectTagging

Cohesity enhances support for the following Amazon S3 APIs:

- PutObject
- GetObject
- CreateMultipartUpload
- CopyObject
- PutBucketLifecycleConfiguration

Support for New Request and Response Headers

Cohesity introduces support for the following new request headers:

- `x-amz-tagging`
- `x-amz-tagging-directive`

Cohesity introduces support for the following new response header:

- `x-amz-tagging-count`

For more information about these APIs, see Amazon S3 API Reference.

Example Usage

To update tags on an existing object, execute the following command:

```
aws --endpoint-url https://<cluster_ip or hostname>:3000 s3api put-object-tagging --bucket <test-bucket>  --key obj2 --tagging '{"TagSet": [{ "Key": "Color", "Value": "Blue" }, { "Key": "Project", "Value": "Alpha" }]}' --profile vmrobo2
```

To get the entire tag set from an existing object, execute the following command:

```
aws --endpoint-url https://<cluster_ip or hostname>:3000 s3api get-object-tagging --bucket <test-bucket> --key obj2 --profile vmrobo2
```

The following is a sample response:

```
{
    "TagSet": [
        {
            "Key": "Color",
            "Value": "Blue"
        },
```

```
        {
            "Key": "Project",
            "Value": "Alpha"
        }
    ]
}
```

To delete all tags from an existing object, execute the following command:

```
aws --endpoint-url https://<cluster_ip or hostname>:3000 s3api delete-object-tagging --bucket <test-bucket>   --key obj2 --profile vmrobo2
```

To create an object with tags, execute the following command:

```
aws --endpoint-url https://<cluster_ip or hostname>:3000 s3api put-object --bucket <test-bucket> --key obj1 --body ~/test/obj1.txt --profile vmrobo2  --tagging 'Color=Red&Project=Beta'
```

The following is a sample response:

```
{
"ETag": "\"0accc61f62bb422443c3f0f2d351ca16\""
}
```

To get the object tag count, execute the following command:

```
aws --endpoint-url https://<cluster_ip or hostname>:3000 s3api get-object --bucket <test-bucket> --key obj1 --profile vmrobo2 outfile
```

The following is a sample response:

```
{
    "LastModified": "2022-10-21T13:51:13+00:00",
    "ContentLength": 1024,
    "ETag": "\"0accc61f62bb422443c3f0f2d351ca16\"",
    "Metadata": {},
    "TagCount": 2
}
```

To add tags during the initiation of multipart upload, execute the following command:

```
aws --endpoint-url https://<cluster_ip or hostname>:3000 s3api create-multipart-upload --bucket <test-bucket> --profile vmrobo2 --key obj4 --tagging 'Color=Red&Project=Beta'
```

To verify whether the tags are added, execute the GetObjectTagging API. The following is a sample response:

```
{
    "Bucket": "test-bucket",
    "Key": "obj4",
    "UploadId": "4706"
}
```

> **Note:** Once you complete this multipart upload, you can read/update tags on the resultant object.

To copy an existing object and associated tags, execute the following command:

```
aws --endpoint-url https://<cluster_ip or hostname>:3000 s3api copy-object --copy-source test-bucket/obj1 --key obj2 --bucket <test-bucket> --profile vmrobo2 --tagging-directive COPY
```

> **Note:** Even if you do not specify the `--tagging-directive COPY` header, the `CopyObject API` copies all object tags.

The following is a sample response:

```
{
    "CopyObjectResult": {
        "ETag": "\"0accc61f62bb422443c3f0f2d351ca16\"",
        "LastModified": "2022-10-21T13:58:44+00:00"
    }
}
```

To copy an existing object and add new tags on the copy, execute the following command:

```
aws --endpoint-url https://<cluster_ip or hostname>:3000 s3api copy-object --copy-source test-bucket/obj1 --key obj2 --bucket <test-bucket> --profile vmrobo2 --tagging-directive REPLACE  --tagging '{"TagSet":[{"Key":"Owner1", "Value":"Blue"}]}'
```

The following is a sample response:

```
{
    "CopyObjectResult": {
        "ETag": "\"0accc61f62bb422443c3f0f2d351ca16\"",
        "LastModified": "2022-10-21T13:58:44+00:00"
    }
}
```

To specify object tags while creating a new lifecycle configuration for the bucket, execute the following command:

```
aws --endpoint-url https://<cluster_ip or hostname>:3000 s3api put-bucket-lifecycle-configuration --bucket <test-bucket> --lifecycle-configuration
```

The following is a sample response:

```
'{
  "Rules": [
    {
```

```
      "ID": "id0",
      "Status": "Enabled",
      "Filter": {
        "Tag": {
          "Key": "k0",
          "Value": "v0"
        }
      },
      "Expiration": {
        "Days": 1
      }
    }
  ]
}'
```

Use Object Tags with S3 Lifecycle Management

You can use object tags to enable fine-grained object lifecycle management by specifying a tag-based filter in a lifecycle management rule. The `PutBucketLifecycleConfiguration` API has been enhanced to accept `Tag` and `And` filters.

Use Object Tags with Bucket Policy

You can use object tags to enable fine-grained access control of permissions by specifying object tags in the condition of an access policy. You can use bucket access policies to restrict access to data with specific tags, group objects with unique compliance requirements, or create lifecycle policies for objects with specific tags.

Cohesity supports the following three condition keys:

- `s3:ExistingObjectTag/<tag-key>`—Use this condition key in the policy to grant users permission to perform specific operations on objects. The condition limits the permission to only objects that have the tag key and tag value specified in `s3:ExistingObjectTag/<tag-key>`.
- `s3:RequestObjectTagKeys`—Use this condition key to restrict tag keys that the user wants to allow on objects. This is useful when adding tags to objects using the `PutObjectTagging` and `PutObject` requests.
- `s3:RequestObjectTag/<tag-key>`—Use this condition key to restrict tag keys and tag values the user wants to allow on objects. This is useful when adding tags to objects using the `PutObjectTagging` and `PutObject` requests.

Support for UploadPartCopy API

You can use the `UploadPartCopy` API to upload a part by copying data from an existing object as the data source. In your request, specify the following:

- Data source by adding the `x-amz-copy-source` request header
- Byte range by adding the `x-amz-copy-source-range` request header

For more information, see Amazon S3 REST API Documentation.

S3 Access Control Lists

Cohesity supports Access Control Lists (ACLs) for both buckets and objects. You can specify ACL grantees to define fine-grained access control. Cohesity supports all the features of AWS S3 ACL.

> **Note:** Cohesity recommends using bucket policies instead of ACLs for managing access control. Bucket policies provide more granular control and flexibility in defining access permissions for buckets and objects. For more information about bucket policies, see S3 Bucket Policy.

The table below provides an overview of the ACL permissions and their corresponding API permissions when ACL permissions are granted on a bucket or an object:

ACL Permission	API Permissions Granted on a Bucket	API Permissions Granted on an Object
`READ`	• `s3:ListBucket` • `s3:ListBucketVersions` • `s3:ListBucketMultipartUploads`	• `s3:GetObject` • `s3:GetObjectVersion`
`WRITE`	• `s3:PutObject` • `s3:DeleteObject` The bucket owner can create, overwrite, or delete any object in the bucket.	Not applicable
`READ_ACP`	• `s3:GetBucketAcl`	• `s3:GetObjectAcl` • `s3:GetObjectVersionAcl`

ACL Permission	API Permissions Granted on a Bucket	API Permissions Granted on an Object
`WRITE_ACP`	• `s3:PutBucketAcl`	• `s3:PutObjectAcl` • `s3:PutObjectVersionAcl`
`FULL_CONTROL`	Equivalent to granting `READ`, `WRITE`, `READ_ACP`, and `WRITE_ACP` ACL permissions. Additionally, the following API permissions are granted: • `s3:GetObjectRetention` • `s3:PutObjectRetention` • `s3:BypassGovernanceRetention` • `s3:GetObjectLegalHold` • `s3:PutObjectLegalHold` • `s3:PutObjectTagging` • `s3:PutObjectVersionTagging` • `s3:GetObjectTagging` • `s3:GetObjectVersionTagging` • `s3:DeleteObjectTagging` • `s3:DeleteObjectVersionTagging`	Equivalent to granting `READ`, `READ_ACP`, and `WRITE_ACP` ACL permissions.

The following additional permissions can only be assigned to the bucket owner:

- `s3:DeleteObjectVersion`
- `s3:PutBucketObjectLockConfiguration`
- `s3:GetBucketObjectLockConfiguration`

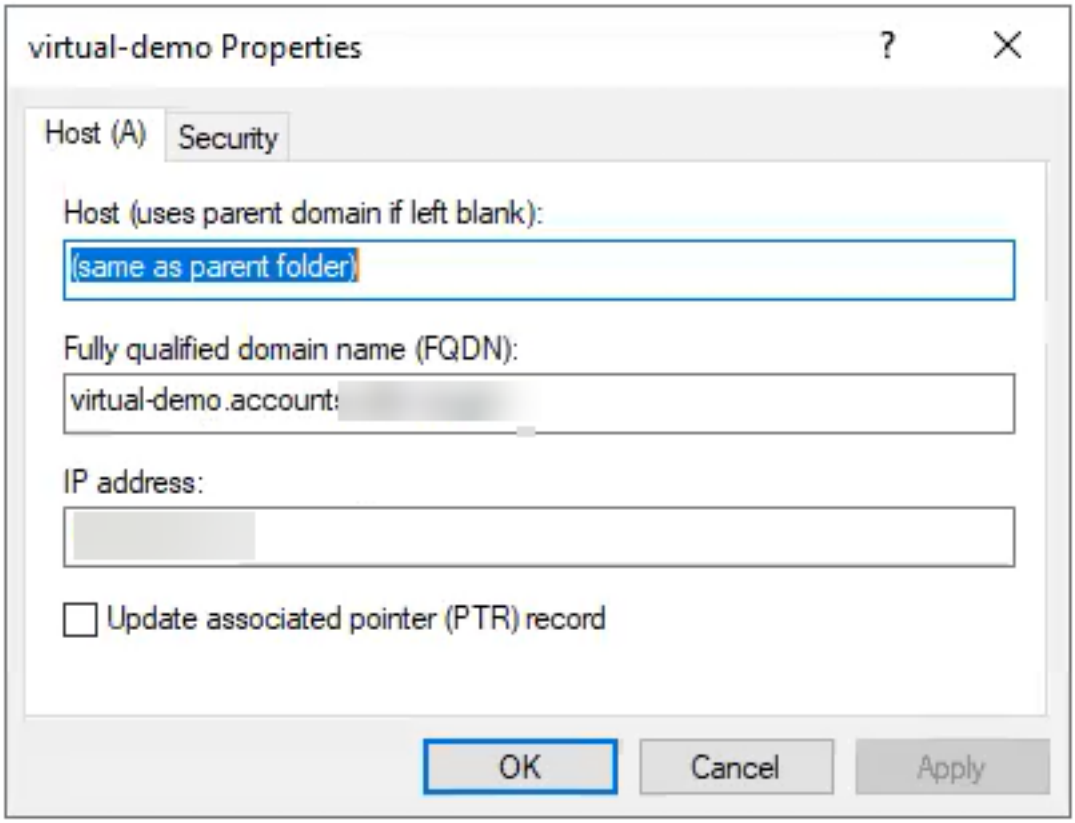
S3 Virtual-Hosted–Style Requests

Cohesity supports virtual-hosted–style requests. In a virtual-hosted–style request, the bucket name is part of the domain name in the URL. For example, `https://bucket-name.cohesity.com/key-name`.

> **Note:** This feature allows Cohesity SmartFiles to function as storage for Snowflake external tables. For more information about Cohesity SmartFiles integration with Snowflake Data Cloud, see Extend Snowflake Data Access Securely and Cost Effectively.

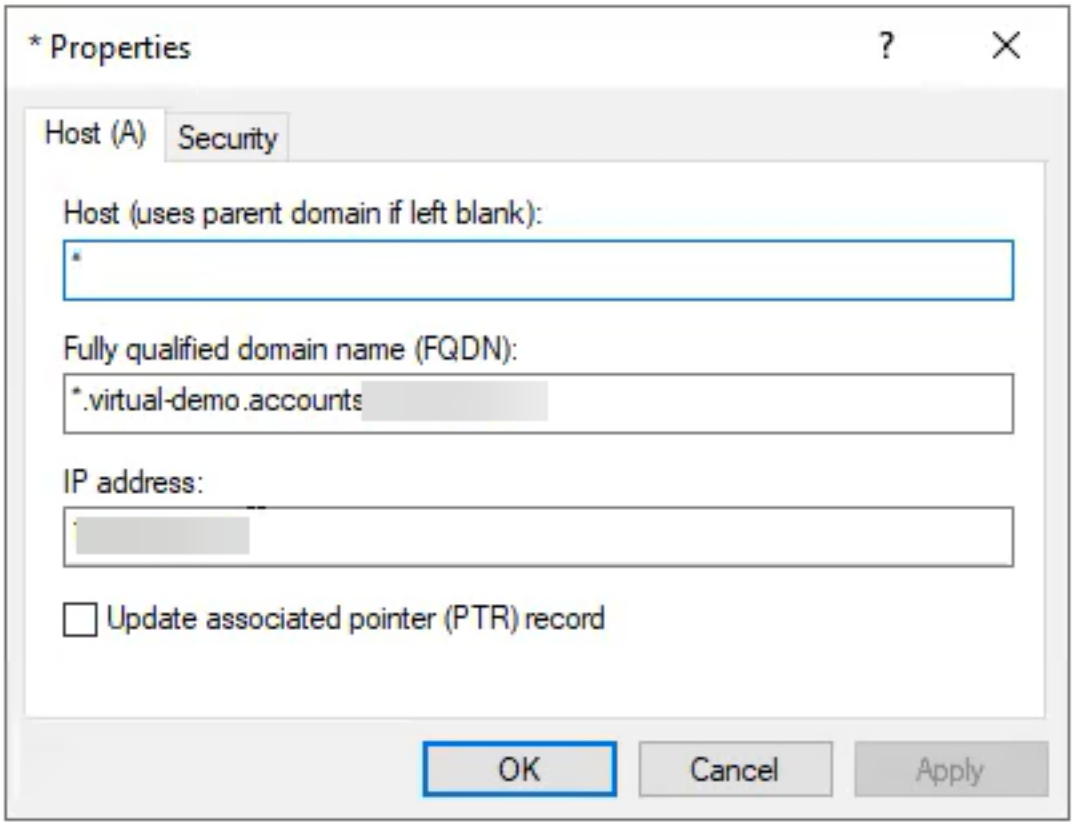
Prerequisites

- Add a DNS A record in the DNS management software by specifying the IP address of the Cohesity cluster and its fully qualified domain name (FQDN). The cluster IP address must be DNS-resolvable. The following is an example of a DNS record:



- To enable the resolution of any bucket name added to the FQDN to the Cohesity cluster, include a DNS A record with a wildcard (*) in the FQDN. The following is an

example of (*) in the FQDN:



Enable Virtual Hosted Style Requests

You can only enable virtual-hosted-style requests through the CLI.

To enable virtual-hosted-style requests, do the following:

1. Log in to Cohesity CLI. For more information, see Using the Cohesity CLI.
2. Enter the following command:

   ```
   iris_cli cluster update-s3-virtual-hosted-domain-names virtual-hosted-domain-names=<domain names>
   ```

   > **Note:** You can add multiple domain names separated by a comma.

3. Enter the username and password.
4. Verify whether the virtual-hosted-style requests are enabled by executing the following command:

   ```
   iris_cli cluster info
   ```

   If the feature is enabled, the following field is displayed:

   ```
   S3 VIRTUAL HOSTED DOMAIN NAMES
   ```

Important Points to Note

- If the Host header value ends with one of the specified hostnames, the request is interpreted as following the virtual-hosted-style request, and the initial section of the header is treated as the bucket name. Consequently, the URL is considered to have an object key only.
- If the Host header value is exactly the same as one of the hostnames, the request is considered to be a path-style request.
- You can access an S3 bucket using a path-style request or a virtual-hosted-style request.

Presigned URLs

Presigned URLs allow temporary access to a specific S3 resource and operation without requiring additional authentication or authorization. All authentication information, including the request signature, is included directly in the query string. This type of URL is referred to as a presigned URL.

Presigned URLs have an expiration time. You can create and manage presigned URLs through AWS CLI or AWS SDKs. You can set expiration times up to seven days from the time of URL signing.

> **Note:** Cohesity supports only the AWS4-HMAC-SHA256 algorithm.

Cohesity supports the following query parameters:

- X-Amz-Algorithm
- X-Amz-Credential
- X-Amz-Date
- X-Amz-Expires
- X-Amz-SignedHeaders
- X-Amz-Signature

For more information about managing presigned URLs through AWS CLI or AWS SDKs, see Sharing objects with presigned URLs.

For multi-part uploads with presigned URLs, complete the following steps:

1. **Initiate Multi-part Upload**: Authorize the initiation using HTTP Headers, and obtain a UploadId in the response.
2. **Generate Presigned URLs**: Create presigned URLs for each part using the obtained UploadId.
3. **Upload Parts**: Use the corresponding presigned URL for each part. These uploads are authorized using query string parameters. The response for each upload contains an ETag.
4. **Complete the Upload**: Authorize the completion using HTTP Headers. This step requires the ETags received in the PUT requests from the previous step.

Add Subnets to Allowlists

Before you can mount and access a view, ensure the IP address of the system that is mounting the view is specified in a subnet that has been added to an allowlist.

Cohesity supports the following types of allowlists:

- **Global Allowlist**—The global allowlist applies to all views on the Cohesity cluster, but is overridden by a view allowlist or view share allowlist, if they exist.
- **View Allowlist**—Only the systems with IP addresses in the subnets listed in the view's allowlist have privileges to access and mount this view.

Update the Global Allowlist

To add a subnet to the Cohesity cluster's global allowlist:

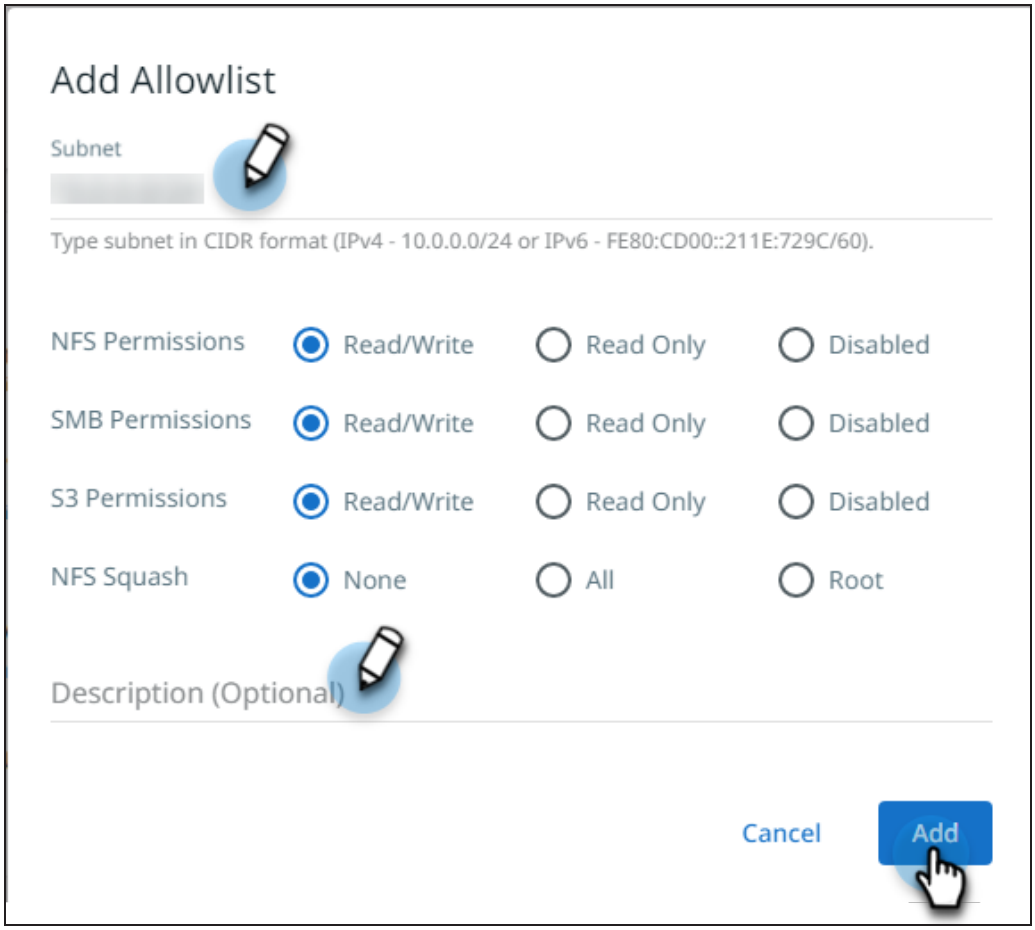
1. Navigate to **SmartFiles > Views**.
2. Click the **Global Settings** tab.
3. In the **Global Subnet Allowlist** section, click **Add**.
4. In the **Add Allowlist** dialog, enter a Subnet IP in CIDR format (IPv4 - 10.0.0.0/24 or IPv6 - FE80:CD00::211E:729C/60).

   > **Note:** CIDR prefix values are allowed from 0 to 32.

5. Select any or all permissions as required.

> **Important:** By default, the ability to set **S3 Permissions** for restricting access to specific subnets is disabled. To limit S3-based access to specific subnets, review the How To Enable SmartFiles S3 View Allowlisting KB article.

6. Select **NFS Root Squash** as applicable.
7. In the **Description** field, enter a description for the allowlist.
8. Click **Add**:



9. Repeat the preceding steps for specifying additional subnets in the global allowlist.

Update a View Allowlist

To add a subnet to an existing view's allowlist:

1. Navigate to **SmartFiles > Views**.
2. Locate the required View in the list, click the ⋮, and select **Edit** ( ).
3. In Advanced settings, click **Edit** for the Security category.

4. **Override Global IP Allowlist:** Turn on **Override Global IP Allowlist** if you want to specify a custom list for this view. Only the systems with IP addresses in the subnets listed in the view's allowlist have privileges to access and mount this view. If you enable the **Override Global IP Allowlist** toggle, the machines listed in the subnets of the global Cohesity cluster allowlist cannot access or mount this view unless the IP address of the machine is also listed in the View's Allowlist.

   Extend Global IP Allowlist: Allows you to extend the Global IP Allowlist.

   To add subnets to the allowlist of this view:

   a. Under **IP Allowlist**, select: **Override Global IP Allowlist** or **Extend Global IP Allowlist**.
   b. Click **Add**.
   c. In the **Add Allowlist** screen, type subnet in CIDR format.
   d. Select any or all permissions as required.
   e. Select **NFS Squash** options.

   The **NFS all squash** option is like NFS Root Squash. However, for given IP addresses, all users are mapped to the All Squash User/Group configured in the view. The default All Squash User for all views is "nobody".

   > **Note:** If the **Override Global Allowlist** toggle is off, this view can only be accessed and mounted by systems specified by the global Cohesity cluster allowlist.

5. Click **Update View**.

For more information on global settings for each protocol, see the following topics:

- Global Settings for NFS
- Global Settings for SMB

SmartFiles Dashboard

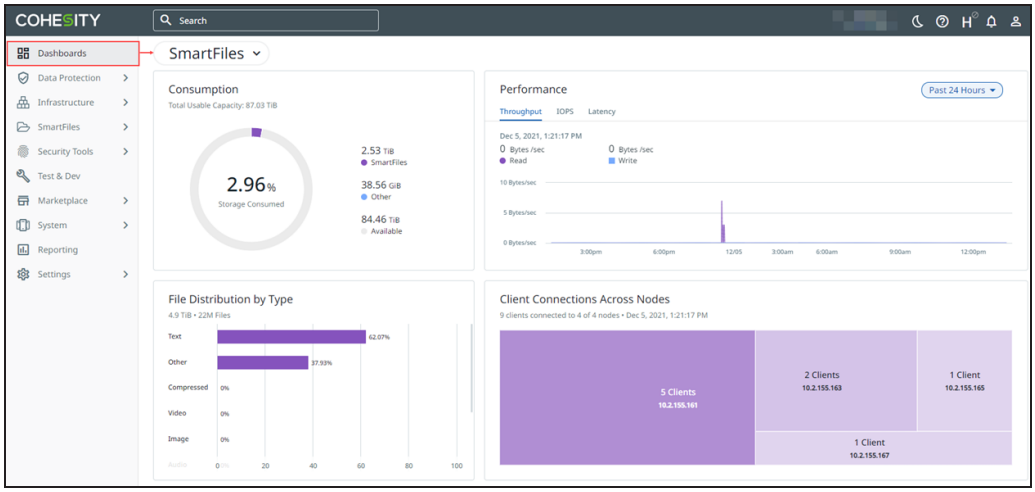
The SmartFiles dashboard provides several key metrics for better performance visibility. You can proactively monitor the performance and manage your SmartFiles deployments more effectively. The SmartFiles dashboard provides:

- Consumption metrics to track the total usable capacity and storage consumed
- Performance metrics such as throughput, IOPS, and latency
- File distribution by type
- Clients connected across nodes

To view the **SmartFiles** dashboard:

1. Log in to the Cohesity cluster.
2. Click **Dashboards** and select **SmartFiles** from the drop-down list

   The following illustration shows an example of the **SmartFiles** dashboard:

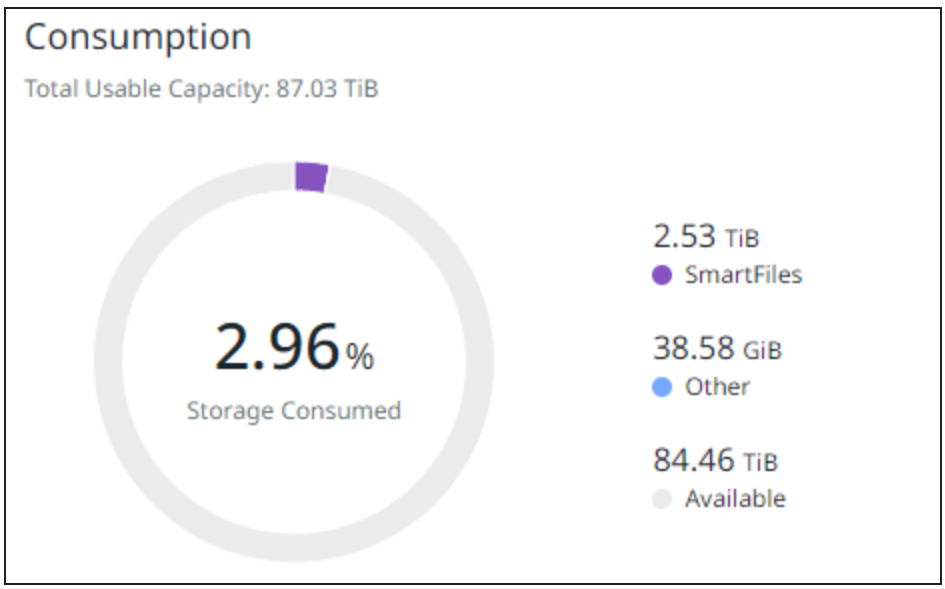


Consumption

The **Consumption** widget in the SmartFiles dashboard provides a summary of the total usable capacity and the following metrics:

- Storage consumed by SmartFiles
- Storage consumed by other services
- Storage available for consumption

The following illustration shows an example of the **Consumption** widget. Click the widget to drill down to the **Consumption** page:



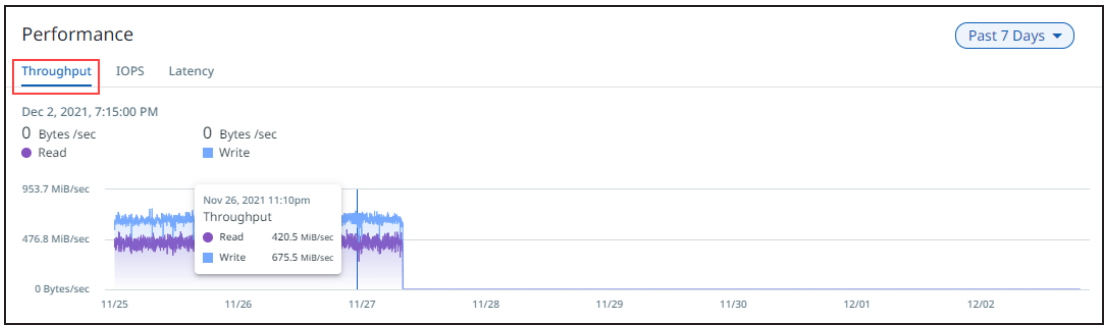
For more information, see Consumption Page.

Performance

The **Performance** widget in the SmartFiles dashboard displays performance metrics such as throughput, IOPS, and latency. You can view the performance data for the past 1 hour, past 12 hours, past 24 hours, past 7 days, or past 30 days. Click the widget to drill down to the **Performance** page.

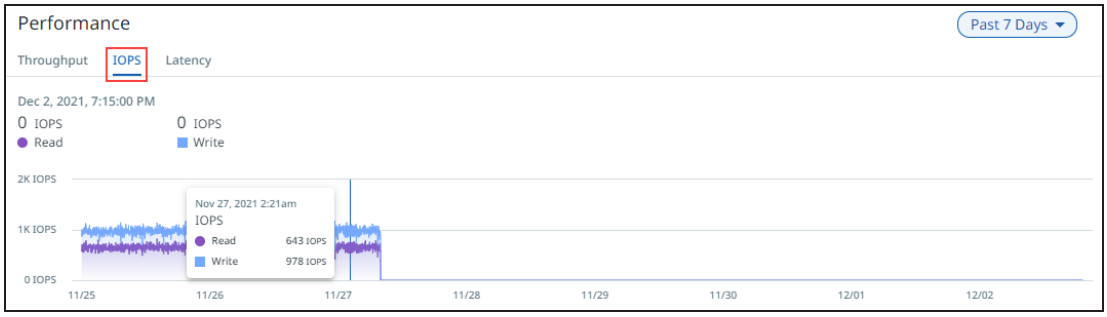
Throughput

The **Throughput** chart displays the amount of data transferred through external network interfaces in the cluster. Hover over the chart to view the throughput for read and write operations at a particular date and time. The following illustration shows an example of the **Throughput** chart:



IOPS

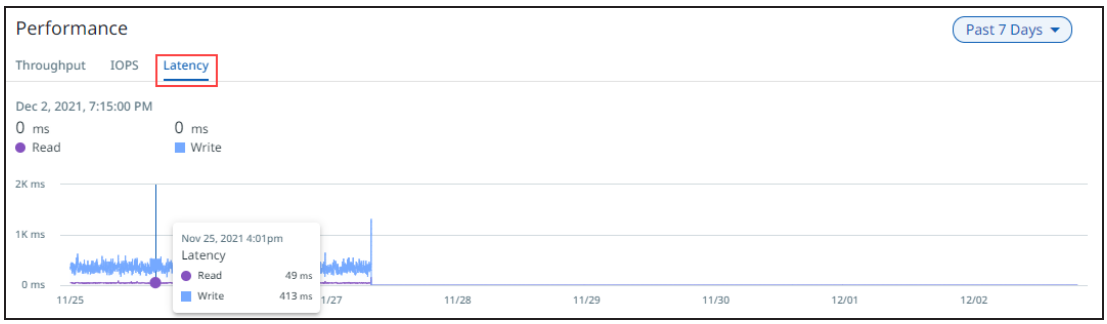
The **IOPS** chart displays the average number of read, write, or metadata operations from external clients serviced per second. Hover over the chart to view the IOPS for read and write operations at a particular date and time. The following illustration shows an example of the **IOPS** chart:



Latency

The **Latency** chart displays the average amount of time required for the cluster to process incoming and outgoing external client requests. Clients might observe additional latencies caused by the network. Hover over the chart to view the latency for read and write

operations at a particular date and time. The following illustration shows an example of the **Latency** chart:



For more information, see Performance Page.

File Distribution by Type

The **File Distribution by Type** widget in the SmartFiles dashboard displays the distribution of files by type on SmartFiles views. The widget displays the total storage consumed and the total number of files. On the chart, hover over the file type to view the storage consumed and the number of files for the corresponding file type.

To view the **File Distribution by Type** widget:

1. Log in to the Cohesity cluster.
2. Click **Dashboards** and select **SmartFiles** from the drop-down list.

   The **File Distribution by Type** widget appears in the SmartFiles dashboard:

   In the **File Distribution by Type** widget, file types are categorized into the following groups:

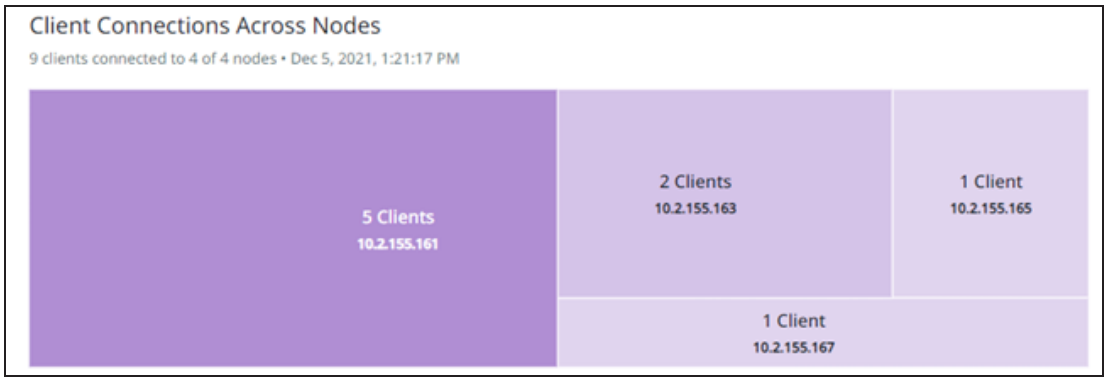
- **Text**—.doc, .docx, .pdf, .txt, .ods, .xls, .xlsx, .ppt, .pptx, and .key
- **Image**—.jpeg, .jpg, .png, .bmp, and .gif
- **Audio**—.mp3, .wav, .mp4, .aif, and .mid
- **Video**—.mpg, .mov, .wmv, .rm, and .3gp
- **Log**—.log, .info, .error, and .warning
- **Compressed**—.7z, .rar, .rpm, .gz, .z, .zip, .pkg, and .deb
- **Database**—.csv, .dat, .db, .dbf, .mdb, .sql, and .xml
- **Executable**—.apk, .bat, .bin, .exe, .jar, .py, .cgi, and .com

Client Connections Across Nodes

The **Client Connections Across Nodes** widget in the SmartFiles dashboard displays a summary of clients connected across nodes. Hover over a section in the widget to view the following details:

- Node IP address
- Total number of clients connected
- Total number of NFS clients
- Total number of SMB clients

The following illustration shows an example of clients connected across nodes:



Click any node IP address in the widget to drill down to the **Client Connections** page. The client(s) connected to the specific node are displayed on the table.

For more information, see Client Connections Page.

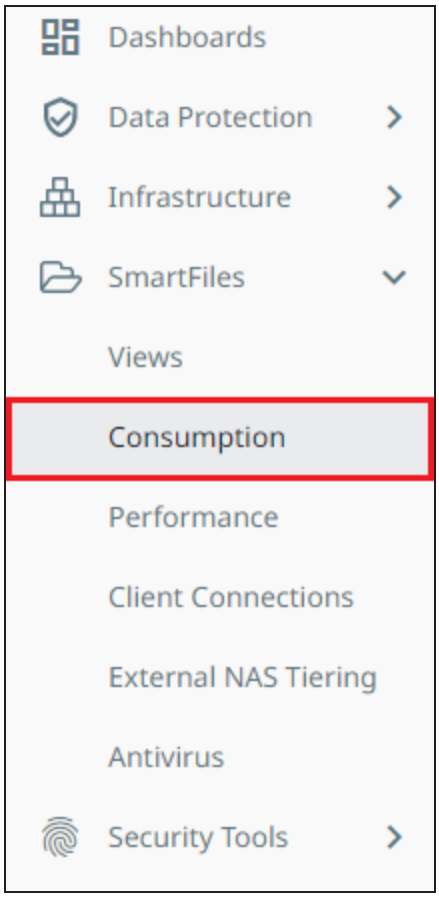
Consumption Page

The **Consumption** page includes the following sections:

- Glance bar
- Trend chart
- Total consumption per View

To view the **Consumption** page:

1. Log in to the Cohesity cluster.
2. Go to **SmartFiles > Consumption**:



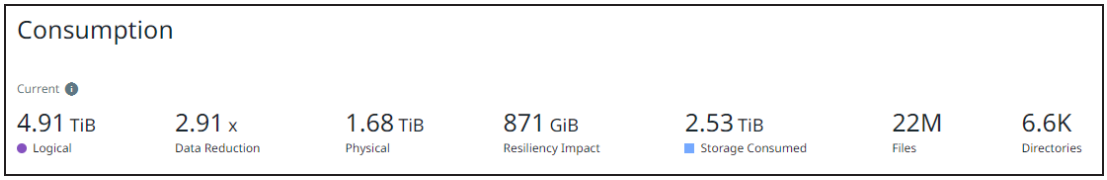
Glance Bar

The glance bar provides an overall summary of the consumption metrics. The following metrics are displayed:

- Logical—Logical size of your active file system. Logical usage is updated every four hours.
- Data Reduction—Size reduction ratio. This is the logical data divided by physical.
- Physical—Storage capacity consumed after data reduction operations such as deduplication and compression.

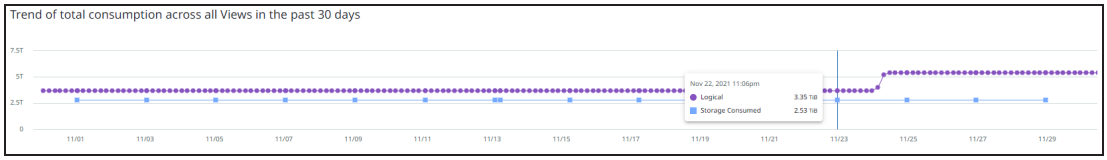
- Resiliency Impact—Storage consumed by resiliency operations such as erasure coding and redundancy factor.
- Storage Consumed—Final storage consumed after including resiliency impact. Storage consumed is updated every two days.
- Files—Number of files stored.
- Directories—Number of directories stored.

The following is an illustration of the glance bar:



Trend Chart

The trend chart displays the trend of total consumption across all views in the past 30 days. Hover over the chart to view the logical and storage consumed data at a particular date and time:



Total Consumption Per View

The Total consumption per View table lists all the views and displays the total consumption and the percentage of logical quota consumed for each view.

If there are a large number of views, you can enter the view name in the search bar to instantly filter the views. Click the view name to drill down to the view details page.

The following is an illustration of the table:

Consumption Growth Tab

The **SmartFiles > Consumption** page now includes a **Growth** tab which displays various metrics and trends to measure the growth in storage consumption for the:

- Past 24 hours
- Past 7 days
- Past 30 days

Glance Bar

The glance bar displays the following details:

- **Logical**—Growth in the logical size of your active file system.
- **Physical**—Growth in the physical storage.
- **Storage Consumed**—Growth in the final storage consumed after including resiliency impact.
- **Files**—Growth in the number of files stored.
- **Directories**—Growth in the number of directories stored.

Trend Chart

The trend chart displays the trend of consumption growth across all views for the time range you selected.

Click **Logical & Storage Consumed** to view the trend for logical and storage consumed. Hover over the chart to view the logical and storage consumed data at a particular date and time.

Click **Files & Directories** to view the growth trend for files and directories. Hover over the chart to view the files and directories stored at a particular date and time.

Growth Per View

The **Growth per View** table lists all the views and displays the consumption growth of each view. If there are a large number of views, you can enter the view name in the search bar to instantly filter the views. Click the view name to drill down to the view details page.

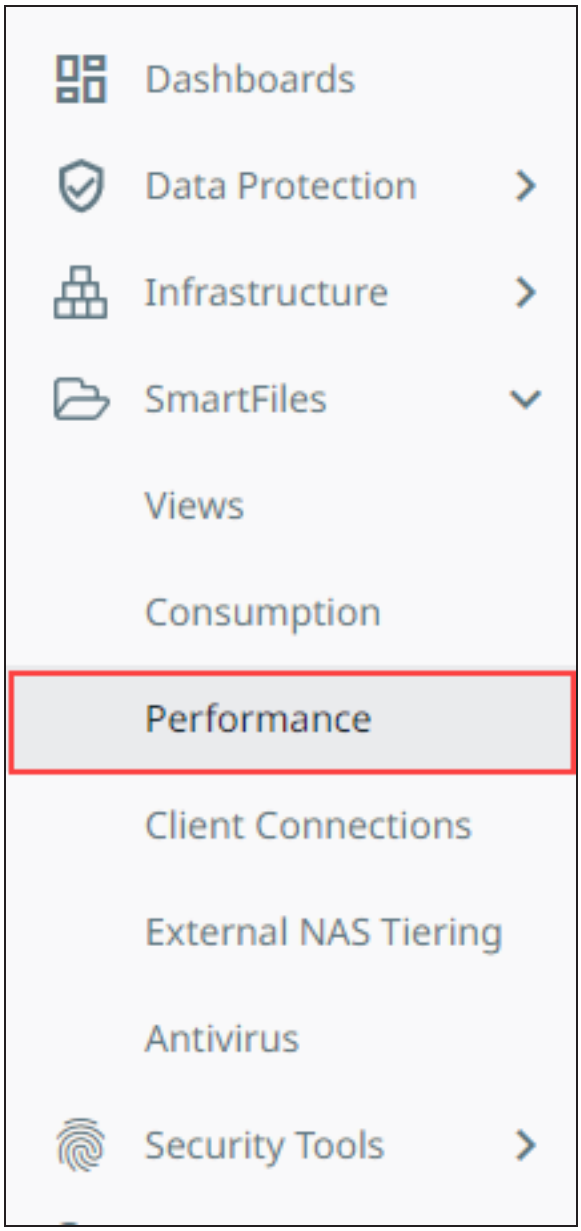
The growth is displayed in bytes and percentages. Click **Bytes** or **%** to update the table data. You can sort the columns in ascending or descending order. For example, if you sort the **Files** column, you can identify the view storing the most number of files and the growth.

Performance Page

The **Performance** page provides the overall trend for all views, top views, the overall trend for all clients, and top clients.

To view the **Performance** page:

1. Log in to the Cohesity cluster.
2. Go to **SmartFiles > Performance**:



View Performance by Views

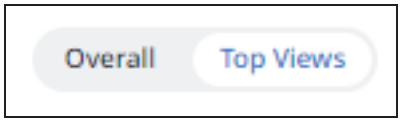
The **Performance** page includes multiple filters that allow you to pare down data. To view performance by views, click the **By** filter and select **View**:

- **Protocol**—Select the protocol: **NFS**, **SMB**, or **S3**.
- **Metrics**—After you select the protocol, you can select the metric(s). The options listed in the **Metrics** drop-down list are populated based on the protocol you select. The data for each metric is graphically represented so that you can better understand trends and patterns. For more information about metrics, see:

  - NFS Metrics
  - SMB Metrics
  - S3 Metrics
- **View**—Select a view to see the trends specific to the view.
- **Range**—Select a time range: Past 1 Hour, Past 12 Hours, Past 24 Hours, Past 7 Days, or Past 30 Days.

The following illustration shows an example of the overall trend of all views:

To view the top views, click **Top Views**:



The time range for **Top Views** can be Past 1 Hour, Past 12 Hours, or Past 24 Hours.

You can sort NFS and SMB views by Read (Peak) or Write (Peak) and you can sort the S3 views by Put (Peak) or Get (Peak).

View Performance by Clients

The **Performance** page includes multiple filters that allow you to pare down data. To view performance by clients, click the **By** filter and select **Client**:

- **Protocol**—Select the protocol: **NFS**, **SMB**, or **S3**.
- **Metrics**—After you select the protocol, you can select the metric(s). The options listed in the **Metrics** drop-down list are populated based on the protocol you select. The data for each metric is graphically represented so that you can better understand trends and patterns.

> **Note:** Client statistics for Throughput, Latency, IOPS, and Error metrics are aggregated for all protocols, irrespective of the selected protocol.

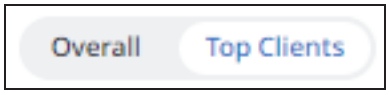
For more information about metrics, see:

- NFS Metrics
- SMB Metrics
- S3 Metrics

- **Client**—Select a client to view the trends specific to the client.
- **Range**—Select a time range: Past 1 Hour, Past 12 Hours, Past 24 Hours, Past 7 Days, or Past 30 Days.

The following illustration shows an example of the overall trend of all clients:

To view the top clients, click **Top Clients**:



The time range for **Top Clients** can be Past 1 Hour, Past 12 Hours, or Past 24 Hours.

View Performance by Nodes

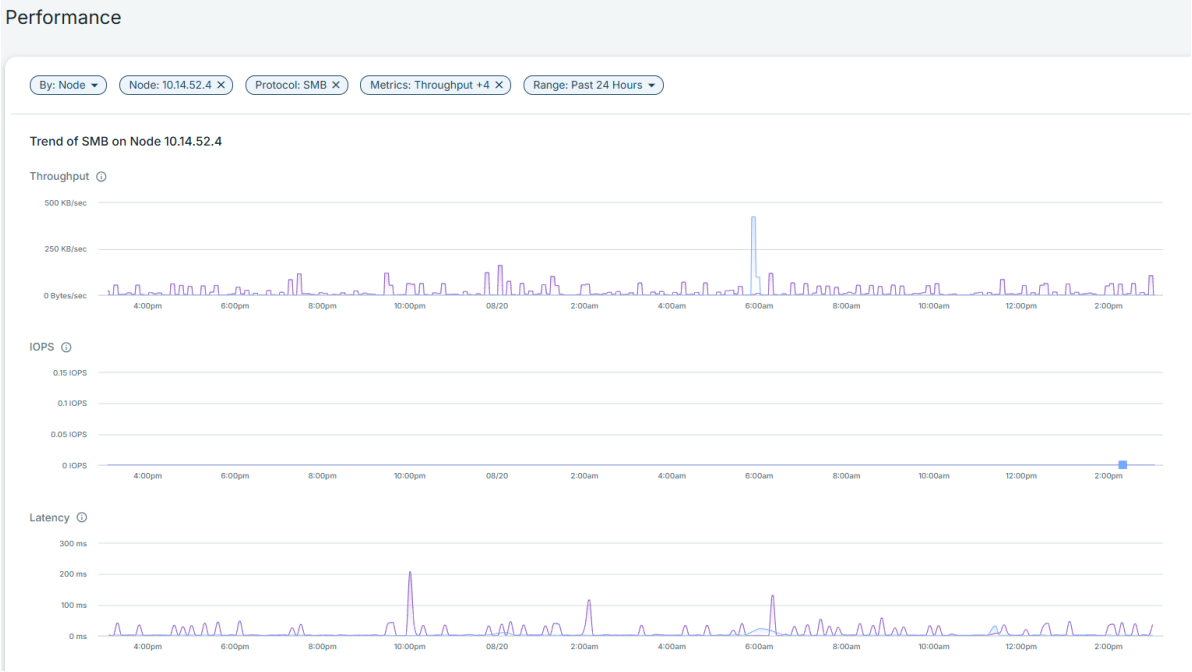
The **Performance** page includes multiple filters that allow you to analyze the performance of specific entities. To view performance by nodes, click the By filter and select **Node**:

- **Node** – Select a node to see the trends specific to the node.
- **Disk** – Select a disk to see the trends specific to the disk in the selected node.
- **Protocol** - Select the protocol: *NFS, SMB, or S3*.

> **Note:** You cannot filter by Disk and Protocol together.

- **Metrics** - Select the required metric(s). The options listed in the Metrics drop-down list are populated based on the protocol you select. If you do not select a protocol, only the metrics that apply to all protocols are displayed. The data for each metric is graphically represented so that you can better understand trends and patterns. For more information about metrics, see:
  - NFS Metrics
  - SMB Metrics
  - S3 Metrics
- **Range** - Select a time range: Past 1 Hour, Past 12 Hours, Past 24 Hours, Past 7 Days, or Past 30 Days.

The following illustration shows an example of the overall trend of all clients:



NFS Metrics

Metric	Description
IOPS	The average number of read, write, or metadata operations from external clients serviced per second.
Throughput	The amount of data transferred through external network interfaces in the Cohesity cluster.

Metric	Description
Latency	The average amount of time required for the Cohesity cluster to process incoming and outgoing external client requests. Clients might observe additional latencies caused by the network.
Error	The number of data read and write errors generated in serving external client requests.
Mount	IOPS and latency for NFS client requests to mount file systems over the network.
Unmount	IOPS and latency for NFS client requests to unmount file systems over the network.
Create File	IOPS and latency for NFS client requests to create a file.
Make Directory	IOPS and latency for NFS client requests to create a directory.
Remove File	IOPS and latency for NFS client requests to remove a file.
Remove Directory	IOPS and latency for NFS client requests to remove a directory.
Read Directory	IOPS and latency for NFS client requests to read the filenames in a directory.
Read Directory Plus	IOPS and latency for NFSv3 client requests to read the filenames and attributes in a directory.
Rename	IOPS and latency for NFS client requests to rename a directory.
Lookup	IOPS and latency for NFS client requests to search a directory for a file.
Symlink	IOPS and latency for NFS client requests to create a symbolic link in a remote file system.

SMB Metrics

Metric	Description
IOPS	The average number of read, write, or metadata operations from external clients serviced per second.
Throughput	The amount of data transferred through external network interfaces in the Cohesity cluster.
Latency	The average amount of time required for the Cohesity cluster to process incoming and outgoing external client requests. Clients might observe additional latencies caused by the network.

Metric	Description
Error	The number of data read and write errors generated in serving external client requests.
Session Setup	IOPS and latency for SMB client requests for a new authenticated session.
Logoff	IOPS and latency for SMB client requests to log off from the session.
Tree Connect	IOPS and latency for SMB client requests to request access to a share.
Tree Disconnect	IOPS and latency for SMB client requests to disconnect from a share.
Open	IOPS and latency for SMB client requests to open a file.
Close	IOPS and latency for SMB client requests to close a file.
Create File	IOPS and latency for SMB client requests to create a file.
Make Directory	IOPS and latency for SMB client requests to create a directory.
Delete File	IOPS and latency for SMB client requests to remove a file.
Remove Directory	IOPS and latency for SMB client requests to remove a directory.
Rename	IOPS and latency for SMB client requests to rename a directory.
Read Directory	IOPS and latency for SMB client requests to read a directory entry.
Get Information	IOPS and latency for SMB client requests to get information on a file.
Set Information	IOPS and latency for SMB client requests to set information on a file.

S3 Metrics

Metric	Description
IOPS	The average number of put, get, list, or delete operations from external clients serviced per second.
Throughput	The amount of data transferred through external network interfaces in the Cohesity cluster.

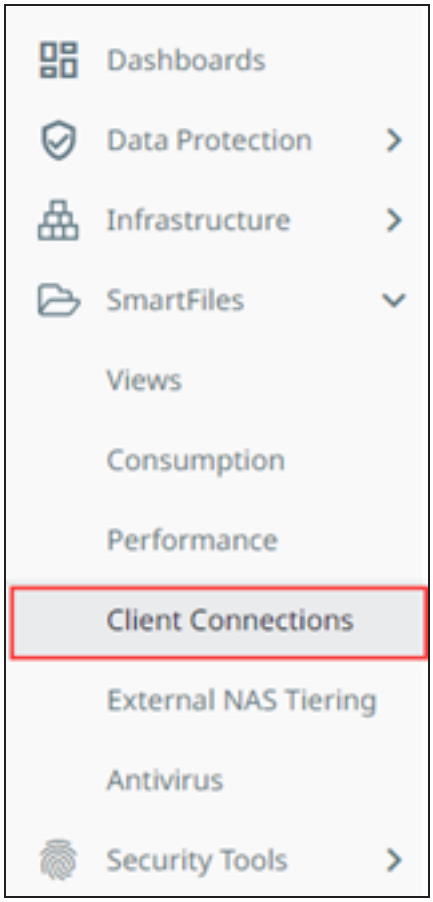
Metric	Description
Latency	The average amount of time required for the Cohesity cluster to process incoming and outgoing external client requests. Clients might observe additional latencies caused by the network.
Error	The number of put, get, list, or delete errors generated in serving external client requests.
Size	Sum of get and put data transferred through external client requests.

Client Connections Page

The **Client Connections** page provides details of all clients connected across nodes.

To view the **Client Connections** page:

1. Log in to the Cohesity cluster.
2. Go to **SmartFiles > Client Connections**:



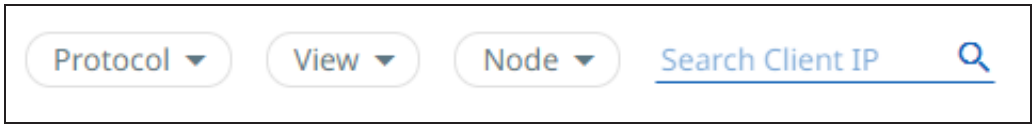
View Client Connection Client Details

The **Client Connections** page is displayed. The table supports the following filters:

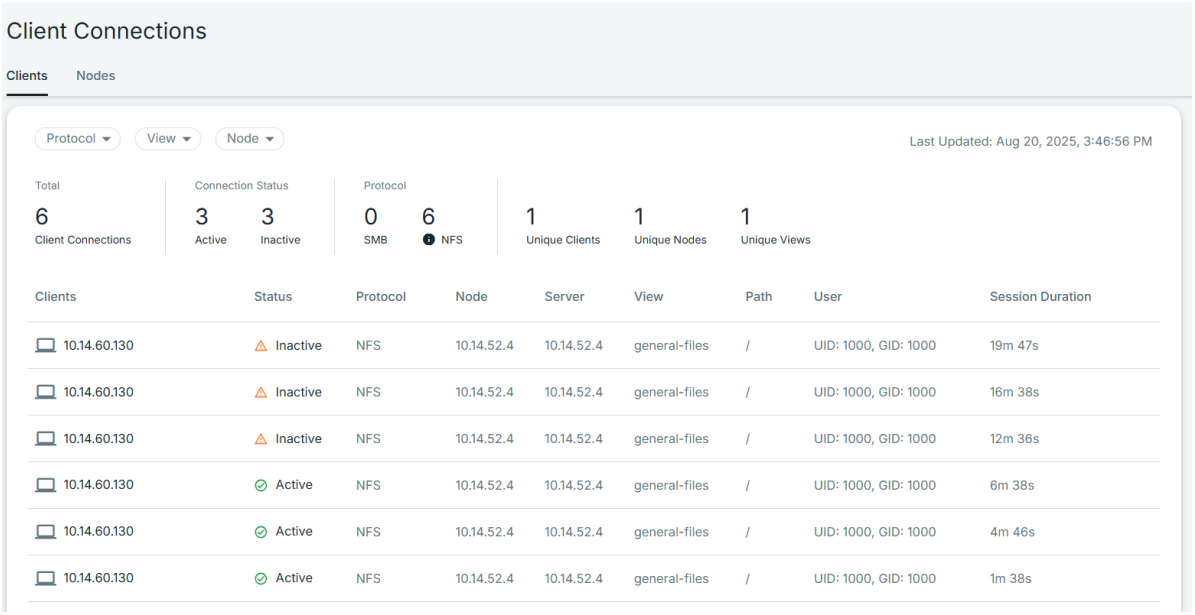
- **Protocol**—Select **NFSv3** or **SMB**.

  > **Note:** In the 6.7 release, data about NFSv4.1 clients are not displayed on this page.

- **View**—Select a view to see the client(s) connected to the view.
- **Node**—Select a node to see the client(s) connected to the node.
- **Search Client IP**—Hover over the search icon to view the **Search Client IP** search bar. Enter the IP address of the client to filter the clients based on the IP address:



The following illustration shows an example of the **Client Connections** table:



The table displays the following details:

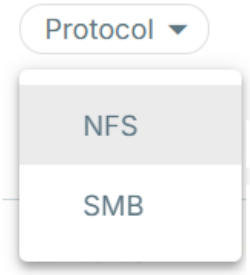
- **Clients**—IP address of the client.
- **Protocol**—Protocol of the client: NFS v3 or SMB 3.0.
- **Node**—IP address of the node.
- **VIP**—Virtual IP address of the node.
- **View**—Name of the view.
- **Path**—Mount path details.
- **User**—User or group details.

- **Session Duration**—Duration for which the client is connected. You can sort this column according to the client session duration. You can sort the column and identify:
  - Clients that have been connected for the longest period of time
  - Clients that have been connected for the shortest period of time

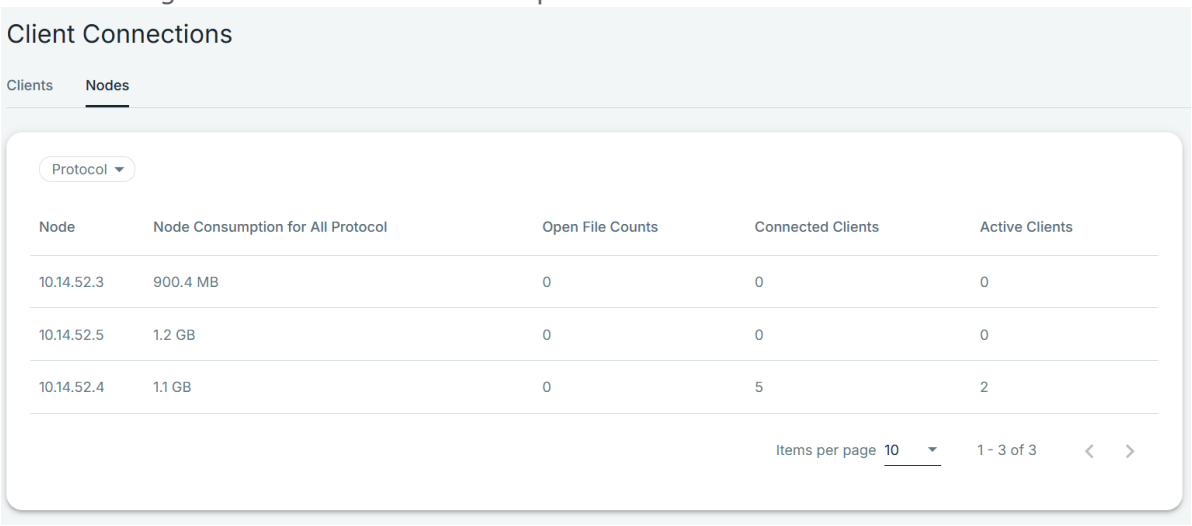
View Client Connection Node Details

The table supports the following filter:

- **Protocol**—Select **NFS** or **SMB**.



The following illustration shows an example of the Nodes table:



The table displays the following details:

- **Node** – IP address of the node.
- **Node Consumption for All Protocol** - Storage capacity consumed by the node for all the protocols.
- **Open File Counts** - Number of open files.
- **Connected Clients** - Number of connected clients.
- **Active Clients** - Number of active clients.

OpenStack Integration

Cohesity supports the OpenStack Swift Storage protocol. Cohesity Swift services function as a third-party Swift implementation for the OpenStack environments.

You can create a Cohesity view, assign it to the Swift Only protocol, and then authenticated Swift clients can use Swift APIs to access the view as they would use an OpenStack container.

The OpenStack Keystone identity service is used to authenticate and authorize the Swift clients.

> **Note:** Cohesity cluster communicates with the Keystone Server using the identity API v3. So, the Keystone server must support the identity API v3. For more information, see OpenStack API Documentation.

You must add a Keystone server and configure default Swift options to use the Swift protocol when the Organizations feature is disabled.

> **Note:** You can manually add the Cohesity Swift service endpoint in the Keystone server for clients using the OpenStack command line to discover the Cohesity Swift service.

OpenStack Project and Domain Concepts

Project

Projects are an equivalent concept of tenancy in the Openstack environment. From Swift perspective, Containers tagged with the project ID can be given ownership to Users / User groups using the concept of roles. When you create a Swift Only view, you create a Swift container and tag that view to a Project in your Openstack environment. The view that you created is associated with the Project that you defined when creating the Swift Only view.

Domain

A Domain is a namespace within the Openstack environment. All the entities such as Projects, Users, and Roles belong to a namespace by default. In the OpenStack environment, a domain isolates one business entity from other business entities.

Swift Authentication and Authorization

Swift protocol authentication and authorization go through a Keystone server. All users are created and managed independently in the external Keystone server. Each user has at least one proper role and project assigned under some domain to operate on the Cohesity

Swift service. A user who is a Swift operator can create Swift Only View using cURL. All authorized Swift users can provide access to other users using Access Control Lists (ACL) based on the container owned by the Swift user. ACLs allow access to Swift containers/objects.

For example, a Swift user who owns a container A, can provide access to container A using ACL.

> **Note:**
> - Cohesity supports only Container level ACLs. For more info, see OpenStack Access Control Lists (ACLs).
> - Cohesity Swift service grants access to the users based on the ACL setting on the container when the user does not have the required roles assigned. A Swift container owner can provide access to the container to other authorized Swift users using ACL.

Keystone uses token-based authentication. Before doing any operation on Swift, a user must request a token from the Keystone server by providing its user credentials. If verification of user credentials succeeds, the user is assigned a token. Then the user could use the token to send a request to Swift service.

The Swift service authenticates itself with a Keystone server and obtains a token. To authenticate the user's token, Swift service sends the user token to the Keystone server. After the Keystone server verifies the user's token, Swift service will be able to grant authorization based on the information returned by the Keystone server.

Multitenancy Support (Organizations)

Cohesity Swift implementation supports multitenancy by assigning a Keystone config to each tenant.

For a multi-tenant Cohesity cluster (with the Organizations feature enabled), consider the following:

- You must add a Keystone server and complete Swift config to use the Swift protocol in both organizations and single tenancy environments.
- Assign the Keystone server to the Cohesity cluster and Swift user.
- If the Organization feature is enabled on the Cohesity cluster, you can have multiple Keystone servers and can be assigned to multiple tenants.

> **Note:** You cannot disable the Organizations feature once it is enabled.

- If the Organizations feature is not enabled on the Cohesity cluster, you can have only one Keystone server.
- You can assign only one Keystone configuration per organization.
- You must choose an existing Keystone config and complete Swift config for the required tenant if you want to use Swift service in the tenant.

Supported Swift APIs

The following tables indicate which Swift APIs are supported and unsupported by the Cohesity Swift service. For more information about all Swift APIs, see Object Storage API.

You can use Swift APIs to create Swift Only view from the Cohesity Dashboard and also using cURL commands. The Swift Only view can be created for both cluster with multitenancy and without multitenancy.

To use Swift APIs, you must first fetch a token from a Keystone server and use it in the Object Storage API.

Operation on the Discoverability

Operation	Supported
GET	NO

Operations on the Accounts

Operation	Supported
GET ACCOUNT	YES
HEAD ACCOUNT	YES
POST ACCOUNT	YES

Operations on the Containers

Operation	Supported
GET CONTAINER	YES
PUT CONTAINER	YES

Operation	Supported
DELETE CONTAINER	YES
POST CONTAINER	YES
HEAD CONTAINER	YES

Operations on the Objects

Operation	Supported
GET OBJECT	YES
PUT OBJECT	YES
DELETE OBJECT	YES
HEAD OBJECT	YES
POST OBJECT	YES
COPY OBJECT	NO

Operations on the Endpoints

Operation	Supported
GET ENDPOINT	NO

Following are the common functionalities supported by the above APIs:

- Pseudo-hierarchical folders and directories
- Page through large lists of containers or objects
- Serialized response formats: JSON

> **Note:** Serialized response formats in .XML are not supported.

Add a Keystone Server

The Keystone Server in the OpenStack environment provides secure controlled access to all of the OpenStack services. To create a Swift Only view, you must add a Keystone config for authentication and access management.

Prerequisites:

- Keystone Authentication URL
- Keystone admin credentials

To add a Keystone Server:

1. In the Cohesity Dashboard, select **Settings > Access Management**.
2. Click the **Keystone** tab.
3. On the Keystone page, click **Add Keystone Server**.
4. In the **Edit Keystone Server** page, complete the following:
    1. Type Keystone configuration name.
    2. Type or copy-paste the Keystone Authentication URL.
    3. Provide Admin Credentials.
        1. Admin Domain
        2. User name
        3. Password
    4. Provide Admin Scope, type Project name and Domain name.

    > **Note:** Admin scope is a configuration that defines Cohesity to get the admin token

5. Click **Add Keystone Server**.

Manage Swift Roles for the Single Tenancy

You can manage Swift roles for a single-tenant(default tenant) by adding or updating the Swift roles.

Swift roles are already defined roles on the Keystone server. These roles are used by Swift clients to send requests to a Cohesity cluster. When you add a Swift role, the Cohesity Swift service verifies that the role exists on the Keystone server.

To add or modify Swift roles:

1. In the Cohesity Dashboard, select **Settings > Access Management**.
2. Click the **Keystone** tab.

3. In the **Default Swift Options** section of the Keystone page, click the edit icon.
4. In the **Edit Default Swift Options** screen, add or delete Swift roles.
5. Click **Save**.

Register Cohesity Swift Service on OpenStack

Prerequisites

- You must add a KeyStone server and assign the Keystone server to the organization.
- Swift configuration must be complete for the organization.

You can register Cohesity Swift Service on the Keystone server for better integration of the OpenStack system.

To register the Swift Service on the Keystone server:

1. Log in to the Cohesity cluster.
2. Run the following command:

```
iris_cli
```

3. Run the following command:

```
swift register tenant-id=<tenant_id>
```

> **Note:**
> If the Organizations feature is not enabled on the Cohesity cluster, to register the swift service, use the following command:
>
> ```
> swift register tenant-id=''
> ```

As part of the registration process the following steps are performed on the Keystone server:

- The Cohesity cluster sends a request to the Keystone server to create a Region for the tenant. The Region name is a combination of the cluster-id and tenant-id.
- Ensure a Service Id is available for the Swift service on the Keystone server. If a Service Id is not available, then the Cohesity cluster sends a request to the Keystone server to create a Service Id.
- The Cohesity cluster sends a request to the Keystone server to create Endpoints for the Service Id in the created Region.

Unregister Cohesity Swift Service on OpenStack

You can unregister Cohesity Swift Service on the Keystone server.

To unregister the Swift Service on the Keystone server:

1. Log in to the Cohesity cluster.
2. Run the following command:

```
iris_cli
```

3. Run the following command:

```
swift unregister tenant-id=<tenant_id>
```

> **Note:**
> If the Organizations feature is not enabled on the Cohesity cluster, to unregister the swift service, use the following command:
>
> ```
> swift unregister tenant-id='
> ```

As part of the unregistration process, the Cohesity cluster deletes the Endpoints, Service Id, and Region on the Keystone server.

Create a Swift-Only View

A Swift Only view provides storage space for authorized Keystone users. The Swift Only view is tagged to a Project within a Domain. Only authorized Keystone users can access Swift Only views.

> **Note:** You cannot convert a view created with other protocols to Swift Only view later. Nor can you convert a Swift Only view to another protocol.

After creating a Swift Only view (container), you can use a Swift API compatible client or cURL to send requests to a Cohesity cluster. You must use the 3001 port to perform any operations supported by the Swift APIs. For example, the Swift client can be OpenStack CLI, Swift CLI, or cURL. You must log in to the Keystone server to use the Swift CLI and OpenStack CLI.

> **Note:** You must have OpenStack Object Storage Framework installed to send requests to the Cohesity cluster when using OpenStack and Swift command lines.

Prerequisites:

- Keystone Config and Swift config are configured before creating a Swift Only view.
- Project and Domain already exist on the Keystone server.

- Details of a Keystone Project and Domain for which you want to provide the view ownership.

To create a Swift only view:

1. In the Cohesity Dashboard, select **SmartFiles > Views**.
2. To create a new view, click **Create > View** at the top right of the page.
3. In the **Create View** page, type a name for a new **View**.
4. Select a Storage Domain or use the default Storage Domain.
5. Select the **Swift only** option for **View Protocol**.

   > **Note:** You cannot convert a View created with the All option to Swift Only View later.

6. Provide **Project** name and **Domain** for the View ownership.

   > **Note:** When you provide the Swift Ownership, you are tagging the View to an existing Keystone Project.

7. (Optional) Provide a Keystone username for the Swift Ownership.

   > **Note:** This field will be used to set the initial container level ACL.

8. Select **Object Key Pattern:**This option cannot be changed after the view is created. For more information, see Object Keys.
9. **Case Sensitive:** Toggle on if you want the uppercase and lowercase versions of the same letter in a file or folder name to be treated differently on this view, for example: `A` is different from `a`.

   You cannot edit this setting after you create the view.

   Optional—Cohesity recommends entering a description for the view, for example, the reason why the view is being created.
10. Provide a description for the View.
11. Select QoS Policy for performance. **QoS Policy:** A QoS Policy determines to which storage media data is written and the priority of I/O when contention occurs. Select an appropriate QoS policy for the view. By specifying a priority and the type of workload you expect, the Cohesity cluster can optimize how it processes data in regard to latency, throughput, and priority.For details and recommendations, see QoS Policies for Cohesity Views.

12. **Security:**
    - **Override Global IP Allowlist:** Turn on **Override Global IP Allowlist** if you want to specify a custom list for this view. Only the systems with IP addresses in the subnets listed in the view's allowlist have privileges to access and mount this view. If you enable the **Override Global IP Allowlist** toggle, the machines listed in the subnets of the global Cohesity cluster allowlist cannot access or mount this view unless the IP address of the machine is also listed in the View's Allowlist.

      Extend Global IP Allowlist: Allows you to extend the Global IP Allowlist.

      To add subnets to the allowlist of this view:

      a. Under **IP Allowlist**, select: **Override Global IP Allowlist** or **Extend Global IP Allowlist**.
      b. Click **Add**.
      c. In the **Add Allowlist** screen, type subnet in CIDR format.
      d. Select any or all permissions as required.
      e. Select **NFS Squash** options.

      The **NFS all squash** option is like NFS Root Squash. However, for given IP addresses, all users are mapped to the All Squash User/Group configured in the view. The default All Squash User for all views is "nobody".

      > **Note:** If the **Override Global Allowlist** toggle is off, this view can only be accessed and mounted by systems specified by the global Cohesity cluster allowlist.

13. **Dedupe & Compression:** Toggle on to always use post-processing, irrespective of storage domain policy. This applies only when the storage domain has enabled deduplication or compression.
14. **Quota:** If applicable, the view inherits quota and alert settings from its storage domain by default. You can optionally **Override** these.

    Optionally toggle on **Logical Quota** and set the view's logical data capacity limit. (Logical data is fully hydrated and expanded.) Capacities must use whole numbers only.

    You can also choose to receive an alert when the view's capacity reaches a specified threshold.

    (After the view is created, you can define user quotas.)
15. **File DataLock:** Toggle on to make the files in this view immutable based on the settings described below. File level DataLock is typically used for compliance and

regulatory purposes.

> **Note:** The File DataLock option is only applicable for NFS and SMB View types.

- **File DataLock Mode:** Select one of the following modes:

  Compliance: Once File DataLock is enabled for the view, it cannot be disabled by anyone. However, a Cohesity user with Data Security privileges can edit the other DataLock settings. Compliance mode means the view complies with SEC Rule 17a-4.

  Enterprise: A Cohesity user with Admin privileges or Data Security privileges can rename the view, delete the view, switch to Compliance mode, and edit the File DataLock settings. This mode is useful for giving storage administrators additional control over the view.

  > **Note:** Enterprise mode is supported on 6.4.1 and later Cohesity clusters. If the view is replicated to a pre-6.4.1 Cohesity cluster, Enterprise mode is automatically changed to Compliance mode. If the view is then replicated back to a 6.4.1 or later Cohesity cluster, it retains the Compliance mode setting.

- **Default Retention:** Indicate the default time period that locked files remain locked if a user or application does not specify a retention default. When the time period ends, files can be deleted but not changed.
- **Autolock Files:** Indicate whether files are automatically locked after the specified period of I/O inactivity (based on the last modified time stamp).
- **Manually Lock Using:** By default, manual file locking occurs when a user or application sets the file's read-only attribute. Click the edit icon to set the following:

  Select **Read-Only** to lock files when the file permission is set to read only, for example, by setting the Windows file properties attribute or using the Linux `chmod` command.

  Select **FutureATime** to lock files when the last access time (atime) is set, for example, by using Windows PowerShell commands or the Linux `touch` command.

  Optionally set a **Minimum Retention** and/or a **Maximum Retention** period to ensure that a file's last access time cannot be set outside this period. A request to do so results in a permission denied error if manual locking mode is

FutureATime. Otherwise, the request will be silently rejected and the file will be locked for the minimum retention duration.

- **Override - Lock all files until:** Indicate whether the lock on files expires on a specific date. This setting is typically used for legal hold purposes. Files in a lock expired state cannot be deleted until this date.

  In **Compliance** mode, a user with Data Security privileges can extend the override date into the future, but no one can shorten the date.

  In **Enterprise** mode, a user with Admin or Data Security privileges can extend or shorten the override date.

16. **File System:** Toggle on **File Filtering** if you want to block or allow files with the specified file extensions from being written to this view. Select one of the following options:
    - Select **Denylist** if you want to specify a list of file extensions for files that are blocked from being written to this view. For example, if you specify a list with the `.exe` and `.dll` extensions, files with these extensions are blocked from writing to this view.
    - Select **Allowlist** if you want to specify a list of file extensions for files that are allowed to be written to this view. For example, if you specify a list with the `.cvs` and `.txt` extensions, only files with these extensions can be written to this view.
      - Enter file extensions separated with commas, spaces, tabs or newlines and click **Add**
17. Click **Create View**.

Assign a Keystone Config to an Organization

After you create an Organization on the Cohesity cluster, you must map a Keystone config to use the Cohesity Swift service in the Organization.

> **Note:** You can also assign a Keystone config when adding a new Organization.

To map a Keystone Server to an Organization:

1. In the Cohesity Dashboard, select **Settings > Access Management**.
2. In the **Organizations** page, select a required organization from the list.
3. In the selected organization page, click the edit pencil icon on the top-right corner of the screen.
4. In the **Edit Organization** page, click the **Assign AD/LDAP/Keystone** link.
5. In the **Assigning AD/LDAP** page, the **Keystone** tab displays the registered Keystone servers. Select one Keystone server and click **Assign**.

6. In the **Swift Roles** section of the **Edit Organization** page, click the pencil icon. In the **Edit Default Swift** options, add or modify the required Swift roles and click **Save**.

   > **Note:** You can only add the roles defined on the OpenStack server.

7. To further isolate network traffic for the organization, assign VLAN IDs. VLANs can be added and removed later. Using VLANs is optional but recommended.

   > **Note:** All the swift requests whose tenancy cannot be determined will fail.

   > **Note:** If the **Enable for all Organization** option is selected for a VLAN and the VLAN is assigned to an Organization, the Swift clients cannot access Cohesity Swift Service through this shared VLAN.

8. Click **Save**.

Accessing Swift Services

After you configure a Keystone config on the Cohesity cluster and complete the configuration steps, you can access the Cohesity Swift service by using Swift APIs.

You can use a Swift API compatible client to send requests to a Cohesity Swift service by using the 3001 port to perform any operations supported by Swift APIs. For example, the Swift client can use OpenStack, Swift CLI, or cURL. For more information on Swift APIs, see Object Storage API.

You can use the following endpoint format with the Swift APIs:

Endpoint format:

https://<host>:3001/v1/AUTH_<project_id>

The host can be any of the following:

- Cohesity cluster hostname
- Cohesity cluster node IP
- VLAN hostname
- VIP

> **Note:** To use Swift APIs, you must first fetch a token from a Keystone server and use it in the Object Storage API. For more information, see API Examples using Curl.

For information about creating a Container on a Cohesity cluster API, see Object Storage API.

Examples:

Request a token from a Keystone server (10.1.22.33)

```
keystone_server='10.1.22.33'

curl -w "\n" -i -H "Content-Type: application/json" -d '
{ "auth": { "identity": {
    "methods": [ "password" ],
    "password": { "user": {
      "name": "admin",
      "domain": { "id": "default" },
      "password": "bd4dd51646714fd3"
    }}},
    "scope": { "project": { "domain": { "id": "default" }, "name": "admin" } }
  }
}' "http://${keystone_server}:5000/v3/auth/tokens"
```

```
Response (body is omitted)
```

```

Server: CohesitySwift
Transfer-Encoding: chunked
Date: Thu, 02 Apr 2020 21:08:47 GMT
Connection: keep-alive
```

Edit a Swift only View

You can edit a Swift Only view and make changes to the view properties. You can update the following details in the View properties:

- View name
- Swift Ownership (Only project name and domain name can be updated.)
- Advanced options

To edit the Swift only view:

1. In the Cohesity Dashboard, select **SmartFiles > Views**
2. In the Views tab, click ⋮ and select **Edit**.
3. In the **Edit View** page, you can edit the following:
    - View Name
    - Swift Ownership
    - Description
    - Advanced Options
4. Click **Update View**.

Edit Keystone Config

You might need to edit the Keystone config details to update the authentication path, name of the Keystone config, admin credentials, or admin scope.

Points to consider when editing the Keystone config:

- When modifying the Cohesity Keystone config, the Cohesity Swift service verifies all the config contents specified in the Keystone and Swift by communicating with the Keystone Server. If the verification fails, the Swift configuration creation or modification fails.
- Similarly, when modifying a Keystone config shared by multiple organizations, all the roles of all the organizations sharing this Keystone config will be verified through this modified Keystone config. If verification fails, the Keystone config modification also fails.

To edit Keystone Server details:

1. In the Cohesity Dashboard **Settings > Access Management**.
2. Click the **Keystone** tab.
3. In the **Keystone** tab, click the Keystone config name link under the **Config Name**.
4. On the **Edit Keystone Server** page, you can edit and update the following:

- Keystone Configuration Name
- Authentication URL
- Details in the Admin Credentials

> **Note:** The Cohesity Dashboard does not display the current password. If you do not want to change the password, leave the field blank. If you want to change it, type a new password.

- Details in the **Admin Scope**.

5. Click **Save**.

Delete a Keystone Server

You can delete a Keystone config from the Cohesity cluster if you decide to stop using the Cohesity Swift service.

Once you delete the Keystone config, clients cannot access the Cohesity Swift service anymore, including the views and objects in the view.

To delete a Keystone server:

1. In the Cohesity Dashboard **Settings > Access Management**.
2. Click the **Keystone** tab.
3. Click the delete icon for the required **Keystone Server**.
4. In the **Delete Keystone Server** screen, provide the Keystone Admin Password.
5. Click **Delete**.

NAS Tiering

In primary storage devices such as NAS, there is unused or infrequently used data that remains relevant to the organization or must be retained for future reference or regulatory compliance reasons. As a result, the growing data takes more space in primary storage, which has a higher cost than secondary storage.

Cohesity supports the tiering of unused or infrequently used data from NAS primary storage to the Cohesity cluster. The process of moving unused data from the primary NAS storage to the Cohesity cluster is called downtiering. Based on a tiering policy the administrator sets while creating a data tiering task, the data from the NAS primary storage that is unused or infrequently used is periodically moved to the Cohesity cluster. When creating a data tiering task, the administrator determines how frequently the data tiering task runs and sets a tiering policy based on various parameters, such as:

- The last time the file was accessed
- The last time the file was modified
- The size of the file
- The file type to be allowed or denied for downtiering

> **Note:** Data tiering is supported only for NAS storage that is registered as mount points of type SMB or NFS.

> **Note:** Mac clients are not supported to access files via symbolic links.

> **Important:** Uptiering is not supported. By default, orphan data deletion is disabled.

When data is tiered from the primary storage, a symbolic link is created for the original file. The name of this symbolic link is the same as that of the original file, ensuring that users and applications continue to access the data as before. On a Windows server, local-to-local symbolic links and local-to-remote symbolic links are enabled. However, remote-to-local symbolic links and remote-to-remote symbolic links are disabled by default. Therefore you must run the following commands on the Windows server to enable the symbolic link access:

```
C:\Windows\system32>fsutil behavior set SymlinkEvaluation R2R:1
```

```
C:\Windows\system32>fsutil behavior query SymlinkEvaluation
```

If you are permanently moving the unused data to the Cohesity cluster, you can choose not to create this symbolic link after tiering while creating a tiering task.

For NFS shares, for the user or applications to access the data that was tiered to the Cohesity View, the View needs to be mounted on the NFS client. The mount path where the Cohesity View will be mounted on the host must be provided when you create the data tiering task. This mount path cannot be changed later. All the NFS clients should use this mount path to mount the Cohesity View. For more information on mounting a view using NFS, see Mount a View Using NFS.

Once the data is tiered to the Cohesity cluster, the subsequent read and write operations of the tiered data are performed on the Cohesity server hosting the data.

A user with an admin role also can restore the tiered data back to the primary storage by mounting the Cohesity target (server hosting the data) view on a Windows client and then copying the data.

Supported Sources for NAS Downtiering

The following is the support matrix for NAS downtiering:

Source	Protocol	Without Stubbing	With Stubbing
Unix/Linux	NFSv3	Yes	Yes
Windows	SMB	Yes	Yes
	NFSv3	Yes	Yes
Cohesity	SMB	Yes	Yes
	S3	No	No
	MultiProtocol	No	No
Isilon	NFSv3	Yes	Yes
	SMB	Yes	Yes
	S3	No	No
	MultiProtocol	No	No
NetApp	NFSv3	Yes	Yes
	SMB	Yes	No
	S3	No	No
	MultiProtocol	No	No

Note:

- Currently, you must add all sources as **Generic NAS** only.
- Uptiering is not supported.

Backups and Access to Older Versions of Tiered Files

NAS downtiering is not a replacement for backing up primary NAS storage.

Changes made to files in the target are not visible to the primary storage. Consequently, Cohesity recommends taking snapshots of the target storage and replicating them, similar to the backup process for any SmartFiles content on Cohesity. You cannot restore these files from snapshots on the primary storage but can recover them by mounting the target view.

Prevent Unintentional Access to the Target View

For symlinks to work, there needs to be a connection from the user's systems to the target. To facilitate backup and restore, the target view is available in SmartFiles. You must choose a view name that indicates its purpose is solely for file recovery. If users mount the target and delete files, the symlinks on the source will become inactive.

Considerations

- Cohesity does not support downtiering of junction points present on the NAS source.
- If the downtiering task was created in a version prior to 7.0 and if the Cohesity cluster is upgraded to 7.0, the downtiering task is based on the old policy. You cannot edit the downtiering task. If you want to edit the downtiering task, Cohesity recommends doing the following:
    - Delete the previously created downtiering task
    - Create a new downtiering task
- If the downtiering task was created in a version prior to 7.0 and if the Cohesity cluster is upgraded to 7.0, the downtiering task is based on the old policy. You cannot edit the grouping of this downtiering task. If you want to edit the grouping, Cohesity recommends doing the following:
    - Delete the previously created downtiering task
    - Create a new downtiering task and edit the grouping
- If SMB permissions are modified on the original source, these changes are not fetched and applied to the data tiered on Cohesity.
- Avoid utilizing NAS downtiering for home directories or datasets with active user modifications. If used for such cases, consider the following:
    - When using **Save As** within certain applications after accessing the symlink, the new file is automatically written to the target instead of the source by default. Consequently, when searching for such files later, you must check the target location.
    - Installer programs that delete themselves upon completion may erase the file in the target, rather than removing the symbolic link on the primary. This results in a non-functional link remaining on the primary system.

  - Users with an older version of Windows 10 that does not support long path names might encounter difficulties when mass copying files from the downtiered target for tasks such as manual uptiering or restoring older versions. To address this, a newer system that supports long path names may be necessary to easily copy the files back.
  - Deleting the symbolic link will not automatically free up space on Cohesity.

    Contact Cohesity Support to free up space.
  - Before 6.8.1_u7, commands existed to uptier and delete orphaned files — files whose symlinks were deleted or renamed by the user. If a user moves or renames one of the Cohesity-created symlinks, the `delete orphaned` command removes the file from Cohesity, and the `uptier` command restores the file under its old name, potentially overwriting a new file that reuses the original symlink name. To mitigate this risk, `uptier` and `delete orphaned` commands were removed in 6.8.1_u7 or later versions. If link alterations may have occurred, contact Cohesity Support to run diagnostics to identify and address such issues.
- Cohesity does not recommend downtiering of nested shares.
- Downtiering symlink source files without the stub option may result in dangling symlinks.
- NAS Tiering is not supported in multitenant environments, and organization administrators do not have the ability to configure NAS Tiering.
- You cannot modify the File Level DataLock on the tiering target view.
- The File Level DataLock configuration will be removed from the destination cluster's view when replicating a tiering target view.
- The **Tiering Audit** option is enabled by default starting from version 7.2.2, and audit logs for tiering jobs will be recorded. For clusters running version 7.2.1 or earlier, you must manually enable tiering audit logs.
- You cannot configure Lifecycle Management on a tiering target view.
- If the source is Dell EMC Isilon, orphan data deletion (ODD) is not supported.
- If a directory is deleted on the source and ODD is enabled, the corresponding directory on the target is deleted once it is empty. This process may take multiple runs to complete.
- Deletes and renames require multiple runs to complete.

NAS Tiering Dashboard

The **NAS Tiering** page consists of the following two sections:

- Capacity Trend
- Tiering by Source

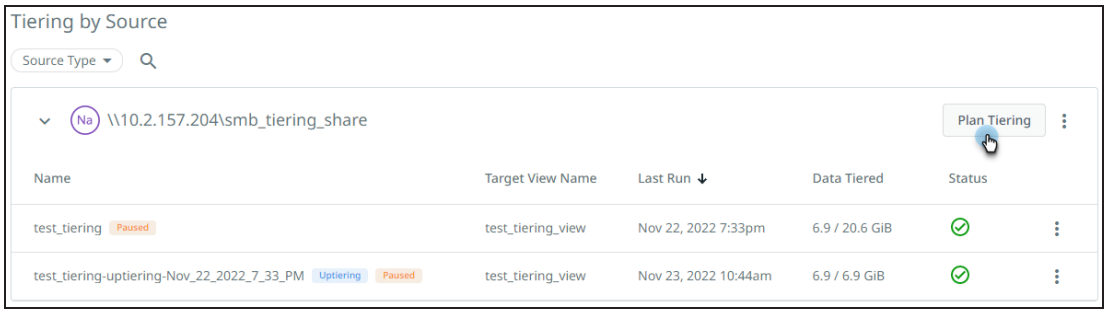
Capacity Trend

The **Capacity Trend** section provides a graphical representation of the data on the source and the data down-tiered to the Cohesity cluster. The **Capacity Trend** histogram enables you to generate periodic analysis and predict the capacity needs. You can:

- Select a range—Past 12 Hours, Past 7 Days, Past 30 Days, or Past 90 Days.
- Filter the data by source if multiple sources are registered.
- Click on the legends to add or remove data displayed on the histogram. For example, if you click Hot, data pertaining to hot is removed from the histogram and if you click Hot again, the data is added back to the histogram.
- Hover over the bar graph to the Data on Source and Data on Cohesity for a particular day.
- Analyze the cost savings for the selected time range.

Tiering by Source Pane

The **Tiering by Source** pane lists the NAS sources that are registered with the Cohesity cluster for tiering. You can analyze the data available on the registered source by clicking **Analyze**. After analysis, click **Plan Tiering** to set a tiering policy, and based on this policy you can create a tiering task:

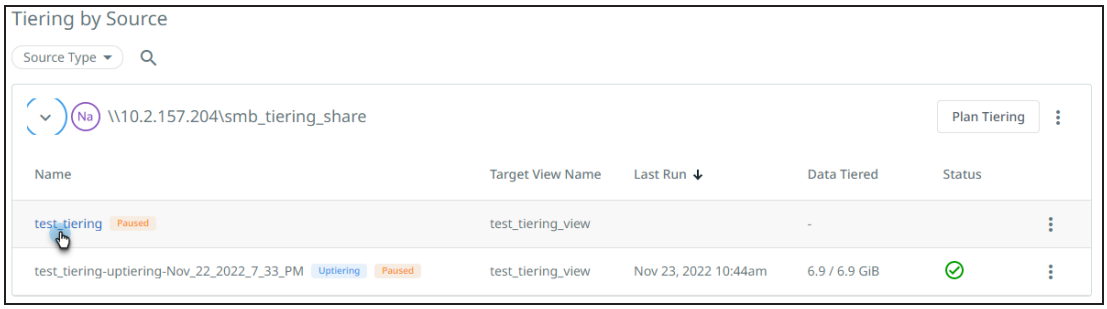


Once you execute the tiering of a registered source, you can click the arrow icon next to the registered source to view the following details:

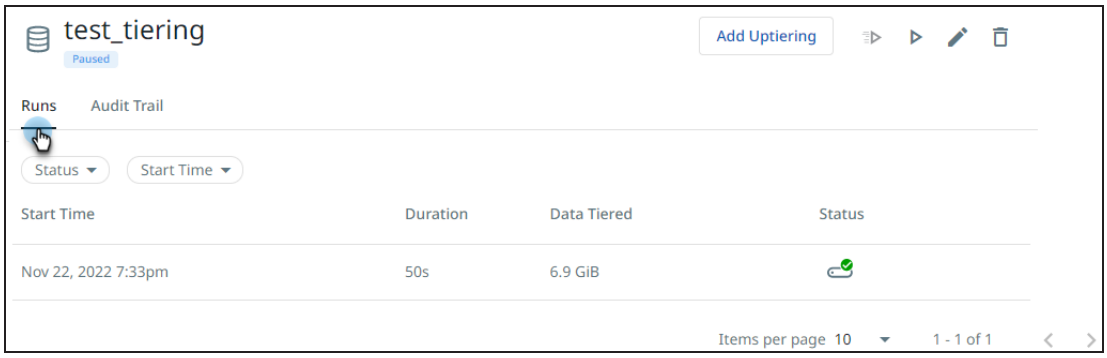
- **Name**—The name of the tiering task. Click on the link to drill down and view more information about the tiering task such as runs, run details, and audit trail.
- **Target View Name**—The name of the View to which the data is tiered.
- **Last Run**—The last time the tiering task was run.
- **Data Tiered**—The total number of bytes tiered during the tiering task.
- **Status**—The status of the tiering task.
- Actions menu—To manage an existing tiering task, click the Actions menu (⋮) corresponding to the task and select one of the following options:
  - **Run Now**—Instantly initiates the tiering task.
  - **Pause Future Runs** or **Resume Future Runs**—Pause or resume the future tiering task runs.
  - **Edit**—Configure the settings of a tiering task. For more information, see Downtier Data.
  - **Delete**—Deletes the tiering task. The data that was tiered before deleting the tiering task will be stored in the Target View hosted on the Cohesity cluster. You can continue to access this data through symlinks created during the down-tiering task.

View Data Tiering Task Details

You can view the details of each tiering task by clicking the view name:

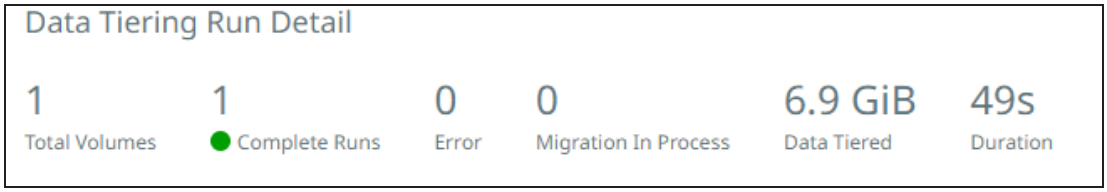


From the tiering details page, you can do the following to manage the data tiering run from the **Runs** tab:



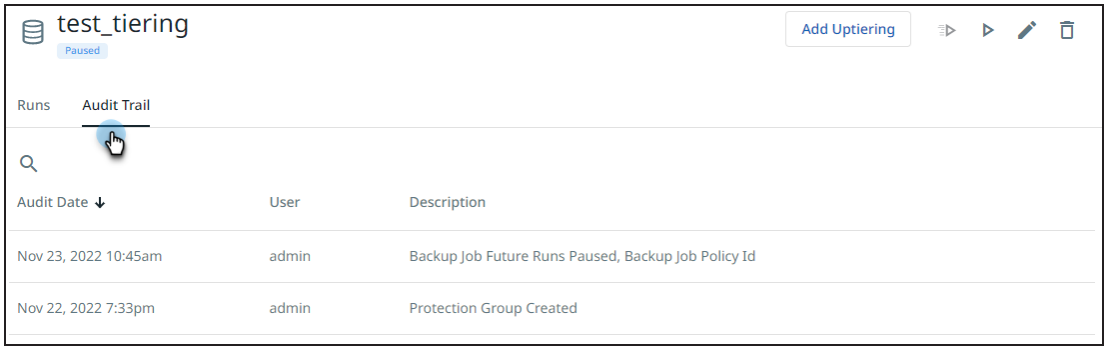
- **Run Now**—Instantly initiates the tiering task.
- **Pause Future Runs** or **Resume Future Runs**—Pause or resume the future runs of the tiering task.
- **Edit**—Edit the configuration settings of a tiering task. Follow the instructions provided in the Plan Tiering section.
- **Delete**—Deletes the tiering task. The data that was tiered before deleting the tiering task is stored in the Target View hosted on the Cohesity cluster. You can continue to access this data through symlinks created during the down-tiering task.

Click the data tiering run to navigate to the **Run Details** page. This page includes a summary bar, a filter option, and a table. The following is an illustration of the summary bar:



- **Mount Path**—The path used for mounting the NAS.
- **Target View Name**—The name of the View to which the data is tiered.
- **Start Time**—The date and time when the tiering run started.
- **Duration**—The time (in seconds) taken for the tiering run to complete.
- **Data Tiered**—The total number of bytes tiered during the tiering run.
- **Status**—The status of the tiering run.
- **Delete Run Snapshot**—After the tiering run is complete, you can delete the snapshot for a specific run of a tiering task without deleting the entire task.

Click the **Audit Trail** tab to view a sequential record of the events:



- **Audit Date**—Date and time of the event.
- **User**—Username of the person who initiated the event.
- **Description**—Description of the event.

Downtier Data

Downtiering involves the following steps:

1. Register the NAS Source
2. Analyze the Source
3. Plan Tiering
4. Configure a Down-Tiering Task

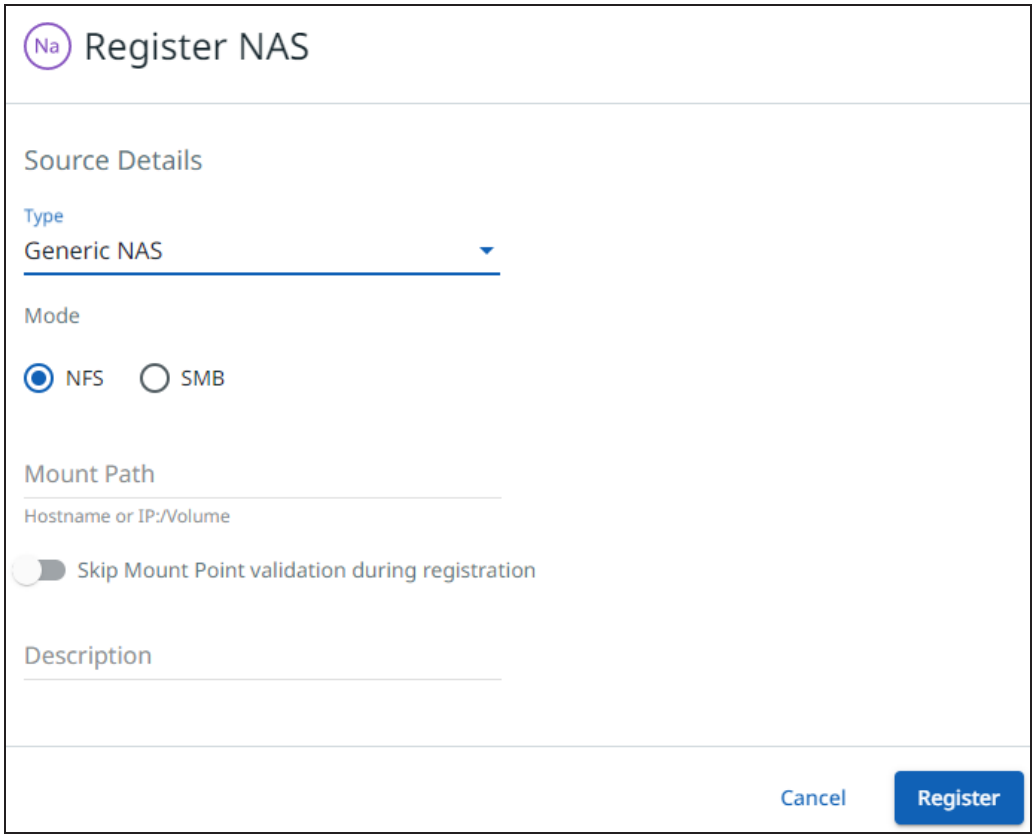
Register the NAS Source

To down-tier data from the NAS primary storage to the Cohesity cluster, you must first register the NAS as a source with the Cohesity cluster.

To register NAS:

1. Navigate to **SmartFiles > NAS Tiering**.
2. Click **Add** in the upper-right corner of the page and select **Register New Source**.

   The **Register NAS** dialog is displayed and **Generic NAS** is automatically selected in the **Type** field:



3. Select the Mode—**NFS** or **SMB**.
4. If you select **SMB**, provide the following details:

- **Username**—SMB mount credentials that allow reading, writing, and backing up of files.
- **Password**—SMB mount credentials that allow reading and backing up of files.

> **Note:** For downtiering, the user must have read, write, and backup permissions. For up-tiering, the user must have Full Control permissions.

5. **Mount Path**—The path for mounting the NAS. Use the following format:
   - **NFS**—Hostname or IP:/Volume
   - **SMB**—\\Hostname or IP\Share path

   > **Note:** Do not edit an existing mount path. If you need to change the mount path, register the mount path as a new source.

6. Optionally, you can skip mount point validation during registration.
7. **Description**—Optionally, you can enter a description for identifying the mount path.
8. Click **Register**.

   Once the registration is complete, the NAS source appears on the NAS Tiering page. You can now analyze the data on the source.

Analyze the Source

Once you register the source, you can analyze the data on the source. After the analysis is done, by default, the data on the source is classified on the basis of the following categories or parameters:

- **File Size**—Files are organized into groups based on the size of the file.
- **File Type**—Files are organized into groups based on the file type such as text, audio, and database.
- **Date of Last Access**—Files are organized into groups based on the last date on which the data was accessed.

When you plan to tier, the Cohesity cluster displays the histogram based on the groups of these categories. You can choose to view the histogram either based on the file type or file size, and the data is displayed against the date of the last access grouping (x-axis). To customize the buckets of these categories, see Edit Grouping.

To analyze the source, on the **NAS Tiering** page, click **Analyze** for the source you registered.

The analysis process will be initiated. The duration of the analysis may vary based on the number of files and directories in the source, and it may take some time to complete.

Refresh Analysis

To refresh the analysis done on the data of the source:

1. On the **NAS Tiering** page, go to the **Tiering by Source** pane.
2. Click the Actions menu (⋮) corresponding to the source you analyzed:

3. Click **Refresh Analysis**.

   The data on the source is analyzed again.

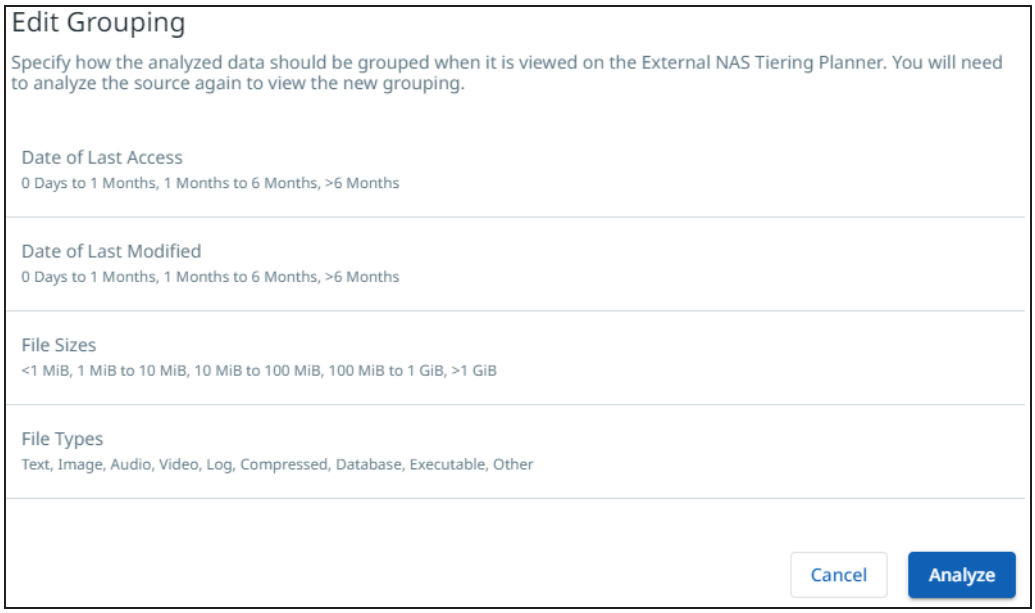
Edit Grouping

Once the initial analysis is complete, you can optionally customize the grouping within each category. By default, the data is grouped into **Hot**, **Warm**, or **Cold**. Once you customize the existing groups, a new analysis task is triggered. This analysis is performed on the basis of the new grouping. When you plan to tier, the Cohesity cluster will display the histogram based on the updated grouping.

To edit the grouping:

1. On the **NAS Tiering** page, go to the **Tiering by Source** pane.
2. Click the Actions menu (⋮) corresponding to the source you analyzed:
3. Click **Edit Grouping**.

   The **Edit Grouping** dialog is displayed:

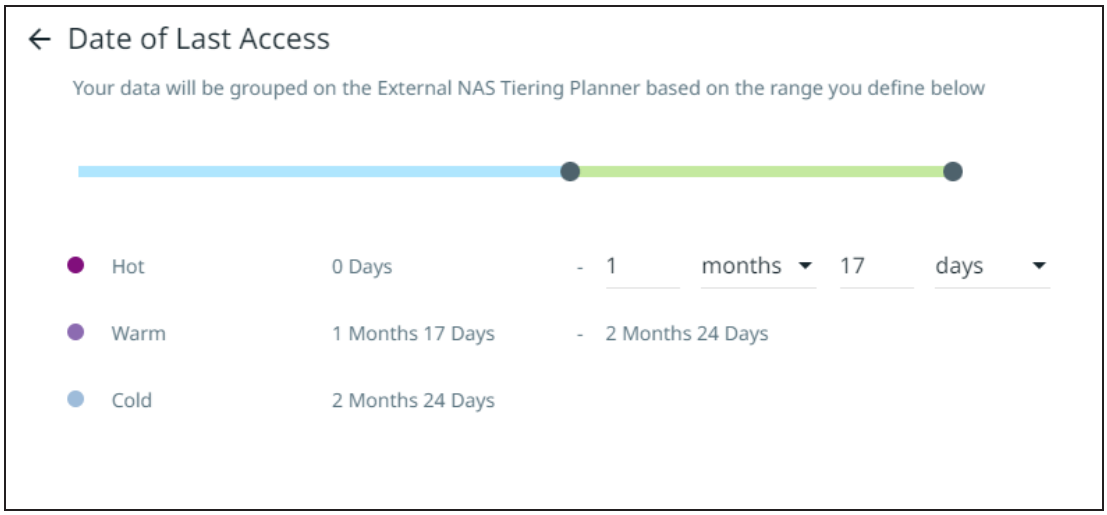


4. Hover over the group that you want to update, click the edit icon, and update grouping:
    - Date of Last Access
    - Date of Last Modified
    - File Sizes
    - File Types
5. Click **Analyze**.

Date of Last Access

The data accessed within the defined range are grouped and displayed on the **Select Data To Tier** page. To update a group, you can do one of the following:

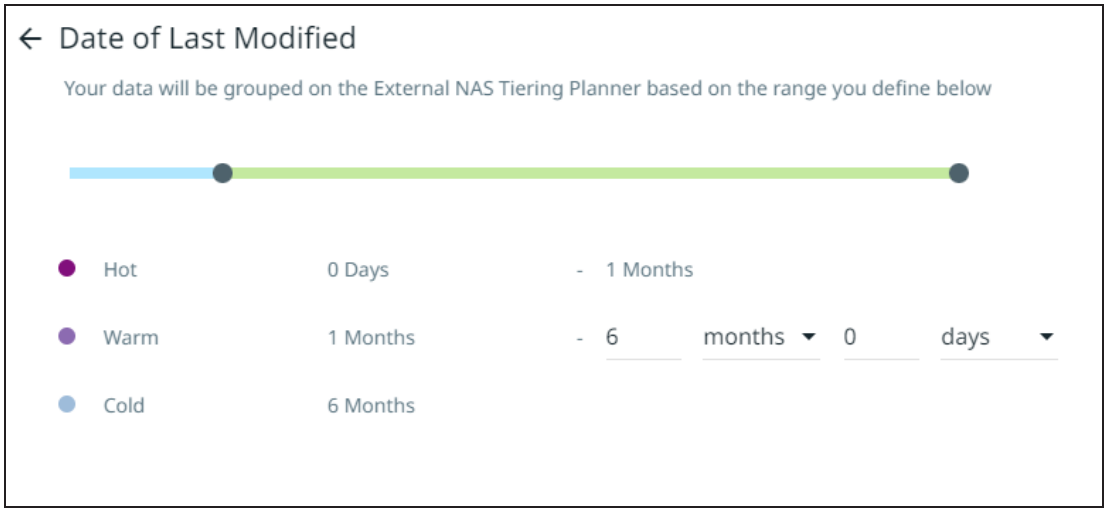
- Click on the defined range and update the value
- Move the slider and update the value



Date of Last Modified

The data modified within the defined range are grouped and displayed on the **Select Data To Tier** page. To update a group, you can do one of the following:

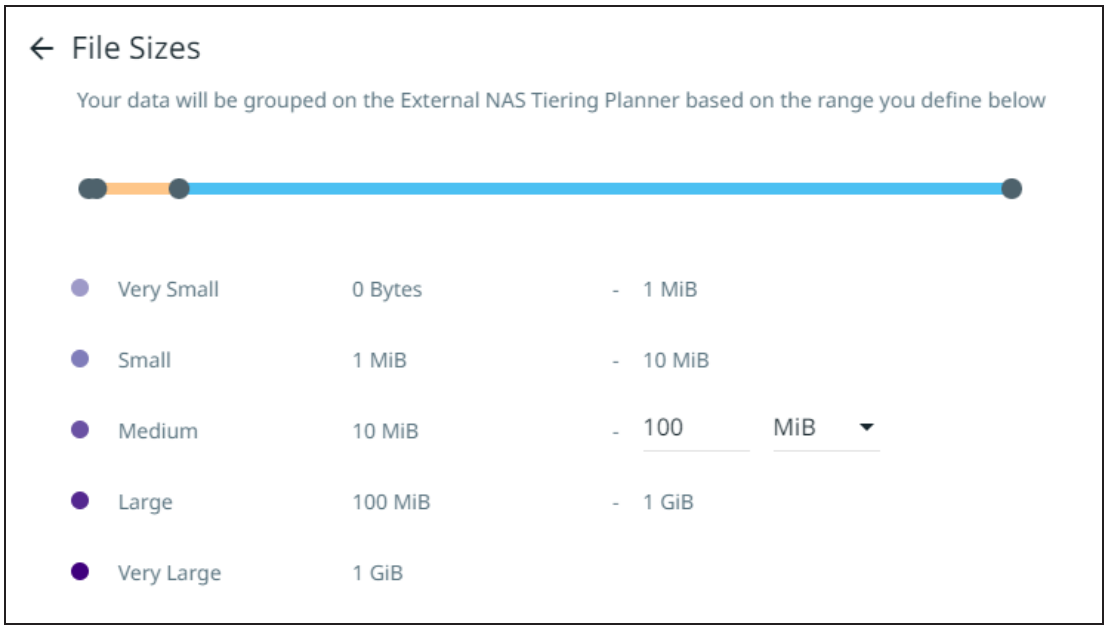
- Click on the defined range and update the value
- Move the slider and update the value



File Sizes

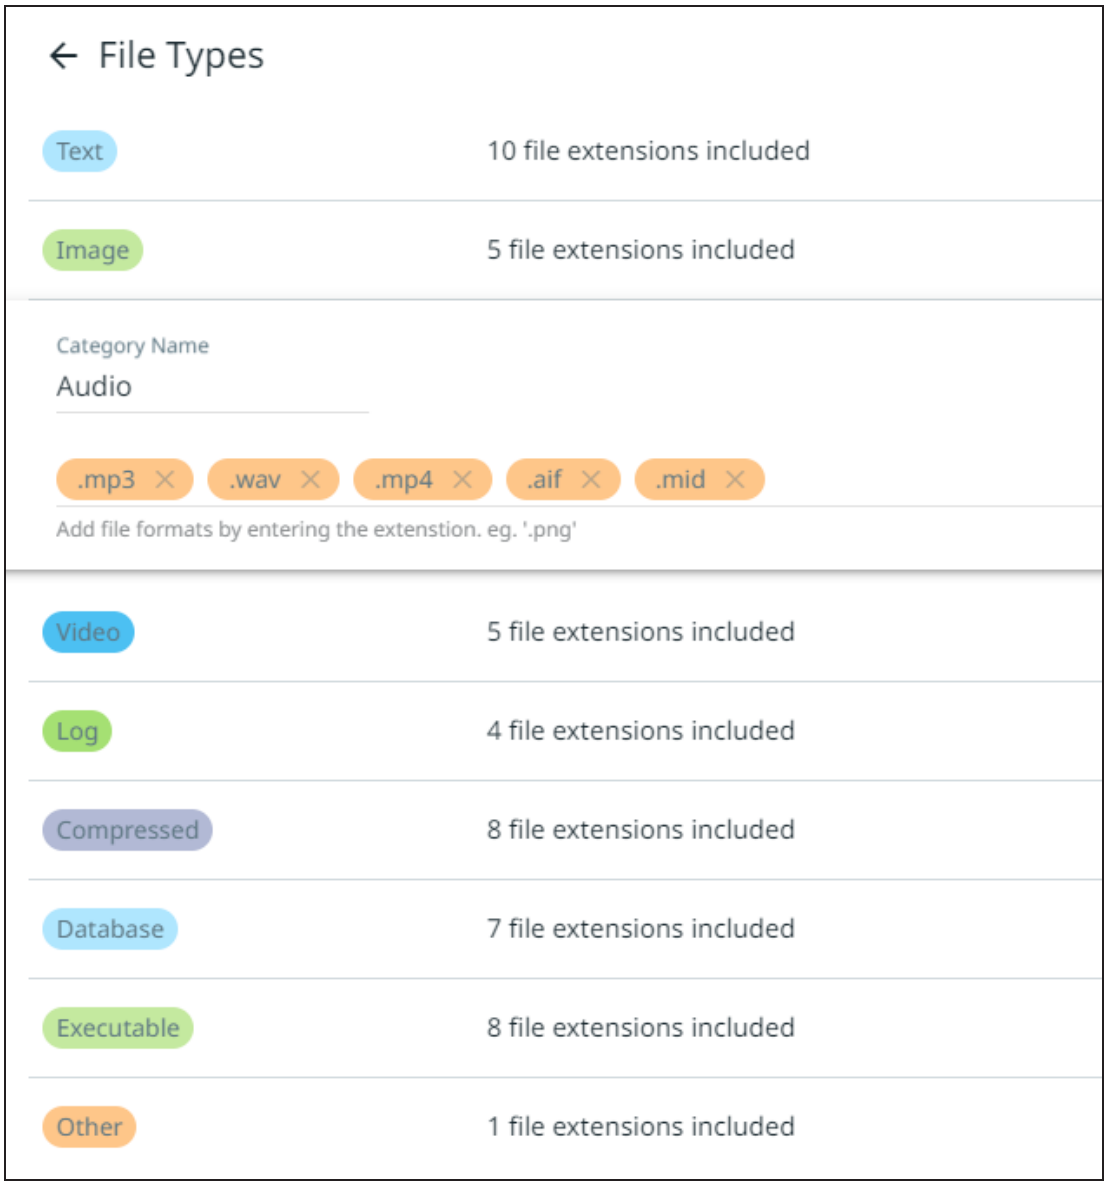
The files within this defined file size range are grouped and displayed on the **Select Data To Tier** page. To update a group, you can do one of the following:

- Click on the defined range and update the value
- Move the slider and update the value



File Types

The files based on the category are grouped and displayed on the **Select Data To Tier** page. Click on a category to enter the extension of the file format you want to group under this category. You cannot enter an extension that is already a part of another file category.



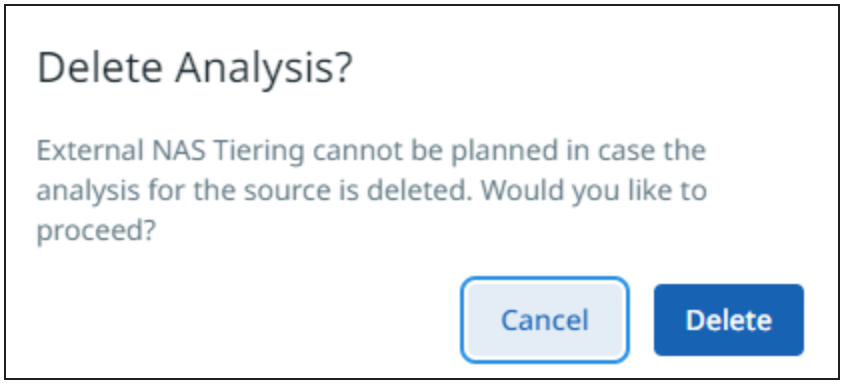
Delete Analysis

To delete the data analysis done on the source:

1. On the **NAS Tiering** page, go to the **Tiering by Source** pane.
2. Click the Actions menu (⋮) corresponding to the source you analyzed:
3. Click **Delete Analysis**.

   The **Delete Analysis** dialog is displayed.

4. Click **Delete** to confirm your action:

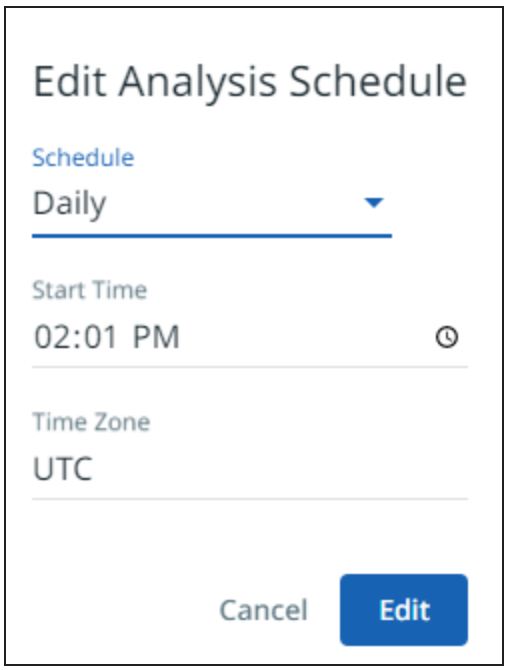


Edit Analysis Schedule

You can edit the schedule on an analysis run.

To edit the analysis schedule:

1. On the **NAS Tiering** page, go to the **Tiering by Source** pane.
2. Click the Actions menu (⋮) corresponding to the source you analyzed:
3. Click **Edit Analysis Schedule**.
4. The **Edit Analysis Schedule** dialog is displayed:

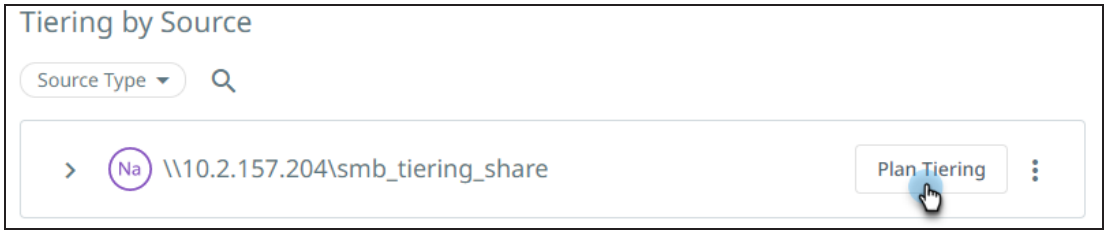


5. Modify the schedule as necessary and click **Edit** to save the changes.

Plan Tiering

Once the analysis is complete, based on the data analysis done, you can plan the tiering for your data on the NAS source. To plan data tiering to the Cohesity cluster, click the **Plan**

Tiering option that appears once you complete the analysis:



Plan tiering involves the following steps:

- Select Data To Tier
- Configure a Down-Tiering Task

Select Data To Tier

After you click **Plan Tiering**, the **Select Data To Tier** page is displayed. This page displays the name of the registered source and includes the following sections:

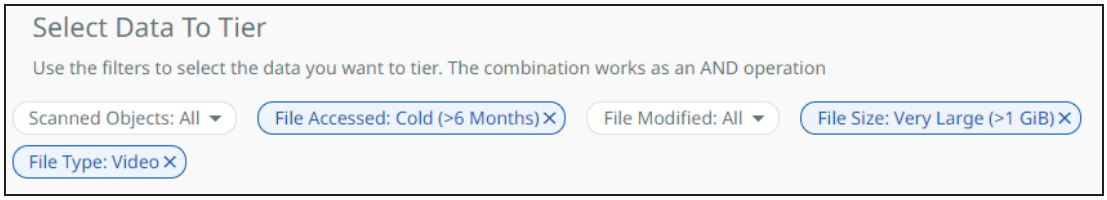
- Select Data To Tier
- Selection Summary
- Data Distribution Chart
- Data per Share

Select Data To Tier

In the **Select Data To Tier** section, you can select the files to tier. By default, the filters are set as follows:

- Scanned Objects—**All**
- File Accessed—**Warm** and **Cold**
- File Modified—**All**
- File Size—**All**
- File Type—**All**

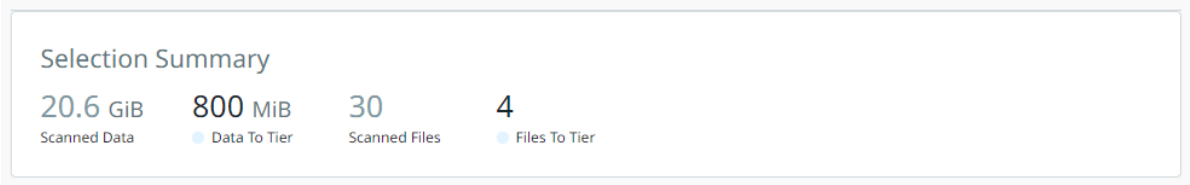
You can modify the filters and select the data you want to tier. For example, if you select **File Accessed** as greater than six months, **File Size** as greater than 1 GiB, and **File Type** as Video, video files greater than 1 GiB that were accessed more than six months ago will be down-tiered:



> **Important:** The combination works as an AND operation.

Selection Summary

The **Selection Summary** section displays the summary:

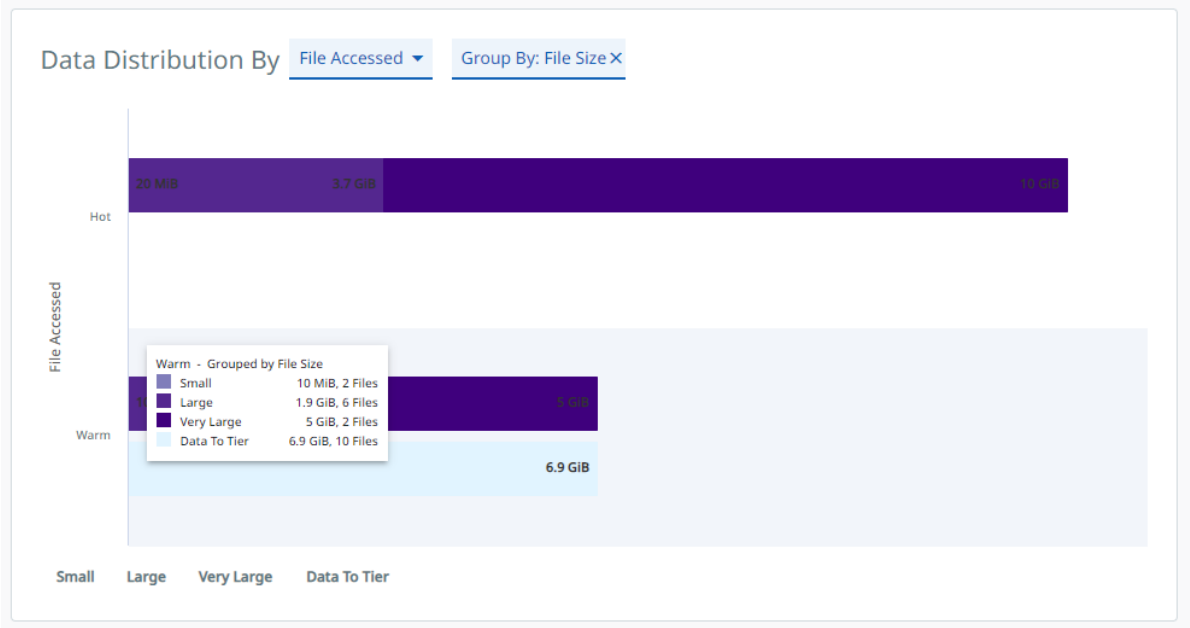


- Total size of scanned data
- Size of data that will be tiered
- Number of scanned files
- Number of files that will be tiered

Data Distribution Chart

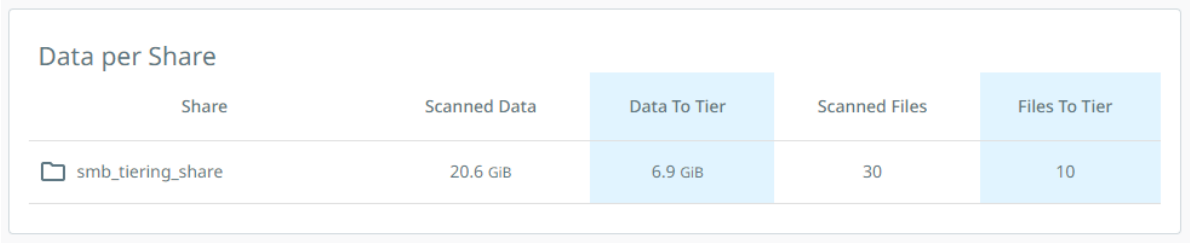
The **Data Distribution** chart provides a graphical representation of the data (histogram) available on the source by distribution and group.

The following is an illustration of the data distribution by file accessed and grouped by file size. Hover over the chart to view granular details:



Data per Share

The **Data per Share** section displays the following data per share:



- Name of the share
- Scanned data
- Data to tier
- Scanned files
- Number of files to tier

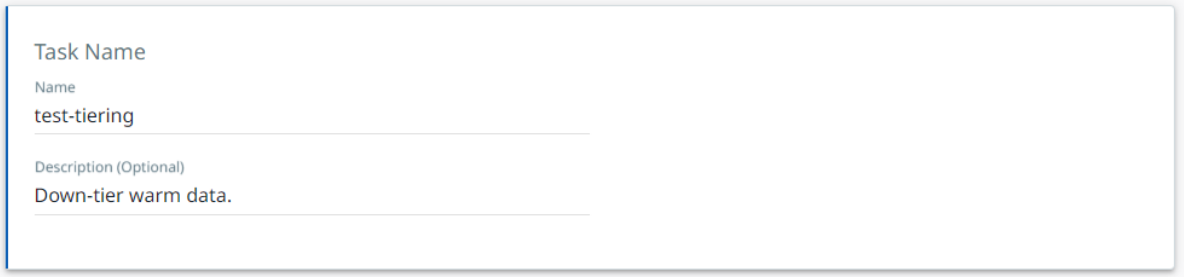
> **Note:** Cohesity currently supports only one share per source. If you want to include another share, you must register the share as a new source.

Click **Continue** to navigate to the **Configure Tiering Task** page.

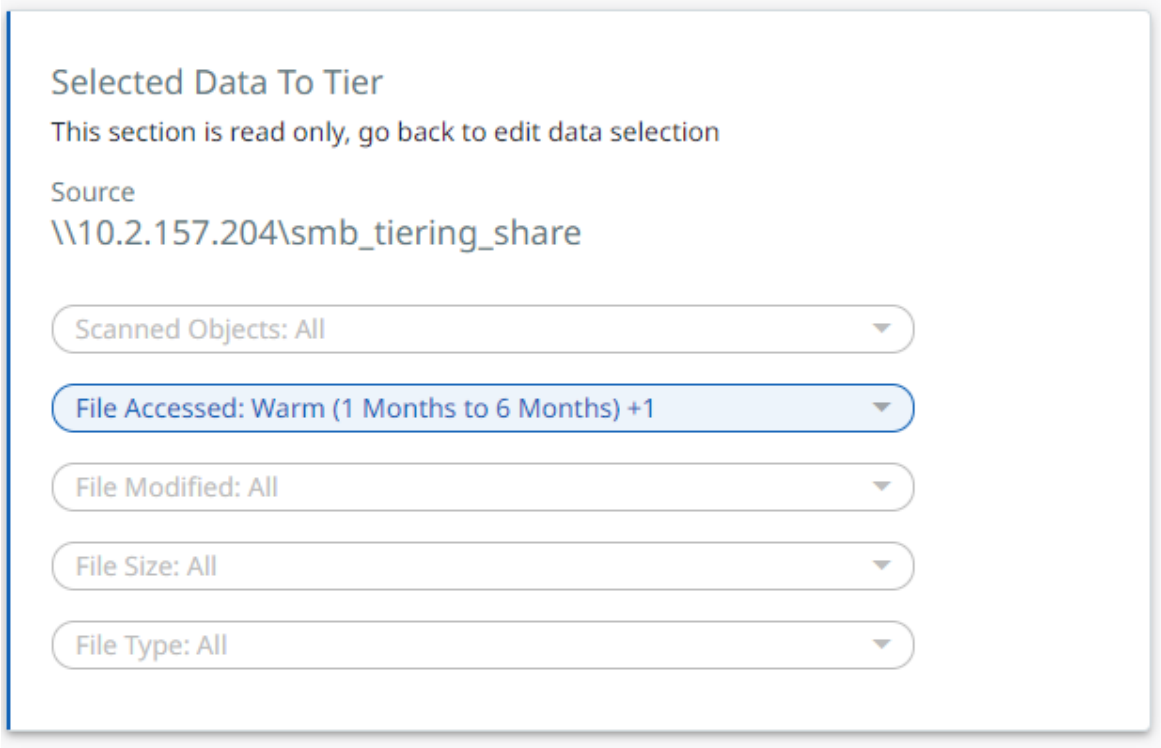
Configure a Down-Tiering Task

To configure a downtiering task, complete the steps described in the Select Data To Tier section and proceed:

1. In the **Task Name** section:
   - Enter a name for the tiering task
   - Optionally, enter a description.



2. View the selected data to tier. The **Selected Data To Tier** section is read-only and displays the data that you selected in the **Select Data to Tier** section:



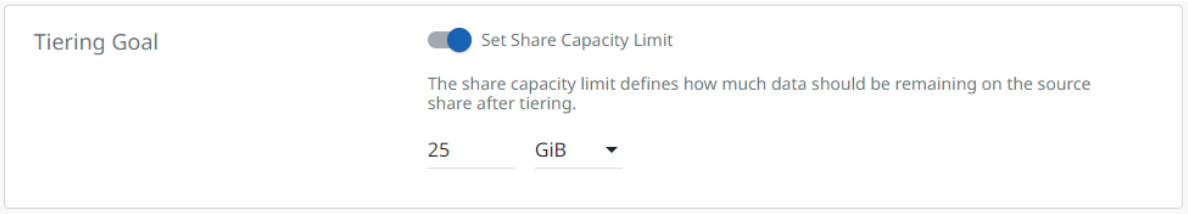
3. Select a storage domain where you would want the target View to be created.
4. Enter a name for the target View that will be created.
5. **Task Schedule**—Schedule the tiering task, by default it is set to **Daily**.
6. **Retain Snapshots**—Specify the number of days the snapshots are retained on the Cohesity cluster. At the end of each task run, a snapshot of the View is captured. This snapshot is retained for the number of days specified.
7. Select one of the following **Symbolic Links** options:
   - **Tier with symbolic links**—Select this option if you want to create symbolic links when data is tiered. When data is tiered from the primary storage, symbolic links are substituted in place of the original file. The name of this symbolic link is the same as that of the original file, ensuring that users and applications continue to access the data as before. Optionally, you can also delete data on the Cohesity target when the symbolic link is deleted.

     > **Note:** If you use the **Tier with symbolic links** option, you cannot use Mac clients to access data tiered with symbolic links.

   - **Tier without symbolic links**—Select this option if you do not want to create symbolic links when data is tiered. You can select this option if no user or

application will access the data on the source and you are permanently moving the unused data to the Cohesity cluster.

8. Click **More Options** to view additional settings.
9. **Audit Logging**—Enable this option if you want to log the information of the data down-tiered. You can also check the logs related to the symlinks created by the downtiering task and the files that are renamed or deleted. The audit log file is saved in the **tiering_audit** directory of the **COHESITY_AUDIT_VIEW** View. You can access this file by mounting the View as NFS share: *<cluster_ip>*:/COHESITY_AUDIT_VIEW.
10. **Tiering Goal**—Turn on the **Set Share Capacity Limit** toggle to set the amount of data you want to retain at the source. Depending on the value you set, Cohesity provides a recommendation for tiering data based on the last accessed date:



11. **QoS Policy**—Select an appropriate Quality of Service (QoS) Policy:
    - **Backup HDD**—The Cohesity cluster writes the data directly to an HDD drive for this tiering task.
    - **Backup SSD**—The Cohesity cluster writes the data directly to an SSD drive for this tiering task. Specify this policy only if you need fast ingest speed for a small number of tiering tasks.

    > **Note:** Cohesity recommends specifying a **Backup HDD**, which is the default.

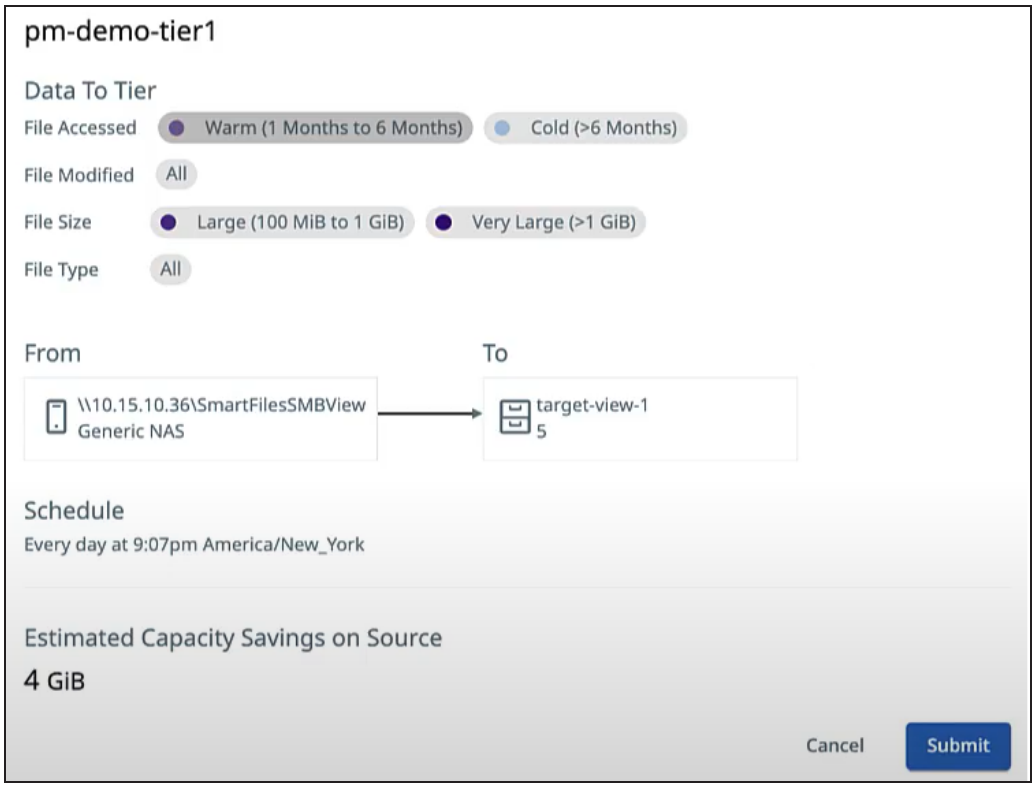
12. **Indexing**—Enable this option to index the data of the tiering task. Indexing improves files and folder search. By default, a rule to include the root directory (/) is defined, and therefore by default, the entire file system is indexed. Indexing is recursive, so if a directory is indexed, all of the child subdirectories are also indexed.
13. **Alerts**—Select one or more of the following settings if you want alerts to be created for the following triggers: Success, Failure, or SLA Violation.

    Email Recipients—Click **Add** and enter an email address to the tiering task to notify the email recipients when alerts are triggered for the task.

    > **Note:** Emails are not sent when informational alerts are created.

14. Click **Create**.

    The summary dialog displays the details of the tiering task and the estimated capacity savings on source:



15. Click **Submit**.

    The downtiering task is created and will run at the specified scheduled time.

Tiering Audit

The **Tiering Audit** option at the cluster level and the **Audit Logging** option in the downtiering task record details about the downtiered data. This includes logs for created symlinks and files that have been renamed or deleted during the downtiering process. The audit log file is stored in the `tiering_audit` directory within the `COHESITY_AUDIT_VIEW` View. Mount the View as an NFS share at `<*cluster_ip*>:/COHESITY_AUDIT_VIEW` to access this file.

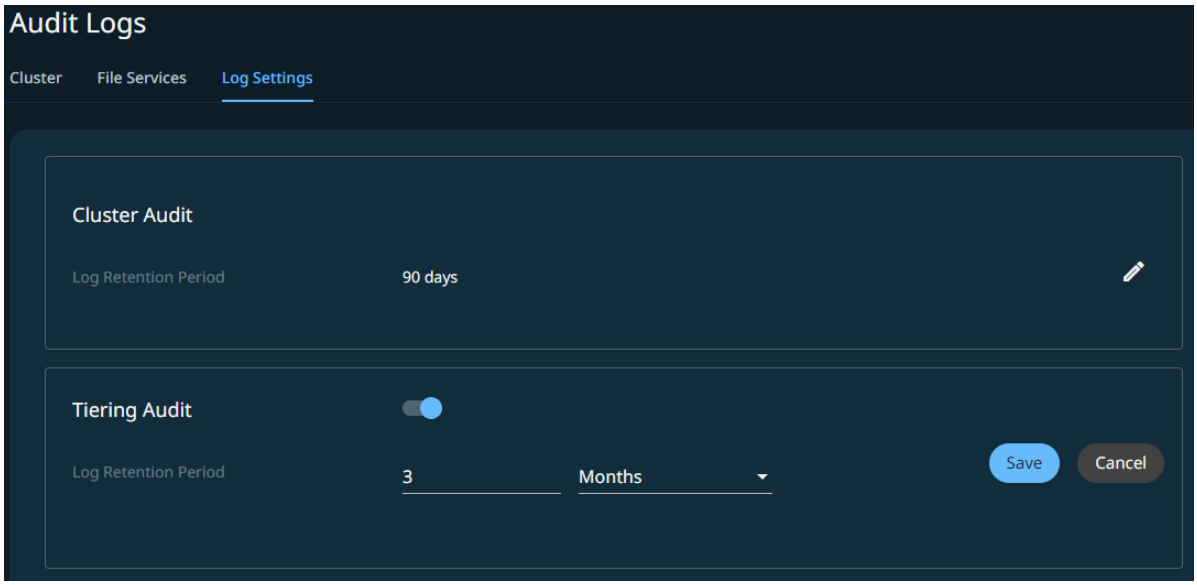
The following is an example audit log of a file that was down-tiered:

```
{"Timestamp" : "2024-07-23T06:10:04.314Z", "TieringAction" : "DownTier", "RemoteShare" :
"10.14.59.185:/source_view", "ViewName" : "target_view", "EntityPath" : "/err.txt", "EntityModifyTimestamp" :
"2024-07-23T06:09:50.491Z", "EntityAccessTimestamp" : "2024-07-23T06:09:50.535Z", "EntityMode" : 33152,
"EntityUserID" : 0, "EntityGroupID" : 0, "EntitySize" : 3, "EntityInode" : 154514, "JobName" : "tier"}
```

Enable Tiering Audit at the Cluster Level

To enable tiering audit logs at the cluster level:

1. Navigate to **System > Audit Logs > Log Settings**.
2. Turn on the **Tiering Audit** toggle:

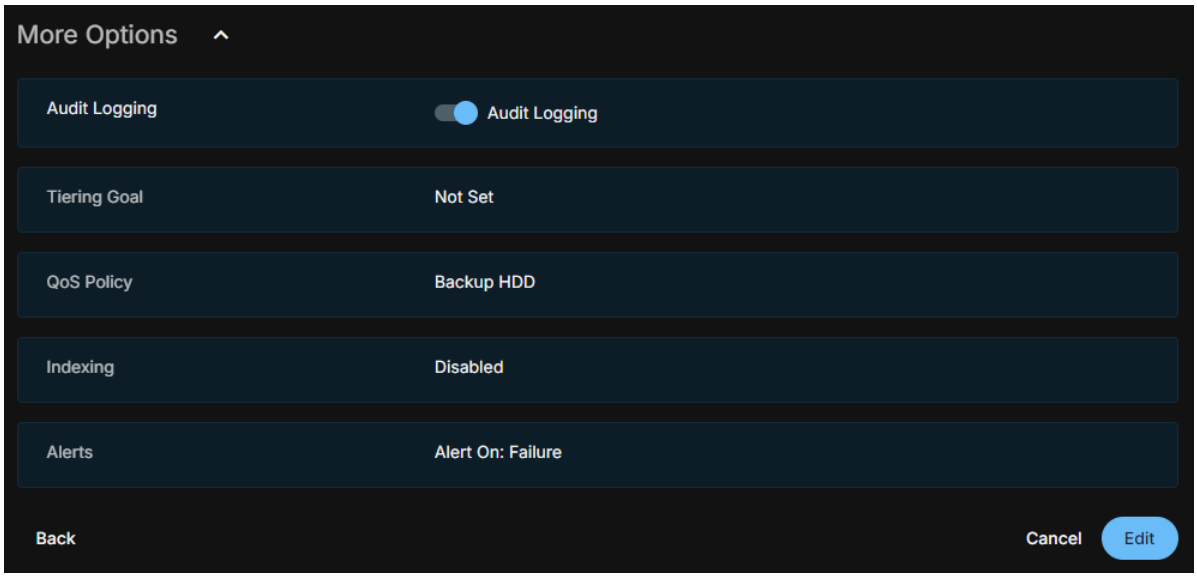


3. Update the log retention period as required.
4. Click **Save**.

Enable Audit Logs in the Downtiering Task

You can enable tiering audit logs for each downtiering task when creating or modifying a tiering job. Complete the following steps:

1. Navigate to **SmartFiles > NAS Tiering**.
2. In the **Tiering by Source** section, locate the registered source for which you want to enable audit logging:
   - To enable audit logging while creating a new tiering job, click **Plan Tiering** and **Select Data To Tier**.
   - To enable audit logging for an existing tiering job, hover over the job name and select **Edit**. On the **Select Data To Tier** page, click **Continue**.
3. Click **More Options** and turn on the **Audit Logging** option:



4. Click **Create** if you are creating a new job or **Edit** if you are modifying an existing job.

File Services Audit Logs

The File Services Audit Logs feature enables you to record and monitor events occurring on your SMB and NFS views.

Unlike the cluster-level audit logs, the logs for views are not displayed in the Cohesity GUI. The file services audit logs are saved in an internal view called ***filesystem_audit***. You can access these views by mounting the path ***COHESITY_AUDIT_VIEW\filesystem_audit***.

The **File Services** tab in the **Audit Log** page provides two mount paths for NFS and SMB. You can mount these paths to access and view the audit logs.

You can set permissions for the view and restrict access only to required subnets or users. Only the subnet's IP addresses in the allowlist can access and view the audit logs.

> **Note:**
>
> By default, when you create a view, the **Audit Log** option is disabled. You must manually enable it when creating the view or after creation.

Events Logged for NFS Views

Event	Description
Mount	To mount a view using NFS.
File Create	To create a file.
Link	To create a hard link to a file.
Folder Create	To create a folder.
Mknod	To create a special file used for resource like a device.
File Remove	To delete a file.
Folder Remove	To delete a folder.
Rename	To rename a file or folder.
Change Mode	To change the Unix mode bits of a file or folder for permission.
Change Ownership	To change the Unix UID or GID of a file or folder.
Modify Content	To modify the file's content.
Symlink	To create a soft link to a file or folder.

The following information is logged for NFS views. The information logged depends on the event type.

- Timestamp
- RecordID
- Protocol
- Client IP
- UserID
- ViewName
- Fsid
- RequestType
- Result
- EntityType

- EntityPath
- EntityInode
- EntityMode
- PrevEntityMode
- EntityUserID
- PrevEntityUserID
- EntityGroupID
- PrevEntityGroupID
- EntityModifyTimestamp
- DestinationEntityPath
- DestinationEntityInode
- InodeSizeBytes
- SourceParentEntityInode

Events Logged for SMB Views

Event	Description
Mount	To mount a view using SMB.
Logon	To establish an SMB session.
Logoff	To disconnect the current SMB session.
Close	To close a file or folder.
Create	To create a file or folder.
File Open	To open a file.
Delete	To delete a file or folder.
Rename	To rename a file or folder.
Modify Content	To modify the content of a file.
Change Ownership	To change the owner of a file or folder.

Event	Description
Change Permission	To add or remove the ACL permission of a file or folder.
File Change Protection	To enable or disable the Windows file protection of a file or folder.

The following information is logged for SMB views. The information logged depends on the event type.

- Timestamp
- RecordID
- Protocol
- Client IP
- Username
- UserID
- DomainName
- UserSID
- ViewName
- ViewAliasName
- Fsid
- RequestType
- Result
- EntityType
- EntityPath
- EntityInode
- EntityMode
- EntityUserID
- EntityGroupID
- SecurityDescriptor
- PrevSecurityDescriptor
- EntityModifyTimestamp
- EntityAccessMask
- DestinationEntityPath
- DestinationEntityInode
- DeleteOnClose

- InodeSizeBytes
- SourceParentEntityInode

Settings for File Services Audit Logs

Enable or Disable File Services Audit Logs

By default, the File Services Audit setting is disabled. You should enable the File Services Audit option for Cohesity to start logging operations on the cluster's views for auditing purposes.

You can disable or enable it back from the **Settings** tab of the **Audit Logs** page. When you disable the option, the old logs are retained until the retention period ends.

To enable or disable File Services Audit, complete the following:

1. Navigate to **System > Audit Logs** > **Log Settings**.
2. In the **Log Settings** tab, turn on/off the **File Services Audit** toggle to enable or disable.

After enabling the **File Services Audit**, the **Log Retention Period** audit information option appears. Use this option to set the audit logs retention period.

Set Log Retention Period for File Services Audit Logs

You can set the retention period for file services audit logs on the Cohesity cluster.

> **Note:** The default retention period is 90 days. You can increase or decrease the renewal period. Once the retention period expires, the audit logs are deleted automatically.

Prerequisite:

- You must enable the File Services Audit option. For more information, see Settings for File Services Audit Logs.

To set a retention period for File Services Audit Logs, complete the following:

1. Navigate to **System > Audit Logs** > **Log Settings**.
2. In the **File Services Audit** section of the **Log Settings** tab, click the icon for the **Log Retention Period** option, type the desired number, and select the retention period (Days, Weeks, Months, or Years).

   The Log Retention Period is displayed in days as Cohesity converts weeks, months, or years into days.
3. Click **Save**

Add IP Allowlist for File Services Audit Logs

By default, every client that is part of the Global Allowlist set at the cluster level can access the File Services audit logs. You can change access permission by the **Override Allowlist** option to allow or deny access to a subnet. Additionally, access can also be restricted using SMB Permissions on the view for AD or LOCAL principals.

As the file services audit logs are saved in an internal view, you can provide access only to required networks by adding them to the allowlist along with Allow Deny setting for NFS/SMB Clients in the allowlist.

To override the global IP allowlist set at the cluster level and add a subnet to the allowlist for file service audit:

1. Navigate to **System > Audit Logs** > **Log Settings**.
2. In the **IP Allowlist** section of the **Log Settings** page, turn on the **Override Global IP Allowlist** toggle.
3. Click **Add**.
4. In the **Add Allowlist** dialog, complete the following:
    1. Type the Subnet IP address in CIDR format.

       Example: Subnet in CIDR format (IPv4 - 10.0.0.0/24 or IPv6 - FE80:CD00::211E:729C/60).
    2. Select **NFS Permissions**, **SMB Permissions**, or **S3 Permissions**. (**Read/Write**, **Read Only**, or **Disabled**).
    3. Optionally, type a description.
    4. Click **Add**.

    The added allowlist IP subnet details appear in the File Services Audit section of the page.

Edit IP Allowlist for File Services Audit Logs

You can edit the IP allowlist for File Services audit logs if you need to change the subnet or change the permission for access.

To provide access to a network by adding to the IP allowlist for file service audit:

1. Navigate to **System > Audit Logs** > **Log Settings**.
2. In the **IP Allowlist** section of the **Log Settings** page, click the ✎ for the required subnet.
3. In the **Edit Allowlist** dialog, complete the following:
    1. Modify the Subnet IP address.

       Example: Subnet in CIDR format (IPv4 - 10.0.0.0/24 or IPv6 - FE80:CD00::211E:729C/60).

2. Modify **NFS Permissions**, **SMB Permissions**, or **S3 Permissions**. (**Read/Write**, **Read Only**, or **Disabled**).
3. Optionally, type a description.
4. Click **Add**.

The added allowlist IP subnet details appear in the File Services Audit section of the page.

Delete Allowlist for File Services Audit Logs

You can delete the allowlist IP subnet to remove access to a network. After deleting, clients in the deleted subnet cannot access the audit log files.

To delete an allowlist for File Services Audit logs:

1. Navigate to **System> Audit Logs>Log Settings**.
2. In the **IP Allowlist** section of the **Log Settings** page, click the delete icon for the required subnet.
3. In the **Delete Allowlist** dialog, enter **YES** to confirm, and click **Delete**.

The subnet disappears from the list and the audit logs view is restricted for the deleted subnet.

Add SMB Permissions for File Services Audit Logs

You can provide permission for SMB domain users and groups. The access permission is Read-Only and access type can be Allow or Deny.

To add SMB permissions for the File Services audit log:

1. Navigate to **System > Audit Logs** > **Log Settings**.
2. In the **SMB Permissions** section of the **Log Settings** page, click the **Add**.
    1. In the **Add SMB Permission** dialog, complete the following:
    2. Select an **AD Domain** from the list.
    3. Select a **Principal** from the list.
    4. Select Type: **Allow** or **Deny**.
    5. Click **Add**.

    The new permission appears under the SMB Permissions section.

Delete SMB Permissions for File Services Audit Logs

You can delete an SMB permission to remove the set permission (Allow or Deny) for a principal (user or group).

To delete SMB permissions for file services audit log, complete the following:

1. Navigate to **System > Audit Logs** > **Log Settings**.
2. In the **SMB Permissions** section of the **Log Settings** page, click the delete icon for the required SMB permission.
3. In the **Delete SMB Permission** screen, type **Yes** for confirmation.
4. Click **Delete**.

Access NFS Audit Logs using a Mount Path

Prerequisite:

- The subnet you are using should have read-only permission to the File services audit log view.

To access NFS audit logs, complete the following steps:

1. Navigate to **System > Audit Logs** > **File Services**.
2. In the **Log Location** section of the **File Services** tab, click the copy icon for NFS and mount using the following steps:
    1. Mount the path using the syntax given below:

        ```
        mount cluster_name:/COHESITY_AUDIT_VIEW/filesystem_audit /mnt/path
        ```

    2. Connect to a hidden internal view 'COHESITY_AUDIT_VIEW'.
    3. Connect to `mount cluster_name:/COHESITY_AUDIT_VIEW/filesystem_audit /mnt/path`.

Sample NFS Audit Log

```
{"Timestamp" : "2022-03-10T22:12:17.838Z", "RecordID" : "bd65:2afc4", "Pro-
tocol" : "NFS3", "ClientIP" : "10.2.223.127", "UserID" : 1000, "ViewName" :
"test", "Fsid" : 4377, "RequestType" : "Delete", "Result" : "NFS3_OK",
"EntityType" : "File", "EntityPath" : "bbb", "EntityInode" : 9422800,
"SourceParentEntityInode" : 9422329}
```

Access SMB Audit Logs using a Mount Path

Prerequisites:

- The subnet you are using should have read-only permission to the File services audit log View.
- As an SMB user, you must have permission to access the File services audit log View.

To access SMB audit logs, complete the following steps:

1. Navigate to **System > Audit Logs** > **File Services**.
2. In the **Log Location** section of the **File Services** tab, click the copy icon for SMB and mount using the following steps:
    1. Connect to a hidden internal view 'COHESITY_AUDIT_VIEW'.
    2. Access `\\cluster_name\COHESITY_AUDIT_VIEW\filesystem_audit`.

Sample SMB Audit Log

```
{"Timestamp" : "2022-03-04T00:01:40.503Z", "RecordID" : "30fe:216", "Pro-
tocol" : "SMB", "ClientIP" : "10.14.0.41", "UserName" : "Administrator",
"UserID" : 500, "DomainName" : "w2k16-0.qa.local", "UserSID" : "S-1-5-21-
2148495376-676708989-2532157484-500", "ViewName" : "audit_filer_actions",
"Fsid" : 6642, "RequestType" : "SetAttributes", "Result" : "Ok",
"EntityType" : "File", "EntityPath" : "audit-actions/d1/e1/f1.txt",
"EntityInode" : 6214}
```

Check Audit Logs Status for Views

You can enable or disable the status of the Audit Logs option for views.

You can check the audit status for views to know whether audit logs are being logged for required views. The GUI displays all views with the status and it allows you to filter the views to see the audit log enabled or disabled list of views.

To check the audit status for views, complete the following:

1. Navigate to **System > Audit Logs** > **File Services**.
2. In the **Audit Status of Views** section, click the **Audit Logs** drop-down menu and select **Enabled** or **Disabled**, and click **Apply**

Based on your selection, the list of views with **Audit Log enabled** or **disabled** status appears.

Enable or Disable Audit Logs for Views

You can check the audit status of a view to know whether audit logs are being logged for required the view and enable or disable the **Audit Log** option.

You can also enable or disable the Audit Logs option for a view from: **SmartFiles > Views**, click the actions menu (⋮) and select **Edit** > **Audit Logs.**

To enable or disable audit logs status for a view, complete the following:

1. Navigate to **System > Audit Logs** > **File Services**.
2. In the **Audit Status of Views** section, click the **Audit Logs** drop-down menu and select **Enabled** or **Disabled**, and click **Apply**.

3. Based on your selection, the list of views with **Audit Log** enabled or disabled status appears.
4. To enable or disable audit logs, click the toggle corresponding to the view under the **Audit Logs** column.

Antivirus Software to Protect Cluster Data

You can enable antivirus software to protect your data on the Cohesity cluster from viruses. Once an antivirus software scans a file and detects a threat, the Cohesity cluster reports the threat on the Cohesity Dashboard. The administrators can either quarantine, unquarantine, reset, or delete the infected file.

Perform the following steps to enable antivirus scanning and manage threats:

1. Add an Antivirus Provider
2. Enable Antivirus Scan on a View
3. View and Manage Threats

Add an Antivirus Provider

To perform an antivirus scanning on your data in the Cohesity cluster, you must first add the antivirus software to the Cohesity cluster. You can add the software in one of the following ways:

- Register External Antivirus Software
- Install the Antivirus App from the Cohesity Marketplace

Register External Antivirus Software

1. Navigate to **SmartFiles > Antivirus** and click the **Providers** tab.
2. Click **Add External Provider** in the upper-right corner of the page.
3. In the **New External Provider** field, enter the name of the antivirus software provider of your choice.
4. (Optional) Describe the provider.
5. Enter the ICAP Server URL in the following format: `icap://<server>:<port>/<uri>`

Option	Description
icap	Indicates the required protocol identifier that enables communication with external servers hosting third-party antivirus software.

Option	Description
server	Specifies the domain name or IP address of the external server (ICAP server) hosting the third-party antivirus software.
port	Specifies the port that the external server monitors for incoming requests. If not specified, the default icap port, 1344 will be used.
uri	Specifies the path of the ICAP service.

6. (*Optional*) Click **Add** to register more than one external ICAP server.
7. Click **Check ICAP Server Connection Status** to check the status of the external antivirus software.

   If the connection is not successful, ensure that you have provided the correct ICAP URL and the external server is up and running.
8. Click **Add**.

   The antivirus software is registered on the Cohesity cluster.

Install the Antivirus App from the Cohesity Marketplace

1. Navigate to **SmartFiles > Antivirus** and click the **Providers** tab.
2. Click **Install Antivirus App** at the top right of the page.

   You will be directed to the Cohesity App Marketplace.
3. Click **GET APP** for the Antivirus App you want to install on the Cohesity cluster.

   You will be directed to the Helios login page.
4. Log in to Cohesity Helios, select the Cohesity cluster on which you want to install the Antivirus App, and click **Install**. You also have the option to install the App later.
5. Go back to the Cohesity cluster and go to **Marketplace > My Apps**.

   The page displays the list of Apps that are available on the Cohesity cluster.
6. Click **Run App** to create an instance of the Antivirus App.

   The instance created will be displayed as an Antivirus provider on the **Providers** tab.

Enable Antivirus Provider

1. Navigate to **SmartFiles > Antivirus** and click the **Providers** tab.

   The page displays the list of antivirus providers that can be enabled for antivirus scanning.
2. From the Action menu, toggle on the **Enable** option.

   You can enable only one antivirus provider group at a time.

Enable Antivirus Scan on a View

Once you install the antivirus software on the Cohesity cluster, you can enable the antivirus scan on a View.

To enable antivirus scan on a view:

1. Navigate to **SmartFiles > Antivirus** and click the **Secured Views** tab.
2. Click **Add a View** at the top right of the page.
3. From the View drop-down list, select a view for which you want to perform the scanning of files.

   Antivirus scanning is supported only on Views with SMB protocol. Therefore, the drop-down list displays the Views which support SMB protocol.
4. Provide the following details either by clicking **Edit All** or by clicking the **Edit** option for each scan settings option:

Option	Description
Scan on	Antivirus scans can be configured to send the files for scanning when they are closed, opened, or both. In each case, all the files to be scanned are added in a queue and sent to the antivirus provider(s) for scanning, as per the queue order. • **Close**: Files are scanned after they are closed (Default) With this configuration, you can access the files without any delay as file scanning is done after the user's file operation. This type of scanning is faster but less secure. • **Open**: Files are scanned before they are opened. With this configuration, you can access the files once they are scanned. You must wait for the file scan to complete. This type of scanning is slower but more secure. • **Open and Close**: Scans the files before they are opened and after they are closed. This type of scanning is the slowest and most secure, as the scanning queue includes all the live files (opened and closed). Cohesity recommends scanning the file after they are closed as this configuration ensures that the files are accessible even if the antivirus provider(s) or scanning network is down, unavailable or unreachable.

Option	Description
Files to Scan	• **All Files**: Select this option to scan all the files in the View. • **All Files Except**: Select this option to exclude files in the view from scanning. You can specify the file extensions (comma-separated) to be excluded in the **File extensions to skip** field. • **Only These Files**: Select this option to scan only the selected files. You can specify the file extensions (Comma-separated) to be included in the **File extensions to scan** field.
	Exclude files based on file size: Enable this option to exclude files based on the file size. In the **Max File Size** field, you can specify the file size limit for scanning. The default file size limit is 50 MB. The maximum file size limit is 125 MB.
Scan Timeout	Set the maximum amount of time (in seconds) that a scan can take before timing out.
If Scan Cannot Be Completed	Blocks file access if the antivirus servers are unavailable or are unable to scan the file due to any issue. This option is disabled by default to ensure that the files stay accessible even if the antivirus provider(s) or scanning network is down, unavailable, or unreachable.

5. Click **Add**.

You can also enable antivirus scan while creating a View or by editing an existing View.

View and Manage Threats

After you enable the antivirus scan on the View, you can view the scanned report from the **Threats** page and take action on the infected files.

To view the scanned report:

Navigate to **SmartFiles > Antivirus** to view the **Threats** page.

Alternatively, on the **Secured Views** page, click the view for which you want to view the reports.

The Threats page displays the following details:

- The total number of quarantined files
- The total number of unquarantined files
- The total number of views that are affected by the virus
- Option to filter the report based on the status of the file and View
- Information on the files that are affected:

Field	Description
Filename	The files that are infected, along with the file path. A lock icon will be displayed along with the file name if you have enabled the **File DataLock** option while creating the View.
View	The View name of the files. A lock icon will be displayed along with the View name if you have cloned the View as DataLock.
Threat	The threat type or virus signature along with the ICAP server URL that detected the threat.
Provider Name	The antivirus software provider that detected the threat.
Scan Time	The time at which the file is scanned for viruses.
Status	The status of the threat: • **Quarantine**: The file is determined to be unsafe. All access to the file is blocked until the administrator manually changes the file state. • **Unquarantine**: Allow file access. The file is not scanned again until the file state is reset.

Manage Threats

You can manage threats by performing the following actions from the **Threats** page:

Action	Description	How to
Unquarantine Files	Move the files from the quarantined state to allow file access. Unquarantined files are not scanned again.	Select the checkbox next to file names and then click **Unquarantine Files**.
Delete Files	Deletes the quarantined files. You cannot delete unquarantine files.	Select the checkbox next to file names and then click **Delete Files**.
Reset Files	Reset the unquarantine files. You cannot reset quarantine files	Select the checkbox next to file names and then click **Reset Files**.

Access Management

The following topics provide information about user and group access management:

Active Directory (AD)

Active Directory (AD) in Cohesity Access Management is a directory service implemented by Microsoft that provides several services such as LDAP (Lightweight Directory Access Protocol), Kerberos, and DNS. It is used for user and group identity management and authentication within a Cohesity cluster.

You can join the Cohesity cluster to one or more Active Directory (AD) domains. Joining to AD allows the following:

- Existing AD users and groups can be assigned Cohesity roles
- SMB shares created by the Cohesity cluster can be authenticated based on AD credentials

Cohesity Roles

Once the Cohesity cluster is joined to an AD domain, existing AD principals can be added assigned different roles so they can access the Cohesity Dashboard. For example, you can assign the View role to the AD group "ITGroup." This gives all group members read-only access to the Cohesity Dashboard. You can also assign the Admin role to the AD user "ITManager."

Cohesity SMB Share Access

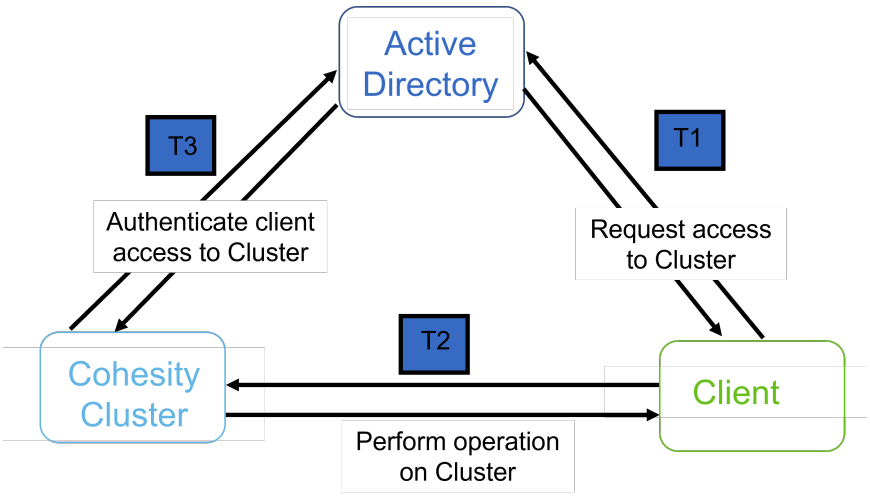
The action steps in the following procedure are represented in the figure below with blue numbered time squares: T1 . The procedure assumes the Cohesity cluster is already joined to an Active Directory domain.

Client access to an Active Directory-joined Cohesity cluster SMB share consists of the following actions:

T1) A client requests access to a Cohesity cluster SMB share.

T2) The client attempts to perform an operation on the Cohesity cluster SMB share.

T3) Active Directory authenticates the client's membership within a group that can perform the requested operations on the Cohesity cluster SMB share.



Join to Active Directory Domain

For detailed instructions, see Join to Active Directory.

Join Active Directory

This topic explains how to configure a Cohesity cluster to use Active Directory (AD) credentials for SMB access to views and to access the Cohesity Dashboard. (For information about protecting Active Directory domain controllers, see About Active Directory Data Protection.)

Joining the Cohesity cluster to an AD domain is optional. You can join the Cohesity cluster to one or more AD domains to enable:

- existing AD users can access Cohesity cluster SMB shares based on their AD credentials
- existing AD users and groups can be assigned Cohesity roles and access the Cohesity Dashboard

On Cohesity clusters that are **not** joined to AD, all views are accessible as SMB shares and there is no authentication. If the AD administrator blocks NTLM, the shares on the Cohesity cluster are not accessible.

All accounts and Cohesity cluster SMB share privileges for users in AD are managed through Active Directory or where the SMB shares are mounted. Non-admin AD users must be granted backup and restore privileges on Windows clients explicitly. This is in addition to backup and restore privileges for the Cohesity cluster.

Migrated AD Users and Groups with Historical SIDs

Cohesity supports migrated AD users and groups with historical SIDs and grants access accordingly in Active Directory domains. The SID history retains user and group membership and access rights during Active Directory domain migration.

Considerations

Review the following considerations of migrated AD users and groups with historical SIDs:

- Historical SIDs with multiprotocol access is not supported.
- Historical SIDs user quota accounting is not supported.
- Privilege assignment for Historical SIDs is not supported.

Prerequisites and Considerations

For information about the required firewall ports for AD, see Manage Firewall Ports.

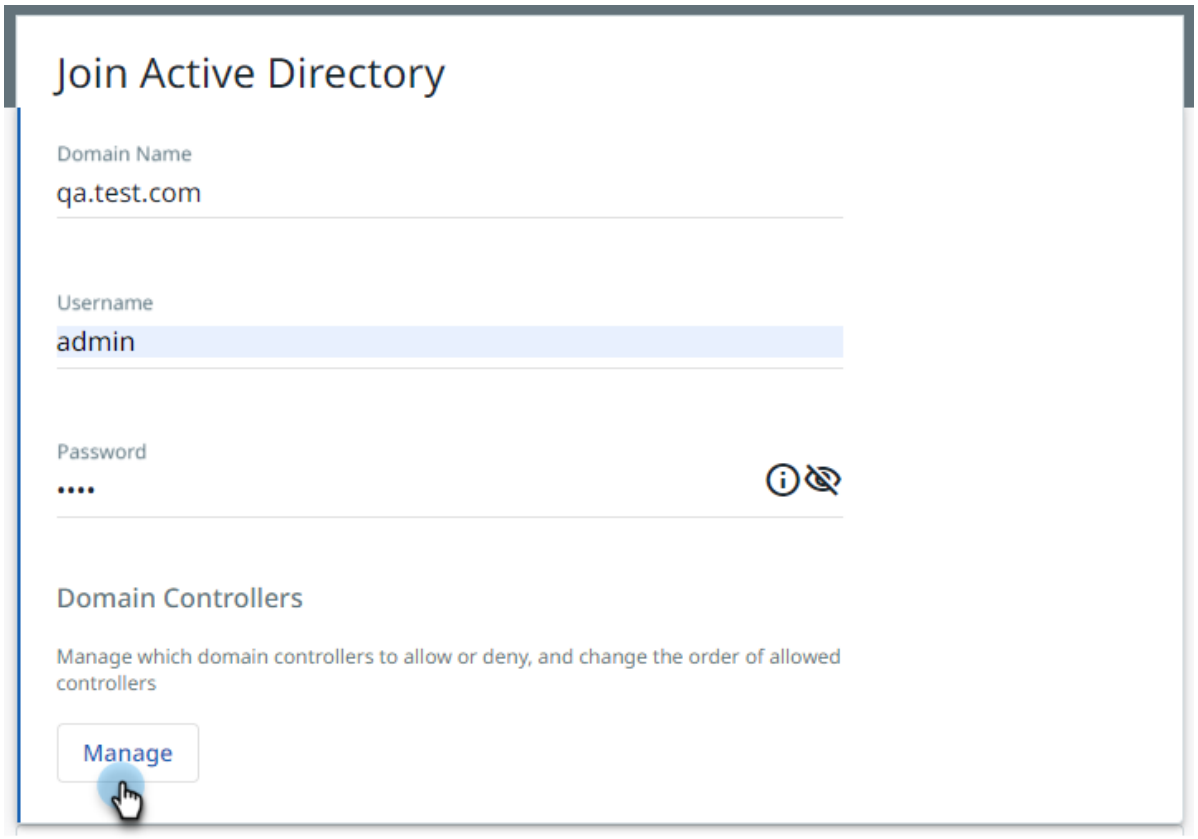
Join the Cohesity cluster to an AD Domain

1. Go to **Settings > Access Management** and click the **Active Directory** tab.
2. Click **Add Active Directory**.

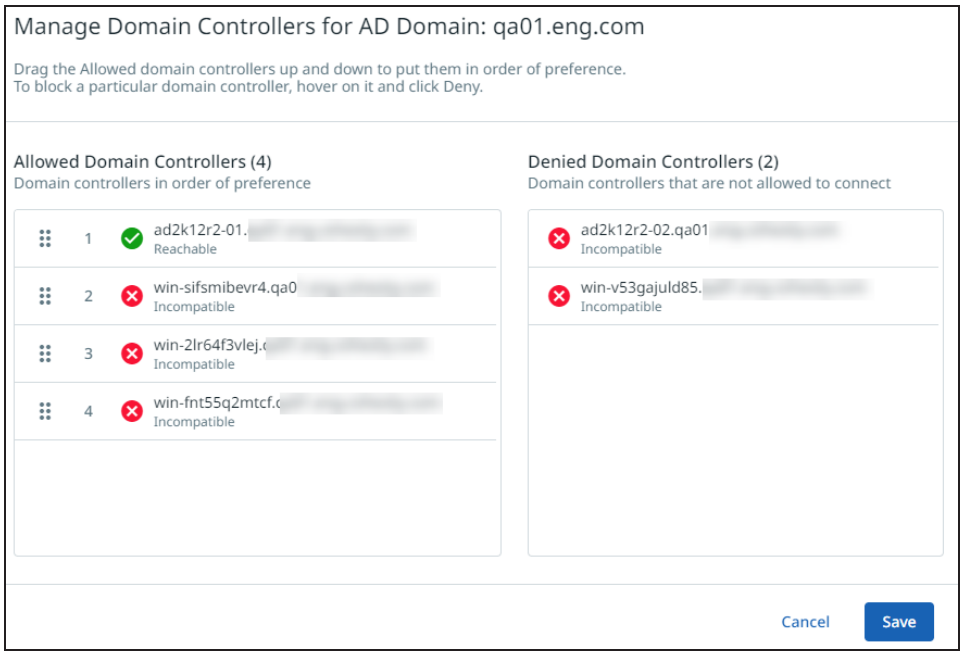
3. **Domain Name:** Provide the fully qualified domain name (FQDN) of the Active Directory domain to join.
4. **Username**: Provide the samAccountName.
5. **Password**: Provide the password for the username.
6. **Domain Controllers:** Add preferred domain controllers to the AD domain to ensure that the Cohesity cluster uses a local domain controller (when possible) to speed up AD queries. You can set preferred domain controllers for the following:
   - Domain controllers
   - Trusted domains of the domain controller

   > **Note:**
   > - The SRV records must exist for the domain (the list of domain controllers displayed in the Cohesity Dashboard is generated by querying the SRV records).
   > - You can add any number of preferred domain controllers.

   1. Click **Manage** to allow or deny domain controllers and change the order of allowed controllers:



2. In the **Manage Domain Controllers for AD Domain** dialog, the domain controllers are listed in order of preference. You can move the allowed domain controller(s) up and down to put them in order of preference. To block a particular domain controller, hover on it and click **Deny:**



3. Click **Save**.

   The allowed domain controllers are listed in the **Domain Controllers** section:

   The Cohesity cluster uses these domain controllers to join the AD domain and for all future communication with the AD domain.

7. **Machine Accounts:** Click **Add** and specify the following details:

   - **Machine Account**—Provide at least one machine account to identify the Cohesity cluster on the domain. For example, you can use the Cohesity cluster name.
   - **DNS Hostname**—Optionally, specify the DNS hostname of the machine account. For AD to work with the internal DNS server, apart from machine account names, you should add DNS hostnames that should be configured for each machine account. The DNS hostnames should have one of the In Bound DNS zone suffixes configured for the internal DNS server. For more information, see Internal DNS for Load Balancing.

> **Note:**
> - When you specify the DNS hostname, it is treated as a customized Service Principal Name (SPN), resulting in successful Kerberos authentication with this customized SPN.
> - If the DNS Hostname is modified when editing the machine accounts, all existing configuration of the machine account is overwritten on the Active Directory.

- **Encryption Types**—Optionally, select the encryption type(s) that must be used by the machine account. You can select multiple encryption types. The following encryption types are supported:
  - AES128-CTS-HMAC-SHA1-96
  - AES256-CTS-HMAC-SHA1-96
- **SPNs**—Service Principal Names (SPNs) are identifiers used to associate a service with a specific AD account. SPNs enable authentication and authorization for services. Specify the SPN in the following format:

  <service class>/<host>:<port>/<service name>

  The SPN syntax has four elements.
  - The following two elements are required:
    - **Service Class**: Specify the type of service.
    - **Host**: Specify the hostname or Fully Qualified Domain Name (FQDN) of the server on which the service is hosted.
  - If necessary, you can specify the following optional elements:
    - **Port**: Specify the port number on which the service is running.
    - **Service Name**: Specify the specific service instance on the host.

Note:

- All (or a subset) of the VIPs will resolve to the machine account. You can optionally add multiple machine accounts, which creates aliases for the same cluster. You can map these aliases to a subset (or all) of the VIPs to direct I/O to a subset (or all) of the nodes. Separate names with commas. For example: cluster1, cluster1-vip1, cluster1-vip2, cluster1-vip3, cluster1-vip4.
- If using VLANs—One of the machine accounts must be a DNS hostname for a virtual IP (VIP) of a VLAN configured on the cluster in order to recover to servers within that VLAN.
- After adding a Cohesity cluster to an AD, ensure the machine account used to register the Cohesity cluster in AD has the **Read membership** permissions across all users and groups.
- The same configuration must be done on every additional domain to which the Cohesity cluster is joined.
- The machine account must follow NetBIOS naming conventions of 15 maximum character length, those described in Naming conventions in Active Directory for computers, domains, sites, and OUs and the additional restriction that the ! @ ( ) characters are not supported.

8. **Use the above Machine Accounts even if they already exist in AD Domain:** Optionally toggle on to use the machine accounts that you specified above even if they already exist in the Active Directory domain.
9. **Mapped Provider:** Select the type of mapped provider to join the domain. By default, no mapped provider is selected. Optionally, select **LDAP** or **NIS**. If you select the **LDAP** option, you can select the provider from the **LDAP Provider** drop-down list. If you select the **NIS** option, you can select the NIS provider from the **NIS Provider** drop-down list.
10. **Organizational Unit:** Provide the organizational unit if applicable. Use the format: *OUName* or *OUName*/*SubOUName*. For example: Engineering or Sales/West or West Coast Sales/ North California.
11. **AD Workgroup / NetBIOS Name:** Provide the workgroup / NetBIOS name if applicable.
12. **Discover Trusted Domains:** Optionally, turn on this toggle to discover the trusted domains associated with an AD. You can exclude certain trusted domains after the

Cohesity cluster is joined to the AD domain. For more information, see Trusted Domains.

13. Click **Join**.
14. This step is required only for SMB access to views. On the DNS server that is integrated with the AD domain, add the A record for each machine account used to identify the Cohesity cluster to the AD domain. This is necessary to allow clients to access the Cohesity cluster as a resource. (Adding the A record is not generally necessary for Windows resources because Active Directory automatically adds it to the DNS server. However, the Cohesity cluster does not include the components that enable automatic addition to the DNS server.)
15. Optionally, repeat these steps to join the Cohesity cluster to another AD domain. For more information, see Guidelines for Joining Multiple AD Domains.
16. Optionally, you can add user ID mapping. For more information, see User ID Mapping for Multi Protocol Network Access.

Guidelines for Joining Multiple AD Domains

A cluster can join multiple Active Directory domains even if there are trust relationships between the AD domains.

After the Cohesity cluster joins the AD domain, you can add trusted domains to the allowlist or denylist. By default, all trusted domains are used for authentication unless added to the denylist. For more information, see Trusted Domains.

Only Kerberos authentication is supported for SMB shares when multiple AD domains are joined to the Cohesity cluster. NTLM authentication is disabled.

Leave Active Directory Domain

1. Go to **Settings > Access Management** and click the **Active Directory** tab.
2. Click the domain name and then click the leave domain icon ( ).
3. Provide the **AD Admin** and **Password** for the domain.
4. Click **Leave Domain**.

   When this succeeds, the machine accounts associated with the Cohesity cluster are removed from the Active Directory domain.

   > **Note:** If the Cohesity cluster is removed from a domain, ensure the corresponding DNS entries have been removed from the DNS server.

Enable Load Balancing

You can enable load balancing over multiple Cohesity cluster IPs by following these steps:

> **Note:** These example steps refer to the Windows DNS Manager. If you're using a different DNS Manager, ensure you perform step 3.

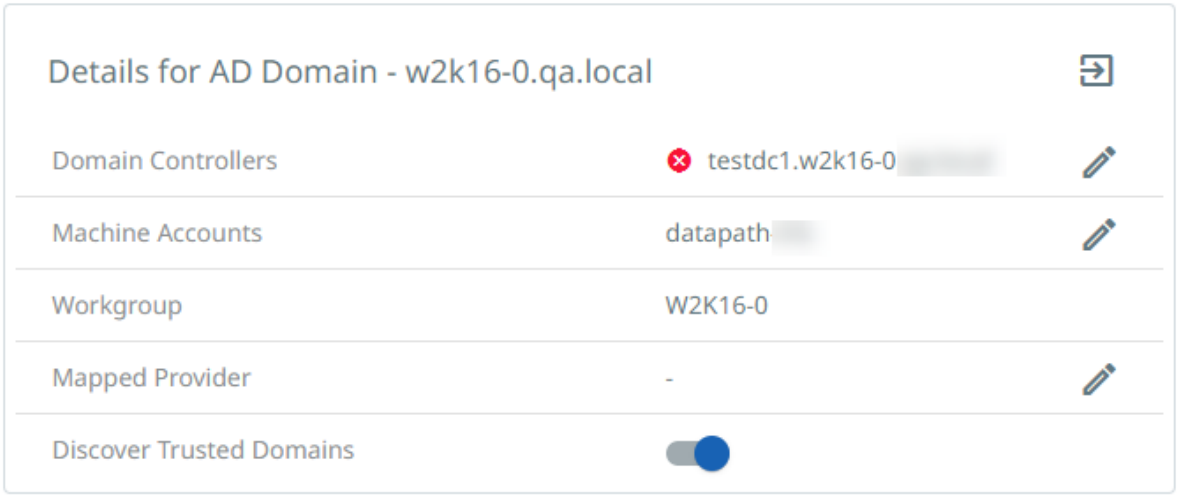
1. Open DNS Manager in Windows using the DNS Admin client: **Control Panel > Administrative Tools > DNS**.
2. Enable the Advanced view: **View > Advanced**.
3. Add multiple entries with the same Cohesity cluster name and do the following:
   - Give each entry a different **IP address** that corresponds to a VIP allocated to the Cohesity cluster in the DNS Zone where it will be added.
   - Generally, you can leave **Time to live (TTL)** at its default setting. You should only change this setting for specific use cases. Set TTL to a low value (such as 5 seconds or less) for backup use cases where a low number of clients are accessing the Cohesity cluster. Set TTL to a high value (such as 12 hours) for file services use cases with a high number of clients. This ensures that clients access the same Cohesity cluster nodes and benefit from caching.

Manage Domain Controllers From the Active Directory Details Page

You can also manage domain controllers from the Active Directory details page.

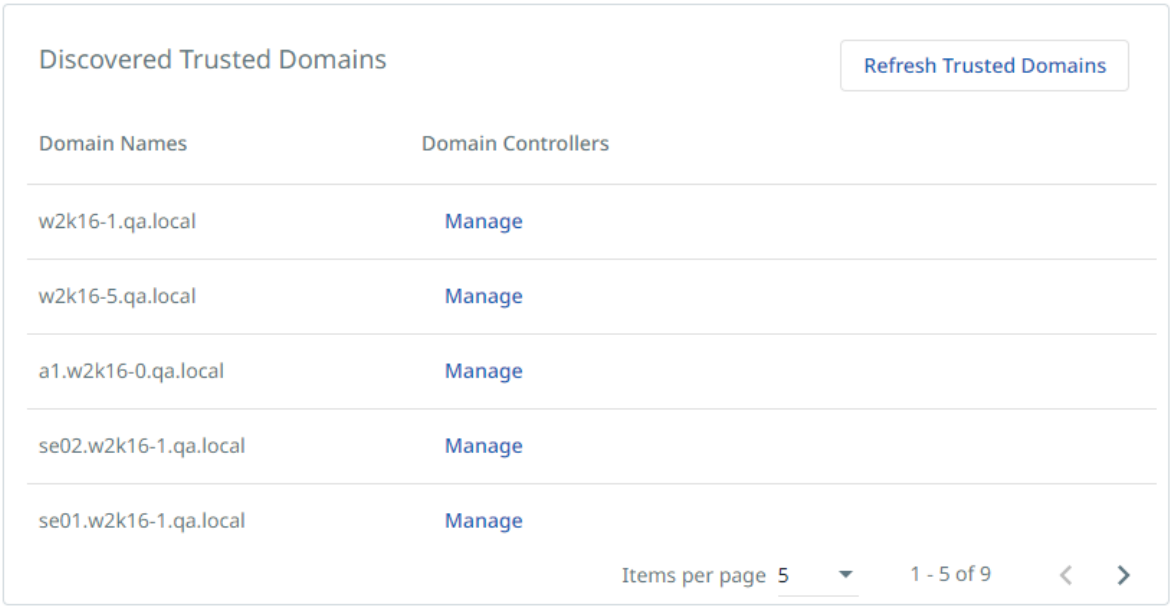
To manage domain controllers from the Active Directory details page:

1. Navigate to **Settings > Access Management** and click the **Active Directory** tab.
2. Click the active directory for which you want to manage domain controllers.
   - In the **Details for AD Domain** section, click the edit icon corresponding to **Domain Controllers**:



The **Manage Domain Controllers for AD Domain** dialog is displayed. You can manage the domain controllers for this AD domain.

- In the **Discovered Trusted Domains** section, the trusted domain controllers associated with the AD are discovered and listed. Click **Manage** corresponding to the domain name:



The **Manage Domain Controllers for AD Domain** dialog is displayed. You can manage the trusted domain controllers for the AD domain:

- **Allowed Domain Controllers**—All the domain controllers for the AD domain are listed in the **Allowed Domain Controllers** section. Drag a domain controller up or down to reorder the preference. To block a domain controller, hover over it and click **Deny**.
- **Denied Domain Controllers**—Domain controllers that are disallowed to connect the AD domain are listed in the **Denied Domain Controllers** section. To unblock a domain controller, hover over it and click **Allow**.

User ID Mapping for Multi Protocol Network Access

After the Cohesity cluster is joined to an Active Directory domain, you can add user ID mapping. The ID map database is stored in AD using industry-standard protocols. For more information, see ID Mapping for Multi-Protocol Views.

1. Go to **Settings > Access Management** and click the **Active Directory** tab.
2. Click **Add ID Mapping** or the edit icon ( ).
3. Select an **ID Mapping Type** and enter the required information:

- **Centrify**
  - **AD Domain:** Name of the Active Directory domain where the corresponding Centrify zone is located.
  - **Centrify Zone:** Selected zone that has the ID mappings.

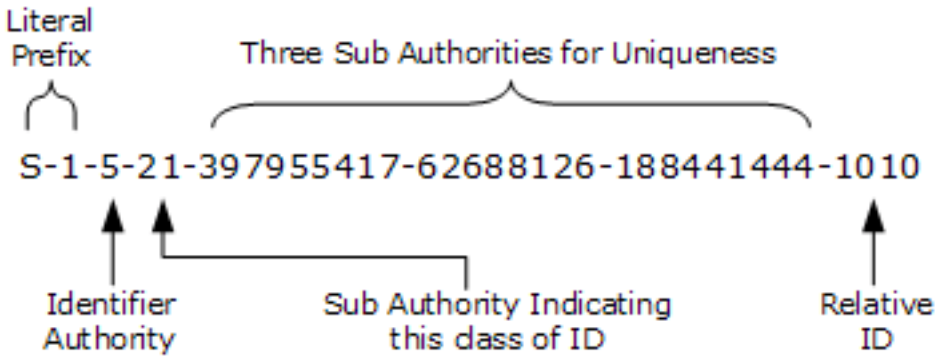
  For Native security style Views, SMB will get Unix IDs from the Active Directory provider and NFS will get Unix IDs from the LDAP provider.

  For Unified or NTFS security style Views, SMB and NFS will get Unix IDs from the corresponding Centrify zone for the Active Directory provider.
- **Fixed**
  - **Unix UID to be applied to all files created:** Enter a user ID to apply to all created files.
  - **Unix GID to be applied to all files created:** Enter a group ID to apply to all created files.
- **LDAP Provider**

  The UID and GID corresponding to the Active Directory users are fetched from the configured LDAP provider. In LDAP, the most commonly used attributes to store the UID and GID are 'uidNumber' and 'gidNumber', respectively.

  All Views, regardless of their security style setting (Native, Unified or NTFS), will get Unix IDs from the LDAP provider and SIDs from the Active Directory provider.
- **RID (Relative ID of SID)**

  RID is a variable length number that is assigned to objects at creation and becomes part of the object's Security Identifier (SID) that uniquely identifies an account or group within a domain. For every Windows user or group, the RID of the corresponding SID is used as the UID or GID.



- **RFC2307**

  In RFC2307, the UID and GID are stored along with Active Directory objects in the following attributes: the UID for a user is stored in the attribute ‘uidNumber’ and GID for a group is stored in the attribute 'gidNumber'.

  For Native security style Views, SMB will get Unix IDs from the Active Directory provider and NFS will get Unix IDs from the LDAP provider.

  For Unified or NTFS security style Views, SMB and NFS will get Unix IDs from the Active Directory provider.

- **SFU (Services for Unix 3.0)**

  In SFU, the UID and GID are stored along with Active Directory objects in the following attributes: the UID for a user is stored in the attribute ‘uidNumber’ and GID for a group is stored in the attribute 'gidNumber'.

  For Native security style Views, SMB will get Unix IDs from the Active Directory provider and NFS will get Unix IDs from the LDAP provider.

  For Unified or NTFS security style Views, SMB and NFS will get Unix IDs from the Active Directory provider.

4. Select a **Fallback Option** to use if the selected ID Mapping Type is, for instance, not populated. This is available if the ID Mapping Type is not Fixed or RID.

   If you select Fixed for the Fallback Option, provide the following information:

   - **Unix UID to be applied to all files created:** Enter a user ID to apply to all created files.
   - **Unix GID to be applied to all files created:** Enter a group ID to apply to all created files.
5. Select the **AD User mapped to the Linux Root User** by selecting the AD domain and user.
6. Click **Save**.

Trusted Domains

After the Cohesity cluster joins the Active Directory domain, you can add trusted domains to the allowlist or denylist. By default, all trusted domains are used for authentication unless added to the denylist. You can add trusted domains to the allowlist so that only trusted domains added to the allowlist are used for authentication.

> **Note:** If the domain controller is not functioning correctly, the discovery of trusted domains may take a relatively long period of time or may provide inconsistent results. Therefore, a trusted domain might not be discovered at all. You must manually enter such domains in the allowlist or denylist.

A trusted domain forest can have multiple trusted domains. To provide optimized access, you can use a subset of trusted domains so that the Cohesity cluster does not send group membership queries to all trusted domains. You can choose a subset of trusted domains by using one of the following modes:

- **Denylist**—Ignores specified trusted domains. For example, if there are three trusted domains T1, T2, and T3 and if T2 is added to the denylist, T1 and T3 are the trusted domains used for authentication.
- **Allowlist**—Allows only specified trusted domains. For example, if there are three trusted domains T1, T2, and T3 and if T1 and T2 are added to the allowlist, T1 and T2 are the trusted domains used for authentication.

Add Trusted Domains to the Allowlist

To add a trusted domain to the allowlist:

1. Navigate to **Settings > Access Management** and click the **Active Directory** tab.
2. Click the domain name to navigate to the AD domain details page.
3. Click the edit icon in the **Denied Trusted Domains** section.
4. Click **Allowlist** and add the domain name in the **Allowed Trusted Domains** field. Click + to add another domain.

   Cohesity recommends adding at least one domain or switching to a denylist.
5. Click **Save**.

   The trusted domain is added to the allowlist.

Add Trusted Domains to the Denylist

If you want Cohesity to ignore specific trusted domains so that their principals are not assigned roles and denied access to Cohesity SMB shares, you can add the desired domains to the denylist.

To add a trusted domain to the denylist:

1. Navigate to **Settings > Access Management** and click the **Active Directory** tab.
2. Click the domain name to navigate to the AD domain details page.
3. Click the edit icon in the **Denied Trusted Domains** section.
4. Click **Denylist** and add the domain name in the **Denied Trusted Domains** field. Click + to add another domain.
5. Click **Save**.

   The trusted domain is added to the denylist.

Refresh Trusted Domains

If the **Discover Trusted Domains** option is enabled, the trusted domains associated with the AD are discovered and listed in the **Discovered Trusted Domains** section. After any

configuration change, trusted domains are not automatically refreshed in the **Discovered Trusted Domains** section. You must manually refresh the trusted domains.

To refresh the trusted domains list:

1. Navigate to **Settings > Access Management** and click the **Active Directory** tab.
2. Click the domain name to navigate to the AD domain details page:
3. In the **Discovered Trusted Domains** section, click **Refresh Trusted Domains**.

Add or Edit Preferred Domain Controllers

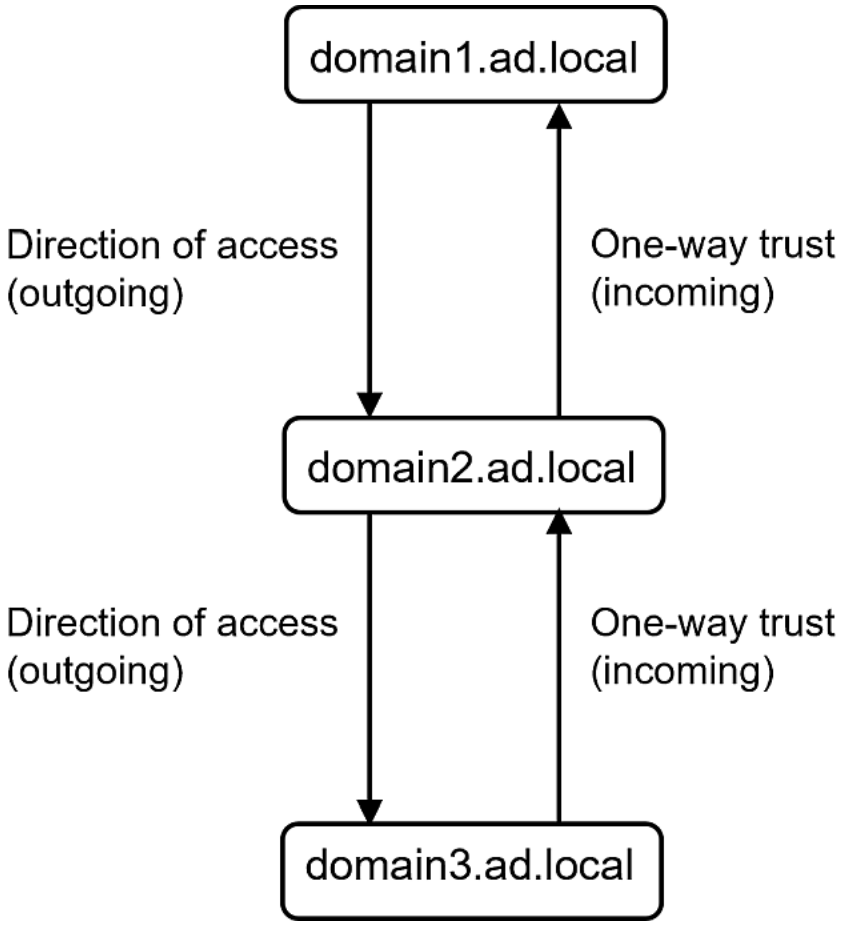
To add or edit preferred domain controllers of the discovered trusted domains:

1. Navigate to **Settings > Access Management** and click the **Active Directory** tab.
2. Click the domain name to navigate to the AD domain details page:
3. In the **Discovered Trusted Domains** section, click **Select** corresponding to the domain name.
4. On the **Edit Preferred Domain Controllers** dialog, modify the domain controllers and click **Save**.

One-Way Trust

A one-way trust is a unidirectional authentication path created between two AD domains. In a one-way trust, the trust relationship is only one way.

The following is an illustration of one-way trust and the direction of access:



As shown in the above figure:

- domain2.ad.local has a one-way trust with domain1.ad.local. domain1.ad.local does not have a trust relationship with domain2.ad.local. Users in domain2.ad.local can access resources in domain1.ad.local. However, users in domain1.ad.local cannot access resources in domain2.ad.local.
- domain3.ad.local has a one-way trust with domain2.ad.local. domain2.ad.local does not have a trust relationship with domain3.ad.local. Users in domain3.ad.local can access resources in domain2.ad.local. However, users in domain2.ad.local cannot access resources in domain3.ad.local.

In a one-way trust, the direction of trust is the opposite of the direction of access. An outgoing trust allows incoming access and an incoming trust allows outgoing access.

If one-way trust is enabled on the AD domain, trusted domains are listed in the following way in the Cohesity cluster:

- If the Cohesity cluster joins domain2.ad.local and if trusted domains are enabled:
    - domain1.ad.local is displayed as a trusted domain because domain1.ad.local trusts domain2.ad.local

    - domain3.ad.local is not displayed as a trusted domain because domain3.ad.local does not trust domain2.ad.local
- If the Cohesity cluster joins domain3.ad.local, both domain2.ad.local and domain1.ad.local are displayed as trusted domains because domain2.ad.local trusts domain3.ad.local and domain1.ad.local trusts domain2.ad.local.
- If the Cohesity cluster joins domain1.ad.local, no domain is displayed as a trusted domain because domain1.ad.local does not have a trust relationship with domain2.ad.local or domain3.ad.local.

View Active Directory Join and Leave Status

You can add one or more Active Directory (AD) domains to a Cohesity cluster. Joining the AD domain to a Cohesity cluster is a multi-step process and involves the following steps:

- Connecting to the DNS server
- Getting the list of domain controllers from the DNS server
- Connecting to the DC server
- Adding machine account(s)
- Setting the encryption type

You can view the progress of each subtask. For example, while joining an AD domain, you can check whether the machine account was added successfully. This log helps in troubleshooting and identifying the exact step at which the task failed.

View Active Directory Join Status

To view the AD join status:

1. Follow the steps described on the Join Active Directory page to join the Cohesity cluster to the AD domain.
2. After you click **Join**, the following error message is displayed if the process fails:

   ```
   Joining Active Directory <ad-domain-name> failed. Show Subtasks
   ```

3. Click **Show Subtasks**.

   A dialog is displayed and the subtasks are listed.

   You can view the subtask at which the process failed.

You can also view the status when you edit an AD domain. For example, if you add or modify a machine account after the Cohesity cluster joins the AD domain and if the process fails, you can view the status by following the steps outlined below:

1. Navigate to **Settings > Access Management** and click the **Active Directory** tab.
2. Click the AD domain that you want to edit.

   The AD Domain details page is displayed.

3. Click the edit icon corresponding to **Machine Accounts**.
4. Modify the machine account details as necessary.
5. Click **Save**.

   The following error message is displayed if the process fails:

   ```
   Failed to join Active Directory. Show Subtasks
   ```

6. Click **Show Subtasks** to view the subtask at which the process failed.

View Active Directory Leave Status

Leaving an AD domain is a multi-step process. You can view the progress of each subtask. For example, while leaving an AD domain, you can check whether the machine account was removed successfully. This log helps in troubleshooting and identifying the exact step at which the task failed.

To view the AD leave status:

1. Follow the steps described in the Leave Active Directory Domain section to remove the Cohesity cluster from an AD domain.
2. Click **Leave Domain**.

   The following error message is displayed if the process fails:

   ```
   Failed to leave Active Directory. Show Subtasks
   ```

3. Click **Show Subtasks** to view the subtask at which the process failed.

Users and Groups

Cohesity allows adding users with different privileges by assigning them various roles within the cluster. These users and groups can manage data and view statistics based on their assigned roles.

Cohesity supports the following types of users and groups. Except for the **support** user, all user types can log in to the Cohesity Dashboard to manage data on the Cohesity cluster and view statistics, depending on their role.

- **Local users:** Local users exist on the Cohesity cluster only.
- **Local groups:** You can define groups by adding local users and Active Directory principals.
- **SSO users:** If the Cohesity cluster is configured to use an identity provider for single sign-on access, you can add SSO users and assign them roles. For more information, see SSO Users.
- **Active Directory principals:** If the Cohesity cluster is joined to an AD domain, you can assign roles to principals in the AD or the AD's trusted domains, which determine the Cohesity cluster access. For more information, see Active Directory (AD).

- **Support user:** Used to access the bash shell of the Cohesity cluster using SSH. The support user account is disabled by default. For more information, see Manage Support User.

Types of Users and Groups

Local Users

Local users are exclusive to the Cohesity cluster. They can be created and managed directly within the system.

Add or Edit a Local User

1. Navigate to **Settings > Access Management**.

   In the **Users & Groups** tab, from the **Add AD Users & Groups** drop-down list, select **Add Local User**, or click the action menu and select **Edit** to edit a local user.

2. Enter the following information:

Add Local User	Enter the user name. Do not enter whitespace characters such as spaces. Do not specify any of these characters: `/ < > : #`
Email Address	Enter the email address associated with this user.
Password	Enter a password that is at least eight characters.
Confirm Password	Enter the same password again to confirm.
Groups	Add the user to one or more user groups by selecting the groups from the drop-down list
Roles	(Optional) Select the appropriate roles. For a detailed description of each role, see Manage Roles.
Effective Date	Specify the date that the user can begin using the account.
Expiration Date	Specify the date when the user's access will be revoked.

Restrict access to specific Objects	Optionally restrict access to specific Objects and Views only by toggling this option on. By default, the allowed actions apply to all Source Objects registered with the Cohesity cluster and all Views. After restricting access, you must specifically add Objects and Views through **Add Registered Object(s)** and **Add Cohesity View(s)**. The user or group does not have access to any Objects or Views until you add them. When a user has access to an Object, that user also has access to all previous Snapshots of that Object and any Objects added to the selected Source folder in the future. For example, if a user has access to an ESX host, they will also have access to VMs added to the host later. Users that have access restricted to specific Objects cannot modify users or Sources even if their role grants them these privileges. Object permissions are replicated for Virtual Machine Objects but not currently for physical Server and View Objects. The Object permissions for a local user or group are not replicated to the remote Cohesity cluster. Local users inherit the permissions of the Restricted Objects provided to the Restricted Groups to which the users belong. Users that have access restricted to specific objects cannot update the Protection Group created by an admin user even if the restricted user has access to all the objects in the Protection Group.
Set Primary User Group for File Access	Enable this option for the user to access file services. From the **Primary Group** drop-down list, select a group as a Primary group. The user can be a part of one or more groups and the SMB/NFS protocol requires a primary group to access the files.

3. Click **Add** or **Save Changes** if editing a user.

Local Groups

Local groups consist of local users and Active Directory (AD) principals. These groups can be defined and managed within the Cohesity cluster.

Add or Edit a Local Group

1. Navigate to **Settings > Access Management**.
2. In the **Users & Groups** tab, from the **Add Users & Groups** drop-down list, select **Add Local Group**, or click the action menu and select **Edit** for a local group.

3. Enter the following information:

Group Name	Enter the group name. Do not enter whitespace characters such as spaces. Only letters, numbers and the special characters given below are allowed: _ - .
Local User	Add one or more users to the group by selecting the users from the drop-down list.
Roles	Select the appropriate roles from the drop-down list. For more information on roles, see Manage Roles.
Effective date	Specify the date when the user group can begin using the account
Restrict access to specific Object	Optionally restrict access to specific Objects and Views only by toggling this option on. By default, the allowed actions apply to all Source Objects registered with the Cohesity cluster and all Views. After restricting access, you must specifically add Objects and Views through **Add Registered Object(s)** and **Add Cohesity View(s)**. The user or group does not have access to any Objects or Views until you add them. When a user has access to an Object, that user also has access to all previous Snapshots of that Object and any Objects added to the selected Source folder in the future. For example, if a user has access to an ESX host, they will also have access to VMs added to the host later. Users that have access restricted to specific Objects cannot modify users or Sources even if their role grants them these privileges. Object permissions are replicated for Virtual Machine Objects but not currently for physical Server and View Objects.
Set Primary User Group for File Access	Enable this option for the user to access file services. From the **Primary Group** drop-down list, select a group as a Primary group. The user can be a part of one or more groups and the SMB/NFS protocol requires a primary group to access the files.

4. Click **Add**, or **Save Changes** if editing a group.

Add a Local Administrator Group Using the CLI

You can use local administrator groups to grant SMB access to views and/or administrative access to the Cohesity cluster.

The Cohesity cluster has a built-in local administrators group called Administrators. By default, the group has only SMB Security privileges and the standard Windows administrator Security ID (SID) S-1-5-32-544. You can use and modify the Administrators group, or create your own local administrator groups and assign roles and SIDs by using the Cohesity CLI.

1. Start the Cohesity CLI remotely or locally as described in the Cohesity CLI Reference Guide.

   Specify the static IPv4 or IPv6 address of one of the Cohesity nodes. For example, if the CLI was downloaded to a Linux system, you might use the following command. Provide a Cohesity cluster username and password.

   ```
   ./iris_cli -server 172.16.3.101 -username=admin
   ```

2. Use the following command syntax to add a local administrator group.

   ```
   group add name=<group-name> smb-only=true roles=<cohesity_roles>
   ```

   (You can use the `role list` command to list the roles defined in the Cohesity cluster.)

   For example:

   ```
   admin@node1> group add name=admin2 smb-only=true roles=cohesity_admin
   GROUP NAME                    : admin2
   DOMAIN                        : LOCAL
   ROLES                         : COHESITY_ADMIN
   SMB PRINCIPAL ENABLED         : true
   ```

Use the following command syntax to add a user or group.

```
group add-smb-principal name=<group_name> type=<user or group> domain=<AD_
domain> principal-name=<user or group> sid=<SID>
```

For example:

```
admin@node1> group add-smb-principal name=admin2 type=group
domain=myorg.ad.domain.com principal-name=PIMS sid=S-1-5-21-4152169185-
4221176486-4244366766-1001
GROUP NAME                    : admin2
DOMAIN                        : LOCAL
ROLES                         : COHESITY_ADMIN
SMB PRINCIPAL ENABLED         : true
SMB PRINCIPAL                 :
NAME                          : PIMS
DOMAIN NAME                   : myorg.ad.domain.com
SID                           : S-1-5-21-4152169185-4221176486-4244366766-
1001
TYPE                          : group
```

> **Tip:** Use the CLI Help by running the following command: `group add-smb-principal help`.

CLI Option	Example	Description
`domain=`	`org.ad.domain.com`	Optional. The AD domain name that includes the principal you are adding.
`name=`	`admin2`	Required. Your choice of a name for the local administrator group.
`principal-name=`	`group1` `jsmith`	Optional. The name of the SMB principal user or group. The name must exist in the AD domain.
`sid=`	`S-1-100-21-8372`	Optional. A unique Security ID for the principal.
`type=`	`group` or `user`	Optional. Specify `user` or `group` to indicate the type of principal you are adding.

Enable User Account Lockout

The admin user can enable account lockout on the user account. User accounts can get locked after a threshold number of failed login attempts. The user cannot log in to the Cohesity Dashboard after three consecutive invalid login attempts for 15 minutes.

> **Note:** You can enable account lockout only for non-admin local users.

Perform the following steps to enable user account lockout:

1. Navigate to **Settings > Access Management**.
2. Select the **Users & Groups** tab.
3. Select the user, click the actions menu (⋮) and select **Lock**.

Disable User Account Lockout

The admin user can disable the account lockout on a user account.

Perform the following steps to disable user account lockout:

1. Navigate to **Settings > Access Management**.
2. Select the **Users & Groups** tab.
3. Select the user, click the actions menu (⋮) and select **Unlock**.

Delete Users and Groups

You can delete users and groups.

> **Note:** You cannot delete default users and groups.

Perform the following steps to delete user and group:

1. Navigate to **Settings > Access Management**.
2. Select the **Users & Groups** tab.
3. Select the user, click the actions menu (⋮) and select **Delete**.
4. Click **Delete**.

Change Local User Password

Using the Cohesity Dashboard, you can change your local user password. By default, the new password must replace at least eight characters with the current password.

Using the following Cohesity CLI command, you can define the number of characters you have to replace in your existing local user password:

```
iris_cli security-config update num-diff-chars=<number_of_characters>
```

For example:

If you want to restrict those six characters in your existing local user password must be replaced while changing the password, then use the following command:

```
iris_cli security-config update num-diff-chars=6
```

> **Note:** The restriction is not applicable if the admin user wants to change the password of other local users in the Cohesity cluster.

To change the local user password:

1. Navigate to **Settings** > **Access Management**.
2. Click the actions menu (⋮) next to the user and click **Edit**.
3. In the **Edit Local User: <user>** page:
    1. Enable **Change Password**.
    2. Enter the **Current Password** and then enter and confirm the new **Password**.
    3. Click **Save Changes**.

Manage LDAP Providers

A Unix user belonging to a primary group can also be a member of many other groups defined in the database. Because of an NFS protocol limitation, NFS users who belong to

more than 16 groups have access issues.

You can add an LDAP provider to the Cohesity cluster to provide access to NFS exports for Unix users belonging to more than 16 groups. The LDAP server provides a central repository to store user identities in a network security system. The Unix group information (GIDs) is stored on the LDAP server. When a Unix user accesses data through NFS on Cohesity, the GIDs corresponding to the users are fetched from the configured LDAP server using the credentials configured by the administrator from the Cohesity GUI.

> **Note:** Cohesity does not support user authentication to the Cohesity Dashboard through LDAP.

If the Cohesity cluster is joined to an Active Directory domain, you can map the AD domain to an LDAP provider across SMB and NFS protocols so users can access the same files on the Cohesity cluster from both Windows and Linux systems. Mapping happens based on the user name in Windows and the user ID in Unix.

> **Note:** Cohesity supports SASL over LDAP by default. If you are seeking stronger security, we recommend you to refer Secure LDAP for LDAP over SSL.

Prerequisites

- Cohesity supports LDAP version 3.
- The port that the LDAP provider listens on must be open. The default port is 389 (outgoing, TCP/UDP).
- Only administrators or users who have the **Manage AD and LDAP** role assigned can add or modify the LDAP provider.

Add an LDAP Provider to the Cohesity cluster

1. Navigate to **Settings > Access Management** and select the **LDAP** tab.
2. Click **Add LDAP Provider**.
3. Specify the name of the LDAP provider. You can change the name later.
4. **LDAP Servers**—Identify the LDAP server to use.
    - **IP or FQDN**—The IP addresses or fully qualified domain names for the LDAP server.
    - **Domain Name**—The domain name to use when querying LDAP from DNS.
    - **Port**—The port on which the LDAP server is listening. The default port is 389.
        - **Base Distinguished Name**—The base distinguished name to use for the LDAP server.
5. **Authentication Type**—Select the authentication type to use:

- **Simple**—The Bind Distinguished Name and bind password to use for authentication to the LDAP server. Indicate whether to use SSL for LDAP connections.
- **Anonymous**—There is no username and password provided to bind to an LDAP server. The bind session has no user associated with it.

6. **Mapped AD Domain**—Select the Active Directory domain to which you want to map the LDAP server.
7. Click **More Options**.
8. **Additional Attributes**—Default values are populated for the following attributes. If required, you can modify the attributes:
   - Common Name Attribute
   - UID Attribute
   - GID Attribute
   - Member of Attribute
   - Username Attribute
9. **Group Query**—A default value is populated. If required, you can modify the **Group Object Class**.
10. **User Query**—A default value is populated. If required, you can modify the **User Object Class**.
11. Click **Add**.

    The LDAP provider is added and the status is displayed on the **Access Management > LDAP** page.

Edit an LDAP Provider

To edit an LDAP Provider:

1. Navigate to **Settings > Access Management** and select the **LDAP** tab.
2. Hover over the LDAP provider that you want to edit, click ⋮, and select **Edit**.
3. On the **Edit LDAP Provider** page, modify the settings as required.
4. Click **Save**.

Delete an LDAP Provider

To delete an LDAP Provider:

1. Navigate to **Settings > Access Management** and select the **LDAP** tab.
2. Hover over the LDAP provider that you want to delete, click ⋮, and select **Delete**.
3. In the **Delete LDAP Provider** dialog, enter **YES** to confirm.
4. Click **Delete**.

Secure LDAP

Lightweight Directory Access Protocol (LDAP) is a protocol used for interacting with Active Directory servers. By default, LDAP traffic is not encrypted. The Cohesity cluster uses the LDAP service to:

- Search users and groups
- Get the group membership of users and groups
- Get the SID of a user or group

> **Note:** This is an Early Access feature. Contact your Cohesity account team to enable the feature.

LDAP over SSL (LDAPS) uses SSL to secure communication. As a result, all LDAP traffic is encrypted. LDAPS communication occurs over port TCP 636. To enable LDAPS, you must install an SSL certificate on every node in the Cohesity cluster.

Considerations

- Open port 389 while:
  - Joining AD
  - Changing configuration on an already joined AD
  - Leaving AD
- Kerberos bind is not supported on port 636. Instead, a simple bind is performed using LDAP bind credentials.
- If you configure AD to use port 636, the setting is global. You cannot configure one AD to use port 389 and another AD to use port 636.
- NTLM authentication is not supported.

LDAP Bind Credentials

LDAP channel binding helps make LDAP authentication over SSL more secure. Bind operations are used to authenticate clients. LDAP bind credentials are stored in the Advanced Encryption Standard (AES) format in the Cohesity cluster and these are used whenever the cluster needs to create a new LDAP connection to the AD. LDAP bind credentials must be the same for all trusted domains.

Use the following CLI to update bind credentials periodically:

```
iris_cli ad update-ldap-bind-credentials domain-name=<example> user-name=<test> password=<test123>
```

After you update the bind credentials, you must restart the I/O Operations service using the following command:

```
admin@198.51.100.12>cluster restart service-names=bridge
```

Use the following CLI to clear LDAP bind credentials:

```
iris_cli ad update-ldap-bind-credentials domain-name=<example> clear-
credentials={}
```

Install SSL Certificates

To enable LDAPS, you must install an SSL certificate on every node in the Cohesity cluster.

> **Important:** Use the Host Shell to perform the steps to install the SSL certificate on every node in the Cohesity cluster.

To install the certificate:

1. Create a `.pem` file from the certificate file imported from the Active Directory domain controller. You can perform this step on any Linux system on which the OpenSSL tool is available. The filename must be in lowercase letters and be the same as the AD domain FQDN:

   ```
   $ openssl x509 -text -in <certificate>.cer -out <example>.pem
   ```

2. If the following directories do not exist, create these directories on the Cohesity cluster node(s):

   ```
   /home/cohesity/data/bridge/openldap/certs
   ```

   ```
   /home/cohesity/data/bridge/openldap/cacerts
   ```

3. Copy the `.pem` file to the `/home/cohesity/data/bridge/openldap/certs` directory.
4. Generate the certificate hash from the `.pem` file:

   ```
   $ openssl x509 -in <example>.pem -hash -noout
   ```

   For example, the certificate hash can be `75b8ef63`.

5. Use the certificate hash to create symbolic links in the `cacerts` directory and point it to the `certs` directory:

   ```
   $ ln -s /home/cohesity/data/bridge/openldap/certs/<example>.pem
   /home/cohesity/data/bridge/openldap/cacerts/75b8ef63.0
   ```

   > **Note:** .0 indicates the version number of the certificate. Each hash is identified by the subject hash. You can install multiple certificates from the same or different AD. The OpenLDAP library picks the correct certificate file for verification using this hash.

Chapter 9: Cloud Platforms

This chapter includes the following topics:

AWS 1403
Requirements 1741
Considerations 1741
Register SQL Server on Linux OS 1742
Azure 1884
GCP 2116
Prerequisites 2128
Add Project IDs to Allowlist 2131

AWS

Cohesity provides a simple and fast backup, recovery, and data management solution for Amazon Web Service (AWS) workloads.

Cohesity supports the following solutions on AWS:

- Cloud Edition

  Deploy Cohesity clusters in AWS to backup workloads to AWS.

- Backup and Recovery

  Backup and recover Amazon services such as EC2 and RDS to Cohesity deployed on-premise or AWS.

- Disaster Recovery

  Disaster recovery failover and failback of VMware VMs backed up using the on-prem Cohesity cluster to AWS using Cloud Edition.

- Replication

Replicate data from on-premise Cohesity cluster to Cloud Edition in AWS.

- Clone VMs Using CloudSpin

  Convert VMware VMs backed up using on-premises Cohesity cluster to Amazon EC2 instances.

- CloudArchive

  Archive data backed up using Cohesity cluster to Amazon S3 for long-term retention.

This chapter includes the following topics:

Supported AWS Regions

Cohesity supports the protection of AWS services in the following regions:

Region Name	Region
US East (N. Virginia)	us-east-1
US East (Ohio)	us-east-2
US West (N. California)	us-west-1
US West (Oregon)	us-west-2
Asia Pacific (Hong Kong)	ap-east-1
Asia Pacific (Mumbai)	ap-south-1
Asia Pacific (Osaka)	ap-northeast-3
Asia Pacific (Seoul)	ap-northeast-2
Asia Pacific (Singapore)	ap-southeast-1
Asia Pacific (Sydney)	ap-southeast-2
Asia Pacific (Tokyo)	ap-northeast-1
Canada (Central)	ca-central-1
Europe (Frankfurt)	eu-central-1

Region Name	Region
Europe (Ireland)	eu-west-1
Europe (London)	eu-west-2
Europe (Paris)	eu-west-3
Europe (Stockholm)	eu-north-1
South America (São Paulo)	sa-east-1
AWS GovCloud (US-West)	us-gov-west-1
AWS GovCloud (US-East)	us-gov-east-1

For more details on these regions, see Regions, Availability Zones, and Local Zones.

AWS and AWS GovCloud Permissions

The following tables list the AWS permissions required to use the Cohesity cloud services. The description explains why the permissions are needed. The permissions are for both AWS and AWS GovCloud.

You can create an AWS policy to grant permissions. For more information, see Assign AWS Permissions.

A JSON file is also provided for each set of permissions. See the online help for the JSON file.

Cloud Edition Deployment Using a Control VM

> **Note:** These AWS permissions are required for a fresh deployment of the Cloud Edition or for a node being added to an existing cluster. Once the Cloud Edition is deployed, the IAM permissions are not required and can be removed.

Open the JSON (or right-click and save as a file).

AWS Resource Type	Permissions	Description
IAM	AddRoleToInstanceProfile AttachRolePolicy CreateInstanceProfile CreateRole DeleteInstanceProfile DeleteRole DetachRolePolicy GetInstanceProfile GetPolicy GetPolicyVersion GetRole GetUser ListAttachedUserPolicies ListGroupsForUser ListUsers PassRole RemoveRoleFromInstanceProfile TagRole	Cohesity uses the access key and secret access key provided in the JSON file in the control VM to validate the IAM user. IAM permissions are required to get the user, the policy for the user and to validate the credentials. IAM role and instance profile permissions are required to create a cluster using IAM role. Cluster creation using IAM role involves assuming role attached to the control VM. This requires permissions to attach/detach role policy, create/delete instance profile, pass/delete/get/create role and Remove role from instance profile.
CloudFormation	CreateStack DeleteStack DescribeStacks GetTemplate ListStackResources UpdateStack ValidateTemplate	Cohesity converts the JSON file provided in the control VM into a Cloud Formation template and creates a Cloud Formation stack. When adding/deleting VMs, this previously created stack is fetched and updated. The stack is deleted when the destroy cluster command is used from the control VM. Validate cluster validates the Cloud Formation template which requires the permission "cloudformation:ValidateTemplate". "cloudformation:DeleteStack" is required while executing the destroy cluster command.

AWS Resource Type	Permissions	Description
EC2	AttachNetworkInterface AttachVolume CreateLaunchTemplate CreateNetworkInterface CreateTags CreateVolume DeleteNetworkInterface DeleteTags DeleteVolume DescribeIamInstanceProfileAssociations DescribeInstanceStatus DescribeInstances DescribeNetworkInterfaces DescribeRegions DescribeSecurityGroups DescribeSubnets DescribeVolumes DetachNetworkInterface DetachVolume ModifyNetworkInterfaceAttribute ModifyVolumeAttribute ReplaceIamInstanceProfileAssociation RunInstances StartInstances StopInstances TerminateInstances	Creating a Cloud Edition cluster requires creating AWS EC2 instances. Network Interface and volumes are created and attached to the instance to create a cluster node in a particular region. Tags are created and added to these EC2 services. Permissions to start/stop these instances are required while executing commands to start/stop cluster from the control VM. Permissions to delete all the EC2 services created while creating a cluster are required while executing destroy cluster/delete VMs from the control VM. "ec2:ReplaceIamInstanceProfileAssociation" and "ec2:DescribeIamInstanceProfileAssociation" are required to create cluster using IAM role. These permissions are required to assume the role attached to the control VM.
SSM	GetCommandInvocation SendCommand	Cohesity uses the SSM agent for xlarge nodes only. SSM agent is used to communicate with the cluster node VMs when they come up. This communication is required to send commands to register the external target and setup the tiering. Therefore, SSM commands are required in case of XLarge nodes only.

AWS Resource Type	Permissions	Description
S3	CreateBucket DeleteBucket DeleteObject GetObject PutBucketPublicAccessBlock PutObject ListBucket	These permissions are required when the CloudFormation template size exceeds 51200 bytes and Cohesity needs to upload the template to an S3 bucket. Cohesity supports this in cluster expansion flow.

Cloud Edition Deployment Using Helios

> **Note:** These AWS permissions are required for a fresh deployment of the Cloud Edition or for a node being added to an existing cluster. Once the Cloud Edition is deployed, the IAM permissions are not required and can be removed.

Open the JSON (or right-click and save as a file).

AWS Resource Type	Permissions	Description
IAM	ListAttachedUserPolicies GetPolicyVersion GetPolicy ListGroupsForUser ListUsers ListPolicies GetUser GetRole CreateRole TagRole AttachRolePolicy DetachRolePolicy CreateInstanceProfile RemoveRoleFromInstanceProfile DeleteInstanceProfile PassRole AddRoleToInstanceProfile GetInstanceProfile DeleteRole	Cohesity uses the access key and the secret access key provided to validate the IAM user. IAM permissions are required to get the user, the policy for the user and to validate the credentials. To create a cluster by using Helios, Cohesity uses System Service Manager (SSM). A role is created for SSM and passed onto the service. These IAM permissions are required to create a policy, create a role for SSM operation, attach the policy to this role and pass the role onto the SSM service for performing operations to create a cluster using Helios. Delete role and delete role policy permissions are required to delete the role and policy created for the SSM operation after the task is complete.
CloudFormation	UpdateStack ListStackResources CreateStack GetTemplate DeleteStack DescribeStacks DescribeStackEvents ValidateTemplate	Cohesity creates a CloudFormation template using the information provided on the UI for cluster creation, and creates a CloudFormation stack. The stack is deleted when destroy cluster command is used from the control VM. Validate cluster validates the Cloud Formation template which requires the permission "`cloudformation:ValidateTemplate`". "`cloudformation:DeleteStack`" is required while executing destroy cluster.

AWS Resource Type	Permissions	Description
EC2	AttachNetworkInterface AttachVolume AuthorizeSecurityGroupEgress AuthorizeSecurityGroupIngress CreateLaunchTemplate CreateNetworkInterface CreateSecurityGroup CreateTags CreateVolume DeleteNetworkInterface DeleteSecurityGroup DeleteTags DeleteVolume DescribeAvailabilityZones DescribeIamInstanceProfileAssociations DescribeInstanceStatus DescribeInstances DescribeNetworkInterfaces DescribeRegions DescribeSecurityGroups DescribeSubnets DescribeVolumes DescribeVpcs DetachNetworkInterface DetachVolume ModifyNetworkInterfaceAttribute ModifyVolumeAttribute ReplaceIamInstanceProfileAssociation RevokeSecurityGroupEgress	Creating a cluster requires creating AWS EC2 instances. Network Interface and volumes are created and attached to the instance to create a cluster node in a particular region. Tags are created and added to these EC2 services. Permissions to start/stop these instances are required while executing commands to start/stop cluster from the control VM. Permissions to delete all the EC2 services created while creating cluster are required while executing destroy cluster/delete VMs from the control VM. While creating a cluster using Helios, users can create a new security group and deploy the cluster using that security group instead of using the existing security group. Therefore, Cohesity needs permission to create the security group, delete the security group, authorize the security group ingress and egress, and revoke the security group ingress and egress.

AWS Resource Type	Permissions	Description
	RevokeSecurityGroupIngress RunInstances StartInstances StopInstances TerminateInstances	
SSM	GetCommandInvocation SendCommand	Cohesity uses the SSM agent to communicate with the cluster node VMs when they come up. This communication is required to send commands to create the cluster and also to check the cluster creation status. Therefore, SSM commands are required to create a cluster using Helios.
S3	CreateBucket DeleteBucket DeleteObject GetObject PutBucketPublicAccessBlock PutObject ListBucket GetBucketObjectLockConfiguration GetObjectRetention PutObjectRetention	These permissions are required when the CloudFormation template size exceeds 51200 bytes and Cohesity needs to upload the template to an S3 bucket. `S3:GetBucketObjectLockConfiguration`, `S3:GetObjectRetention`, and `S3:PutObjectRetention` are the permissions required if you are enabling object lock. • `S3:GetBucketObjectLockConfiguration`: Gets the Object Lock configuration for a bucket. • `S3:GetObjectRetention`: Retrieves an object's retention settings. • `S3:PutObjectRetention`: Places an Object Retention configuration on an object.

CloudSpin On Demand

Open the JSON (or right-click and save as a file).

AWS Resource Type	Permissions	Description
IAM	AddRoleToInstanceProfile AttachRolePolicy CreateInstanceProfile CreateRole GetInstanceProfile GetRole GetRolePolicy GetUser PassRole PutRolePolicy TagRole	Cohesity creates a VM import policy which is assigned to a role in AWS IAM. The custom created role is assigned to the S3 bucket where the corresponding VM disks are stored which are later used to import into EC2 images and snapshots. These EC2 images and snapshots are used for launching the instance in AWS during deployment. "iam:GetUser" and "iam:GetRole" are used to fetch the user information and validate the credentials while registering the AWS IAM user on the cluster. "iam:AddRoleToInstanceProfile" is required to register source using IAM role.
S3 Bucket	AbortMultipartUpload CreateBucket DeleteObject DeleteObjectTagging DeleteObjectVersion DeleteObjectVersionTagging GetBucketAcl GetBucketTagging GetObject GetObjectAcl GetObjectTagging GetObjectTorrent GetObjectVersion GetObjectVersionAcl GetObjectVersionTagging GetObjectVersionTorrent ListMultipartUploadParts PutBucketAcl PutBucketTagging PutBucketPublicAccessBlock PutObject PutObjectAcl PutObjectTagging PutObjectVersionAcl PutObjectVersionTagging RestoreObject	Cohesity creates a S3 bucket in AWS. The VM disk is copied and stored as an object in this S3 bucket. A policy is attached to this bucket, which is later used to import into EC2 images and snapshots. These EC2 images and snapshots are used for launching the instance in AWS.

AWS Resource Type	Permissions	Description
EC2	AttachNetworkInterface AttachVolume CancelImportTask CreateImage CreateNetworkInterface CreateSecurityGroup CreateSnapshot CreateTags CreateVolume DeleteNetworkInterface DeleteSnapshot DeleteTags DeleteVolume DeregisterImage DescribeAvailabilityZones DescribeImages DescribeImportImageTasks DescribeImportSnapshotTasks DescribeInstanceStatus DescribeInstanceTypes DescribeInstances DescribeKeyPairs DescribeNetworkInterfaces DescribeRegions DescribeReservedInstancesOfferings DescribeSecurityGroups DescribeSnapshots DescribeSubnets DescribeVolumes DescribeVpcs DetachNetworkInterface DetachVolume ImportImage ImportSnapshot ModifyInstanceAttribute ModifyNetworkInterfaceAttribute ModifyVolumeAttribute RegisterImage	These permissions are required to register the AWS IAM user on the Cohesity cluster. Once the IAM user is registered on the cluster, describe permissions on every EC2 service is required for the user to successfully select from all the avaible options for each EC2 services from the drop down while performing any of the AWS workflows. Cohesity imports the VM disk stored in the S3 bucket into EC2 images and snapshots. These snapshots and images are used to create instance in AWS. While creating the instance, Cohesity creates network interfaces, disks, and volumes. Tags are created and added to these artifacts created in AWS. To tear down this deployment VM, delete permissions are required on all artifacts created in AWS. Once the convert and deploy task is complete for all the volumes, snapshots created for this task are cleaned up. The instance is torn down on demand.

AWS Resource Type	Permissions	Description
	RunInstances StartInstances StopInstances TerminateInstances	
KMS	CreateGrant ReEncryptFrom ReEncryptTo RetireGrant	These permissions are required to Cloudspin and deploying an instance in AWS region with encryption support. These permissions are required while importing images and snapshots in EC2 for AWS region with encryption enabled.
SSM	GetCommandInvocation ListCommandInvocations SendCommand	Cohesity creates a converter instance on AWS to run some commands on the boot disk of VM in order to boot it up as instance on AWS. SSM is used to run these commands on the converter instance.

CloudSpin Policy Based Full Backup

Open the JSON (or right-click and save as a file).

AWS Resource Type	Permissions	Description
IAM	AddRoleToInstanceProfile AttachRolePolicy CreatePolicy CreateRole GetInstanceProfile GetPolicy GetRole GetRolePolicy GetUser GetUserPolicy ListAccessKeys ListPolicies ListRolePolicies PassRole PutRolePolicy TagRole	Cohesity creates a VM import policy which is assigned to a role in AWS IAM. The custom created role is assigned to the S3 bucket where the corresponding VM disks are stored and later used to import into the EC2 images and snapshots. These EC2 images and snapshots are used for launching the instance in AWS. "iam:GetUser", "iam:ListAccessKeys" and "iam:GetUserPolicy" are used to fetch the user information and validate the credentials while registering the AWS IAM user on the cluster. "iam:AddRoleToInstanceProfile" is required to register source using IAM role.
S3 Bucket	CreateBucket DeleteObject GetBucketAcl GetBucketTagging GetBucketPolicy GetObject ListBucket PutBucketPolicy PutBucketTagging PutBucketPublicAccessBlock PutObject	Cohesity creates a S3 bucket in AWS. The VM disk is copied and stored as an object in this S3 bucket. A policy is attached to this bucket, which is later used to import into EC2 images and snapshots. These EC2 images and snapshots are used for launching the instance in AWS.

Once the IAM user is registered on the cluster, describe permissions on every EC2 service is required for the user to successfully select from all the avaible options for each EC2 services from the drop down while performing any of the AWS workflow. Cohesity imports the vm disk stored in the S3 bucket into EC2 image and snapshots. These snapshots and Images are used to create instance in AWS. While creating the instance, we create network interfaces, disks, and volumes. Tags are created and added to these artifacts creates in AWS. To tear down this deployment VM, delete permissions are required on all artifacts created in AWS. Once the retention peroid of the cloud spin task is over, the correcponding EC2 AMI and snapshots are deleted which requires delete permissions as well.

AWS Resource Type	Permissions	Description
	DescribeVolumeStatus DescribeVolumes DescribeVpcAttribute DescribeVpcClassicLink DescribeVpcClassicLinkDnsSupport DescribeVpcEndpointConnections DescribeVpcEndpointServiceConfigurations DescribeVpcEndpointServicePermissions DescribeVpcEndpointServices DescribeVpcEndpoints DescribeVpcPeeringConnections DescribeVpcs DetachVolume ImportImage ImportInstance ImportSnapshot ImportVolume ModifyInstanceAttribute RunInstances StartInstances StopInstances TerminateInstances	
KMS	CreateGrant ReEncryptFrom ReEncryptTo RetireGrant	These permissions are required to Cloudspin and deploying an instance in AWS region with encryption support. These permissions are required while importing images and snapshots in EC2 for AWS region with encryption enabled.
SSM	GetCommandInvocation ListCommandInvocations SendCommand	Cohesity creates a converter instance on AWS to run some commands on the boot disk of VM in order to boot it up as instance on AWS. SSM is used to run these commands on the converter instance.

CloudSpin Policy Based Incremental Backup

Open the JSON (or right-click and save as a file).

AWS Resource Type	Permissions	Description
IAM	AddRoleToInstanceProfile AttachRolePolicy CreatePolicy CreateRole GetInstanceProfile GetPolicy GetRole GetRolePolicy GetUser GetUserPolicy ListAccessKeys ListPolicies ListRolePolicies PassRole PutRolePolicy TagRole	Cohesity creates a VM import policy which is assigned to a role in AWS IAM. The custom created role is assigned to the S3 bucket where the corresponding VM disks are stored, for the first full data copy run of incremental Cloud Spin, which are later used to import into EC2 images and snapshots. These EC2 images and snapshots are used for launching the instance in AWS. "iam:GetUser" and "iam.GetRole" are used to fetch the user information and validate the credentials while registering the AWS IAM user on the cluster. "iam:AddRoleToInstanceProfile" is required to register source using IAM role.
S3 Bucket	CreateBucket DeleteObject GetBucketAcl GetBucketTagging GetBucketPolicy GetObject ListBucket PutBucketPolicy PutBucketTagging PutBucketPublicAccessBlock PutObject	Cohesity creates a S3 bucket in AWS. The VM disk is copied and stored as an object in this S3 bucket. A policy is attached to this bucket, which is later used to import into EC2 images and snapshots. These EC2 images and snapshots are used for launching the instance in AWS.

AWS Resource Type	Permissions	Description
EC2	AttachVolume AuthorizeSecurityGroupIngress CancelImportTask CreateFleet CreateImage CreateNetworkInterface CreateSecurityGroup CreateSnapshot CreateTags CreateVolume DeleteSnapshot DeleteTags DeleteVolume DeregisterImage DescribeAvailabilityZones DescribeFleetInstances DescribeImages DescribeImportImageTasks DescribeImportSnapshotTasks DescribeInstanceAttribute DescribeInstanceCreditSpecifications DescribeInstanceStatus DescribeInstances DescribeKeyPairs DescribeNetworkInterfaces DescribeRegions DescribeReservedInstances DescribeReservedInstancesListings DescribeReservedInstancesModifications DescribeReservedInstancesOfferings DescribeSecurityGroupReferences DescribeSecurityGroups DescribeSnapshotAttribute DescribeSnapshots DescribeSubnets DescribeTags DescribeVolumeAttribute	These permissions are required to register the AWS IAM user on the Cohesity cluster. Once the IAM user is registered on the cluster, describe permissions on every EC2 service is required for the user to successfully select from all the avaible options for each EC2 services from the drop down while performing any of the AWS workflow. Cloud spin of a VM with Incremental Data copy requires the user to provide a VPC and Subnet while policy creation along with the Region, this is required because this workflow creates a temporary instance for copying the difference in data to AWS. Cohesity imports the vm disk stored in the S3 bucket into EC2 image and snapshots. These snapshots and Images are used to create instance in AWS. While creating the instance, we create network interfaces, disks, and volumes. Tags are created and added to these artifacts creates in AWS. To tear down this deployment VM, delete permissions are required on all artifacts created in AWS. Once the retention peroid of the cloud spin task is over, the correcponding EC2 AMI and snapshots are deleted which requires delete permissions as well.

	DescribeVolumeStatus DescribeVolumes DescribeVpcAttribute DescribeVpcClassicLink DescribeVpcClassicLinkDnsSupport DescribeVpcEndpointConnections DescribeVpcEndpointServiceConfigurations DescribeVpcEndpointServicePermissions DescribeVpcEndpointServices DescribeVpcEndpoints DescribeVpcPeeringConnections DescribeVpcs DetachVolume ImportImage ImportInstance ImportSnapshot ImportVolume ModifyInstanceAttribute RunInstances StartInstances StopInstances TerminateInstances	
KMS	CreateGrant ReEncryptFrom ReEncryptTo RetireGrant	These permissions are required to Cloudspin and deploying an instance in AWS region with encryption support. These permissions are required while importing images and snapshots in EC2 for AWS region with encryption enabled.
SSM	GetCommandInvocation ListCommandInvocations SendCommand	Cohesity creates a converter instance on AWS to run some commands on the boot disk of VM in order to boot it up as instance on AWS. SSM is used to run these commands on the converter instance.

Cloud Native Backup and Recovery

Open the JSON (or right-click and save as a file).

AWS Resource Type	Permissions	Description
IAM	AddRoleToInstanceProfile AttachRolePolicy CreateRole DeleteRole DeleteRolePolicy GetAccessKeyLastUsed GetInstanceProfile GetRole GetRolePolicy GetUser GetUserPolicy ListAccessKeys ListRolePolicies ListRoleTags ListRoles PassRole PutRolePolicy TagRole UntagRole UpdateRole UpdateUser	Cohesity uses the secret access key and access key provided to validate the register the source on the cluster. During IAM user registration, the credentials for the user are fetched and validated against the credentails provided. The policy of the user needs to be fetched after registration. IAM permissions are required for these actions. Cohesity creates an S3 bucket and attaches a policy and role to it while recovering the VM back to AWS. The boot disk of the VM is put, as an object, into the bucket which is used for importing the VM disk as an EC2 Image. The AWS EC2 instance is recovered by launching this EC2 Image. IAM permissions are required to create this role and policy and attach it to the bucket. Delete Role and Delete Role policy are required to delete the role and policy created and attached to the S3 bucket after the task is complete. "iam:AddRoleToInstanceProfile" is required to register source using IAM role.
S3	CreateBucket DeleteObject GetBucketLocation GetBucketTagging GetObject ListBucket ListBucketVersions PutBucketTagging PutBucketPublicAccessBlock PutObject	Cohesity creates an S3 bucket and attaches a policy and role to it while recovering the VM back to AWS. This boot disk of the VM is put, as an object, into this bucket which is used for importing the VM disk as an EC2 Image. The AWS EC2 instance is recovered by launching this EC2 Image. S3 permissions are required to create this bucket and put the VM disk as an object into this bucket.

AWS Resource Type	Permissions	Description

S3 Backup and Recovery

Open the JSON (or right-click and save as a file).

AWS Resource Type	Permissions	Description
S3	"s3:GetBucketLocation", "s3:GetBucketOwnershipControls", "s3:GetBucketTagging", "s3:GetBucketVersioning", "s3:GetObject", "s3:GetObjectAcl", "s3:GetObjectVersion", "s3:ListAllMyBuckets", "s3:ListBucket", "s3:PutObject" "s3:ListBucketVersions" "s3:DeleteObject" "s3:ListBucketMultipartUploads" "s3:ListMultipartUploadParts" "s3:AbortMultipartUpload" "s3:DeleteObjectVersion" "s3:GetLifecycleConfiguration" "s3:PutObjectRetention" "s3:RestoreObject"	"s3:GetBucketLocation" is required to get the location of the bucket for cloud tier workflow. "s3:GetBucketVersioning" is used to check whether buckets have versioning enabled. "s3:ListAllMyBuckets" This grants permission to list all buckets owned by the authenticated sender of the request. "s3:PutObjectRetention" is used to set object-level locks in case of WORM enabled archives. "s3:GetBucketTagging" This grants permission to return the tag set associated with an Amazon S3 bucket. "s3:GetObjectAcl" This grants permission to return the access control list (ACL) of an object. "s3:ListAllMyBuckets" This grants permission to list all buckets owned by the authenticated sender of the request. “s3:PutObject" Adds an object to a bucket. "s3:ListBucket" Returns a list of all buckets owned by the authenticated sender of the request. "s3:GetBucketOwnershipControls" This grants permission to retrieve ownership controls on a bucket. "s3:ListBucketVersions" grants permission to list metadata about all the versions of objects in an Amazon S3 bucket. "s3:DeleteObject" Removes an object from a bucket. "s3:ListBucketMultipartUploads" Perform ListMultiPartUploads on the buckets. "s3:ListMultipartUploadParts" This operation lists in-progress multipart uploads in a bucket. "s3:AbortMultipartUpload" This operation aborts a multipart upload. "s3:DeleteObjectVersion" Delete object versions from Amazon S3 buckets. "s3:GetBucketLocation" Required to get the location of the bucket for cloud tier workflow. "s3:GetLifecycleConfiguration" Returns the lifecycle configuration information set on the bucket. "s3:GetBucketVersioning" Returns the versioning state of a

AWS Resource Type	Permissions	Description
		bucket. "s3:PutObjectRetention" Used to set object-level locks in case of WORM enabled archives. "s3:GetLifecycleConfiguration" Returns the lifecycle configuration information "s3:GetBucketVersioning" Used to check whether buckets have versioning enabled. "s3:RestoreObject" Restores an archived copy of an object back into Amazon S3
KMS	"kms:GenerateDataKey"	"kms:GenerateDataKey" This controls permission to use the AWS KMS key to generate data keys. You can use the data keys to encrypt data outside of AWS KMS (For encrypted buckets with managed keys).

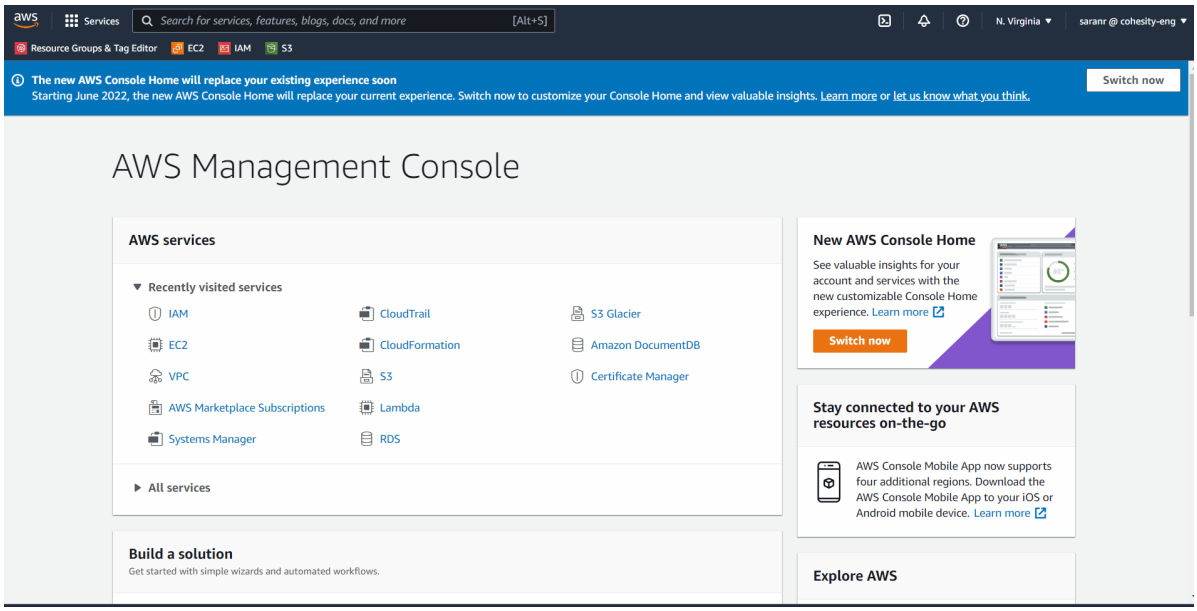
Assign AWS Permissions

AWS permissions are required to use Cohesity cloud services such as CloudArchive and CloudSpin. Cohesity recommends that you create an AWS policy with permissions and then attach it to IAM users. For example, you can create a policy that grants permissions for back up and recovery and attach it to users.

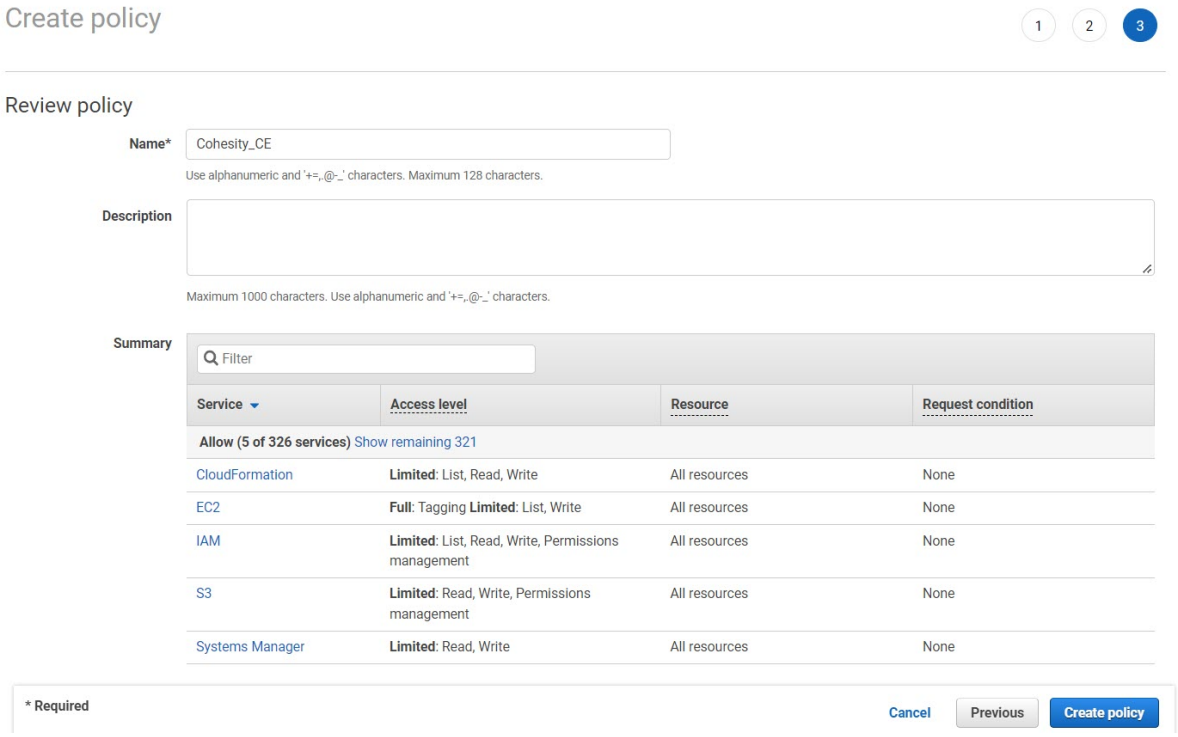
The permissions are available as JSON in AWS and AWS GovCloud Permissions. You can copy the JSON and paste it into the policy, as described below.

Create a Policy with Permissions

1. Log in to the Amazon AWS console using your AWS account with admin privileges.
2. In the top left of the menu bar, select **Services**.
3. Under **Security, Identity & Compliance**, select **IAM**.
4. In the left frame, click **Policies**.
5. Click **Create policy**.
6. In the **Create policy** page, select the **JSON** tab.
7. Copy the appropriate JSON code from AWS and AWS GovCloud Permissions and paste it in the **JSON** tab.
8. Click **Next: Tags**. Adding tags is optional.



9. Click **Next: Review**.
10. Enter a name for the policy and an optional description and click **Create Policy**.

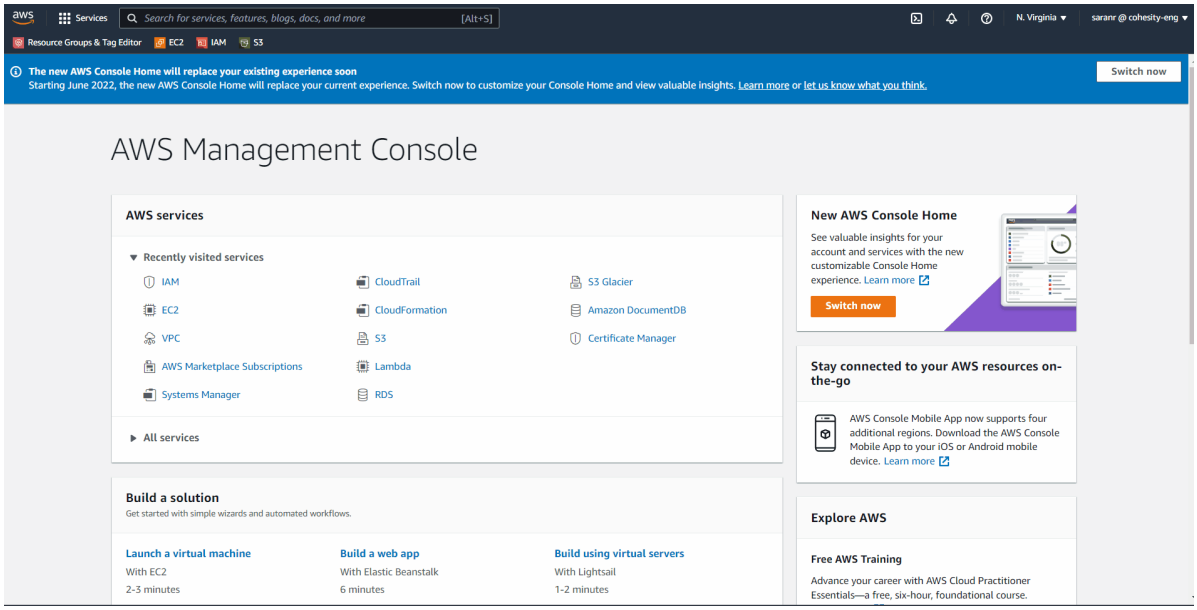


Now you can attach the policy to an IAM user.

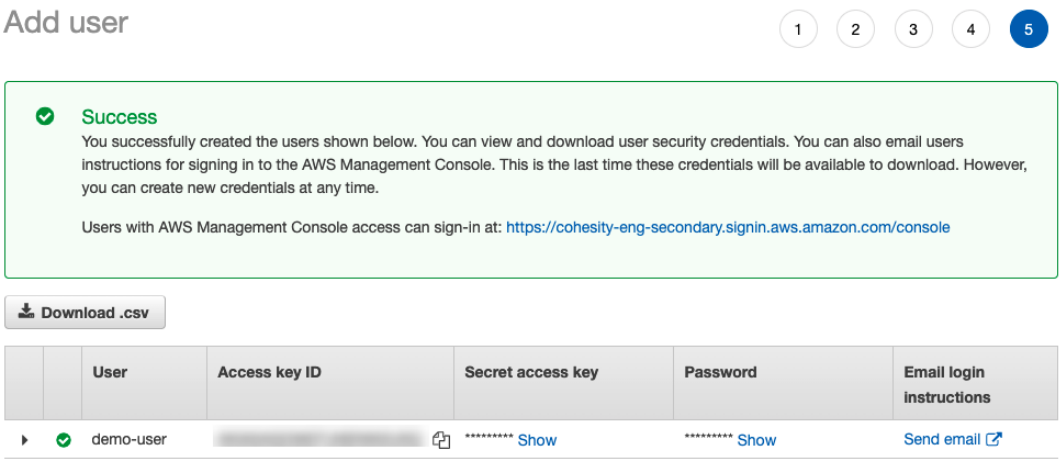
Create an IAM User

1. Log in to the Amazon AWS console using your AWS account with admin privileges.
2. In the top left of the menu bar, select **Services**.

3. Under **Security, Identity & Compliance**, select **IAM**.
4. In the left frame, click **Users**.
5. Click **Add users**.
6. In the **User name** field, enter a user name such as `CohesityCE`.
7. For **Access type**, select **Programmatic access** and click **Next: Permissions**.



8. Click **Attach existing policies directly**, then search for the name of the policy you created previously and select that policy.
9. Click **Next: Tags**.
10. Optionally, enter tags for the policy and then click **Next: Review**.
11. Review your choices and then click **Create User**.
12. In the **Secret access key** column, click **Show**.



13. Copy and paste the **Access key ID** and the **Secret access key** in to a text file. You'll need them later when you register the AWS Cloud source.
14. Click **Close**.

AWS Permission Updates for 7.3.1 Upgrade

If you have upgraded your cluster to Cohesity 7.3.1 from an earlier version and already have an AWS account registered, you must add new permissions to protect the newly supported AWS workloads:

- Amazon RDS (Ingest-based protection)
- Amazon Redshift
- Amazon DocumentDB
- Amazon DynamoDB

AWS Account Registered Using IAM User Method

Update the IAM policy associated with the IAM user and add the following permissions:

> **Note:** You cannot protect Amazon DynamoDB using IAM user method.

Required Permissions

```
rds:CopyDBClusterSnapshot
rds:CreateDBClusterSnapshot
rds:CreateDBInstance
rds:DeleteDBClusterSnapshot
rds:DescribeDBClusterSnapshots
rds:DescribeDBClusters
rds:DescribeTenantDatabases
rds:ModifyDBClusterSnapshotAttribute
rds:RestoreDBClusterFromSnapshot
```

```
docdb-elastic:ListClusters
redshift:DescribeClusters
redshift:GetClusterCredentials
redshift:GetClusterCredentialsWithIAM
redshift:ListDatabases
redshift-data:CancelStatement
redshift-data:DescribeStatement
redshift-data:ExecuteStatement
redshift-data:GetStatementResult
redshift-data:ListDatabases
s3:CreateBucket
s3:ListBucket
s3:GetObjectAcl
s3:GetObject
s3:PutObject
s3:DeleteObject
```

Steps to update IAM Policy Permissions

1. From the AWS Management Console, select **Users**.
2. Open the **Permissions** tab and locate the attached policy.
3. Create new policy or update existing policy with above permissions.

AWS Account Registered Using IAM Role Method

Update the existing *CohesitySourceRegistrationRole* by adding the following permissions.

Permissions for RDS, Redshift, and DocumentDB

```
rds:CopyDBClusterSnapshot
rds:CreateDBClusterSnapshot
rds:CreateDBInstance
rds:DescribeDBClusters
rds:DeleteDBClusterSnapshot
rds:DescribeDBClusterSnapshots
rds:DescribeTenantDatabases
rds:ModifyDBClusterSnapshotAttribute
rds:RestoreDBClusterFromSnapshot
redshift:DescribeClusters
redshift:GetClusterCredentials
redshift:GetClusterCredentialsWithIAM
redshift:ListDatabases
redshift-data:CancelStatement
redshift-data:DescribeStatement
redshift-data:ExecuteStatement
redshift-data:GetStatementResult
redshift-data:ListDatabases
```

Steps to Update Role Permissions

1. Navigate to **IAM** > **Roles** in the AWS Management Console.
2. Search for and open *CohesitySourceRegistrationRole*.
3. Open the **Permissions** tab and locate the inline policy *source-regis-access*.
4. Click **Edit**.
5. Add the permissions to the first statement's Action array.
6. Click **Next**, then save changes.

Add a New Inline Policy for DynamoDB Protection

To protect DynamoDB workloads, you must add a new inline policy:

Steps to Add Inline Policy

1. Go to **IAM** > **Roles**.
2. Open *CohesitySourceRegistrationRole*.
3. Under the **Permissions** tab, select **Add permissions** > **Create inline policy**.
4. Switch to the **JSON** tab.
5. Paste the DynamoDB permissions JSON policy:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DynamoDBManagement",

            "Condition": {
                "StringLike": {
                    "aws:ResourceTag/UniqueTag": "cohesity_*"
                }
            }
        },
        {
            "Sid": "CloudWatchLogsDescribe",
            "Effect": "Allow",
            "Action": [
```

```
                "logs:DescribeLogGroups"
            ],
            "Resource": "arn:aws:logs:*:*:log-group*"
        },
        {
            "Sid": "CloudWatchLogsForDDBAndGlue",
            "Effect": "Allow",
            "Action": [
                "logs:CreateLogGroup",
                "logs:CreateLogStream",
                "logs:DescribeLogStreams",
                "logs:GetLogEvents",
                "logs:PutLogEvents",
                "logs:PutRetentionPolicy"
            ],
            "Resource": [
                "arn:aws:logs:*:*:log-group:/aws-dynamodb/*",
                "arn:aws:logs:*:*:log-group:/aws-glue/*"
            ]
        }
    ]
}
```

6. Assign a policy name (example, *CohesityDynamoDBPolicy*).
7. Click **Create policy**.

Amazon Elastic Compute Cloud Instances

Cohesity provides a simple, fast, and cost-effective backup, recovery, and data management solution for Amazon Elastic Compute Cloud (EC2) instances in your AWS account.

Plan and Prepare for Amazon EC2 Protection

Review the following considerations before you perform the backup and recovery of AWS EC2 instances:

- **Issue**: The backup of the AWS VMs will fail with the following error if you have configured to launch the fleet instance in the VPC and subnet of a region different

from the protected VM's region: `VPC and Subnet are not specified for the fleet instance. Please specify the same by editing the source.`

Workaround: Update the registered AWS source to launch the fleet instance in the same subnet as protected VMs.

- When recovering an AWS EC2 instance running Microsoft Windows OS with UEFI Preferred boot mode, the process will utilize a base AMI based on the 'Current Instance Boot Mode' of the source EC2. For example, if the source EC2 was configured as UEFI-preferred, the recovery will automatically use an AMI that supports UEFI boot mode.
- Cohesity does not support the recovery of AWS EC2 instances to a different zone.
- You cannot recover files and folders or perform IVM from a **Cohesity Protection Service** enabled Protection Group.
- Backups for ARM-based Amazon EC2 instances from the marketplace are only supported using the EBS diff API-based backup method.
- You cannot exclude EBS volumes at the object level (manual volume exclusion) for auto-protected EC2 instances. To exclude EBS volume for auto-protect VMs, you must use the **Volume Exclusion Settings** option in the Additional Settings.
- The following table lists the service endpoints required for registering an AWS source:

AWS Resource Type	Service Endpoints
IAM	iam.amazonaws.com
CloudFormation	cloudformation.<regionId>.amazonaws.com
EC2	ec2.<regionId>.amazonaws.com
KMS	kms.<region>.amazonaws.com
S3	s3.<region>.amazonaws.com s3-fips.<region>.amazonaws.com
SSM	ssm.<region>.amazonaws.com
EBS	ebs.<region>.amazonaws.com
RDS	rds.<region>.amazonaws.com

- File-level recovery is not supported if you have backed up EC2 instances using Snapshot Manager as the Protection Type.

- For recovery to: **Same AWS Account, same AWS Region**: No prerequisites.
- For recovery to: Different AWS Account, same AWS Region:
  - Target AWS account should be registered as a data source in the same destination cloud region.
  - If you have enabled **Encryption Settings** for an EC2 instance that is already encrypted, then the EC2 instance will be recovered with the encryption provided in the **Encryption Settings**.
- For recovery to: Different AWS Account, different AWS Region:
  - Target AWS account should be registered as a data source in the same destination cloud region.
  - If you have enabled **Encryption Settings** for an EC2 instance that is already encrypted, then the EC2 instance will be recovered with the encryption provided in the **Encryption Settings**.
- You can perform files and folder recovery to an EC2 Linux instance only if the EC2 Linux instance is of x86_64 architecture.
- File-level recovery is not supported for AWS EC2 instances with the XFSv5 file system.
- When browsing files or folders for recovery, Cohesity does not display files or folders with an absolute path length exceeding approximately 3,500 characters. To recover these files or folders, select the parent directory.
- The following are the considerations of AWS C2S:
  - Amazon EC2 Simple Systems Manager (SSM) is not available in C2S. You must install the Cohesity Agent on the target machine for FLR.
  - AWS diff APIs are not available in C2S.
  - All VM restores are fleet-based.

Support for HTTP Proxy Server

HTTP Proxy is used if the cluster using the proxy server is behind a private network and cannot reach the internet to go through the proxy. Cohesity cluster supports HTTP proxy for AWS sources for performing the following workflows:

- On-demand CloudSpin
- Policy-based CloudSpin
- Cloud-native backup and recovery
- Disaster recovery failback workflows

To enable HTTP proxy, contact Cohesity Support.

Register an AWS Cloud Source

You can register an AWS Cloud Source to support the following functionality:

- **Backing up AWS infrastructure** — For this functionality, the registered AWS Cloud source contains the Amazon EC2 and/or S3 to back up.

  > **Note:** The backup support for AWS S3 is an Early Access feature. Contact your Cohesity account team to enable the feature.

- **Converting and cloning VMware VMs** to AWS — For this functionality, the registered AWS Cloud source is where the VMs are cloned to. Converting and cloning VMs occur during the following use cases:
  - Clone VMs from On-Premises to a Cloud Service (On-Demand CloudSpin)
  - Clone VMs to Cloud Using CloudSpin
  - Replicate and Clone VMs in Cloud Edition

Supported Authentication Methods

Depending on the platform you have deployed your Cohesity cluster, AWS Account can be registered with the Cohesity cluster with the following augmentation method:

- **IAM User-based authentication method**: This authentication method is supported if you are registering AWS account as a source on a physical cluster, virtual edition cluster, DataProtect for cloud (legacy), or DataProtect for cloud cluster.
- **IAM role-based authentication method**: This authentication method is supported only if you are registering AWS account as a source on both DataProtect for cloud (legacy) and DataProtect for cloud.

Register AWS Standard or Gov Source

To start protecting an Amazon resources, once you meet the requirements, you need to register the AWS account as a source with the Cohesity cluster.

To register the AWS Account as the source:

1. Select **Data Protection** > **Sources**.
2. Select **Register** > **Virtual Machines**.
3. From the **Select Hypervisor Source Type** drop-down, select **AWS : IAM User/Role**.
4. Select the AWS category **Standard** or **Gov**. For information on registering AWS account with C2S as the AWS catergory, see To register an AWS C2S source using IAM Role.
5. Select the authentication method:
   - **IAM User**
   - **IAM Role**

> **Note:** This option to choose authentication method is available only for DataProtect for cloud and DataProtect for cloud (legacy) clusters. For Physical and Virtual Edition clusters, only IAM user-based authentication is available.

6. Perform the steps described in the table depending on the authentication method you choose:

Authentication Method	Steps
IAM User	1. Specify the **Access Key ID** for the new IAM user that was created to back up a AWS Cloud source or convert and clone Amazon EC2 to an AWS Cloud Source. For general information about AWS keys, see Access Keys (Access Key ID and Secret Access Key). 2. Specify the **Secret Access Key** for the new IAM user that was created to back up a AWS Cloud Source or convert and clone Amazon EC2 to an AWS Cloud Source. For general information about AWS keys, see Access Keys (Access Key ID and Secret Access Key). 3. Specify the Amazon Resource Name **(ARN)** of the IAM user in the following format: `arn:aws:iam::<account-id>:user/<username>` For more information, see Amazon Resource Names (ARNs). For more information on authenticating Cohesity cluster for Amazon S3 protection, see Authenticate Using IAM User. **Note:** AWS Security Token Service (STS) must be enabled in all AWS regions that are activated in your AWS account.

Authentication Method	Steps
IAM Role	1. Click the **CloudFormation Template** link to download the CFT file. 2. Run the CloudFormation Template in your AWS account to create the IAM roles and policies that Cohesity requires for authentication. For more information, see Execute CloudFormation Template to Register AWS Using IAM Role. 3. Specify your **AWS Account ID**. 4. Specify the IAM Role in the following format: `arn:aws:iam::<account-id>:role/<role-name>` Where, `<account-id>` is the account ID of the AWS account that has the AWS resources to protect. `<role-name>` is the role created after running the CFT template. For more information on authenticating Cohesity cluster for Amazon S3 protection, see Authenticate Using IAM User. **Note:** • This option is available only for Cloud Editions and not for Physical or VE. • IAM role is not supported for workflows in AWS Gov.

7. (*Applies only for Amazon EC2 instance protection*) **Specify Fleet Settings**: Enable this option to:
   - Specify the VPC and subnet in which the EC2 fleet instance should be launched.
   - Add tags to the EC2 fleet instance.

   By default, this option is disabled and the EC2 fleet instance is launched in the same VPC and subnet of the Amazon EC2 instances that are to be protected.

   Specify the VPC and Subnet

   From the **Fleet Instance location** drop-down list select one of the following options to specify the VPC and subnet in which the fleet instance should be launched.
   - **Same Subnet as protected Amazon EC2**: The fleet instance will be launched in the same VPC and subnet of the Amazon EC2 instances that are to be protected.

- **Select New**: The fleet instance will be launched in the specified VPC and subnet of the specified region. If the AWS source is not registered with the Cohesity cluster, the cluster cannot detect the AWS region, and the associated VPC and subnets. To configure a new VPC and subnet for the fleet instance, you must first register the source and then update the registered source to specify the VPC and subnet. For more information, see Configure a New VPC and Subnet for Fleet Instance.

If you have not selected the **Fleet Instance location** after enabling the **Specify Fleet Settings** option, then the EC2 fleet instance is launched in the same VPC and subnet of the Amazon EC2 instances that are to be protected.

Add a Tag

Tags enable you to categorize and identify your fleet instances. A tag consists of a key and an optional value, both of which you define.

To add a tag to the fleet instances, click **Add Tags** and enter a tag key and value. You can add up to 47 tags to a fleet instance.

Delete a Tag

To delete an existing tag, click the **cross** icon next to the tag.

8. (*Applies only for Amazon S3 buckets protection*) Cohesity utilizes the Amazon S3 inventory report to protect the Amazon S3 bucket. Enable **Inventory Report Location**, provide the following information to create the inventory report:
   - **S3 buckets ARN**: Enter the ARN of the Amazon S3 bucket where you want to create the inventory report. The ARN you provide must be of only those Amazon S3 buckets that are in the same AWS account and cloud region as the Amazon S3 you want to protect.
   - **Prefix**: Add a prefix value to the name of the inventory report that will be created.
     - The prefix can contain any character, including white spaces.

       For example, *Report-Source Bucket*.
     - The prefix should not begin or end with a forward slash (/) .
     - The prefix should not contain consecutive forward slashes.
     - You must not upload any files in the prefix of the inventory report.

   The inventory report will be created at *<Prefix>/<Path_to_inventoy_report>* when you initiate the protection. Cohesity creates the path to the inventory report on AWS based on the cluster, Amazon S3 bucket, and protection.
9. Click **Register**.

To register an AWS C2S source using IAM Role

Cohesity supports Commercial Cloud Services (C2S) region in AWS backup and recovery workflows. C2S is AWS's secret region offered by AWS to the US Intelligence community.

You can register an AWS C2S source only using an IAM role. Contact Cohesity Support to enable the feature.

1. Select **Data Protection > Sources**.
2. Select **Register** > **Virtual Machines**.
3. From the **Select Hypervisor Source Type** drop-down, select **AWS : IAM User/Role**.
4. Choose **Category** as **C2S**.
5. Configure the following parameters:

Field Name	Description
Base URL	URL of the Commercial Cloud Services (C2S) server that contains the Amazon storage provided by the C2S agency.
Agency	The name of the agency that is providing the Commercial Cloud Services (C2S) server.
Mission	The account name for accessing the Commercial Cloud Services (C2S) server which is provided by the C2S agency.
Role	The IAM role to use when accessing the Amazon storage which is provided by the C2S agency.
Password	The password to read the Client Private Key when accessing the Commercial Cloud Services (C2S) server which is provided by the C2S agency.
Server CA Trusted Certificate	Upload the Certificate Authority Trusted Certificate file to access the Commercial Cloud Services (C2S) server which is provided by the C2S agency.
Client Certificate	Upload the Client Certificate file to access the Commercial Cloud Services (C2S) server which is provided by the C2S agency.
Client Private Key	Upload the Client Private Key file to use when accessing the Commercial Cloud Services (C2S) server which is provided by the C2S agency.

Field Name	Description
Specify Fleet Settings (Optional)	Enable this option to: • Specify the VPC and subnet in which the EC2 fleet instance should be launched. • Add tags to the EC2 fleet instance. By default, this option is disabled and the EC2 fleet instance is launched in the same VPC and subnet of the Amazon EC2 instances that are to be protected. > **Note:** This option is applicable only for the fleet instance created for backing up Amazon EC2. **Specify the VPC and Subnet** From the **Fleet Instance location** drop-down list select one of the following options to specify the VPC and subnet in which the fleet instance should be launched. • **Same Subnet as protected VMs**: The fleet instance will be launched in the same VPC and subnet of the Amazon EC2 instances that are to be protected. • **Select New**: The fleet instance will be launched in the specified VPC and subnet of the specified region. If the AWS source is not registered with the Cohesity cluster, the cluster cannot detect the AWS region, and the associated VPC and subnets. To configure a new VPC and subnet for the fleet instance, you must first register the source and then update the registered source to specify the VPC and subnet. For more information, see Configure a New VPC and Subnet for Fleet Instance. If you have not selected the **Fleet Instance location** after enabling the **Specify Fleet Settings** option, then the EC2 fleet instance is launched in the same VPC and subnet of the Amazon EC2 instances that are to be protected. **Add a Tag** Tags enable you to categorize and identify your fleet instances. A tag consists of a key and an optional value, both of which you define. To add a tag to the fleet instances, click **Add Tags** and enter a tag key and value. You can add up to 47 tags to a fleet instance. **Delete a Tag** To delete an existing tag, click the **cross** icon next to the tag.

Configure a New VPC and Subnet for Fleet Instance

To launch EC2 fleet instance will be launched in the specified subnet when you back up the Amazon EC2 instance to the Cohesity cluster. To configure a new VPC and subnet for the fleet instance:

1. In the Cohesity Dashboard select **Data Protection** > **Sources**.
2. Navigate the hierarchy to the registered AWS source for which you want to configure a new VPC and subnet for the fleet instance.
3. Click **Edit** next to the **Specify Subnet for Fleet Instance** text , or click the actions menu next to the AWS source and select **Edit**.

   The Edit Source page appears.
4. Enable the **Specify Fleet Settings** option if you have not enabled when registering the AWS source.
5. From the **Fleet Instance Location** drop-down list, select **Select New**.
6. Select a region, and its VPC and subnet in which the fleet instance should be launched.

   > **Note:** As the Amazon EC2 sources are mostly located in one region, you can select the VPC and subnet of only one region.
7. Click **Save**

Run CloudFormation Template

Execute CloudFormation Template to Register AWS Using IAM Role

If you are using an IAM role to authenticate while registering an AWS source with the Cohesity cluster, you must run the CloudFormation template in the AWS account where the S3 buckets to be protected reside.

This CloudFormation template is available for download during the AWS source registration process in the Cohesity cluster.

Executing the CloudFormation template creates the necessary IAM role and policies required for registering the AWS source.

> **Note:**
> You should run the CloudFormation template only once when registering the AWS source for the first time.
>
> If you need to modify the use cases for an already registered AWS source (for example, to add support for Amazon RDS or Amazon S3 backups), do not download and run the CloudFormation template again. Running the template again will fail due to duplicate resource creation. Instead, update the existing CloudFormation stack in your AWS account to modify the permissions as needed.

Run the CFT

To run the Cohesity CloudFormation Template:

1. Log in to your AWS Management Console.
2. Navigate to **All services** and select **CloudFormation**.
3. Click **Create stack** > **With new resources (standard)** to create a stack using the downloaded CloudFormation Template.
4. In the **Prerequisite - Prepare template** page, select **Upload a template file**.
5. Click **Choose File** to browse and upload the downloaded JSON CloudFormation Template.

   You can download the CFT when you register your AWS account as a source with the Cohesity cluster.
6. Click **Next**.
7. Provide a Stack name. The stack name can include letters (A-Z and a-z), numbers (0-9), and dashes (-).
8. In the **Parameters** section, enter the **AccountID** of your AWS account and select source_registration as the **workflow**.
9. Click **Next**.
10. Retain all the default stack configuration options and click **Next**.
11. On the Review page, select the checkboxes that need to be acknowledged and click **Create stack**.
12. Once the stack creation is successful, view the **Resources** tab to check the created IAM roles.
13. The following IAM roles and profiles are created:
    - *CohesityInstanceRole*
    - *CohesityInstanceProfile*
    - *CohesitySourceRegistrationRole*

Once the CFT has executed, you are ready to register your AWS sources with Cohesity.

Update the Existing CloudFormation Template

If you need to change the use cases in a registered AWS source (such as adding Amzon EC2 or Amazon S3 backups), download the updated CloudFormation template while editing the source in the Cohesity UI, and replace the existing stack in your AWS account to update the required permissions. Do not run a new CloudFormation template from scratch, as this may result in errors due to duplicate resource creation.

To update and run the new CFT template:

1. In the Cohesity cluster, update the CFT by editing the AWS source, changing your settings as necessary, clicking **Next**, and downloading updated CFT.
2. Go to your AWS account, and from the Stack page (**CloudFormation** > **Stacks**), select the primary stack created.
3. Select the **Update** tab.
4. On the Update stack page, select **Replace existing template** and **Upload a template file**.
5. Click **Choose File** to browse and upload the downloaded JSON CloudFormation Template.
6. Click **Next**.
7. Click **Next** and select the checkboxes that need to be acknowledged, and then click **Next**.
8. Review the stack details and then click **Submit**.

Your updated IAM role permissions are now associated with your AWS Source registered with Cohesity.

View the Created IAM Role

To view the IAM role created by the CFT:

1. From the Stack page (**CloudFormation** > **Stacks**), select the primary stack created.
2. Click the **Outputs** tab.

   The value column will display the ARN in the following format, from which you can get the name of the role created:

   ```
   arn:partition:iam::<account-id>:role/role-name
   ```

Attaching the IAM Role to Cloud Edition Nodes

To complete registration, attach the **CohesityInstanceProfile** role to all nodes in the Cloud Edition cluster:

1. Navigate to **Services** > **EC2** > **Instances**.
2. Select the cluster created. For a multi node, the IAM role must be attached on all nodes.
3. Select **Actions** > **Instance Settings** > **Attach/Replace IAM Role**.
4. In the **IAM Role** field, enter the name/search for the Instance Profile that was created.

   Example: *CohesityInstanceProfile*
5. Click **Apply**.

The IAM role is successfully attached to that VM.

6. Click **Close**.

> **Note:** If any new node is added to the cluster, then this role has to be attached to every newly added node in the CE as well.

Completing AWS Source Registration

Once the IAM role is attached, complete the AWS source registration on the cluster, To register an AWS C2S source using IAM Role.

Manage Registered AWS Source

After registering your AWS account as a source, you can:

- Update the AWS source configuration.
- Refresh the source details.
- Unregister the AWS account from Cohesity.

Update the AWS Source Configuration

You can update the AWS source details that you had provided during the registration process.

To edit the AWS source configuration:

1. Select **Data Protection** > **Sources**.
2. Click the actions menu next to the AWS source and select **Edit**.
3. In the **Edit AWS Source** page, update the respective configurations.
4. Click **Update**.

Refresh the AWS Source

The AWS source configuration is refreshed periodically in the background. You can also manually refresh it to fetch the latest changes.

To refresh the AWS source configuration:

1. Select **Data Protection** > **Sources**.
2. Click the actions menu next to the AWS source and select Refresh.

Unregister AWS Source

If you plan to stop taking backups of the Amazon services, you can unregister the AWS source from the Cohesity cluster. Before you unregister, you must delete all the Protection Groups associated with the AWS services. For more information, see Delete the Protection Group.

To unregister the AWS source on the Cohesity cluster:

a. Select **Data Protection** > **Sources**.

b. Click the actions menu next to the AWS source and select **Unregister**.

c. Click **Unregister**.

Protect AWS EC2 Instances

In Cohesity, AWS EC2 instances are protected using a Protection Group and a Protection Policy. A Protection Group uses the schedules and settings defined in the policy to determine when and how backups are captured, archived, or replicated.

A Protection Policy is a reusable set of settings that define how and when objects are protected and replicated. You can select which standard or custom policy to use when creating a Protection Group. For more information, see Create or Edit a Standard Policy.

> **Note:**
> - Backup and recovery of AWS EC2 requires a proxy VM to be launched on the cloud source. For enhanced security, after creating the proxy VM on the cloud source, Cohesity now automatically deploys an X.509 certificate .
> - Cohesity preserves the Instance Metadata Service v2 (IMDSv2) configuration of Amazon EC2 instances during protection.

To add or edit a Protection Group for Amazon RDS or Amazon Aurora, see Add or Edit a Protection Group for Amazon RDS or Amazon Aurora.

To protect AWS EC2 instances:

1. Select **Data Protection > Protection**.
2. Click **Protect** on the top-right of the page and then click **Protect > Virtual Machines**. The **New Protection** page appears.
3. Click **Add Objects**, and from the **Registered Source** drop-down list, select the AWS source you want to protect. You can also register a new source with the Cohesity cluster by clicking the **Register Source** option.
4. From the objects list, select the EC2 instances you want to protect.

   Optionally, you can:

   - Click the icon to enable Auto Protect at various hierarchy levels (account, AWS region, or Availability zone levels). When this option is enabled at a particular level, all the EC2 instances that are added to that level in the future are automatically added to the Protection Group and are protected from the next protection run.
   - Click the **Tags** icon on the right and select tags to:

- Auto Protect ( ) the VMs having these tags.
- Exclude (⊘) the auto protection of VMs having these tags.

If a VM has multiple tags with Auto Protect and Exclude applied, exclusion takes precedence. These excluded VMs are also excluded even if a parent object is auto protected.

The **Tags** button will not be displayed if the Cohesity cluster detects that no sources have tags assigned to them.

- Exclude any volumes of the EC2 instance from protection. To exclude a volume:
  - Click the edit icon displayed next to the EC2 instance of which you want to exclude the volume.

    Unselect the volume which you want to exclude from protection.

    > **Note:**
    > - You cannot exclude the root volume from protection.
    > - You cannot exclude EBS volumes at the object level (manual volume exclusion) for auto-protected EC2 instances. To exclude EBS volume for auto-protect VMs, you must use the **Volume Exclusion Settings** option in the Additional Settings.

    For more information, see Exclude EBS Volumes from EC2 Instance Backup.

5. Click **Continue** to go back to the **New Protection** page.
6. In the **Protection Group** field, enter a name for the Protection Group. The name can contain alphanumeric characters, underscores, dashes, and periods.
7. From the Policy drop-down list, select an existing Protection Policy or create a new Protection Policy. For more information, see Create or Edit a Standard Policy.
8. If you want to change or configure any of the additional settings, then select **More Options** and perform the below steps or else, click **Protect**.
9. Select a **Protection Group Type**:
   - **Native Snapshot**—Back up EC2 instances in an AWS cloud service using the native snapshot API of the cloud service.
   - **Snapshot Manager**—Backup EC2 instances in an AWS cloud service using the Cloud Snapshot Manager APIs of the cloud service.
10. Optionally, from the **Policy** drop-down list, you can change the policy you selected earlier policy or create a new Protection Policy.

11. Select **Storage Domain** and select an existing storage domain or create a new one by selecting Add Storage Domain.
12. **Start Time**: Available only if the selected policy is set to Backup Daily. Indicates when the Protection Group should run. The current time is displayed by default which can be changed. You can change the time zone by selecting a different time zone.
13. **SLA**: The service-level agreement (SLA) defines the expected time to complete either a full backup or incremental backup. The backup completion time depends on the Windows volume size on AD, objects changed between incremental backups, network speed, and other Protection Groups running on the Cohesity cluster.
    - **Incremental**: Enter the number of minutes you expect an incremental protection run to complete. An incremental backup captures only the differences (changed blocks) since the last protection run.
    - **Full**: Enter the number of minutes you expect a full backup protection run to complete. A full backup captures the entire object (all blocks).
14. If you need to change any of the advanced settings on the Protection Group page, click the down arrow icon next to **Additional Settings** and click **Edit** on the right. For more information, see Additional Settings.
15. Click **Protect**.

Additional Settings

Additional Settings	Description
Pause Future Runs	Toggle on this option to stop protection runs of the Protection Group from executing. Once you enable this option, no protection runs will be scheduled for this Protection Group.
End Time	Click and select the date when the Protection Group stops capturing snapshots. A Protection Group run that starts prior to this date runs until completion even if it completes after this date.

Additional Settings	Description
QoS Policy	Select an appropriate quality of service (QoS) policy. **Note:** Cohesity recommends specifying **Backup HDD**, which is the default. • **Backup HDD**: The Cohesity cluster writes the data directly to an HDD drive for this Protection Group. • **Backup SSD**: The Cohesity cluster writes the data directly to an SSD drive for this Protection Group. Only specify this policy if you need fast ingest speed for a small number of Protection Groups. • **Backup Auto**: (Applicable only for Cohesity C6000 series) The Cohesity cluster writes the data to both SSDs and HDDs. The distribution of data will be based on the current usage of SSD and HDD. This policy tries to achieve a similar backup performance as the **Backup SSD** policy and reduces the SSD wear-out compared to the Backup SSD policy.
Indexing	This option is toggled on by default to index the data of the Protection Group. Indexing improves files and folders search. Cohesity performs incremental indexing where only the data that has changed since the previous snapshot is scanned and indexed.
Volume Exclusion Settings	EC2 disks can be excluded based on disk tags using simple query rules. For example, the query, `(type = log AND environment IN (qa, dev)) OR exclude = yes`, excludes all volumes from backup for which the volume tags meet the above condition. For more details, see Exclude EBS Volumes from EC2 Instance Backup. **Note:** Exclusion of disks enabled at the object-level (manual exclusion) will take precedence over the exclusion configured here.
Cancel Run at Quite Start Time	*Available only if the selected policy has at least one quiet time period.* Toggle it on to specify that all currently executing protection runs should abort if a quiet time period specified for the Protection Group starts. If the option is toggled off, then after a protection run starts, it continues to execute even when a quiet time period specified for this Protection Group starts. However, a new protection run will not start during a quiet time period.

Additional Settings	Description
Alerts	Select one or more of the following settings if you want alerts to be created for the following triggers: • **Success**: Creates an informational alert when a Protection Group completes successfully. Emails are not sent when informational alerts are created. • **Failure**: Creates a critical alert if the Protection Group fails to complete. Emails are sent when critical alerts are created. • **SLA Violation**: Creates a warning alert if the Protection Group takes longer than the time period specified in the SLA field. Emails are sent when warning alerts are created. For more information, see Alerts.
Priority	Select a priority for the Protection Group execution. Cohesity supports concurrent backups. However, if the number of protection runs exceeds the ability to process runs, this will be the priority of implementation of the runs: a. High-priority protection runs b. Medium-priority protection runs c. Low-priority protection runs
Email Recipients	You can add email addresses to a Protection Group to notify the email recipients when alerts are triggered for the protection run.
Description	Enter a brief description about the Protection Group.

Exclude EBS Volumes from EC2 Instance Backup

Cohesity supports excluding EBS volumes from EC2 instance backup. The following are important points to note:

- By default, all volumes are included as part of the EC2 instance backup.
- You cannot exclude the root volume.
- You cannot exclude EBS volumes at the object level (manual volume exclusion) for auto-protected EC2 instances. To exclude EBS volume for auto-protect VMs, you must use the **Volume Exclusion Settings** option in the Additional Settings.
- If you exclude a volume from the EC2 instance backup and if any system information is stored on the excluded volume, recovering the EC2 instance fails.

  For example, in the `/etc/fstab` file, if you do not specify the `nofail` option for the excluded volume, recovering the Linux instance fails.

You can exclude EBS volumes from EC2 instance backup using the following two methods:

- Manual volume exclusion (object-level)
- Volume exclusion using rules (Protection Group-level)

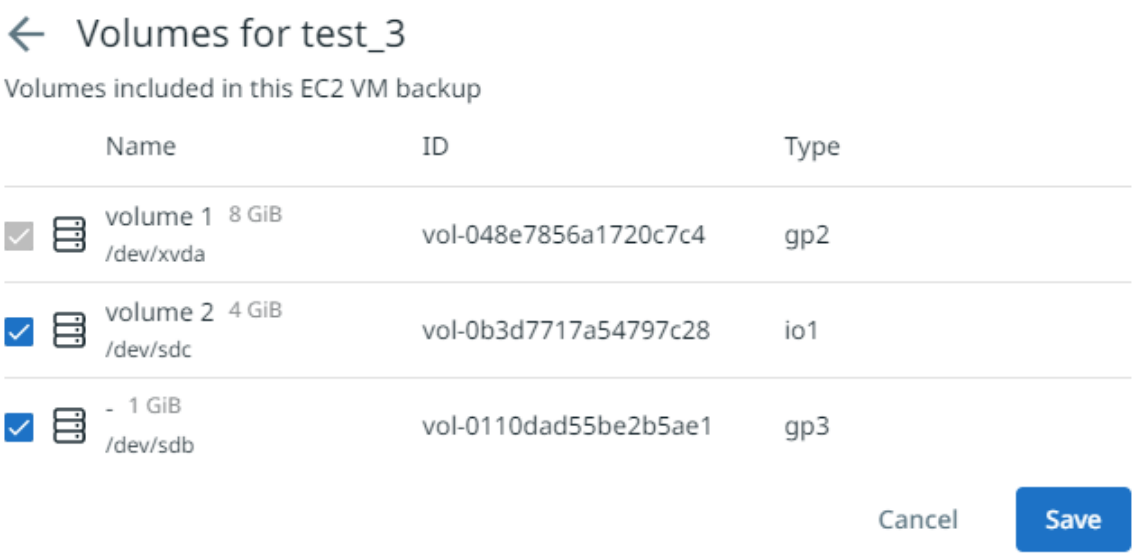
Manual Volume Exclusion

To exclude EBS volumes manually while creating/editing the Protection Group, perform the following steps:

1. Follow steps 1-4 in Protect AWS EC2 Instances.
2. After you select the EC2 instance, the **All Volumes** option is displayed:

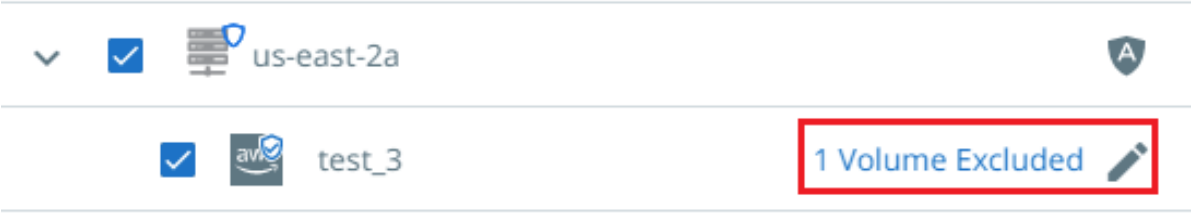
   To edit the volume selection after creating the Protection Group, hover over the EC2 instance, click the action icon (⋮) next to the Protection Group, and select **Edit**.
3. Click **All Volumes**.

   The volumes that are included as a part of the backup are displayed:



4. Select the volume to be excluded by unchecking the corresponding check box.
5. Click **Save**.

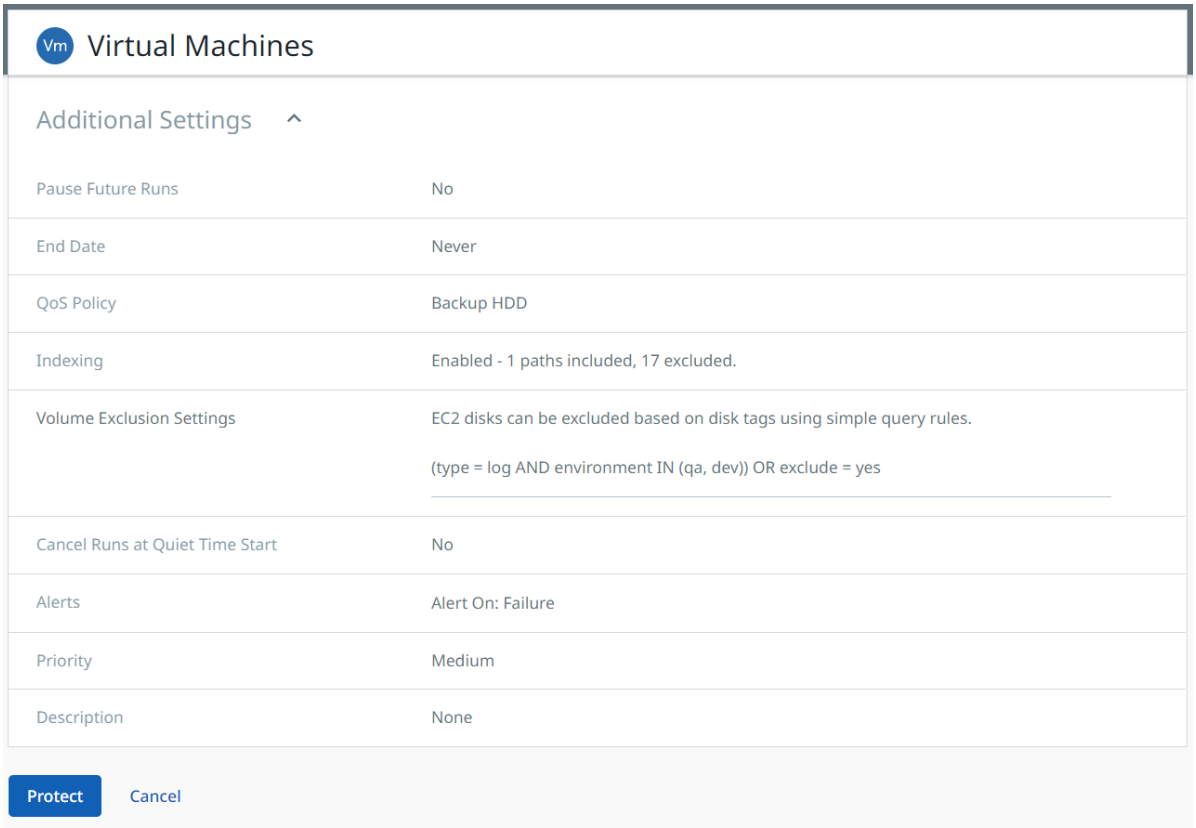
The volumes excluded are displayed next to the corresponding EC2 instance:



Volume Exclusion Using Rules

To exclude EBS volumes after the Protection Group is created, complete the following steps:

1. Follow steps 1-10 in Protect AWS EC2 Instances.
2. In the Additional Settings section, set the rules using queries in the Volume Exclusion Settings field. EC2 disks can be excluded based on disk tags using simple query rules. For example, the query, (type = log AND environment IN (qa, dev)) OR exclude = yes, excludes all volumes from the backup for which the volume tags meet the above condition.

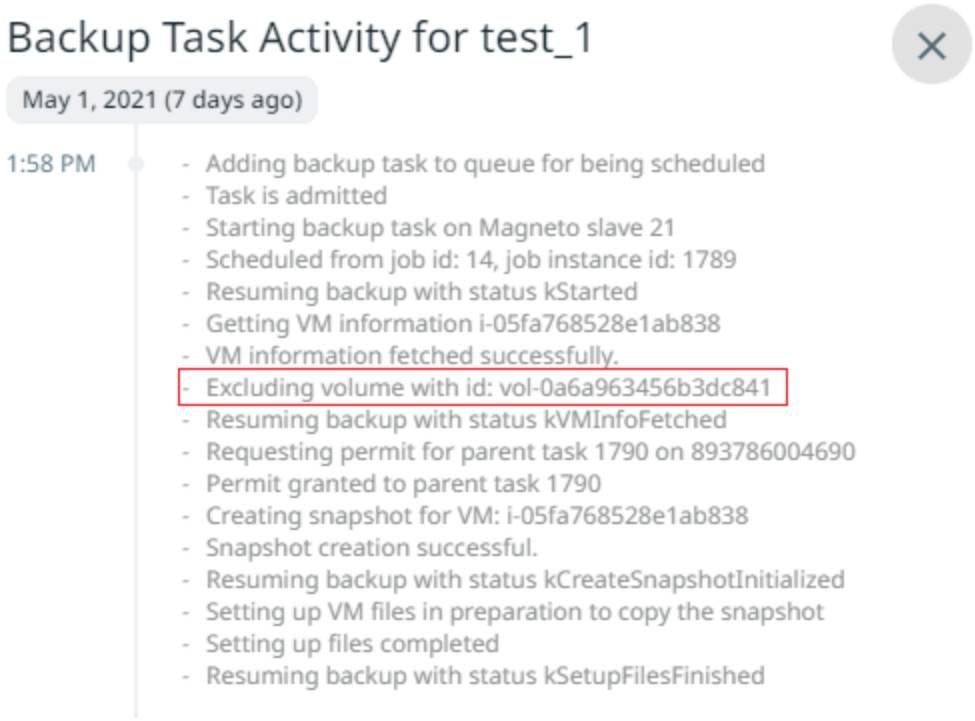


3. Click **Protect**.

To determine whether EBS volumes have been excluded from the backup, complete the following steps:

1. In the Cohesity Dashboard, select **Data Protection > Protection**.
2. On the **Protection** page, click on the protection job.
3. On the **Runs** tab, click on the backup job that is complete.
4. On the **Run Details** page, click on the VM name. The **Backup Task Activity** pop-up window lists the details of all the tasks.

   The details of the excluded volume are displayed:



AWS Backup Use Cases

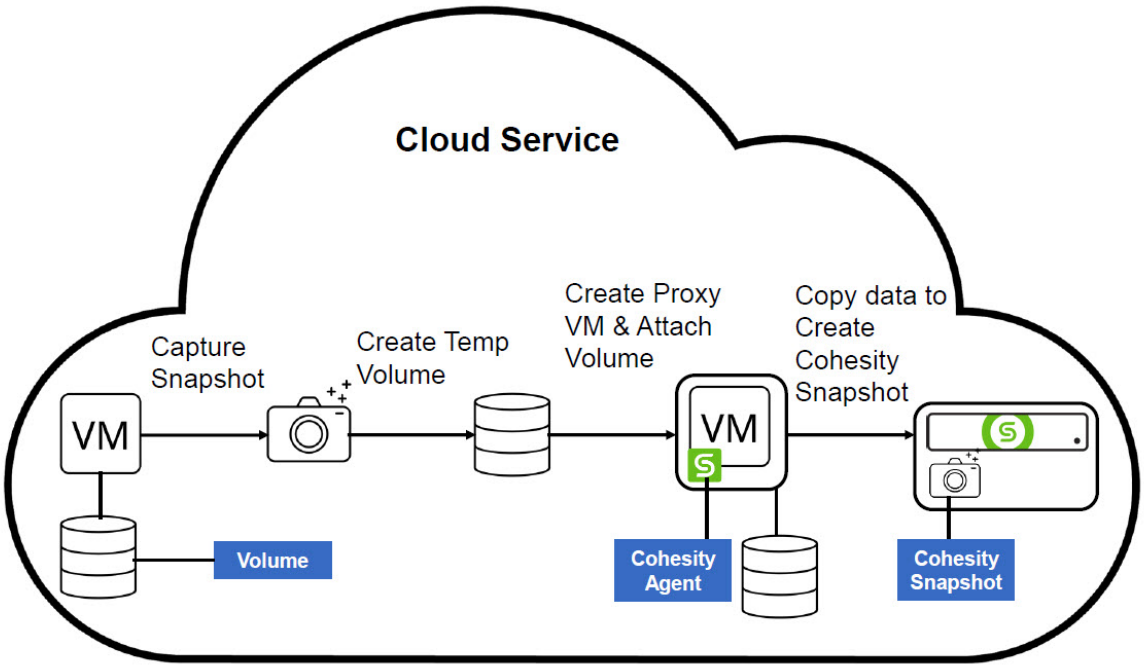
The following are the use cases for backing up Amazon EC2 instances:

Backup On-prem Data Using Cloud Edition

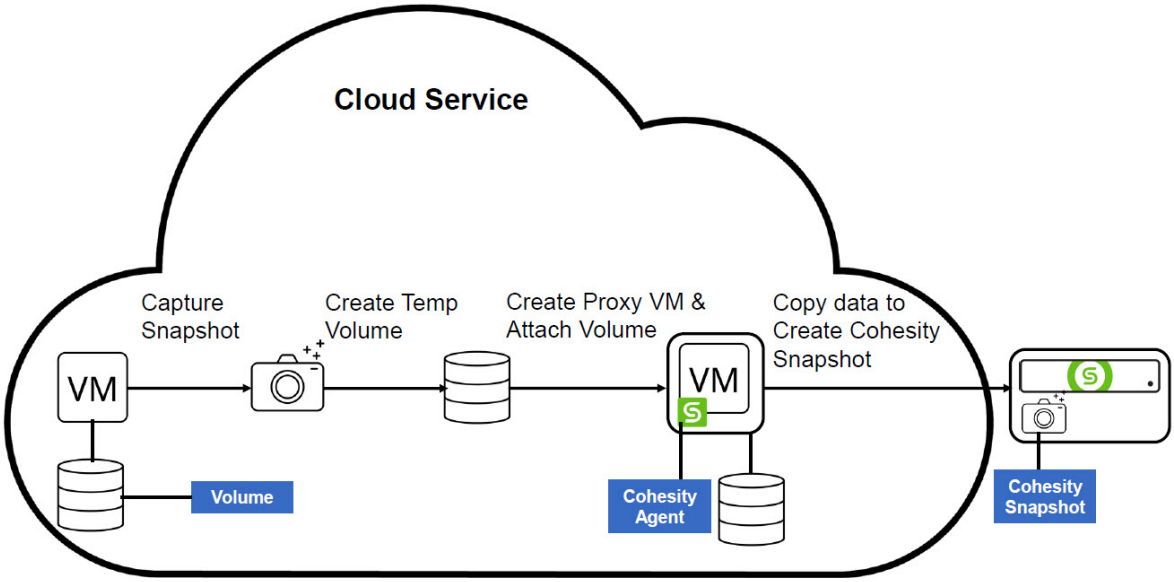
Cloud Edition supports the backup and recovery of Virtual Machines (such as a VM in a vCenter server) to a Cohesity cluster Cloud Edition running in AWS Cloud Service.VMs can be recovered to a new location or back to the original location.

Backup Amazon EC2 to On-Premises or Cloud Edition Cluster using Native Snapshot

Cohesity cluster supports backing up virtual servers using the native snapshot of the cloud service. For example, a virtual server Protection Group backs up Amazon EC2 instances from AWS Cloud service to an on-premises Cohesity cluster. The result of this backup is a snapshot on the on-premises Cohesity cluster.



Cohesity Cloud Edition also supports backing up Amazon EC2 instances using the native snapshot of the Cloud Service. For example, a Virtual Server Protection Group backs up Amazon EC2 instances to a Cloud Edition Cohesity cluster running in the same Cloud service. The result of this backup is Snapshots on the Cloud Edition cluster.



Backup Amazon EC2 Using Snapshot Management

Cohesity uses Snapshot Management APIs to create AWS snapshots for the services such as Amazon EC2 and Amazon RDS. When a Protection Group with Snapshot Manager enabled is

executed, only the metadata is stored on the Cohesity cluster. All snapshot data gets stored in AWS itself.

To enable this feature, you must select Snapshot Manager as the Protection Group Type while creating the Protection Group for protecting AWS service. By default, the snapshots are stored on the same region and account as the AWS source. You can recover these snapshots to a different region and account. Additionally, the snapshots stored in the same AWS region and account as the source can be replicated to a different AWS account or region. For more information, see Use AWS Snapshot Management for Replication.

Use AWS Snapshot Management for Replication

If the policy attached to the Snapshot Manager-enabled Protection Group has replication to AWS enabled, you can replicate the data to different AWS regions or accounts.

To replicate the AWS snapshots to another AWS region:

1. Register an AWS Cloud Source.
2. Create a Policy with replication to AWS enabled.
3. Create a Protection Group:
    - Choose Snapshot Manager as the Protection Group Type.
    - Attach the policy with replication enabled.

This type of replication does not require a Cohesity cluster to serve as the destination for the replication of data. The AWS region serves as the destination. Cohesity replicates the snapshots to the EBS bucket in the selected region.

Manage Recovery

This chapter includes the following topics:

Recover Files or Folders for AWS Native Snapshots to the New Server

Prerequisites

- Firewall port 50051 must be open on the target EC2 instances. For more information, see Manage Firewall Ports
- The target EC2 instances must be reachable with private IP.
- The target EC2 instances must have the IAM role “AmazonEC2RoleforSSM”.
- The AWS SSM agent must be installed on target EC2 instances.

> **Note:** For enhanced security, when installing the agent on the target EC2, Cohesity automatically deploys an X.509 certificate.

> **Note:** You can perform files and folder recovery to an EC2 Linux instance only if the EC2 Linux instance is of x86_64 architecture.

Recover Files and Folders to New Server

Perform the following steps to recover files and folders to the new server:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** at the top right of the page and then select **Files or Folders**.

   The Recover Files or Folders page appears.
3. Select any one of the following options to search for the file or folder:
   - **Files and Folders**: Allows you to search and recover files using file or folder names from any backup available on Cohesity.
   - **Browse or Specify Path for Search**: Allows you to search and recover files using the name of the server or Protection Group from any backup available on Cohesity.

If you select..	Then..
Files and Folders	a. Enter characters of the file name, path, or by specifying the wildcard character *. A list of items displays. You can optionally filter the search results by object type, source, object, Protection Group, Storage Domain, files only, or folders only. b. From the list of search results, select the required files or folders to recover. c. By default, the latest snapshot is selected for recovery. To recover from a different snapshot: i. From the selected list, mouse over the snapshot, and then click the **edit** icon. The Edit recovery point page appears. ii. By default, only the snapshots that are indexed are displayed. To display all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. iii. Select a date range and the snapshot point for recovery. By default, the snapshot is recovered from the local cluster. d. Go to step 4.

If you select..	Then..
Browse	1. Enter the full or partial server or Protection Group name. You can by specify the wildcard character *. You can also optionally filter the search results by object type, source, object, Protection Group, Storage Domain. 2. From the list of search results, select the object whose files or folders are to be recovered. 3. By default, the latest snapshot is selected for recovery. To recover from a different snapshot, click the snapshots drop-down in the top-left corner and select the snapshot you need. 4. **Browse on Indexed Data**: Toggle on this setting to browse the indexed data. It helps to speed up the browsing of recovery data. By default, it only displays the files and folders that are indexed. Hidden files, folders, paths such as /usr, /var, /sys , /Windows, /ProgramData etc. are excluded from indexing. To display all the available files and folders, including hidden files and folders toggle off the **Browse on Indexed Data** setting. **Note:** • Changing the snapshot after selecting the items (files or folder) removes the selected items from the cart. • Enabling or disabling the **Browse on Indexed Data** option after selecting the items (files or folder) removes the selected items from the cart. • Deleted snapshots may be displayed as valid recovery points for a brief period until they are removed from the search index by a background process. 5. Browse to the file or folder that you want to recover by clicking a folder and subfolders. 6. Click **Save**. 7. After saving the selection, if you want to recover from a different snapshot or change the location from where the snapshot is recovered, perform the following steps: 1. From the selected list, mouse over the snapshot, and click the edit icon. The Edit recovery point page appears. 2. By default, only the snapshots that are indexed are displayed. To display

If you select..	Then..
	all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. 3. Select a date range and the snapshot point for recovery. By default, the snapshot is recovered from the local cluster. 8. Go to step 4.

The Cohesity cluster attempts to index all files and folders to a drive on both Windows and Linux systems. If the Cohesity cluster is unable to find mount point information about files or directories, it indexes and displays these files and directories in the `lvol_N` directory, where `N` is a unique number such as `1`.

On Windows systems, if the Cohesity cluster finds the mount point information about files and directories, it indexes and displays these files and directories with a drive letter such as `C:`.

On Linux systems, how files and directories are indexed and displayed is dependent on the conditions specified in the following table.

Server Type	Volume Type	

Linux Virtual Machine	Simple Volume	The Cohesity cluster detects mount points for entries in the `/etc/fstab` file with the following formats:
		`UUID=ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc /mnt ext4 auto 0`
		`UUID="ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc" /mnt ext4 auto 0`
		If the Cohesity cluster can detect a mount point, it indexes and displays files and directories in the volume with the mount point that was specified in the `/etc/fstab` file. For these example entries, files and directories are indexed with the `/mnt` mount path, such as `/mnt/example/test.txt`.
		If the Cohesity cluster cannot detect a mount point, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

Server Type	Volume Type	

Linux Virtual Machine	LVM Volume	The Cohesity cluster detects mount points for entries in the `/etc/fstab` file with the following formats:
		`UUID=ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc /mnt ext4 auto 0`
		`/dev/mapper/VG1-root /mnt ext4 defaults 1 1`
		`/dev/VG1/root /mnt ext4 defaults 1 1`
		If the Cohesity cluster can detect a mount point, it indexes and displays files and directories in the volume with the mount point specified in the `/etc/fstab` file. For these example entries, files and directories are indexed with the `/mnt` mount path, such as `/mnt/example/test.txt`.
		If the Cohesity cluster cannot detect a mount point, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

Linux Physical	LVM Volume	The Cohesity agent can only return mount data when the volume is mounted on the Linux physical Server. If the volume is mounted, the Cohesity cluster indexes and displays files and directories in the volume with the mount point such as `/mnt/example/test.txt`. If the volume is not mounted, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

4. Once you select the files and folder to recover, select one of the following options:
   - **Next: Recover Options**: If you select this option, then continue with the step 5 to configure the file recovery options.
   - **Download Files**: If you are recovering a single file, this option downloads the file to your browser's download folder. For all other selections, this creates a recovery task. When the task is completed, from the Recoveries page, click the task name and then click **Download Files** to download the generated zip file.

     Character replacement explanation for : and \ in file and directory names in zip files

     If the original file or directory name contains a ':', it is replaced with '_COLON_' in the archive.
     Example:

- The original name is "a:b" then the archived name is "a_COLON_b"
- The original name is "a:b:c" then the archived name is "a_COLON_b_COLON_c"

If the original file or directory name contains a '\', it is replaced with '_BACK_SLASH_' in the archive.
Example:

- The original name is "x\y" then the archived name is "x_BACK_SLASH_y"
- The original name is "x\y\z" then the archived name is "x_BACK_SLASH_y_BACK_SLASH_z"

5. From the **Recover To**, select **New Server** to recover the files or folders to a new server.
6. **Source**: From the **Source** drop-down menu, select a registered server to which you want to recover the files and folders. You can also register a new source by clicking **Register Source**.
7. **Target**: From the Target (for VM and physical server) or Volume (for NAS) drop-down menu, select a VM or volume to which the files and files are to be recovered.

   > **Note:** For recovering files and folders of a VMware VM, ensure that VMware Tools are installed and running on the target VM. The target list displayed includes only VMs with VMware Tools installed and running.

8. **Recover to**: In the **Recover to** field, change the default location to which the files or folders are recovered. By default, the files and folders are recovered to the /**tmp**/ directory for VMs.

   For NAS, an example path on an alternate location could be /tmp/recover. You can recover encrypted files/folders to their original location only.

   Example for Windows alternate location:

   - D:\cohesity_restore\1.txt
   - D:\cohesity_restore\bar

   User Account Requirements for VM Protection may need to be met to recover files to a Windows VM.

   If recovering to a standalone Hyper-V host or cluster, you must add the guest VM to the reverse lookup zone in the DNS server to complete the recovery successfully.
9. Optional. Edit the default settings of the following **Recovery options**:
   - **Overwrite Existing File/Folder**: By default, this option is enabled to overwrite the existing files and folders. Disable this option to create the files and folders in the specified location. Any duplicate files are skipped.

Example for a Windows alternate location with **Overwrite Existing File/Folder** enabled and the target already exists:

Files to be recovered: "C:\foo\1.txt", "C:\foo\test\1.txt", "C:\bar", "C:\foo\bar". Specified alternate location: "C:\restore". At the end of the copy, the target folder looks like this:

- C:\restore\1.txt
- C:\restore\cohesity<taskid>_0\1.txt
- C:\restore\bar
- C:\restore\cohesity<taskid>_1\bar

If **Overwrite Existing File/Folder** is enabled, recovering a file to source when the file is in Fuse may cause the open file to be overwritten. Whether overwriting occurs depends on the application using the file.

- **Preserve File/Folder Attributes**: By default, this option is enabled and the ACLs, permissions, and timestamps are preserved for all files and folders. If you disable this option, then ACLs and permissions are not preserved. If recovering both folders and files, then folders will receive the new timestamps, but files retain their original timestamps. If recovering only files, then files will receive the new timestamps.
- **Continue on Error**: Enable this option if you want to continue the recovery even if one of the objects encounters an error. By default, this option is disabled and the recovery operation will fail if one of the objects encounters an error.
- **Cluster Interface**: By default, the Auto Select option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the Interface Group drop-down.
- **Task Name**: Change the default name of the recovery task.

10. Click **Start Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Recover Files or Folders for AWS Native Snapshots to the Original Server

Prerequisites

- Firewall port 50051 must be open on the target EC2 instances. For more information, see Manage Firewall Ports
- The target EC2 instances must be reachable with private IP.
- The target EC2 instances must have the IAM role “AmazonEC2RoleforSSM”.
- The AWS SSM agent must be installed on target EC2 instances.

> **Note:** For enhanced security, when installing the agent on the target EC2, Cohesity automatically deploys an X.509 certificate.

> **Note:** You can perform files and folder recovery to an EC2 Linux instance only if the EC2 Linux instance is of x86_64 architecture.

Recover Files and Folders to Original Server

Perform the following steps to recover files and folders to the original server:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** at the top right of the page and then select **Files or Folders**.

   The Recover Files or Folders page appears.
3. Select any one of the following options to search for the file or folder:
   - **Files and Folders**: Allows you to search and recover files using file or folder names from any backup available on Cohesity.
   - **Browse or Specify Path for Search**: Allows you to search and recover files using the name of the server or Protection Group from any backup available on Cohesity.

If you select..	Then..
Files and Folders	a. Enter characters of the file name, path, or by specifying the wildcard character *. A list of items displays. You can optionally filter the search results by object type, source, object, Protection Group, Storage Domain, files only, or folders only. b. From the list of search results, select the required files or folders to recover. c. By default, the latest snapshot is selected for recovery. To recover from a different snapshot: i. From the selected list, mouse over the snapshot, and then click the **edit** icon. The Edit recovery point page appears. ii. By default, only the snapshots that are indexed are displayed. To display all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. iii. Select a date range and the snapshot point for recovery. By default, the snapshot is recovered from the local cluster. d. Go to step 4.

If you select..	Then..
Browse	1. Enter the full or partial server or Protection Group name. You can by specify the wildcard character *. You can also optionally filter the search results by object type, source, object, Protection Group, Storage Domain. 2. From the list of search results, select the object whose files or folders are to be recovered. 3. By default, the latest snapshot is selected for recovery. To recover from a different snapshot, click the snapshots drop-down in the top-left corner and select the snapshot you need. 4. **Browse on Indexed Data**: Toggle on this setting to browse the indexed data. It helps to speed up the browsing of recovery data. By default, it only displays the files and folders that are indexed. Hidden files, folders, paths such as /usr, /var, /sys , /Windows, /ProgramData etc. are excluded from indexing. To display all the available files and folders, including hidden files and folders toggle off the **Browse on Indexed Data** setting. **Note:** • Changing the snapshot after selecting the items (files or folder) removes the selected items from the cart. • Enabling or disabling the **Browse on Indexed Data** option after selecting the items (files or folder) removes the selected items from the cart. • Deleted snapshots may be displayed as valid recovery points for a brief period until they are removed from the search index by a background process. 5. Browse to the file or folder that you want to recover by clicking a folder and subfolders. 6. Click **Save**. 7. After saving the selection, if you want to recover from a different snapshot or change the location from where the snapshot is recovered, perform the following steps: 1. From the selected list, mouse over the snapshot, and click the edit icon. The Edit recovery point page appears. 2. By default, only the snapshots that are indexed are displayed. To display

If you select..	Then..
	all the available snapshots, toggle off the **Show Indexed Snapshots Only** option. 3. Select a date range and the snapshot point for recovery. By default, the snapshot is recovered from the local cluster. 8. Go to step 4.

The Cohesity cluster attempts to index all files and folders to a drive on both Windows and Linux systems. If the Cohesity cluster is unable to find mount point information about files or directories, it indexes and displays these files and directories in the `lvol_N` directory, where `N` is a unique number such as `1`.

On Windows systems, if the Cohesity cluster finds the mount point information about files and directories, it indexes and displays these files and directories with a drive letter such as `C:`.

On Linux systems, how files and directories are indexed and displayed is dependent on the conditions specified in the following table.

Server Type	Volume Type	

Linux Virtual Machine	Simple Volume	The Cohesity cluster detects mount points for entries in the `/etc/fstab` file with the following formats:
		`UUID=ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc /mnt ext4 auto 0`
		`UUID="ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc" /mnt ext4 auto 0`
		If the Cohesity cluster can detect a mount point, it indexes and displays files and directories in the volume with the mount point that was specified in the `/etc/fstab` file. For these example entries, files and directories are indexed with the `/mnt` mount path, such as `/mnt/example/test.txt`.
		If the Cohesity cluster cannot detect a mount point, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

Server Type	Volume Type	

Linux Virtual Machine	LVM Volume	The Cohesity cluster detects mount points for entries in the `/etc/fstab` file with the following formats:
		`UUID=ccd1d599-e68e-4b88-ba9b-6f75b63f1bdc /mnt ext4 auto 0`
		`/dev/mapper/VG1-root /mnt ext4 defaults 1 1`
		`/dev/VG1/root /mnt ext4 defaults 1 1`
		If the Cohesity cluster can detect a mount point, it indexes and displays files and directories in the volume with the mount point specified in the `/etc/fstab` file. For these example entries, files and directories are indexed with the `/mnt` mount path, such as `/mnt/example/test.txt`.
		If the Cohesity cluster cannot detect a mount point, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

Linux Physical	LVM Volume	The Cohesity agent can only return mount data when the volume is mounted on the Linux physical Server. If the volume is mounted, the Cohesity cluster indexes and displays files and directories in the volume with the mount point such as `/mnt/example/test.txt`. If the volume is not mounted, the Cohesity cluster indexes the files and directories into a `lvol_N` directory. For example, the `/mnt/example/test.txt` file is indexed as `/lvol_1/example/test.txt`.

4. Once you select the files and folder to recover, select one of the following options:
   - **Next: Recover Options**: If you select this option, then continue with the step 5 to configure the file recovery options.
   - **Download Files**: If you are recovering a single file, this option downloads the file to your browser's download folder. For all other selections, this creates a recovery task. When the task is completed, from the Recoveries page, click the task name and then click **Download Files** to download the generated zip file.

     Character replacement explanation for : and \ in file and directory names in zip files

     If the original file or directory name contains a ':', it is replaced with '_COLON_' in the archive.
     Example:

- The original name is "a:b" then the archived name is "a_COLON_b"
- The original name is "a:b:c" then the archived name is "a_COLON_b_COLON_c"

If the original file or directory name contains a '\', it is replaced with '_BACK_SLASH_' in the archive.
Example:

- The original name is "x\y" then the archived name is "x_BACK_SLASH_y"
- The original name is "x\y\z" then the archived name is "x_BACK_SLASH_y_BACK_SLASH_z"

5. From the **Recover To**, select **Original Server** to recover the files or folders to a new server.
6. **Recover to Original Path**: To recover to a different location in the original server, disable the **Recover to Original Path** option, and then provide the location to which the files or folders are to be recovered in the **Recover To** field. By default, the files and folders will be recovered to the original location.
7. Optional. Edit the default settings of the following **Recovery options**:
   - **Overwrite Existing File/Folder**: By default, this option is enabled to overwrite the existing files and folders. Disable this option to create the files and folders in the specified location. Any duplicate files are skipped.

     Example for a Windows alternate location with **Overwrite Existing File/Folder** enabled and the target already exists:

     Files to be recovered: "C:\foo\1.txt", "C:\foo\test\1.txt", "C:\bar", "C:\foo\bar". Specified alternate location: "C:\restore". At the end of the copy, the target folder looks like this:

     - C:\restore\1.txt
     - C:\restore\cohesity<taskid>_0\1.txt
     - C:\restore\bar
     - C:\restore\cohesity<taskid>_1\bar

     If **Overwrite Existing File/Folder** is enabled, recovering a file to source when the file is in Fuse may cause the open file to be overwritten. Whether overwriting occurs depends on the application using the file.
   - **Preserve File/Folder Attributes**: By default, this option is enabled and the ACLs, permissions, and timestamps are preserved for all files and folders. If you disable this option, then ACLs and permissions are not preserved. If recovering both folders and files, then folders will receive the new timestamps, but files retain their original timestamps. If recovering only files, then files will receive the new timestamps.

- **Continue on Error**: Enable this option if you want to continue the recovery even if one of the objects encounters an error. By default, this option is disabled and the recovery operation will fail if one of the objects encounters an error.
- **Cluster Interface**: By default, the Auto Select option is enabled and the recovery task automatically selects the correct VLAN. If you disable this option, then select a configured interface group from the Interface Group drop-down.
- **Task Name**: Change the default name of the recovery task.

8. Click **Start Recovery**.

The recovery task is initiated. You can monitor the recovery task from the Recoveries page.

Recover AWS EC2 Instance to New Location

To recover an AWS EC2 instance to a new location:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** at the top right of the page and then select **VMs**.

   The Virtual Machines page appears.
3. Search for an EC2 instance or Protection Group that contains the snapshots to recover from by entering characters of the EC2 instance name, Protection Group name, or by specifying the wildcard character *.

   A list of EC2 instance displays.

   You can optionally filter the search results by Source, Protection Group, Storage Domain, or Date.
4. From the list of search results, select one or more EC2 instances or Protection Groups that contain the snapshots to recover.
   - If you have selected a Protection Group, then all the EC2 instances backed up in the latest protection run of this Protection Group will be selected for recovery and the option to select those VMs individually will be greyed out in the search result list.
   - You can only select Protection Groups and VMs with snapshots stored in the same Storage Domain and belonging to the same source. Once you select an EC2 instance or Protection Group, the Storage Domain, and Source filters will automatically get locked.
5. By default, the latest snapshot of the VMs is selected for recovery. To recover from a different snapshot, perform the following steps depending on the object selected:

> **Note:** In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

To choose a different snapshot for a...	Then...
Protection Group	1. From the selected lists, mouse over the snapshot, and then click the **edit** icon. 2. From the **Protection** Run drop-down menu, select the snapshot from which you want to recover the EC2 instance. By default the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. 3. Click **Select Recovery Point** and then go to step 6.

To choose a different snapshot for a...	Then...
EC2 instance	From the selected lists, mouse over the snapshot, and then click the edit icon. The Edit recovery point for <VM_name> page appears. By default, the option to select the snapshot is displayed in **Timeline** mode. You can also choose to view the option in **List** mode by clicking the List tab in the top-right corner of the page. • To select a snapshot from the Timeline mode: a. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar. b. Select the snapshot to be recovered by clicking the corresponding blue dot. c. By default, the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. d. Click **Select Recovery Point** and then go to step 6. • To select a snapshot from the **List** mode: a. Select the **List** tab from the top-right corner of the Edit recovery point for <VM_name> page. By default, the page displays the snapshots available in the last one month. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range. b. Select the snapshots to be recovered. c. By default, the snapshot is recovered from the local Cohesity cluster. You can also select snapshots archived in the cloud by clicking the cloud ( ) icon if available in the **Location** option. d. Click **Select Recovery Point** and then go to step 6.

6. Click **Next: Recover Options**.
7. From the **Recover To** options, select **New Location** and provide the following details:
    a. **Source**: Select a registered AWS account as the new recovery destination.
    b. **Region**: Select a destination AWS region.
    c. **Key Pair**: Select an AWS key pair to be associated with the recovered EC2 Instance(s).
    d. **Subnet**: Select the subnet where the recovered EC2 Instance(s) will be launched.
    e. **Network Security Group**: Select the network security group to be associated with the recovered EC2 Instance(s).
8. To recover AWS EC2 instances after protection, Cohesity creates fleet instances to transfer data from the snapshots stored on the Cohesity cluster. Enable **Specify Fleet Settings** to:
    - Specify the VPC and subnet in which the EC2 fleet instance should be launched.

      From the Fleet Instance location drop-down list select one of the following options to specify the VPC and subnet in which the fleet instance should be launched.

        a. **Same Subnet as protected VMs**: The fleet instance will be launched in the same VPC and subnet of the Amazon EC2 instances that are being protected.
        b. **Select New**: The fleet instance will be launched in the specified VPC and subnet of the specified region. If the AWS source is not registered with the Cohesity cluster, the cluster cannot detect the AWS region, and the associated VPC and subnets. To configure a new VPC and subnet for the fleet instance, you must first register the source and then update the registered source to specify the VPC and subnet.

      If you have not selected the **Fleet Instance location** after enabling the **Specify Fleet Settings** option, then the EC2 fleet instance is launched in the same VPC and subnet of the Amazon EC2 instances that are being protected.
    - **Add tags to the EC2 fleet instance**

      Tags enable you to categorize and identify your fleet instances. A tag consists of a key and an optional value, both of which you define.

      To add a tag to the fleet instances, click **Add Tags** and enter a tag key and value. You can add up to 47 tags to a fleet instance.

      To delete an existing tag, click the **cross** icon next to the tag.

By default, this option is disabled and the EC2 fleet instance is launched in the same VPC and subnet of the Amazon EC2 instances that are protected.

9. Under **Recovery Options**, edit the default settings. Click the **edit** icon to edit the settings:
    a. **Rename**: Add a Prefix and/or Suffix to the recovered Amazon EC2 instances.
    b. **Power State**: To ensure that the restored EC2 instances are functioning properly, the EC2 instances are powered on by default after the restoration process. However, you can enable the **Power Off** option if you prefer to keep the VMs powered off once Cohesity verifies their functionality. If you are recovering VMs from a Storage Domain with Cloud Tier enabled, Cohesity recommends keeping the VMs powered off.
    c. **Continue on Error**: Enable this option if you want to continue the recovery even if one of the objects encounters an error. By default, this option is disabled and the recovery operation will fail if one of the objects encounters an error.
    d. **Task Name**: Change the default name of the recovery task.
10. Click **Recover**.

Cohesity begins to restore the selected Amazon EC2 instances.

Recover AWS EC2 Instance to Original Location

To recover an AWS EC2 instance to the original location:

1. Navigate to **Data Protection > Recoveries**.
2. Click **Recover** at the top right of the page and then select **VMs**.

   The Virtual Machines page appears.
3. Search for an EC2 instance or Protection Group that contains the snapshots to recover from by entering characters of the EC2 instance name, Protection Group name, or by specifying the wildcard character *.

   A list of EC2 instance displays.

   You can optionally filter the search results by Source, Protection Group, Storage Domain, or Date.
4. From the list of search results, select one or more EC2 instances or Protection Groups that contain the snapshots to recover.
    - If you have selected a Protection Group, then all the EC2 instances backed up in the latest protection run of this Protection Group will be selected for recovery and the option to select those VMs individually will be greyed out in the search result list.
    - You can only select Protection Groups and VMs with snapshots stored in the same Storage Domain and belonging to the same source. Once you select an

EC2 instance or Protection Group, the Storage Domain, and Source filters will automatically get locked.

5. By default, the latest snapshot of the VMs is selected for recovery. To recover from a different snapshot, perform the following steps depending on the object selected:

> **Note:** In this workflow, deleted snapshots may be displayed as valid recover points for a brief period until they are removed from the search index by a background process.

To choose a different snapshot for a...	Then...
Protection Group	1. From the selected lists, mouse over the snapshot, and then click the **edit** icon. 2. From the **Protection** Run drop-down menu, select the snapshot from which you want to recover the EC2 instance. By default the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. 3. Click **Select Recovery Point** and then go to step 6.

To choose a different snapshot for a...	Then...
EC2 instance	From the selected lists, mouse over the snapshot, and then click the edit icon. The Edit recovery point for <VM_name> page appears. By default, the option to select the snapshot is displayed in **Timeline** mode. You can also choose to view the option in **List** mode by clicking the List tab in the top-right corner of the page. • To select a snapshot from the Timeline mode: a. From the **Choose a date** drop-down, select a date. The snapshots available on the selected date are displayed in blue dots on the timeline bar. b. Select the snapshot to be recovered by clicking the corresponding blue dot. c. By default, the snapshot is recovered from the local Cohesity cluster. You can also select the snapshot archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. d. Click **Select Recovery Point** and then go to step 6. • To select a snapshot from the **List** mode: a. Select the **List** tab from the top-right corner of the Edit recovery point for <VM_name> page. By default, the page displays the snapshots available in the last one month. You can also select a snapshot from a different date range by selecting the date range from the **Date** drop-down list. The page displays the available snapshots in the specified range. b. Select the snapshots to be recovered. c. By default, the snapshot is recovered from the local Cohesity cluster. You can also select snapshots archived to the cloud by clicking the cloud ( ) icon if available in the **Location** option. d. Click **Select Recovery Point** and then go to step 6.

6. Click **Next: Recover Options**.
7. From the **Recover To** options, select **Original Location** to recover the EC2 instance to the original location.
8. To recover AWS EC2 instances after protection, Cohesity creates fleet instances to transfer data from the snapshots stored on the Cohesity cluster. Enable **Specify Fleet Settings** to:
    - Specify the VPC and subnet in which the EC2 fleet instance should be launched.

      From the Fleet Instance location drop-down list select one of the following options to specify the VPC and subnet in which the fleet instance should be launched.

        a. **Same Subnet as protected VMs**: The fleet instance will be launched in the same VPC and subnet of the Amazon EC2 instances that are being protected.

        b. **Select New**: The fleet instance will be launched in the specified VPC and subnet of the specified region. If the AWS source is not registered with the Cohesity cluster, the cluster cannot detect the AWS region, and the associated VPC and subnets. To configure a new VPC and subnet for the fleet instance, you must first register the source and then update the registered source to specify the VPC and subnet.

      If you have not selected the **Fleet Instance location** after enabling the **Specify Fleet Settings** option, then the EC2 fleet instance is launched in the same VPC and subnet of the Amazon EC2 instances that are being protected.
    - **Add tags to the EC2 fleet instance**

      Tags enable you to categorize and identify your fleet instances. A tag consists of a key and an optional value, both of which you define.

      To add a tag to the fleet instances, click **Add Tags** and enter a tag key and value. You can add up to 47 tags to a fleet instance.

      To delete an existing tag, click the **cross** icon next to the tag.

      By default, this option is disabled and the EC2 fleet instance is launched in the same VPC and subnet of the Amazon EC2 instances that are protected.
9. Under **Recovery Options**, edit the default settings. Click the **edit** icon to edit the settings:
    a. **Rename**: Add a Prefix and/or Suffix to the recovered Amazon EC2 instances.

    b. **Power State**: To ensure that the restored EC2 instances are functioning properly, the EC2 instances are powered on by default after the restoration process. However, you can enable the **Power Off** option if you prefer to keep the VMs powered off once Cohesity verifies their functionality. If you are

recovering VMs from a Storage Domain with Cloud Tier enabled, Cohesity recommends keeping the VMs powered off.

c. **Continue on Error**: Enable this option if you want to continue the recovery even if one of the objects encounters an error. By default, this option is disabled and the recovery operation will fail if one of the objects encounters an error.

d. **Task Name**: Change the default name of the recovery task.

10. Click **Recover**.

Recover VMs with Disks > 1 TB from AWS Native API Snapshots

When recovering from backups that were captured using AWS native snapshotting and the disks being restored are greater than 1 TB, the Cohesity cluster uses Proxy VMs to upload the data to the AWS cloud similar to how the Cohesity cluster creates Proxy VMs to download the data from the AWS Cloud to an on-premises Cohesity cluster or Cloud Edition Cluster.

Note the following requirements for supporting the recovery of VMs with disks over 1 TB:

- The VPC where the VM will be recovered to, must be reachable from the Cohesity cluster through a VPN. For more information, see VPN Connections.
- Port 50051 must be open in the network security group where the VMs will be recovered to.

Disaster Recovery of VMs Using AWS Cloud Edition

To provide disaster recovery failover and failback, Cohesity supports the Cloud Migration of VMs between hypervisor servers (VMware vCenter), Cloud Services (AWS and Azure) and Cloud Edition Cohesity clusters. For Hyper-V, Cohesity supports only failover to Azure.

Disaster recovery with Cloud Edition consists of the following two use cases:

Cohesity Import and Export for AWS

Cohesity supports an internal import and export feature that is fast and cost-effective. The number of temporary fleet instances created in the user account is limited by limiting the number of import tasks running at a time. Hence, even if other workloads are not present in the cluster, the number of import tasks will remain the same. For details on setting the number of import tasks, contact Cohesity Support.

Supported Softwares

Cohesity supports import and export from the following software versions:

- CentOS/RHEL 6, 7, 8
- Ubuntu 14, 16, 18
- Windows 2012 server and above.

Limitations

- Import of VMs with Logical Volume Manager (LVM) on root volume spanning across multiple disks is not supported.
- This feature is not supported for:
  - Agent-based backups
  - Full CloudSpin

Back Up VMs to On-Prem, Replicate and Failover to AWS Cloud

To provide disaster recovery failover and failback, Cohesity supports the Cloud Migration of VMs between hypervisor servers (VMware vCenter), Cloud Services (AWS and Azure) and Cloud Edition Cohesity clusters. For Hyper-V, Cohesity supports only failover to Azure. Cohesity Cloud Edition supports the replication of VMs captured on an on-premises Cohesity cluster to Cloud Edition as shown by the example figure below. Starting from the left in the following figure, the use case shows how Protection Groups running on the on-premises Cohesity cluster captures Snapshots of VMs and stores these Snapshots on the on-premises Cluster. The Protection Policies associated with these Jobs, are configured to replicate (or copy) Snapshots from the on-premises Cohesity cluster to the Cloud EditionCohesity cluster.

From the Snapshots stored on the Cloud Edition, you can failover VMs. The failover process creates new VMs running in the Cloud Service (such as AWS or Azure). As part of the Failover process, the VMs are converted and spun up in the Cloud Service.

> **Note:** Multi-Disk Windows and Linux EC2 instances are supported to failover to AWS and failback from AWS.

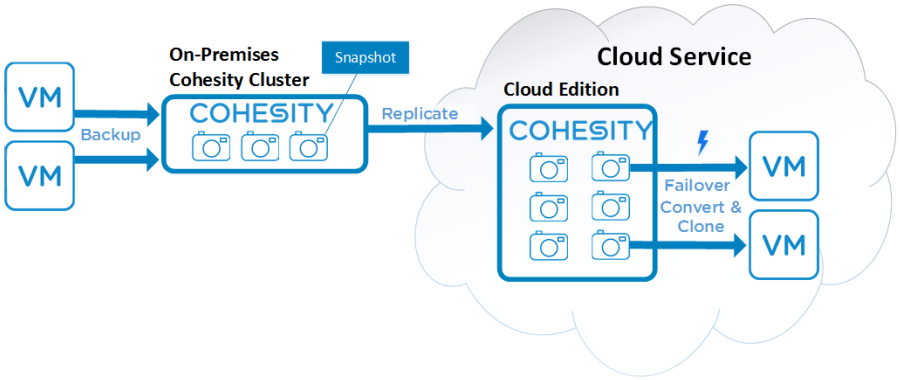
Cohesity supports the failover of VMware VMs with UEFI boot mode enabled to AWS and Azure.

Failover to AWS supports the following UEFI boot mode enabled operating systems:

- Windows Server 2012, 2016, 2019
- Ubuntu 16, 18

Failover to Azure supports the following UEFI boot mode enabled operating systems:

- Windows Server 2012, 2016, 2019



> **Important:** To support the failback (recovery) of these VMs back to the original Hypervisor server (such as VMware vCenter), Cohesity agents must be installed on the Windows VMs prior to backing up the snapshots on the on-premises Cohesity cluster. Failback is described in Back Up AWS Cloud VMs, Replicate to On-Prem and Failback to Hypervisor Server

Verify the following requirements prior to backing up the VMs:

- If you are planning to perform failback (recovery) of the backed-up VMs back to the Hypervisor server from the Cloud Service, then:
  - Before registering the VMs of the Hypervisor server with the on-premises Cohesity cluster, you must install Cohesity agent on the VMs if you are planning to back up the cloud VM back to the Cohesity cluster using the **Cohesity Protection Service** Protection Group type.
  - You do not need to install the Cohesity agent on the VMs if you are planning to back up the cloud VM back to the Cohesity cluster using native snapshots.

    > **Note:** You must install the Cohesity agent on the Windows VMs before registering the VMs of the Hypervisor server with the on-premises Cohesity cluster. The Cohesity agent is required to bring all the disks on the VMs online.

- Failover and Failback of VMware VM to AWS supports the following operating systems:
  - CentOS 6.0+ 64-bit, 7.0 - 7.9 64-bit, 8.0 64-bit
  - RHEL 6.7+ 64-bit, 7.0 - 7.9 64-bit, 8.0 - 8.2 64-bit
  - SUSE Linux Enterprise Server 11 64 bit, 12 64 bit
  - Ubuntu 14.x 64-bit, 16 64-bit, 18 64-bit, 20 64-bit

    - OEL 5.11 - 5.8 64-bit, 6.x 64-bit, 7.0 - 7.9 64-bit
    - Debian 6.0.0-6.0.8 64 bit, 7.0.0-7.8.0 64 bit, 8.0.0 64 bit
    - Fedora Server 19-21 64 bit
    - Windows 10 Desktop Edition, Microsoft Windows Server 2012, Microsoft Windows Server 2016, and Microsoft Windows Server 2019, Windows Server 2022
- VMware vSphere 5.5, 6.0, 6.5, and 6.7 is supported for cloning to Azure.
- AHV, RhV and AWS VMs are *not* supported for cloning to Azure.
- Cloning Snapshots to an Azure Cloud is supported for VMware and Hyper-V VMs with the following operating systems:
    - Linux CentOS 7 on LVM
        - You can clone as many disks as the selected VM supports. For example, if you select a Standard_DS1_v2 VM, four disks can be cloned.
        - When converting and cloning or copying Snapshots of a Linux VM with multiple disks, the disks must be mounted by UUID prior to being backed up by the Protection Group, as shown by the following example entry in a `/etc/fstab`:

          ```
          UUID=e12e623a-c6ee-4718-9b1a-802456e72258 /userdata ext4 defaults,nofail 0 0
          ```

          For detailed instructions, see Edit /etc/fstab to use UUID.
    - Windows
        - You can clone as many disks as the selected VM supports. For example, if you select a Standard_DS1_v2 VM, four disks can be cloned.
        - For a Windows VM, if you want to access the newly created VM in the Cloud service using Remote Desktop, enable the Windows Remote Desktop on the VM prior to capturing the Snapshots of a Windows VM.
        - When backing up Windows VMs with multiple disks, before a Protection Group captures the Snapshot, the Cohesity agent and VMware tools must be installed on the VM and the VM must be running. The Cohesity agents installed must be of the same version as the Cohesity Cluster version. For more information, see Install and Manage the Agent on Windows Servers. In addition, port 50051 must be open in your Firewall. For more information, see Manage Firewall Ports.
        - Due to a Windows issue in builds 14393 and build 15063, a deployed Windows 10 or Windows 2016 VM may not be connected to the network. Resolve this by installing fix KB4073562 for build 14393 or KB4016240 for build 15063 or by updating Windows. For more information, see

Cannot connect remotely to a Windows 10 or Windows Server 2016 VM in Azure because of netvsc.sys.

- Make the disks online by default using the following SAN policy commands:
  - `diskpart`
  - `san policy=OnlineAll`

  For more information, see the SAN Policy documentation.

- Red Hat Enterprise Linux
  - You can clone as many disks as the selected VM supports. For example, if you select a Standard_DS1_v2 VM, four disks can be cloned.
  - For the list of supported RHEL versions, see Supported Software.
  - When converting and cloning or copying Snapshots of a Linux VM with multiple disks, the disks must be mounted by UUID prior to being backed up by the Protection Group, as shown by the following example entry in a `/etc/fstab`:

    ```
    UUID=e12e623a-c6ee-4718-9b1a-802456e72258 /userdata ext4 defaults,nofail 0 0
    ```

    For detailed instructions, see Edit /etc/fstab to use UUID.
- The disk size of the VMware VMs must be a multiple of 1 GB.
- Cohesity does not support the CloudSpin of VMs whose OS Disk is formatted with XFS version 5 to Azure. This limitation applies to both Hyper-V and VMware VMs, regardless of their operating system type.
- Cohesity does not support CloudSpin of VMware VMs from VMware Cloud (VMC) to Azure.

Cloning Hyper-V VMs to Azure

- VMs that have one to five disks can be cloned. Each disk must be smaller than 2 TB.
- SUSE Linux VMs are *not* supported.
- All the Hyper-V versions supported by Cohesity for backup is supported for cloning to Azure. For the list of supported Hyper-V versions, see Supported Software.
- Generation 2 VMs are not supported by all VM sizes in Azure. For information on Generation 2 supported VM series, see Microsoft document.
- Cloning of Hyper-V VMs to Azure Stack Hub is not supported.

- Cloning VMware VMs to an AWS Cloud has the following requirements:

- Cloning snapshots to an AWS Cloud is supported for VMware VMs with specific Linux operating systems. For information on supported operating systems, see Supported Software
- Cloning Snapshots to an AWS Cloud is supported for VMware VMs with the Windows operating system.
- The disk size of the VMware VMs must be a multiple of 1 MB.
- VMs that have one to ten disks can be cloned.
- When converting and cloning or copying Snapshots of a Linux VM with multiple disks, the disks must be mounted by UUID prior to being backed up by the Protection Group, as shown by the following example entry in a `/etc/fstab`:

  ```
  UUID=e12e623a-c6ee-4718-9b1a-802456e72258 /userdata ext4
  defaults,nofail 0 0
  ```

  For detailed instructions, see Edit /etc/fstab to use UUID.

  For AWS, be aware of the following requirements:

  - In addition, the fstab entry for **CentOS 7.4**, **RHEL 7.4**, **RHEL 6.7**, **SUSE 11** and **Ubuntu 16** operating systems must specify the `nofail` option as shown in the following example:

    ```
    UUID=e12e623a-c6ee-4718-9b1a-802456e72258 /userdata ext4
    defaults,nofail 0 0
    ```

  - In addition, the fstab entry for the **Ubuntu 14** operating system must specify the `nobootwait` option as shown in the following example:

    ```
    UUID=2b262696-41a6-47c9-b173-d02717ee0e10 /mnt/expvol ext4
    defaults,nobootwait 0 0
    ```

- For a Windows VM, if you want to access the newly created VM in the Cloud service using Remote Desktop, enable the Windows Remote Desktop on the VM prior to capturing the Snapshots of a Windows VM.

To back up VMs to an on-premises Cluster, replicate and failover to Cloud Edition:

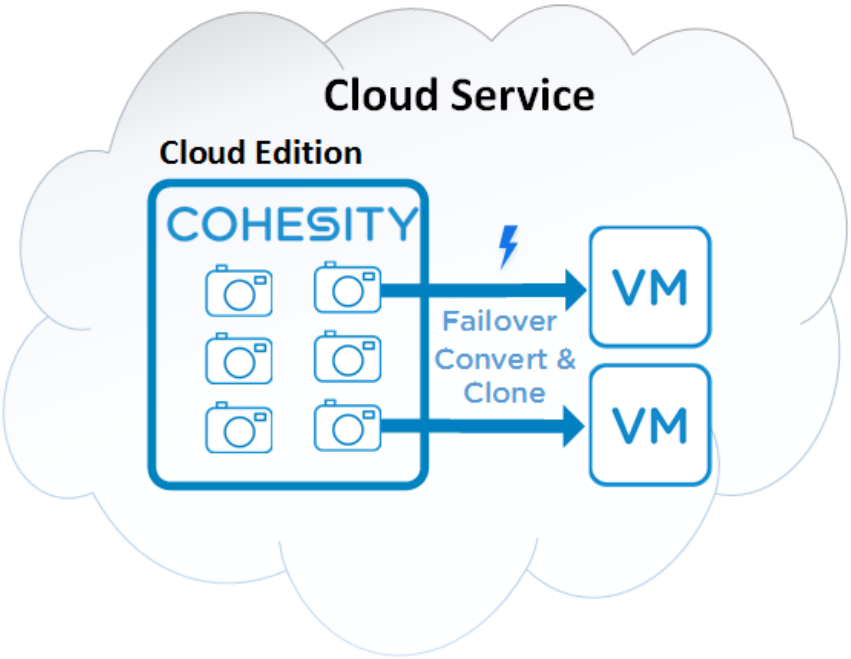
1. Register the Hypervisor server with the on-premises Cohesity cluster
2. Set up replication between the on-premises Cohesity cluster and the Cloud Edition Cohesity cluster. For instructions, see Replication and Remote Access Setup.
3. On the on-premises Cohesity cluster, create a Policy that replicates to a Cloud Edition Cohesity cluster as shown in the top figure. For instructions, see Create or Edit a Standard Policy.
4. On the on-premises Cohesity cluster, create a Virtual Server Protection Group (such as `Win2k12`) that has **Cloud Migration** enabled. For detailed instructions, see Add or

Edit a Protection Group for Virtual Servers. Associate the Policy created in the previous step with this Protection Group.

When selecting Objects to be protected by a Protection Group, you can only select VMs with VMware tools installed, Remote Desktop enabled, and for Windows VM Cohesity agents also must be installed.

When you create a Protection Group on the on-premises Cohesity cluster that replicates to a Cloud Edition Cohesity cluster, after the first Snapshot is replicated to the Cloud Edition Cluster, an Inactive copy of the Protection Group is created on the Cloud Edition Cluster that received the Snapshot. The new Inactive Protection Group on the Cloud Edition Cohesity cluster has the same name as the Protection Group on the on-premises Cohesity cluster, for example: `Win2k12`. The VM must be powered on and connected to the network when the Protection Group is running.

5. You can failover from the Snapshots that were replicated to the Cloud Edition Cluster. The failover process creates new VMs running in the Cloud Service (such as AWS or Azure). As part of the Failover process, the VMs are converted and spun up in the Cloud Service.



To failover from the Snapshots:

a. On the Cloud Edition Cohesity cluster that contains the replicated Snapshots, select **Data Protection > Protection** and browse for the Inactive Protection Group that was automatically created.

b. Click on the inactive Protection Group name.

c. Click the action icon (⋮) next to the Protection Group and select **Failover**.

d. From the **Failover to Source** drop-down, select the name of the registered Cloud Source where the VMs will be cloned to.

e. Click **Continue to Clone**.

f. Follow the instructions provided in Set Clone Options. You can also add custom tags to all the resources created during failover.

A clone task is created and the VM is created in the Cloud Service (such as AWS and Azure) and is powered up if that option is selected.

6. Follow the steps in the next part of the Disaster Recovery workflow which is documented in Back Up AWS Cloud VMs, Replicate to On-Prem and Failback to Hypervisor Server.

You can also use CloudSpin (test/dev clone) workflow to failover individual VMs within the Protection Group instead of failovering all VMs in the Protection Group. For more information, see Test & Dev Using CloudSpin.

Back Up AWS Cloud VMs, Replicate to On-Prem and Failback to Hypervisor Server

To provide disaster recovery failover and failback, Cohesity supports the Cloud Migration of VMs between hypervisor servers (VMware vCenter), Cloud Services (AWS and Azure) and Cloud Edition Cohesity clusters.

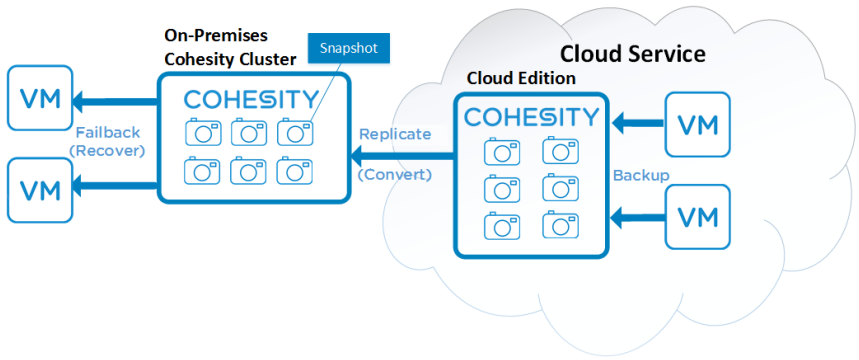
> **Note:** Failover of VMs born in the cloud to VMware vCenter is not supported.

This topic describes the second use case of disaster recovery using Cloud Edition—how to backup cloud VMs to the Cloud Edition cluster, replicate to the on-premise cluster, and then failback to the Hypervisor server.

For information on how the VMs are backed up in the cloud service such as AWS and Azure), see the first process of disaster recovery using Cloud Edition documented in Back Up VMs to On-Prem, Replicate and Failover to AWS Cloud.

Cohesity supports the failback of VMware VMs with UEFI boot mode enabled from AWS. Failback from AWS supports the following UEFI boot mode enabled operating systems:

- Windows Server 2012, 2016, 2019
- Ubuntu 16, 18



As illustrated in the figure above, on the Cloud Edition running in the Cloud Service, a Protection Group using native snapshots or Cohesity Protection Service backs up the cloud VMs (as indicated by the backup arrow in the figure). The policy associated with the Protection Group specifies that these Snapshots are replicated to the on-premises Cohesity cluster (as indicated by the Replicate arrow). From those Snapshots stored on the on-premises Cohesity cluster, you can failback or recover the VMs back to their original location or a new location in your Hypervisor server such as a vCenter Server (as indicated by the Failback (Recover) arrow).

To back Up Cloud VMs to Cloud Edition, replicate to an on-premises Cohesity cluster and failback to a hypervisor server:

Verify the following requirements prior to failback:

- Th VMs that are backed up to the Cloud Service must have VMware Tools and Remote Desktop installed before the original Protection Group captures the Snapshots from the VMware vCenter Server as described in the Back Up VMs to On-Prem, Replicate and Failover to AWS Cloud.
- If you are backing up the Cloud VMs to the Cloud Edition Cluster using the Cohesity Protection Service Protection Group type, then the VMs that are backed up to the Cloud Service must also have Cohesity agent installed.
- For AWS cloud source:
    - Configure the VPC and tunnels so that the source VMs are reachable using private IP addresses.
    - Cohesity fleet instances must have ports 50051 and 22 open, so that the Cohesity cluster can communicate with fleet instances. Cohesity creates one network security group in each VPC, and attaches to the fleet instance.

> **Note:** By default, the inbound rules at the security group will be configured with the CIDR range of the network where the Cohesity cluster is configured. Contact Cohesity Support if you want to configure the security group with a different CIDR range.

- If you are backing up from an AWS Cloud Source, you must use a AWS Cloud Source that has been granted adequate permissions to back up.

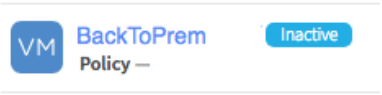
For more on the native snapshot process for creating the Cohesity snapshot, see AWS Backup Use Cases.

Steps:

1. If not already configured, set up replication between the Cloud Edition Cluster and the on-premises Cohesity cluster. For instructions, see Replication and Remote Access Setup.
2. On the Cloud Edition Cluster, create a Policy that replicates from the Cloud Edition Cluster to the on-premises Cohesity cluster as shown in the figure. For instructions, see Create or Edit a Standard Policy.
3. On the Cloud Edition Cluster, refresh the Object hierarchy for the Source of the VMs that will be backed up:
   a. Select **Data Protection > Sources**.
   b. Click the action icon (⋮) next to the Source and select **Refresh**.
4. On the Cloud Edition Cluster, create a Virtual Server Protection Group (such as `BackToPrem`) with Protection Group Type option as **Native Snapshots** or **Cohesity Protection Service**. Associate the Policy created in the previous step with this Protection Group. For detailed instructions, see Add or Edit a Protection Group for Virtual Servers. If **Cohesity Protection Service** is selected as the Protection Group type, then the VMs that are backed up to the Cloud Service (failovered VMs) must have a Cohesity agent installed.

   When selecting Windows VM (Objects) to failover, you can only select Snapshots of VMs that have the Cohesity agent installed when they were created with the Back Up VMs to On-Prem, Replicate and Failover to AWS Cloud process. The VM should be powered on when the Protection Group is running.

   When you create a Protection Group on the Cloud Edition Cluster that replicates to an on-premises Cohesity cluster, after the first Snapshot is replicated to the on-premises Cluster, an Inactive copy of the Job is created on the on-premises Cluster that received the Snapshot. The new Inactive Job on the on-premisses Cohesity cluster has the same name as the Protection Group on the Cloud Edition Cluster, for example: `BackToPrem`.
5. You can failback (recover) the VMs to the original Hypervisor server or an alternate Hypervisor server:
   a. On the on-premises Cohesity cluster that contains the replicated Snapshots, select **Data Protection > Protection** and browse for the Inactive Job that was automatically created.



b. Click on the inactive Job name.
c. Browse for a protection run that captured a Snapshot that you want to recover.
d. Click the action icon (⋮) next to the Job and select **Recover VM**.
e. Follow the instructions provided in Recover VMs.

The VM is created in the Hypervisor server and is powered up if that option is selected. As part of the convert and clone process, the VMware Tools will be uninstalled. You must reinstall the VMware Tools.

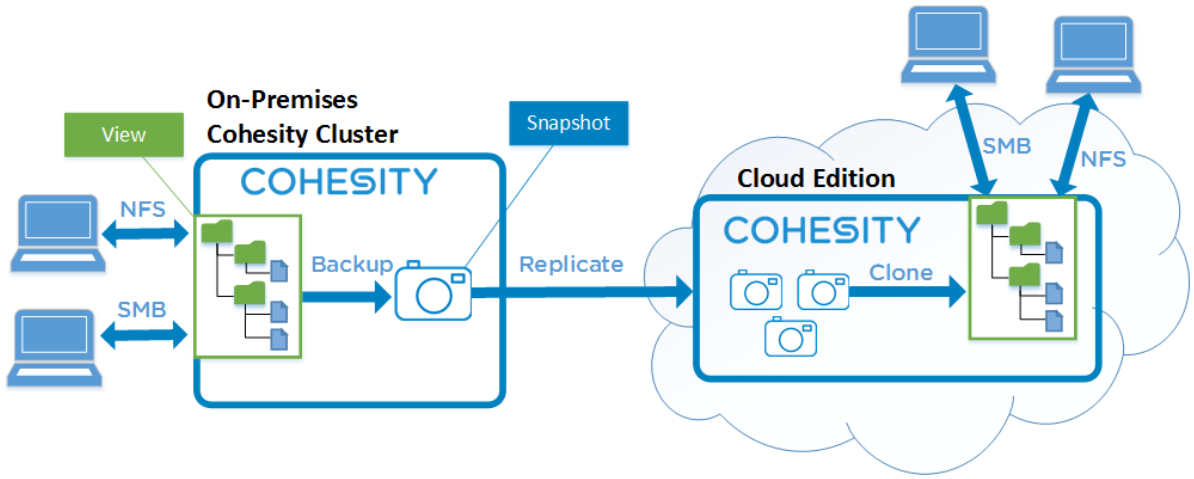
> **Important:** Do not change the size of the partition or the disk of the recovered VM.

Disaster Recovery of Views in AWS Cloud Edition

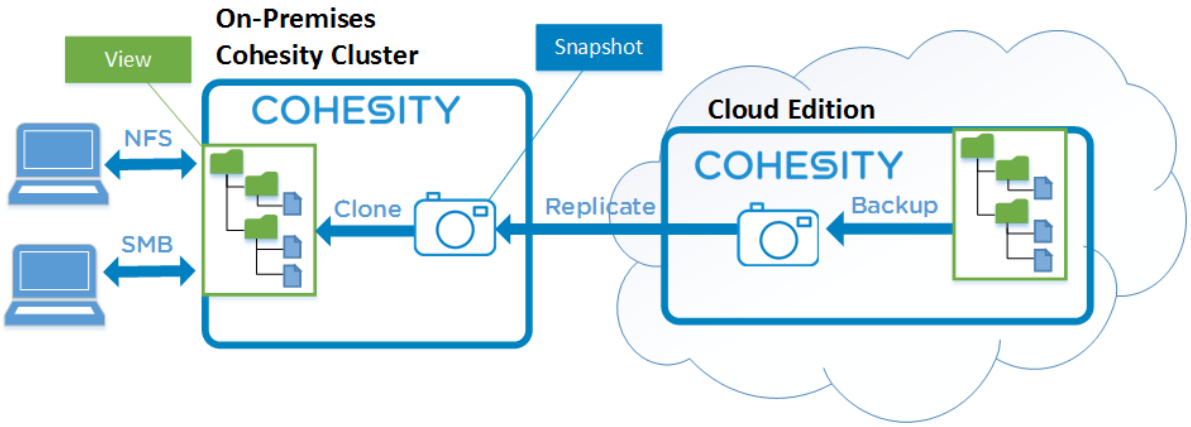
Cohesity Cloud Edition supports the disaster recovery of Views as shown by the following example figures.

Views can be used to store data such as files and directories. For example, other backup products can store data on a view that is hosted on the Cohesity cluster. To access a view from your system, you must mount the view.

On the left of the first figure, shows systems accessing a View hosted on an on-premises Cohesity cluster using the NFS or SMB protocols. A Protection Group running on the on-premises Cohesity cluster captures Snapshots of the View and stores these Snapshots on the Cluster. The Protection Policy associated with this Job, is configured to replicate (or copy) Snapshots from the on-premises Cohesity cluster to the Cohesity cluster Cloud Edition. From these Snapshots stored in the Cloud Edition, you can clone a new View that can be accessed by systems using the NFS or SMB protocols as shown on the right of the first figure.



You can backup Views hosted on the Cloud Edition as shown on the right of the following figure. A Protection Group captures a Snapshot of a View and stores the Snapshot on the Cohesity cluster Cloud Edition. The Protection Policy associated with this Job, is configured to replicate (or copy) Snapshots from the Cohesity cluster Cloud Edition to the on-premises Cohesity cluster. From these View Snapshots stored in the on-premises Cohesity cluster, you clone a View and make it available for mounting as shown on the left of the following figure.



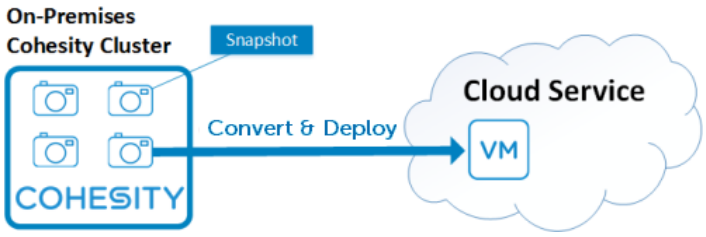
AWS Clone

This chapter includes the following topics:

Clone VMs from On-Premises to AWS Cloud Service (On Demand CloudSpin)

Cohesity supports the conversion of snapshots of VMs from an on-premises Cohesity cluster to an AWS Cloud service. After conversion, the VM runs in the Cloud service.

> **Note:** This use case is not currently supported for the Google Cloud Platform.



Prerequisites and Considerations

- For the list of VMs that supports CloudSpin to AWS, see Supported Software.
- Cohesity supports the CloudSpin of VMware VMs with UEFI boot mode enabled.
- Cohesity supports both on-demand and policy-based CloudSpin for snapshots stored on the Cohesity cluster (primary copy).
- Cohesity does not support on-demand and policy-based CloudSpin for archived or CloudRetrieved snapshots.
- Cohesity supports on-demand CloudSpin for snapshots that are replicated to another Cohesity cluster.
- Cloning VMware VMs to AWS
    - Cloning snapshots to an AWS Cloud is supported for VMware VMs with specific Linux operating systems. For information on supported operating systems, see Supported Software
    - Cloning Snapshots to an AWS Cloud is supported for VMware VMs with the Windows operating system.
    - The disk size of the VMware VMs must be a multiple of 1 MB.
    - VMs that have one to ten disks can be cloned.
    - When cloning a VMware VM that has 1 TB or greater disks, Cohesity launches a temporary EC2 instance and copies data from the Cohesity cluster to the instance. The instance can use the same VPC and subnet that's used for the clone, or you can provide a different VPC and subnet, but they must be

reachable from the cluster.

- When converting and cloning or copying Snapshots of a Linux VM with multiple disks, the disks must be mounted by UUID prior to being backed up by the Protection Group, as shown by the following example entry in a `/etc/fstab`:

  ```
  UUID=e12e623a-c6ee-4718-9b1a-802456e72258 /userdata ext4
  defaults,nofail 0 0
  ```

  For detailed instructions, see Edit /etc/fstab to use UUID.

  For AWS, be aware of the following requirements:

  - In addition, the fstab entry for **CentOS 7.4**, **RHEL 7.4**, **RHEL 6.7**, **SUSE 11** and **Ubuntu 16** operating systems must specify the `nofail` option as shown in the following example:

    ```
    UUID=e12e623a-c6ee-4718-9b1a-802456e72258 /userdata ext4
    defaults,nofail 0 0
    ```

  - In addition, the fstab entry for the **Ubuntu 14** operating system must specify the `nobootwait` option as shown in the following example:

    ```
    UUID=2b262696-41a6-47c9-b173-d02717ee0e10 /mnt/expvol ext4
    defaults,nobootwait 0 0
    ```

- When backing up Windows VMs with multiple disks, before a Protection Group captures the Snapshot, the Cohesity agent and VMware tools must be installed on the VM and the VM must be running. For more information, see Install and Manage the Agent on Windows Servers. In addition, port 50051 must be open in your Firewall. For more information, see Manage Firewall Ports.

  > **Note:**
  > **For Convert and Deploy**: It is mandatory to install the Cohesity agent on the VMs. Windows does not show the data disks if the Cohesity agent is not installed, irrespective of the SAN/Disk Policy.
  >
  > **For Disaster Recovery**: It is mandatory to install the Cohesity agent on multi-disk Windows VMs. Windows does not show the data disks if the Cohesity agent is not installed, irrespective of the SAN/Disk Policy. In addition, the Protection Group capturing the Snapshot must have **Cloud Migration** enabled. For detailed instructions, see Add or Edit a Protection Group for Virtual Servers.

- For a Windows VM, if you want to access the newly created VM in the Cloud service using Remote Desktop, enable the Windows Remote Desktop on the VM prior to capturing the Snapshots of a Windows VM.
- Cohesity does not support CloudSpin of VMs from VMware Cloud (VMC) to AWS.

Convert and Deploy a VM from On-Premises to AWS

Verify that the above prerequisites are met prior to backing up the VMs.

1. Create a Protection Group to capture Snapshots of VMs. For more information, see Add or Edit a Protection Group for Virtual Servers.
2. Register the Cloud service that the VMware VMs are cloned **to**. For detailed instructions, see either Register an Azure Cloud Source at Subscription Level or Register an AWS Cloud Source.
3. Log in to the Cohesity Dashboard of the Cohesity cluster that contains the Snapshots to clone from. For example, log in to the on-premises Cohesity cluster.
4. To clone and convert the Virtual Server (VM), follow the instructions provided in Clone VMs.
5. After the Clone task is completed, log in to the new VM in the Cloud service.

   For AWS:

   a. Log in to the Amazon AWS console using your AWS account.
   b. In the top left of the menu bar, select **Services**.
   c. Select **Compute** > **EC2**.
   d. Select **INSTANCES** > **Instances**.
   e. Browse for the new Virtual Machine name.
   f. Copy the new IP address from the **Private IPs** field.
   g. Log in to the VM using the IP address. Paste the IP address in the browser.
6. Multiple disks are automatically mounted on the Windows VM, if the following conditions are true before the Protection Group captures the Snapshot of a Windows VM:

   - A Cohesity agent is installed on the VM.
   - VMware tools are installed on the VM.
   - VM is running

   If any of the conditions were not true when the Job captured the Snapshot, the `C:` drive is mounted but you must mount the other drives such as `D:` as described here:

   a. If Remote Desktop is installed on the new cloned VM, log in to the new VM, start Remote Desktop Connection, enter the IP of the new cloned VM.
   b. In the new VM, launch the Windows Disk Management.

c. Right click on a disk that is not mounted and select **Online**. Repeat for all other offline disks.

Tear Down a Launched VM from Cohesity Dashboard

1. In the Cohesity Dashboard, select **Test & Dev**.
2. Click the actions menu (⋮) next to the clone task you want to tear down and select **Tear Down**.

AWS Replication

This chapter includes the following topics:

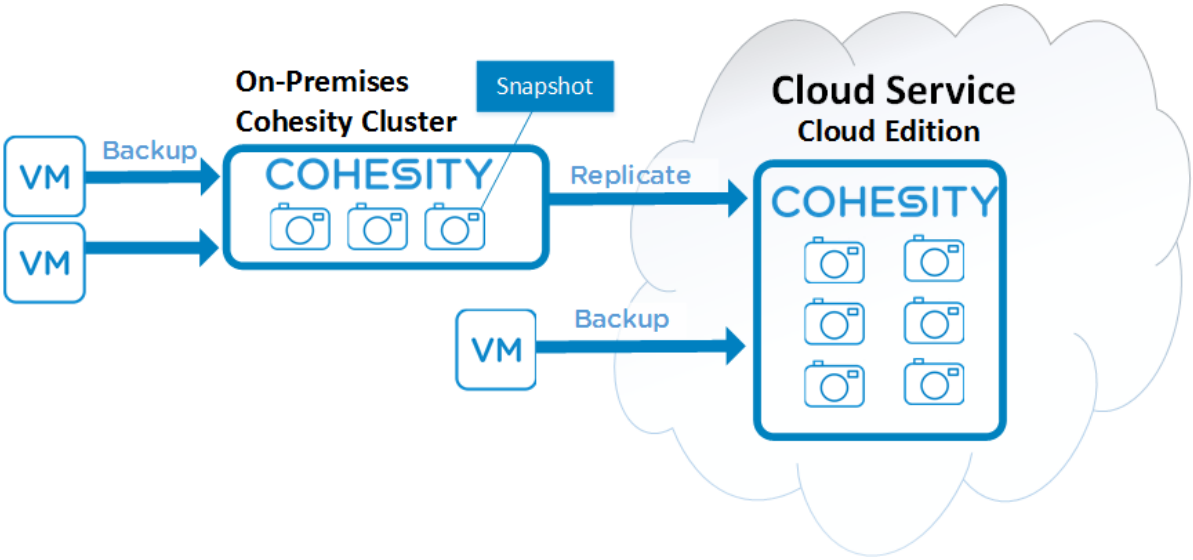
Replicating VMs in AWS Cloud Edition

Cohesity Cloud Edition supports the replication of VMs captured on an on-premises Cohesity cluster to Cloud Edition as shown by the example figure below.

Starting from the left in the following figure, the use case shows how Protection Groups running on the on-premises Cohesity cluster captures Snapshots of VMs and stores these Snapshots on the on-premises Cluster. The Protection Policies associated with these Jobs, are configured to replicate (or copy) Snapshots from the on-premises Cohesity cluster to the Cloud EditionCohesity cluster.

Starting from the left in the following figure, the bottom workflow shows how the Cloud Edition can directly back up a VM that is not in the Cloud. For example a VM in a vCenter server can be backed up directly to Cloud Edition running in a Cloud service such as AWS or Azure.

You can recover VMs from the Snapshots stored in the Cloud Edition running in the Cloud service (such as AWS).



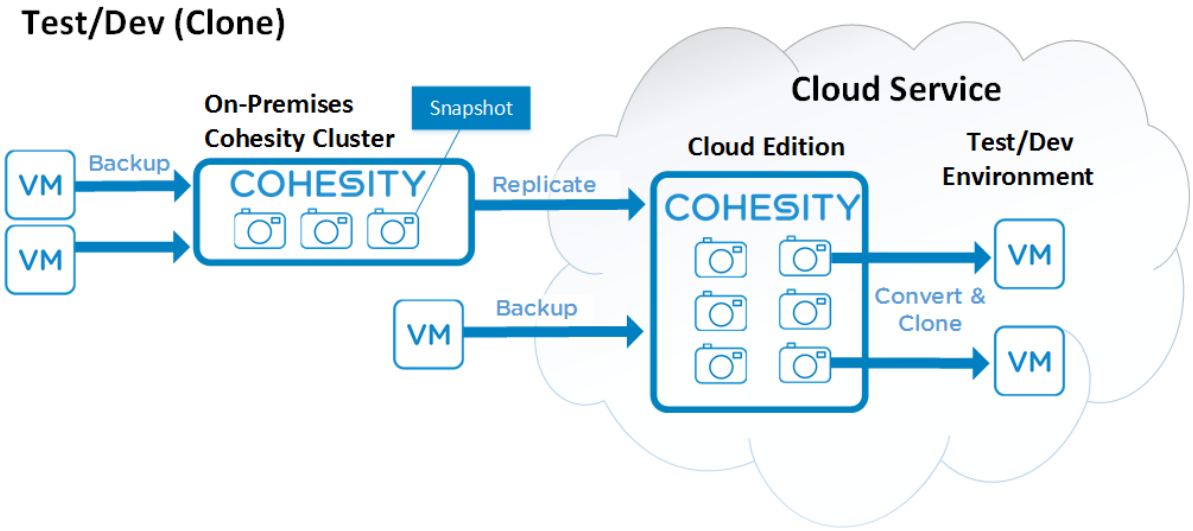
Replicate and Clone VMs in AWS Cloud Edition

Cohesity Cloud Edition supports Test/Dev (cloning) as shown by the following example figure.

Starting from the left in the following figure, the top workflow shows how Protection Groups running on the on-premises Cohesity cluster captures Snapshots of the VMs and stores these Snapshots on the on-premises Cluster. The Protection Policies associated with these Jobs, are configured to replicate (or copy) Snapshots from the on-premises Cohesity cluster to the Cohesity clusterCloud Edition.

Starting from the left in the following figure, the bottom workflow shows how the Cloud Edition can directly back up a VM that is not in the Cloud. For example a VM in a vCenter server can be backed up directly to Cloud Edition running in a Azure Cloud service.

From the Snapshots stored in the Cloud Edition on the Azure Cloud service, you can spin up test/dev environments using cloning.



To convert and clone VMs to a Cloud service:

1. Verify the following requirements prior to backing up the VMs:
   - For the list of VMs that supports CloudSpin to AWS, see Supported Software.
   - All the VMware vSphere versions supported by Cohesity for backup is supported for cloning to AWS. For the list of supported VMware vSphere versions, see Supported Software.
   - AHV, RhV and AWS VMs are *not* supported for cloning to Azure.

   Cloning Snapshots to an Azure Cloud is supported for VMware and Hyper-V VMs with the following operating systems:
   - Linux CentOS 7 on LVM
     - You can clone as many disks as the selected VM supports. For example, if you select a Standard_DS1_v2 VM, four disks can be cloned.
     - When converting and cloning or copying Snapshots of a Linux VM with multiple disks, the disks must be mounted by UUID prior to being backed up by the Protection Group, as shown by the following example entry in a `/etc/fstab`:

       ```
       UUID=e12e623a-c6ee-4718-9b1a-802456e72258 /userdata ext4
       defaults,nofail 0 0
       ```

       For detailed instructions, see Edit /etc/fstab to use UUID.
   - Windows

- You can clone as many disks as the selected VM supports. For example, if you select a Standard_DS1_v2 VM, four disks can be cloned.
- For a Windows VM, if you want to access the newly created VM in the Cloud service using Remote Desktop, enable the Windows Remote Desktop on the VM prior to capturing the Snapshots of a Windows VM.
- When backing up Windows VMs with multiple disks, before a Protection Group captures the Snapshot, the Cohesity agent and VMware tools must be installed on the VM and the VM must be running. The Cohesity agents installed must be of the same version as the Cohesity Cluster version. For more information, see Install and Manage the Agent on Windows Servers. In addition, port 50051 must be open in your Firewall. For more information, see Manage Firewall Ports.
- Due to a Windows issue in builds 14393 and build 15063, a deployed Windows 10 or Windows 2016 VM may not be connected to the network. Resolve this by installing fix KB4073562 for build 14393 or KB4016240 for build 15063 or by updating Windows. For more information, see Cannot connect remotely to a Windows 10 or Windows Server 2016 VM in Azure because of netvsc.sys.
- Make the disks online by default using the following SAN policy commands:
  - `diskpart`
  - `san policy=OnlineAll`

  For more information, see the SAN Policy documentation.

- Red Hat Enterprise Linux
  - You can clone as many disks as the selected VM supports. For example, if you select a Standard_DS1_v2 VM, four disks can be cloned.
  - For the list of supported RHEL versions, see Supported Software.
  - When converting and cloning or copying Snapshots of a Linux VM with multiple disks, the disks must be mounted by UUID prior to being backed up by the Protection Group, as shown by the following example entry in a `/etc/fstab`:

    ```
    UUID=e12e623a-c6ee-4718-9b1a-802456e72258 /userdata ext4
    defaults,nofail 0 0
    ```

    For detailed instructions, see Edit /etc/fstab to use UUID.
- The disk size of the VMware VMs must be a multiple of 1 GB.
- Cohesity does not support the CloudSpin of VMs whose OS Disk is formatted with XFS version 5 to Azure. This limitation applies to both Hyper-V and VMware VMs, regardless of their operating system type.

- Cohesity does not support CloudSpin of VMware VMs from VMware Cloud (VMC) to Azure.

Cloning Hyper-V VMs to Azure

- VMs that have one to five disks can be cloned. Each disk must be smaller than 2 TB.
- SUSE Linux VMs are *not* supported.
